What is Amazon SageMaker?

Amazon SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers can quickly and easily build and train machine learning models, and then directly deploy them into a production-ready hosted environment. It provides an integrated Jupyter authoring notebook instance for easy access to your data sources for exploration and analysis, so you don't have to manage servers. It also provides common machine learning algorithms that are optimized to run efficiently against extremely large data in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows. Deploy a model into a secure and scalable environment by launching it with a few clicks from SageMaker Studio or the SageMaker console.

This guide includes information and tutorials on SageMaker features. For additional information, see Amazon SageMaker developer resources.

Topics

- Amazon SageMaker Features (p. 4)
- Amazon SageMaker Pricing (p. 1)
- Are You a First-time User of Amazon SageMaker? (p. 1)

Amazon SageMaker Pricing

As with other AWS products, there are no contracts or minimum commitments for using Amazon SageMaker. Training and hosting are billed by minutes of usage, with no minimum fees and no upfront commitments. For more information about the cost of using SageMaker, see SageMaker Pricing.

Are You a First-time User of Amazon SageMaker?

If you are a first-time user of SageMaker, we recommend that you do the following:

1. **Read** How Amazon SageMaker Works (p. 2) – This section provides an overview of SageMaker, explains key concepts, and describes the core components involved in building AI solutions with SageMaker. We recommend that you read this topic in the order presented.
2. **Set Up Amazon SageMaker Prerequisites (p. 8)** – This section explains how to set up your AWS account.
3. Amazon SageMaker Autopilot simplifies the machine learning experience by automating machine learning tasks. If you are new to SageMaker, it provides the easiest learning path. It also serves as an excellent ML learning tool that provides visibility into the code with notebooks generated for each of the automated ML tasks. For an introduction to its capabilities, see SageMaker Autopilot (p. 44). To get started building, training, and deploying machine learning models, Autopilot provides:
   - **Example notebooks:** Explore modeling with Amazon SageMaker Autopilot (p. 106)
   - **Videos:** Use Autopilot to automate and explore the machine learning process (p. 107)
   - **Tutorials:** Get started with Amazon SageMaker Autopilot (p. 108)
4. **Get started** *(p. 8)* – This section walks you through training your first model using SageMaker
Studio, or the SageMaker console and the SageMaker API. You use training algorithms provided by SageMaker.

5. **Explore other topics** – Depending on your needs, do the following:
   - **Submit Python code to train with deep learning frameworks** – In SageMaker, you can use your
     own training scripts to train models. For information, see *Machine Learning Frameworks and
     Languages (p. 3610)*.
   - **Use SageMaker directly from Apache Spark** – For information, see *Use Apache Spark with Amazon
     SageMaker (p. 3611)*.
   - **Use SageMaker to train and deploy your own custom algorithms** – Package your custom
     algorithms with Docker so you can train and/or deploy them in SageMaker. To learn how SageMaker
     interacts with Docker containers, and for the SageMaker requirements for Docker images, see *Use
     Docker containers to build models (p. 3281)*.

6. **View the API Reference** – This section describes the SageMaker API operations.

### How Amazon SageMaker Works

SageMaker is a fully managed service that enables you to quickly and easily integrate machine learning-
based models into your applications. This section provides an overview of machine learning and explains
how SageMaker works. If you are a first-time user of SageMaker, we recommend that you read the
following sections in order:

1. **Overview of machine learning with Amazon SageMaker (p. 2)**
2. **Explore, Analyze, and Process Data (p. 1166)**
3. **Train a Model with Amazon SageMaker (p. 1521)**
4. **Deploy a Model in Amazon SageMaker (p. 2339)**
5. **Machine Learning Frameworks and Languages (p. 3610)**
6. **Get started (p. 8)**

### Overview of machine learning with Amazon SageMaker

This section describes a typical machine learning workflow and summarizes how you accomplish those
tasks with Amazon SageMaker.

In machine learning, you "teach" a computer to make predictions, or inferences. First, you use an
algorithm and example data to train a model. Then you integrate your model into your application to
generate inferences in real time and at scale. In a production environment, a model typically learns from
millions of example data items and produces inferences in hundreds to less than 20 milliseconds.

The following diagram illustrates the typical workflow for creating a machine learning model:
As the diagram illustrates, you typically perform the following activities:

1. **Generate example data**—To train a model, you need example data. The type of data that you need depends on the business problem that you want the model to solve (the inferences that you want the model to generate). For example, suppose that you want to create a model to predict a number given an input image of a handwritten digit. To train such a model, you need example images of handwritten numbers.

   Data scientists often spend a lot of time exploring and preprocessing, or “wrangling,” example data before using it for model training. To preprocess data, you typically do the following:

   a. **Fetch the data**—You might have in-house example data repositories, or you might use datasets that are publicly available. Typically, you pull the dataset or datasets into a single repository.

   b. **Clean the data**—To improve model training, inspect the data and clean it as needed. For example, if your data has a country name attribute with values United States and US, you might want to edit the data to be consistent.

   c. **Prepare or transform the data**—To improve performance, you might perform additional data transformations. For example, you might choose to combine attributes. If your model predicts the conditions that require de-icing an aircraft, instead of using temperature and humidity attributes separately, you might combine those attributes into a new attribute to get a better model.

   In SageMaker, you preprocess example data in a Jupyter notebook on your notebook instance. You use your notebook to fetch your dataset, explore it, and prepare it for model training. For more information, see [Explore, Analyze, and Process Data](p. 1166). For more information about preparing data in AWS Marketplace, see data preparation.

2. **Train a model**—Model training includes both training and evaluating the model, as follows:

   a. **Training the model**—To train a model, you need an algorithm or a pre-trained base model. The algorithm you choose depends on a number of factors. For a quick, out-of-the-box solution, you might be able to use one of the algorithms that SageMaker provides. For a list of algorithms provided by SageMaker and related considerations, see [Use Amazon SageMaker Built-in Algorithms or Pre-trained Models](p. 1528). For a UI-based training solution that provides algorithms and models, see [SageMaker JumpStart](p. 161).
You also need compute resources for training. Depending on the size of your training dataset and how quickly you need the results, you can use resources ranging from a single general-purpose instance to a distributed cluster of GPU instances. For more information, see *Train a Model with Amazon SageMaker* (p. 1521).

- **Evaluating the model**—After you've trained your model, you evaluate it to determine whether the accuracy of the inferences is acceptable. In SageMaker, you use either the AWS SDK for Python (Boto) or the high-level Python library that SageMaker provides to send requests to the model for inferences.

  You use a Jupyter notebook in your SageMaker notebook instance to train and evaluate your model.

3. **Deploy the model**—You traditionally re-engineer a model before you integrate it with your application and deploy it. With SageMaker hosting services, you can deploy your model independently, decoupling it from your application code. For more information, see *Deploy models for inference* (p. 2335).

Machine learning is a continuous cycle. After deploying a model, you monitor the inferences, collect "ground truth," and evaluate the model to identify drift. You then increase the accuracy of your inferences by updating your training data to include the newly collected ground truth. You do this by retraining the model with the new dataset. As more and more example data becomes available, you continue retraining your model to increase accuracy.

### Amazon SageMaker Features

Amazon SageMaker includes the following features.

**Topics**
- New features for re:Invent 2022 (p. 4)
- Machine learning environments (p. 5)
- Major features (p. 5)

### New features for re:Invent 2022

SageMaker includes the following new features for re:Invent 2022.

**SageMaker geospatial capabilities (p. 548)**

Build, train, and deploy ML models using geospatial data.

**SageMaker Model Cards (p. 3245)**

Document information about your ML models in a single place for streamlined governance and reporting throughout the ML lifecycle.

**SageMaker Model Dashboard (p. 3271)**

A pre-built, visual overview of all the models in your account. Model Dashboard integrates information from SageMaker Model Monitor, transform jobs, endpoints, lineage tracking, and CloudWatch so you can access high-level model information and track model performance in one unified view.
SageMaker Role Manager (p. 3410)

Administrators can define least-privilege permissions for common ML activities using custom and preconfigured persona-based IAM roles.

AutoML step (p. 2815)

Create an AutoML job to automatically train a model in SageMaker Pipelines.

Collaboration with shared spaces (p. 28)

A shared space consists of a shared JupyterServer application and a shared directory. All user profiles in a Domain have access to all shared spaces in the Domain.

Data Wrangler data preparation widget (p. 1334)

Interact with your data, get visualizations, explore actionable insights, and fix data quality issues.

Inference shadow tests (p. 2610)

Evaluate any changes to your model-serving infrastructure by comparing its performance against the currently deployed infrastructure.

Notebook-based Workflows (p. 2948)

Run your SageMaker Studio notebook as a non-interactive, scheduled job.

Studio Git extension (p. 283)

A Git extension to enter the URL of a Git repository, clone it into your environment, push changes, and view commit history.

Machine learning environments

SageMaker includes the following machine learning environments.

SageMaker Studio (p. 204)

An integrated machine learning environment where you can build, train, deploy, and analyze your models all in the same application.

SageMaker Studio Lab (p. 340)

A free service that gives customers access to AWS compute resources in an environment based on open-source JupyterLab.

SageMaker Canvas (p. 368)

An auto ML service that gives people with no coding experience the ability to build models and make predictions with them.

RStudio on Amazon SageMaker (p. 602)

An integrated development environment for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management.

Major features

SageMaker includes the following major features in alphabetical order excluding any SageMaker prefix.
Amazon Augmented AI (p. 1081)

Build the workflows required for human review of ML predictions. Amazon A2I brings human review to all developers, removing the undifferentiated heavy lifting associated with building human review systems or managing large numbers of human reviewers.

SageMaker Autopilot (p. 44)

Users without machine learning knowledge can quickly build classification and regression models.

Batch Transform (p. 2545)

Preprocess datasets, run inference when you don't need a persistent endpoint, and associate input records with inferences to assist the interpretation of results.

SageMaker Clarify (p. 3134)

Improve your machine learning models by detecting potential bias and help explain the predictions that models make.

SageMaker Data Wrangler (p. 1167)

Import, analyze, prepare, and featurize data in SageMaker Studio. You can integrate Data Wrangler into your machine learning workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize your data prep workflow.

SageMaker Debugger (p. 1916)

Inspect training parameters and data throughout the training process. Automatically detect and alert users to commonly occurring errors such as parameter values getting too large or small.

SageMaker Edge Manager (p. 2641)

Optimize custom models for edge devices, create and manage fleets and run models with an efficient runtime.

SageMaker Elastic Inference (p. 2760)

Speed up the throughput and decrease the latency of getting real-time inferences.

SageMaker Experiments (p. 1838)

Experiment management and tracking. You can use the tracked data to reconstruct an experiment, incrementally build on experiments conducted by peers, and trace model lineage for compliance and audit verifications.

SageMaker Feature Store (p. 1413)

A centralized store for features and associated metadata so features can be easily discovered and reused. You can create two types of stores, an Online or Offline store. The Online Store can be used for low latency, real-time inference use cases and the Offline Store can be used for training and batch inference.

SageMaker Ground Truth (p. 640)

High-quality training datasets by using workers along with machine learning to create labeled datasets.

SageMaker Ground Truth Plus (p. 958)

A turnkey data labeling feature to create high-quality training datasets without having to build labeling applications and manage the labeling workforce on your own.

SageMaker Inference Recommender (p. 2340)

Get recommendations on inference instance types and configurations (e.g. instance count, container parameters and model optimizations) to use your ML models and workloads.
SageMaker JumpStart (p. 161)

Learn about SageMaker features and capabilities through curated 1-click solutions, example notebooks, and pretrained models that you can deploy. You can also fine-tune the models and deploy them.

SageMaker ML Lineage Tracking (p. 2973)

Track the lineage of machine learning workflows.

SageMaker Model Building Pipelines (p. 2805)

Create and manage machine learning pipelines integrated directly with SageMaker jobs.

SageMaker Model Monitor (p. 3051)

Monitor and analyze models in production (endpoints) to detect data drift and deviations in model quality.

SageMaker Model Registry (p. 2989)

Versioning, artifact and lineage tracking, approval workflow, and cross account support for deployment of your machine learning models.

SageMaker Neo (p. 2693)

Train machine learning models once, then run anywhere in the cloud and at the edge.

Preprocessing (p. 1399)

Analyze and preprocess data, tackle feature engineering, and evaluate models.

SageMaker Projects (p. 3017)

Create end-to-end ML solutions with CI/CD by using SageMaker projects.

Reinforcement Learning (p. 1807)

Maximize the long-term reward that an agent receives as a result of its actions.

SageMaker Serverless Endpoints (p. 2496)

A serverless endpoint option for hosting your ML model. Automatically scales in capacity to serve your endpoint traffic. Removes the need to select instance types or manage scaling policies on an endpoint.

SageMaker Studio Notebooks (p. 221)

The next generation of SageMaker notebooks that include AWS IAM Identity Center (IAM Identity Center) integration, fast start-up times, and single-click sharing.

SageMaker Studio Notebooks and Amazon EMR (p. 1364)

Easily discover, connect to, create, terminate and manage Amazon EMR clusters in single account and cross account configurations directly from SageMaker Studio.

SageMaker Training Compiler (p. 2229)

Train deep learning models faster on scalable GPU instances managed by SageMaker.
Get started

Before you can use Amazon SageMaker, you must sign up for an AWS account and create an administrative user by following the steps in Set Up Amazon SageMaker Prerequisites (p. 8).

Amazon SageMaker Studio Lab does not require an AWS account or IAM integration.

After you complete these tasks, continue to one of the following topics, depending on your use case.

• Onboard to Amazon SageMaker Domain (p. 10): Follow these steps to create a Domain, which gives you access to Amazon SageMaker Studio and RStudio on Amazon SageMaker. For more information about Domains, see Amazon SageMaker Domain (p. 11).

Topics
• Set Up Amazon SageMaker Prerequisites (p. 8)
• Onboard to Amazon SageMaker Domain (p. 10)
• Supported Regions and Quotas (p. 43)

Set Up Amazon SageMaker Prerequisites

In this section, you sign up for an AWS account and create an AWS Identity and Access Management (IAM) admin user.

If you're new to SageMaker, we recommend that you read How Amazon SageMaker Works (p. 2).

Topics
• Create an AWS Account (p. 8)
• Create an Administrative User and Group (p. 9)
• AWS CLI Prerequisites (p. 9)

Create an AWS Account

In this section, you sign up for an AWS account. If you already have an AWS account, skip this step.

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all AWS services, including SageMaker. You are charged only for the services that you use.

To create an AWS account

2. Follow the online instructions.
   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

   Write down your AWS account ID because you'll need it for the next task.
Create an Administrative User and Group

When you create an AWS account, you get a single sign-in identity that has complete access to all of the AWS services and resources in the account. This identity is called the AWS account root user. Signing in to the AWS console using the email address and password that you used to create the account gives you complete access to all of the AWS resources in your account.

We strongly recommend that you not use the root user for everyday tasks, even the administrative ones. Instead, adhere to the Security best practices in IAM, and create an administrative user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

To create an administrative user

1. Create an administrative user in your AWS account. For instructions, see Create an administrative user in the IAM User Guide.

   Note
   We assume that you use administrator user credentials for the exercises and procedures in this guide. If you choose to create and use another user, grant that user minimum permissions. For more information, see Authenticating with Identities (p. 3350).

2. Ensure that your administrator user has the AmazonSageMakerFullAccess policy, as well as a policy with the following content needed to create a SageMaker domain. For more information about creating IAM policies, see Creating IAM policies.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["sagemaker:*"],
      "Resource": [
        "arn:aws:sagemaker:*:*:domain/*",
        "arn:aws:sagemaker:*:*:user-profile/*",
        "arn:aws:sagemaker:*:*:app/*",
        "arn:aws:sagemaker:*:*:flow-definition/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": ["iam:GetRole", "servicecatalog:*"],
      "Resource": ["*"],
      "Condition": 
    }
  ]
}
```

AWS CLI Prerequisites

The following prerequisites are required to onboard to a Domain using the AWS CLI.

- Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
• From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.

Onboard to Amazon SageMaker Domain

An Amazon SageMaker Domain consists of the following:

• An associated Amazon Elastic File System (Amazon EFS) volume;
• A list of authorized users;
• A variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations.

To use Amazon SageMaker Studio, Amazon SageMaker Studio notebooks, and RStudio, you must complete the Amazon SageMaker Domain onboarding process using the SageMaker console or the AWS CLI. For more information about an Amazon SageMaker Domain, see Amazon SageMaker Domain (p. 11).

When onboarding, you can choose to use either AWS IAM Identity Center or AWS Identity and Access Management (IAM) for authentication methods. When you use IAM authentication, you can choose either the Quick setup or the Standard setup procedure. RStudio setup is only available when using the Standard setup procedure.

Note
If you onboard using IAM authentication and want to switch to authentication using IAM Identity Center later, you must delete the Domain that you created. Then, you need to manually re-import all notebooks and other user data that you created. For more information, see Delete an Amazon SageMaker Domain (p. 21).

The simplest way to create an Amazon SageMaker Domain is to follow the Quick setup procedure from the SageMaker console. Quick setup uses the same default settings as the Standard setup procedures. These settings include shareable notebooks and public internet access. For more control, including the option of using authentication using IAM Identity Center and RStudio, use the Standard setup procedures.

Authentication using IAM Identity Center

To use authentication using IAM Identity Center with Studio and RStudio, you must onboard to an organization in AWS Organizations.

Note
The AWS Organizations account must be in the same AWS Region as Studio and RStudio.

Authentication using IAM Identity Center provides the following benefits over IAM authentication:

• Members given access to Studio have a unique sign-in URL that directly opens Studio, and they sign in with their IAM Identity Center credentials. When you use IAM authentication, you must sign in through the SageMaker console.
• Organizations manage their members in IAM Identity Center instead of the Domain. You can assign multiple members access to the Domain at the same time. When you use IAM authentication, you must add and manage members manually, one at a time, using the Domain Control Panel.

Topics

• Amazon SageMaker Domain (p. 11)
• Onboard to Amazon SageMaker Domain using Quick setup (p. 34)
• Onboard to Amazon SageMaker Domain using IAM Identity Center (p. 35)
Amazon SageMaker Domain

Amazon SageMaker Domain supports SageMaker machine learning (ML) environments. A SageMaker Domain is composed of the following entities. For onboarding steps to create a Domain, see Onboard to Amazon SageMaker Domain (p. 10).

- **Domain**: An Amazon SageMaker Domain consists of an associated Amazon Elastic File System (Amazon EFS) volume; a list of authorized users; and a variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations. Users within a Domain can share notebook files and other artifacts with each other. An account can have multiple Domains. For more information about multiple Domains, see Multiple Domains Overview (p. 14).
- **UserProfile**: A user profile represents a single user within a Domain. It is the main way to reference a user for the purposes of sharing, reporting, and other user-oriented features. This entity is created when a user onboards to the Amazon SageMaker Domain. For more information about user profiles, see Domain User Profiles (p. 24).
- **shared space**: A shared space consists of a shared JupyterServer application and shared directory. All users within the Domain have access to the shared space. All user profiles in a Domain have access to all shared spaces in the Domain. For more information about shared spaces, see Collaborate with shared spaces (p. 28).
- **App**: An app represents an application that supports the reading and execution experience of the user's notebooks, terminals, and consoles. The type of app can be JupyterServer, KernelGateway, RStudioServerPro, or RSession. A user may have multiple apps active simultaneously.

The following tables describe the status values for the Domain, UserProfile, shared space, and App entities. Where applicable, they also give troubleshooting steps.

### Domain status values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pending</td>
<td>Ongoing creation of Domain.</td>
</tr>
<tr>
<td>InService</td>
<td>Successful creation of Domain.</td>

</table>

### Maintenance of applications

At least once every 90 days, SageMaker performs security and performance updates to the underlying software for Amazon SageMaker Studio JupyterServer and KernelGateway, SageMaker Canvas, and Amazon SageMaker Data Wrangler applications. Some maintenance items, such as operating system upgrades, require that SageMaker takes your application offline for a short time during the maintenance window. Because this maintenance takes the application offline, you cannot perform any operations while the underlying software is being updated. When the maintenance activity is in progress, the state of the application transitions from **InService** to **Pending**. When maintenance is complete, the status of the application returns to **InService**. If patching fails, then the status of the application becomes **Failed**. If an application is in the **Failed** state, we recommend creating a new application of the same type. For information about creating Studio applications, see [Shut Down and Update SageMaker Studio and Studio Apps](p. 292). For information about creating SageMaker Canvas applications, see [Manage apps](p. 402).

For more information, contact https://aws.amazon.com/premiumsupport/.

### Topics

- [Prerequisites](p. 14)
- [Multiple Domains Overview](p. 14)
- [Domain resource isolation](p. 15)
- [Setting Defaults for a Domain](p. 18)
- [Environment](p. 19)
Prerequisites

To use the features available in an Amazon SageMaker Domain, you must first onboard to a Domain. For more information, see Onboard to Amazon SageMaker Domain.

If you are interacting with your Domain using the AWS CLI, you must also complete the following prerequisites.

- Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.

Multiple Domains Overview

Amazon SageMaker supports the creation of multiple Amazon SageMaker Domains in a single AWS Region for each account. Additional Domains in a Region have the same features and capabilities as the first Domain in a Region. Each Domain can have distinct Domain settings. The same user profile cannot be added to multiple Domains in a single Region within the same account. For more information about Domain limits, see Amazon SageMaker endpoints and quotas.

Topics

- Automatic tag propagation (p. 14)
- Domain resource display filtering (p. 15)
- Backfilling Domain tags (p. 15)

Automatic tag propagation

By default, any SageMaker resources that support tagging and are created from within the Studio UI after 11/30/2022 are automatically tagged with a Domain ARN tag. The Domain ARN tag is based on the Domain ID of the Domain that the resource is created in. The following list describes the only SageMaker resources that do not support automatic tag propagation, as well as the impacted API calls where the tag is not returned because it was not automatically set.

You can also use these tags for cost allocation using AWS Billing and Cost Management. For more information, see Using AWS cost allocation tags.

**Note**

All SageMaker List APIs do not support tag-based resource isolation.

The default app, which manages the Studio UI, is not automatically tagged.

<table>
<thead>
<tr>
<th>SageMaker resource</th>
<th>Affected API calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageVersionArn</td>
<td>• describe-image-version</td>
</tr>
<tr>
<td></td>
<td>• update-image-version</td>
</tr>
<tr>
<td></td>
<td>• delete-image-version</td>
</tr>
<tr>
<td>ModelCardExportJobArn</td>
<td>describe-model-card-export-job</td>
</tr>
</tbody>
</table>
Domain resource display filtering

By default, SageMaker filters resources displayed within Studio at the domain level. SageMaker implements resource filtration in Studio using the `sagemaker:domain-arn` tag attached to SageMaker resources.

**Note**
This only applies to the Studio UI. SageMaker does not support resource filtering using the AWS CLI by default.

Using this resource filtration, SageMaker only displays SageMaker resources created in the domain, as well as SageMaker resources that do not have a `sagemaker:domain-arn` tag associated to them. These untagged resources are either created outside the context of a domain or were created before 11/30/2022. You can add a tag to these untagged resources for better filtration by following the steps in Backfilling Domain tags (p. 15). Resources created in other domains are automatically filtered out.

All resources created in shared spaces are automatically filtered to that space.

Backfilling Domain tags

If you have created resources in a Domain before 11/30/2022, those resources are not automatically tagged with the Domain Amazon Resource Name (ARN) tag.

To accurately attribute resources to their respective Domain, you must add the Domain tag to existing resources using the AWS CLI, as follows.

1. Map all existing SageMaker resources and their respective ARNs to the Domains that exist in your account.
2. Run the following command from your local machine to tag the resource with the ARN of the resource's respective Domain. This must be repeated for every SageMaker resource in your account.

   ```
   aws resourcegroupstaggingapi tag-resources \
   --resource-arn-list arn:aws:sagemaker:region:account-id:space/domin-id/space-name \
   ```

Domain resource isolation

You can isolate resources between each of the Domains in your account and Region using an AWS Identity and Access Management policy. With resource isolation, SageMaker resources, such as models, experiments, training jobs, and pipelines created in one Domain, cannot be accessed from other Domains. The following topic shows how to create a new IAM policy that limits access to resources in the Domain to user profiles with the Domain tag, as well as how to attach this policy to the IAM execution role of the Domain. You must repeat this process for each Domain in your account. For more information about Domain tags and backfilling these tags, see Multiple Domains Overview (p. 14).

Console

The following section shows how to create a new IAM policy that limits access to resources in the Domain to user profiles with the Domain tag, as well as how to attach this policy to the IAM execution role of the Domain, from the Amazon SageMaker console.

1. Create an IAM policy named `StudioDomainResourceIsolationPolicy-domain-id` with the following JSON policy document by completing the steps in Creating IAM policies (console).
2. Attach the StudioDomainResourceIsolationPolicy-\textit{domain-id} policy to the Domain's execution role by completing the steps in \textit{Modifying a role (console)}.

\section*{AWS CLI}

The following section shows how to create a new IAM policy that limits access to resources in the Domain to user profiles with the Domain tag, as well as how to attach this policy to the execution role of the Domain, from the AWS CLI.

1. Create a file named StudioDomainResourceIsolationPolicy-\textit{domain-id} with the following content from your local machine.

```bash
```

3. Attach the newly created policy to a new or existing role that is used as the Domain's execution role.

```bash
aws iam attach-role-policy --policy-arn arn:aws:iam::account-id:policy/StudioDomainResourceIsolationPolicy-\textit{domain-id} --role-name domain-execution-role
```
Setting Defaults for a Domain

With SageMaker, you can set default settings for your resources at the Amazon SageMaker Domain level. These default settings are used in the creation of resources within the Domain. The following sections list default settings for Domain and give information on using context keys when setting defaults.

Topics

- Domain default settings (p. 18)
- Context keys (p. 18)

Domain default settings

You can set the following defaults when creating or updating a Domain. Values passed at the user profile and shared space level override defaults set at the Domain level.

- DefaultUserSettings
- DefaultSpaceSettings

Note

DefaultSpaceSettings only supports the use of JupyterLab 3 image ARNs for SageMakerImageArn. For more information, see JupyterLab Versioning (p. 211).

```
"DefaultSpaceSettings": {
  "ExecutionRole": "string",
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "InstanceType": "string",
      "LifecycleConfigArn": "string",
      "SageMakerImageArn": "string",
      "SageMakerImageVersionArn": "string"
    },
    "LifecycleConfigArns": [ "string" ]
  },
  "KernelGatewayAppSettings": {
    "CustomImages": [
      {
        "AppImageConfigName": "string",
        "ImageName": "string",
        "ImageVersionNumber": number
      }
    ],
    "DefaultResourceSpec": {
      "InstanceType": "string",
      "LifecycleConfigArn": "string",
      "SageMakerImageArn": "string",
      "SageMakerImageVersionArn": "string"
    },
    "LifecycleConfigArns": [ "string" ]
  },
  "SecurityGroups": [ "string" ]
}
```

Context keys

You can add context keys to the IAM policy that creates a Domain. This restricts the values that users can pass for those fields. The following list shows the context keys that Domain supports and where they're implemented.
• sagemaker:ImageArns

• sagemaker:VpcSecurityGroupIds
  • **Implemented as part of DefaultUserSettings**: SecurityGroups in DefaultUserSettings.
  • **Implemented as part of DefaultSpaceSettings**: SecurityGroups in DefaultSpaceSettings.

• sagemaker:DomainSharingOutputKmsKey
  • **Implemented as part of DefaultUserSettings**: S3KmsKeyId in DefaultSpaceSettings.SharingSettings.

You cannot restrict users to passing incompatible values when using context keys for the defaults. For example, the values for SageMakerImageArn set as part of DefaultUserSettings and DefaultSpaceSettings must be compatible. You cannot set the following incompatible default values. For more information about the available JupyterLab version ARNs, see [Setting a default JupyterLab version](p. 213).

• Only a JupyterLab version 1 ARN can be used for the SageMakerImageArn value in DefaultUserSettings
• Only a JupyterLab version 3 ARN can be used for the SageMakerImageArn value in DefaultSpaceSettings

**Environment**

This page gives information about modifications to the Amazon SageMaker Domain environment. This includes custom images, lifecycle configurations, and git repositories attached to a Domain environment. These can also be attached to a shared space using the AWS CLI by passing values to the create-space command using the space-settings parameter.

For more information about bringing a custom Amazon SageMaker Studio image, see [Bring your own SageMaker image](#).

For more information about bringing a custom RStudio image, see [Bring your own image to RStudio on SageMaker](#).

For instructions on using a lifecycle configuration with Studio, see [Use Lifecycle Configurations with Amazon SageMaker Studio](#).

For information about attaching a git repository to a Domain, see [Attach Suggested Git Repos to SageMaker](#).

Complete the following procedure to view the custom images, lifecycle configurations, and git repositories attached to a Domain environment.

**Open the Environment page**

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select a Domain to open the Environment page.

View and Edit Domains

This topic shows how to view a list of your Amazon SageMaker Domains, view the details of a Domain, and edit Domain settings from the Amazon SageMaker console or AWS Command Line Interface (AWS CLI).

Topics
- View Domains (p. 20)
- Edit Domain settings (p. 20)

View Domains

The following section shows how to view a list of your Domains, and details of an individual Domain from the SageMaker console or the AWS CLI.

Console

The console's Domain overview page gives information about the structure of a Domain, and it provides a list of your Domains. The page's Domain structure diagram describes Domain components and how they interact with each other.

The following procedure shows how to view a list of your Domains from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.

To view the details of the Domain, complete the following procedure. This page gives information about the general settings for the Domain, including the name, Domain ID, execution role used to create the Domain, and the authentication method of the Domain.

1. From the list of Domains, select the Domain that you want to open the Domain settings page for.
2. On the Domain details page, choose the Domain settings tab.

AWS CLI

Run the following command from the terminal of your local machine to view a list of Domains from the AWS CLI.

```bash
aws sagemaker list-domains --region region
```

Edit Domain settings

You can edit the settings of a Domain from the SageMaker console or the AWS CLI. The following considerations apply when updating the settings of a Domain.

- If DefaultUserSettings and DefaultSpaceSettings are set, they cannot be unset.
• DefaultUserSettings.ExecutionRole can only be updated if there are no applications running in any user profile within the Domain. This value cannot be unset.
• DefaultSpaceSettings.ExecutionRole can only be updated if there are no applications running in any of shared spaces within the Domain. This value cannot be unset.
• If the Domain was created in VPC only mode, SageMaker automatically applies updates to the security group settings defined for the Domain to all shared spaces created in the Domain.
• DomainId cannot be updated.

The following section shows how to edit Domain settings from the SageMaker console or the AWS CLI.

Console

You can edit the Domain from the SageMaker console using the following procedure.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to open the Domain settings page for.
5. On the Domain details page, choose the Domain settings tab.
6. Choose Edit.

AWS CLI

Run the following command from the terminal of your local machine to update a Domain from the AWS CLI. For more information about the structure of default-user-settings, see CreateDomain.

```
aws sagemaker update-domain
--domain-id domain-id
--default-user-settings default-user-settings
--default-space-settings default-space-settings
--domain-settings-for-update settings-for-update
--region region
```

Delete an Amazon SageMaker Domain

A Domain consists of a list of authorized users, configuration settings, and an Amazon Elastic File System (Amazon EFS) volume. The Amazon EFS volume contains data for the users, including notebooks, resources, and artifacts. A user can have multiple applications (apps) which support the reading and execution experience of the user’s notebooks, terminals, and consoles.

You can delete your Domain using one of the following:

• AWS console
• AWS Command Line Interface (AWS CLI)
• SageMaker SDK

The following sections explain how to delete a Domain and the requirements for doing so.

Requirements

You must satisfy the following requirements to delete a Domain.
• You must have admin permission to delete a Domain.
• You can only delete an app with the status InService displayed as Ready in the Domain. To delete the containing Domain, you don't need to delete an app whose status is Failed. In the Domain, an attempt to delete an app in the failed state results in an error.
• To delete a Domain, the Domain cannot contain any user profiles or shared spaces. To delete a user profile or shared space, the user profile or space cannot contain any non-failed apps.

When you delete these resources, the following occurs:
• App – The data (files and notebooks) in a user's home directory is saved. Unsaved notebook data is lost.
• User profile – The user can no longer sign in to the Domain. The user loses access to their home directory, but the data is not deleted. An admin can retrieve the data from the Amazon EFS volume where it is stored under the user's AWS account.
• To switch authentication modes from IAM to IAM Identity Center, you must delete the Domain.

EFS files

Your files are kept in an Amazon EFS volume as a backup. This backup includes the files in the mounted directory, which is /home/sagemaker-user for Jupyter and /root for your kernel.

When you delete files from these mounted directories, the kernel or app may move the deleted files into a hidden trash folder. If the trash folder is inside the mounted directory, those files are copied into the Amazon EFS volume and will incur charges. To avoid these Amazon EFS charges, you must identify and clean the trash folder location. The trash folder location for default apps and kernels is ~/.local/. This may vary depending on the Linux distribution used for custom apps or kernels. For more information about the Amazon EFS volume, see Manage Your Amazon EFS Storage Volume in SageMaker Studio (p. 291).

When you use the SageMaker console to delete the Domain, the Amazon EFS volume is detached but not deleted. The same behavior occurs by default when you use the AWS CLI or the SageMaker Python SDK to delete the Domain. However, when you use the AWS CLI or the SageMaker Python SDK, you can set the RetentionPolicy to HomeEfsFileSystem=Delete to delete the Amazon EFS volume along with the Domain.

Delete an Amazon SageMaker Domain (console)

To delete a Domain

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain that you want to delete.
5. Repeat the following steps for each user in the User profiles list.
   a. Choose the user.
   b. On the User Details page, for each non-failed app in the Apps list, choose Action.
   c. From the dropdown list, choose Delete.
   d. On the Delete app dialog box, choose Yes, delete app. Then enter delete in the confirmation field, and choose Delete.
   e. When Status shows as Deleted for all apps, choose Edit.
   f. On the Edit User page, choose Delete user.
   g. On the Delete user dialog box, choose Yes, delete user. Then enter delete in the confirmation field, and choose Delete.
Important
When a user is deleted, they lose access to the Amazon EFS volume that contains their data, including notebooks and other artifacts. The data is not deleted and can be accessed by an administrator.

6. When all users are deleted, choose the Space management tab.
7. Repeat the following steps for each shared space in the Spaces list.
   a. Select the name of the shared space.
   b. Choose Delete app for every app.
   c. On the Delete app dialog box, choose Yes, delete app. Then enter delete in the confirmation field, and choose Delete.
   d. Choose Cancel.
   e. Select the shared space.
   f. Choose Delete.
   g. On the Delete space dialog box, choose Yes, delete space. Then enter delete in the confirmation field, and choose Delete space.
8. When all users and shared spaces are deleted, choose the Domain settings tab.
9. Choose Edit.
11. On the Delete Domain dialog box, choose Yes, delete Domain. Then enter delete in the confirmation field, and choose Delete.

Delete an Amazon SageMaker Domain (AWS CLI)

To delete a Domain

1. Retrieve the list of Domains in your account.

```bash
aws --region Region sagemaker list-domains
```

2. Retrieve the list of applications for the Domain to be deleted.

```bash
aws --region Region sagemaker list-apps
   --domain-id-equals DomainId
```

3. Delete each application in the list.

```bash
aws --region Region sagemaker delete-app
   --domain-id DomainId
   --app-name AppName
   --app-type AppType
   --user-profile-name UserProfileName
```

4. Retrieve the list of user profiles in the Domain.

```bash
aws --region Region sagemaker list-user-profiles
   --domain-id-equals DomainId
```

5. Delete each user profile in the list.

```bash
aws --region Region sagemaker delete-user-profile
   --domain-id DomainId
```
6. Retrieve the list of shared spaces in the Domain.

```bash
aws --region Region sagemaker list-spaces \
    --domain-id DomainId
```

7. Delete each shared space in the list.

```bash
aws --region Region sagemaker delete-space \
    --domain-id DomainId \
    --space-name SpaceName
```

8. Delete the Domain. To also delete the Amazon EFS volume, specify HomeEfsFileSystem=Delete.

```bash
aws --region Region sagemaker delete-domain \
    --domain-id DomainId \
    --retention-policy HomeEfsFileSystem=Rretain
```

## Domain User Profiles

A user profile represents a single user within an Amazon SageMaker Domain. The user profile is the main way to reference a user for the purposes of sharing, reporting, and other user-oriented features. This entity is created when a user onboards to the Amazon SageMaker Domain. A user profile can have (at most) a single JupyterServer application outside the context of a shared space. The user profile's Studio application is directly associated with the user profile and has an isolated Amazon EFS directory, an execution role associated with the user profile, and Kernel Gateway applications.

**Topics**

- [Add and Remove User Profiles](#add-and-remove-user-profiles) (p. 24)
- [View User Profiles and User Profile Details](#view-user-profiles-and-user-profile-details) (p. 26)

## Add and Remove User Profiles

The following sections demonstrate how to add and remove user profiles from an Amazon SageMaker Domain using the SageMaker console or the AWS Command Line Interface (AWS CLI).

**Topics**

- [Add user profiles](#add-user-profiles) (p. 24)
- [Remove user profiles](#remove-user-profiles) (p. 26)

### Add user profiles

The following section shows how to add user profiles to a Domain using the SageMaker console or the AWS CLI.

**Add user profiles from the console**

You can add user profiles to a Domain from the SageMaker console by following this procedure.

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to add a user profile to.
5. On the Domain details page, choose the User profiles tab.
6. Choose Add user. This opens a new page.
7. Use the default name for your user profile or add a custom name.
8. For Execution role, choose an option from the role selector. If you choose Enter a custom IAM role ARN, the role must have, at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles.

If you choose Create a new role, the Create an IAM role dialog box opens:

a. For S3 buckets you specify, specify additional Amazon S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose None.

b. Choose Create role. SageMaker creates a new IAM role, AmazonSageMaker-ExecutionPolicy, with the AmazonSageMakerFullAccess policy attached.

9. (Optional) Add tags to the user profile. All resources that the user profile creates will have a Domain ARN tag and a user profile ARN tag. The Domain ARN tag is based on Domain ID, while the user profile ARN tag is based on the user profile name.

10. Choose Next.
11. Under Default JupyterLab version, select a JupyterLab version from the dropdown to use as the default for your user profile. For information about selecting a JupyterLab version, see JupyterLab Versioning.

12. In the SageMaker Projects and JumpStart section, you have two options. You can accept the default Project and JumpStart settings, or you can customize whether the user profile can create projects and use JumpStart. For more information, see SageMaker Studio Permissions Required to Use Projects.

13. Choose Next.
14. (Optional) If the Domain has an RStudio license associated, select whether you want to create the user with one of the following authorizations:
   - Unauthorized
   - RStudio Admin
   - RStudio User

15. Choose Next.
16. For the Canvas base permissions configuration, select whether to establish the minimum required permissions to use the SageMaker Canvas application.

17. (Optional) For the Time series forecasting configuration: To grant user permissions for time series forecasting in SageMaker Canvas, leave the Enable time series forecasting option turned on. It is turned on by default.

18. (Optional) If you left Enable time series forecasting turned on, select Create and use a new execution role. Alternatively, if you already have an IAM role with the required Amazon Forecast permissions attached, select Use an existing execution role. For more information, see the IAM role setup method (p. 396).

19. Choose Submit.

Create user profiles from the AWS CLI

To create a user profile in a Domain from the AWS CLI, run the following command from the terminal of your local machine. For information about the available JupyterLab version ARNs, see Setting a default JupyterLab version (p. 213).

```
aws --region region \n  sagemaker create-user-profile \n  --domain-id domain-id \n```
Remove user profiles

All apps launched by a user profile must be deleted to delete the user profile. The following section shows how to remove user profiles from a Domain using the SageMaker console or AWS CLI.

Remove user profiles from the console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to remove a user profile from.
5. On the Domain details page, choose the User profiles tab.
6. Select the user profile that you want to delete. The user profile must not contain any non-failed apps.
7. On the User details page, choose Edit.
8. Choose Delete user. This opens a new pop-up.
9. On the Delete user pop-up, choose Yes, delete user.
10. Enter delete in the field to confirm deletion.
11. Choose Delete.

Remove user profiles from the AWS CLI

To delete a user profile from the AWS CLI, run the following command from the terminal of your local machine.

```bash
aws sagemaker delete-user-profile \ 
  --region region \ 
  --domain-id domain-id \ 
  --user-profile-name user-name
```

View User Profiles and User Profile Details

This topic shows how to view a list of user profiles in an Amazon SageMaker Domain, and view details for a user profile from the SageMaker console or the AWS Command Line Interface (AWS CLI).

Topics

- View user profiles (p. 26)
- View user profile details (p. 27)

View user profiles

The following section describes how to view a list of user profiles in a Domain from the SageMaker console or the AWS CLI.
View user profiles from the console

Complete the following procedure to view a list of user profiles in the Domain from the SageMaker console.

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to view a list of user profiles for.
5. On the Domain details page, choose the User profiles tab.

View user profiles from the AWS CLI

To view the user profiles in a Domain from the AWS CLI, run the following command from the terminal of your local machine.

```
aws sagemaker list-user-profiles \
--region region \
--domain-id domain-id
```

View user profile details

The following section describes how to view the details of a user profile from the SageMaker console or the AWS CLI.

View user profile details from the console

Complete the following procedure to view the details of a user profile from the SageMaker console.

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to view a list of user profiles for.
5. On the Domain details page, choose the User profiles tab.
6. Select the user profile that you want to view details for.

View user profile details from the AWS CLI

To describe a user profile from the AWS CLI, run the following command from the terminal of your local machine.

```
aws sagemaker describe-user-profile \
--region region \
--domain-id domain-id \
--user-profile-name user-name
```

IAM Identity Center Groups in a Domain

If you use AWS IAM Identity Center authentication for your Amazon SageMaker Domain, you can add and edit group and user access to a Domain. For more information about IAM Identity Center authentication, see What is IAM Identity Center?. The following topics show how to manage IAM Identity Center users and groups that have access to a Domain.
View groups and users

Complete the following procedure to view a list of IAM Identity Center groups and users from the Amazon SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to open the Domain settings page for.
5. On the Domain details page, choose the Groups tab.

Add groups and users

Complete the following procedure to add groups and users to your Domain from the SageMaker console.

1. On the Groups tab, choose Assign users and groups.
2. On the Assign users and groups page, select the users and groups that you want to add.
3. Choose Assign users and groups.

Remove groups

Complete the following procedure to remove groups from your Domain from the SageMaker console. For information about deleting a user, see Remove user profiles (p. 26).

1. On the Groups tab, choose the group that you want to remove.
2. Choose Unassign groups.
3. On the pop-up window, choose Yes, unassign groups.
4. Enter unassign in the field.
5. Choose Unassign groups.

Collaborate with shared spaces

A shared space consists of a shared JupyterServer application and a shared directory. All user profiles in a Domain have access to all shared spaces in the Domain. Amazon SageMaker automatically scopes resources in a shared space within the context of the Amazon SageMaker Studio application that you launch in that shared space. Resources in a shared space include notebooks, files, experiments, and models.

A shared space only supports Studio and KernelGateway applications. A shared space only supports the use of a JupyterLab 3 image Amazon Resource Name (ARN). For more information, see JupyterLab Versioning (p. 211).

Amazon SageMaker automatically tags all SageMaker resources that you create within the scope of a shared space. You can use these tags to monitor costs and plan budgets using tools, such as AWS Budgets.

A shared space uses the same VPC settings as the Domain that it's created in.
**Note**
Domains with AWS IAM Identity Center authentication do not currently support the use of shared spaces. Shared spaces do not support the use of Amazon SageMaker Data Wrangler or Amazon EMR cross-account clusters.

**Automatic tagging**

All resources created in a shared space are automatically tagged with a Domain ARN tag and shared space ARN tag. The Domain ARN tag is based on the Domain ID, while the shared space ARN tag is based on the shared space name.

You can use these tags to monitor AWS CloudTrail usage. For more information, see [Log Amazon SageMaker API Calls with AWS CloudTrail](#).

You can also use these tags to monitor costs with AWS Billing and Cost Management. For more information, see [Using AWS cost allocation tags](#).

**Real time co-editing of notebooks**

A key benefit of a shared space is that it facilitates collaboration between members of the shared space in real time. Users collaborating in a workspace get access to a shared Studio application where they can access, read, and edit their notebooks in real time. Real time collaboration is only supported for JupyterServer applications within a shared space.

Users with access to a shared space can simultaneously open, view, edit, and execute Jupyter notebooks in the shared Studio application in that space.

The notebook indicates each co-editing user with a different cursor that shows the user profile name. While multiple users can view the same notebook, co-editing is best suited for small groups of two to five users.

To track changes being made by multiple users, we strongly recommended using Studio's built-in Git-based version control.

**JupyterServer 2**

To use shared spaces, Jupyter Server version 2 is required. Certain JupyterLab extensions and packages can forcefully downgrade Jupyter Server to version 1. This prevents the use of shared space. Run the following from the command prompt to change the version number and continue using shared spaces.

```bash
conda activate studio
pip install jupyter-server==2.0.0rc3
```

**Customize a shared space**

To attach a lifecycle configuration or custom image to a shared space, you must use the AWS CLI. For more information about creating and attaching lifecycle configurations, see [Create and associate a lifecycle configuration](#). For more information about creating and attaching custom images, see [Bring your own SageMaker image](#).

**Create a shared space**

The following topic demonstrates how to create a shared space in an existing Amazon SageMaker Domain. If you created your Domain without support for shared spaces, you must add support for shared spaces to your existing Domain before you can create a shared space.

**Topics**

- [Add shared space support to an existing Domain](#)
Add shared space support to an existing Domain

You can use the SageMaker console or the AWS CLI to add support for shared spaces to an existing Domain.

**Console**

Complete the following procedure to add support for shared spaces to an existing Domain from the SageMaker console.

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of Domains, select the Domain that you want to open the **Domain settings** page for.
5. On the **Domain details** page, choose the **Domain settings** tab.
6. Choose **Edit**.
7. For **Space default execution role**, set an IAM role that is used by default for all shared spaces created in the Domain.
8. Choose **Next**.
9. Choose **Next**.
10. Choose **Next**.
11. Choose **Submit**.

**AWS CLI**

Run the following command from the terminal of your local machine to add default shared space settings to a Domain from the AWS CLI. If you are adding default shared space settings to a Domain within an Amazon VPC, you must also include a list of security groups. Shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see [JupyterLab Versioning](p. 211).

```bash
# Public Internet domain
aws --region region \ 
sagemaker update-domain \  
--domain-id domain-id \ 
--default-space-settings "ExecutionRole=execution-role-arn,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=system,SageMakerImageArn=sagemaker-image-arn}}"

# VPCOnly domain
aws --region region \ 
sagemaker update-domain \  
--domain-id domain-id \ 
--default-space-settings "ExecutionRole=execution-role-arn,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=system,SageMakerImageArn=sagemaker-image-arn}},SecurityGroups=[security-groups]"
```

Verify that the default shared space settings have been updated.

```bash
aws --region region \ 
sagemaker describe-domain \ 
```
Create from the console

Complete the following procedure to create a shared space in a Domain from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to create a shared space for.
5. On the Domain details page, choose the Space management tab.
6. Choose Create.
7. Enter a name for your shared space. shared space names within a Domain must be unique. The execution role for the shared space is set to the Domain IAM execution role.

Create from AWS CLI

This section shows how to create a shared space from the AWS CLI.

You cannot set the execution role of a shared space when creating or updating it. The DefaultDomainExecRole can only be set when creating or updating the Domain. shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see JupyterLab Versioning (p. 211).

To create a shared space from the AWS CLI, run the following command from the terminal of your local machine.

```bash
aws --region region \
  sagemaker create-space \
  --domain-id domain-id \
  --space-name space-name \
  --space-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "SageMakerImageArn": "sagemaker-image-arn",
        "InstanceType": "system"
      }
    }
  }'
```

List and Describe shared spaces

This guide shows how to access a list of shared spaces in an Amazon SageMaker Domain with the Amazon SageMaker console or the AWS CLI. It also shows how to view details of a shared space from the AWS CLI.

Topics

- List shared spaces (p. 31)
- View shared space details (p. 32)

List shared spaces

The following topic describes how to view a list of shared spaces within a Domain from the SageMaker console or the AWS CLI.
List shared spaces from the console

Complete the following procedure to view a list of the shared spaces in a Domain from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to view the list of shared spaces for.
5. On the Domain details page, choose the Space management tab.

List shared spaces from the AWS CLI

To list the shared spaces in a Domain from the AWS CLI, run the following command from the terminal of your local machine.

```bash
aws --region region \n  sagemaker list-spaces \n  --domain-id domain-id
```

View shared space details

The following section describes how to view shared space details from the SageMaker console or the AWS CLI.

View shared space details from the console

You can view the details of a shared space from the SageMaker console using the following procedure.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to view the list of shared spaces for.
5. On the Domain details page, choose the Space management tab.
6. Select the name of the space to open a new page that lists details about the shared space.

View shared space details from the AWS CLI

To view the details of a shared space from the AWS CLI, run the following command from the terminal of your local machine.

```bash
aws --region region \n  sagemaker describe-space \n  --domain-id domain-id \n  --space-name space-name
```

Edit a shared space

You can only edit the details for a shared space using the AWS CLI. This is not currently supported from the Amazon SageMaker console. You can only update workspace attributes when there are no running applications in the shared space.
To edit the details of a shared space from the AWS CLI, run the following command from the terminal of your local machine. Shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see *JupyterLab Versioning (p. 211)*.

```
aws --region region \n  sagemaker update-space \n    --domain-id domain-id \n    --space-name space-name \n    --query SpaceArn --output text \n    --space-settings '{
      "JupyterServerAppSettings": {
        "DefaultResourceSpec": {
          "SageMakerImageArn": "sagemaker-image-arn",
          "InstanceType": "system"
        }
      }
    },'
```

**Delete a shared space**

The following topic shows how to delete a shared space from the Amazon SageMaker console or AWS CLI. A shared space can only be deleted if it has no running applications.

**Topics**

- *Console (p. 33)*
- *AWS CLI (p. 33)*

**Console**

Complete the following procedure to delete a shared space in the Amazon SageMaker Domain from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose *Admin configurations*.
3. Under *Admin configurations*, choose *Domains*.
4. From the list of Domains, select the Domain that you want to create a shared space for.
5. On the *Domain details* page, select the *Space management* tab.
6. Select the shared space that you want to delete. The shared space must not contain any non-failed apps.
7. Choose *Delete*. This opens a new window.
8. Choose *Yes, delete space*.
9. Enter *delete* in the field.
10. Choose *Delete space*.

**AWS CLI**

To delete a shared space from the AWS CLI, run the following command from the terminal of your local machine.

```
aws --region region \n  sagemaker delete-space \n    --domain-id domain-id \n    --space-name space-name
```
Onboard to Amazon SageMaker Domain using Quick setup

This topic describes how to onboard to Amazon SageMaker Domain by using the Quick setup procedure from the SageMaker console. This procedure uses AWS Identity and Access Management (IAM) authentication. For information on how to onboard using the standard IAM procedure, see Onboard using IAM (p. 39).

RStudio support is not currently available when onboarding using the Quick setup procedure. To use RStudio, you must onboard using the Standard setup procedure.

Default settings

When you onboard to Amazon SageMaker Domain using the Quick setup procedure, SageMaker uses the following defaults as part of the domain and user profile creation. You can't modify these defaults using the Quick setup procedure.

- **Domain name**: SageMaker automatically assigns the name of the domain with a timestamp in the following format.
  
  QuickSetupDomain-YYYYMMDDTHHMMSS

- **User profile name**: SageMaker automatically assigns the name of the user profile with a timestamp in the following format.
  
  default-YYYYMMDDTHHMMSS

- **Domain execution role**: SageMaker creates a new IAM role and attaches the AmazonSageMakerFullAccess policy.

- **User profile execution role**: SageMaker sets the user profile execution role to the same IAM role used for the domain execution role.

- **Shared space execution role**: SageMaker sets the shared space execution role to the same IAM role used for the domain execution role.

- **SageMaker Canvas time series forecasting role**: SageMaker creates a new IAM role with the permissions required to use the SageMaker Canvas time series forecasting feature.

- **Amazon S3 bucket**: SageMaker creates an Amazon S3 bucket named with the following format for notebook sharing.
  
  sagemaker-studio-XXXXXXXXXXXXXXX

- **Amazon VPC**: SageMaker selects a public VPC with the following logic.
  
  1. If there is a default VPC with associated subnets in the Region, SageMaker uses it.
  2. If there is no default VPC or the default VPC has no associated subnets, then SageMaker uses any existing VPC with associated subnets. If there are multiple existing VPCs, SageMaker can select any of them.

For information about onboarding with AWS IAM Identity Center, see Onboard using IAM Identity Center (p. 35).

To onboard to the Domain using Quick setup

1. Open the SageMaker console.
2. Choose Amazon SageMaker at the left of the page to open the SageMaker landing page.
3. Under **New to SageMaker?**, choose **Set up for single user**. Your domain and user profile are created automatically.

Now that you've onboarded to the Domain, you can launch an app following the steps in [Launch Amazon SageMaker Studio](p. 209). For information about adding users to your Domain, see [Add and Remove User Profiles](p. 24).

For information about using SageMaker Studio, see [SageMaker Studio](p. 204).

### Onboard to Amazon SageMaker Domain using IAM Identity Center

This topic describes how to onboard to Amazon SageMaker Domain using authentication using IAM Identity Center from the SageMaker console or the AWS CLI. For information about setting up IAM Identity Center for use with a Domain, see [Set up IAM Identity Center for use with Amazon SageMaker Domain](p. 38). For information on how to onboard using AWS Identity and Access Management (IAM) authentication, see [Onboard using Quick setup](p. 34) or [Onboard using IAM](p. 39).

### Onboard from the console

**To onboard to Domain using IAM Identity Center**

1. Open the [SageMaker console](#).
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the **Domains** page, choose **Create domain**.
5. On the **Setup SageMaker Domain** page, choose **Standard setup**.
6. Select **Configure**.

**Step 1: General settings**

1. For **Domain Name**, enter a unique name for your Domain.
2. For **Authentication**, choose **AWS IAM Identity Center**.
3. If you don't have IAM Identity Center created in the same Region as your SageMaker Domain, you must create IAM Identity Center in the correct Region before proceeding. To continue to onboard without IAM Identity Center, choose the **AWS Identity and Access Management (IAM)** authentication method or the **Quick setup** procedure, which also uses IAM.

   For information about setting up IAM Identity Center for use with Domain, see [Set up IAM Identity Center for use with Amazon SageMaker Domain](p. 38).

4. Under **Permission**, for **Default execution role**, choose an option from the role selector.

   If you choose **Enter a custom IAM role ARN**, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see [SageMaker Roles](p. 3387).

   If you choose **Create a new role**, the **Create an IAM role** dialog box opens:

   a. For **S3 buckets you specify**, specify additional Amazon S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose **None**.

   b. Choose **Create role**. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the **AmazonSageMakerFullAccess** policy attached.
5. Under **Network and storage**, specify the following:

- Your Amazon Virtual Private Cloud (Amazon VPC) information – For more information, see [Choose an Amazon VPC](p. 42).

- **(Optional) Encryption key** – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see [Protect Data at Rest Using Encryption](p. 3344).

  **Note**
  Encryption in transit is only available for Amazon SageMaker Studio.

6. Select **Next**.

**Step 2: Studio settings**

1. Under **Default JupyterLab version**, select a JupyterLab version from the dropdown to use as the default for your Domain. For information on selecting a JupyterLab version, see [JupyterLab Versioning](p. 211).

2. Under **Notebook Sharing Configuration**, accept the default notebook sharing configuration or customize the options.

3. Under **SageMaker Projects and JumpStart**, accept the default Project and JumpStart settings, or customize whether administrators and users can create projects and use JumpStart. For more information, see [SageMaker Studio Permissions Required to Use Projects](p. 3021).

4. Select **Next**.

**Step 3: RStudio settings**

1. Under **RStudio Workbench**, verify that your RStudio license is automatically detected. For more information about getting an RStudio license and activating it with SageMaker, see [RStudio license](p. 604).

2. Select an instance type to launch your RStudio Server on. For more information, see [RStudioServerPro instance type](p. 610).

3. Under **Permission**, create your role or select an existing role. The role must have the following permissions policy. This policy allows the RStudioServerPro app to access necessary resources. It also allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status. For information about adding permissions to a role, see [Modifying a role permissions policy (console)].

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "license-manager:ExtendLicenseConsumption",
        "license-manager:ListReceivedLicenses",
        "license-manager:GetLicense",
        "license-manager:CheckoutLicense",
        "license-manager:CheckInLicense",
        "logs:CreateLogDelivery",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DeleteLogDelivery",
        "logs:Describe*",
        "logs:GetLogDelivery",
        "logs:GetLogEvents",
      ],
    }
  ]
}
```
4. **Under RStudio Connect**, add the URL for your RStudio Connect server. RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. When you onboard to RStudio on SageMaker, an RStudio Connect server is not created. For more information, see [RStudio Connect URL](p. 611).

5. **Under RStudio Package Manager**, add the URL for your RStudio Package Manager. SageMaker creates a default package repository for the Package Manager when you onboard RStudio. For more information about RStudio Package Manager, see [RStudio Package Manager](p. 611).

6. Select Next.

### Step 4: SageMaker Canvas settings

1. For the **Canvas base permissions configuration**, keep the **Enable Canvas base permissions** option turned on (it is turned on by default). This establishes the minimum required permissions to use the SageMaker Canvas app.

2. (Optional) For the **Time series forecasting configuration**, keep the **Enable time series forecasting** option turned on. This gives your users permissions to do time series forecasting in SageMaker Canvas. This is turned on by default.

3. (Optional) If you left **Enable time series forecasting** turned on, select **Create and use a new execution role**. However, if you already have an IAM role with the required Amazon Forecast permissions attached, select **Use an existing execution role**. For more information, see the [IAM role setup method](p. 396).

4. Use the default IAM role suffix or provide a custom suffix for the role.

5. For **Local file upload configuration**, select **Enable local file upload** to let users upload local files into their SageMaker Canvas application. This is selected by default.

6. Choose **Submit**.

### Onboard from the AWS CLI

Use the following commands to onboard to a Domain using authentication using IAM Identity Center from the AWS CLI.

1. Create an execution role that is used to create a Domain and attach the AmazonSageMakerFullAccess policy. You can also use an existing role that has, at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see [SageMaker Roles](p. 3387).

   ```bash
   aws iam create-role --role-name execution-role-name
   aws iam attach-role-policy --role-name execution-role-name --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
   ```

2. Get the default Amazon Virtual Private Cloud (Amazon VPC) of your account.

   ```bash
   aws --region region ec2 describe-vpcs --filters Name=isDefault,Values=true --query "Vpcs[0].VpcId" --output text
   ```
3. Get the list of subnets in the default Amazon VPC.

```
aws --region region ec2 describe-subnets --filters Name=vpc-id,Values=default-vpc-id --query "Subnets[*].SubnetId" --output json
```

4. Create a Domain by passing the default Amazon VPC ID, subnets, and execution role ARN. You must also pass a SageMaker image ARN. For information on the available JupyterLab version ARNs, see Setting a default JupyterLab version (p. 213).

```
aws --region region sagemaker create-domain --domain-name domain-name --vpc-id default-vpc-id --subnet-ids subnet-ids --auth-mode SSO --default-user-settings "ExecutionRole=arn:aws:iam::account-number:role/execution-role-name,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=system,SageMakerImageArn=image-arn}}" --query DomainArn --output text
```

5. Verify that the Domain has been created.

```
aws --region region sagemaker list-domains
```

To access the Domain after onboarding

After you are given access to the Domain, you are sent an email inviting you to create a password and use IAM Identity Center. The email also contains the URL to sign in to the Domain. For more information about signing in and session duration, see How to sign in to the user portal.

After you activate your account, go to the Domain URL, sign in, and wait for your user profile to be created. On subsequent visits, you only need to wait for the Studio or RStudio app to load.

Bookmark the URL. The URL is also available on the Domain settings page.

For information about using Studio, see SageMaker Studio (p. 204).

For information about using RStudio, see RStudio on Amazon SageMaker (p. 602).

Set up IAM Identity Center for use with Amazon SageMaker Domain

To use authentication in IAM Identity Center, you must belong to an organization in AWS Organizations. If you don’t belong to an organization, you can create one by following the steps in Tutorial: Creating and configuring an organization.

After you have created your organization and user, you can create a SageMaker user profile for that user in IAM Identity Center as follows.

1. From the Amazon SageMaker console: You can use the Amazon SageMaker console to create a user profile for the user in IAM Identity Center. If the user in IAM Identity Center hasn’t already been associated with the Domain, it is automatically associated.

2. Using the AWS CLI or AWS CloudFormation – A user in IAM Identity Center assigned to the Domain can create a user profile using the SageMaker console, the AWS CLI or AWS CloudFormation.
   - First, you must use the IAM Identity Center console to assign the user or the user’s group to the Domain. For more information about application assignment, see Assign user access.
   - Then, use the AWS CLI or AWS CloudFormation to create a SageMaker user profile for the user.

Note
To simplify administration of access permissions, we recommend using IAM Identity Center to assign groups to the Domain (instead of assigning users). Groups allow permissions to be
granted or denied to multiple users at once. A user can be moved out of a group or to a different

group if needed. When assigning user access to applications, IAM Identity Center does not

currently support users being added to nested groups. If a user is added to a nested group, they

might receive a "You do not have any applications" error message during sign-in. Assignments must be made to the immediate group the user is a member of.

Return to the Domains page to continue to onboard using IAM Identity Center authentication.

Onboard to Amazon SageMaker Domain using IAM

This topic describes how to onboard to Amazon SageMaker Domain using the standard setup procedure

for AWS Identity and Access Management (IAM) authentication from the SageMaker console or the AWS

CLI. To onboard faster using IAM, see Onboard using Quick setup (p. 34).

For information on how to onboard using AWS IAM Identity Center (IAM Identity Center), see Onboard

using IAM Identity Center (p. 35).

Onboard using console

To onboard to Domain using IAM

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the Domains page, choose Create domain.
6. Select Configure.

Step 1: General settings

1. For Domain Name, enter a unique name for your Domain.
2. For Authentication, choose AWS Identity and Access Management (IAM).
3. Under Permission, for Default execution role, choose an option from the role selector.

   If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust

   policy that grants SageMaker permission to assume the role. For more information, see SageMaker

   Roles (p. 3387).

   If you choose Create a new role, the Create an IAM role dialog box opens:

   a. For S3 buckets you specify, specify additional Amazon S3 buckets that users of your notebooks

      can access. If you don't want to add access to more buckets, choose None.

   b. Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role

      with the AmazonSageMakerFullAccess policy attached.
4. For Space default execution role, choose an option from the role selector.

   If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust

   policy that grants SageMaker permission to assume the role. For more information, see SageMaker

   Roles (p. 3387).

   If you choose Create a new role, the Create an IAM role dialog box opens:

   a. For S3 buckets you specify, specify additional Amazon S3 buckets that users of your notebooks

      can access. If you don't want to add access to more buckets, choose None.
b. Choose **Create role**. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the **AmazonSageMakerFullAccess** policy attached.

5. **Under Network and storage**, specify the following:

   - Your Amazon Virtual Private Cloud (Amazon VPC) information – For more information, see [Choose an Amazon VPC](p. 42).
   - (Optional) **Encryption key** – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see [Protect Data at Rest Using Encryption](p. 3344).

   **Note**
   Encryption in transit is only available for Amazon SageMaker Studio.

6. Select **Next**.

**Step 2: Studio settings**

1. Under **Default JupyterLab version**, select a JupyterLab version from the dropdown to use as the default for your Domain. For information on selecting a JupyterLab version, see [JupyterLab Versioning](p. 211).

2. Under **Notebook Sharing Configuration**, accept the default notebook sharing configuration or customize the options.

3. Under **SageMaker Projects and JumpStart**, accept the default Project and JumpStart settings or customize whether administrators and user can create projects and use JumpStart. For more information, see [SageMaker Studio Permissions Required to Use Projects](p. 3021).

4. Select **Next**.

**Step 3: RStudio settings**

1. Under **RStudio Workbench**, verify that your RStudio license is automatically detected. For more information about getting an RStudio license and activating it with SageMaker, see [RStudio license](p. 604).

2. Select an instance type to launch your RStudio Server on. For more information, see [RStudioServerPro instance type](p. 610).

3. Under **Permission**, create your role or select an existing role. The role must have the following permissions policy. This policy allows the RStudioServerPro app to access necessary resources and allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status. For information on adding permissions to a role, see [Modifying a role permissions policy (console)].

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "license-manager:ExtendLicenseConsumption",
        "license-manager:ListReceivedLicenses",
        "license-manager:GetLicense",
        "license-manager:CheckoutLicense",
        "license-manager:CheckInLicense",
        "logs:CreateLogDelivery",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DeleteLogDelivery",
```
4. Under RStudio Connect, add the URL for your RStudio Connect Server. RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. When you onboard to RStudio on Amazon SageMaker, an RStudio Connect server is not created. You must create an RStudio Connect server on an EC2 instance to use Connect with Amazon SageMaker. For more information, see RStudio Connect URL (p. 611).

5. Under RStudio Package Manager, add the URL for your RStudio Package Manager. SageMaker creates a default package repository for the Package Manager when you onboard RStudio. For more information about RStudio Package Manager, see RStudio Package Manager (p. 611).

6. Select Next.

Step 4: SageMaker Canvas settings

1. For the Canvas base permissions configuration, leave the Enable Canvas base permissions option turned on (it is turned on by default). This establishes the minimum required permissions to use the SageMaker Canvas app.

2. (Optional) For the Time series forecasting configuration, leave the Enable time series forecasting option turned on to give your users permissions to do time series forecasting in SageMaker Canvas (it is turned on by default).

3. (Optional) If you left Enable time series forecasting turned on, select Create and use a new execution role, or select Use an existing execution role if you already have an IAM role with the required Amazon Forecast permissions attached (for more information, see the IAM role setup method (p. 396)).

4. Use the default IAM role suffix or provide a custom suffix for the role.

5. For Local file upload configuration, select Enable local file upload to enable users to upload local files into their SageMaker Canvas application (it's already checked by default).

6. Choose Submit.

Onboard using the AWS CLI

Use the following commands to onboard to a Domain using authentication using IAM from the AWS CLI.

1. Create an execution role that is used to create a Domain and attach the AmazonSageMakerFullAccess policy. You can also use an existing role that has, at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3387).

   ```bash
   aws iam create-role --role-name execution-role-name
   aws iam attach-role-policy --role-name execution-role-name --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
   ```

2. Get the default Amazon Virtual Private Cloud (Amazon VPC) of your account.
Choose an Amazon VPC

This topic provides detailed information about choosing an Amazon Virtual Private Cloud (Amazon VPC) when you onboard to Amazon SageMaker Domain. For more information about onboarding to SageMaker Domain, see Onboard to Amazon SageMaker Domain (p. 10).

By default, SageMaker Domain uses two Amazon VPC. One Amazon VPC is managed by Amazon SageMaker and provides direct internet access. You specify the other Amazon VPC, which provides encrypted traffic between the Domain and your Amazon Elastic File System (Amazon EFS) volume.

You can change this behavior so that SageMaker sends all traffic over your specified Amazon VPC. When you choose this option, you must provide the subnets, security groups, and interface endpoints that are necessary to communicate with the SageMaker API and SageMaker runtime, and various AWS services, such as Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch, that are used by Amazon SageMaker Studio and your Studio notebooks.

When you onboard to SageMaker Domain, you tell SageMaker to send all traffic over your Amazon VPC by setting the network access type to VPC only.

### To specify the Amazon VPC information

When you specify the Amazon VPC entities (that is, the Amazon VPC, subnet, or security group) in the following procedure, one of three options is presented based on the number of entities you have in the current AWS Region. The behavior is as follows:

- **One entity** – SageMaker uses that entity. This can't be changed.
- **Multiple entities** – You must choose the entities from the dropdown list.
- **No entities** – You must create one or more entities in order to use Domain. Choose Create <entity> to open the VPC console in a new browser tab. After you create the entities, return to the Domain Get started page to continue the onboarding process.
This procedure is part of the Amazon SageMaker Domain onboarding process when you choose Standard setup. Your Amazon VPC information is specified under the Network section.

1. Choose the Amazon VPC.
2. Choose one or more subnets. If you don't choose any subnets, SageMaker uses all the subnets in the Amazon VPC. We recommend that you use multiple subnets that are not created in constrained Availability Zones. Using subnets in these constrained Availability Zones can result in insufficient capacity errors and longer application creation times. For more information about constrained Availability Zones, see Availability Zones.
3. Select the network access type.

   **Note**
   If VPC only is selected, SageMaker automatically applies the security group settings defined for the Domain to all shared spaces created in the Domain. If Public internet only is selected, SageMaker does not apply the security group settings to shared spaces created in the Domain.

   - **Public internet only** – Non-Amazon EFS traffic goes through a SageMaker managed Amazon VPC, which allows internet access. Traffic between the Domain and your Amazon EFS volume is through the specified Amazon VPC.
   - **VPC only** – All SageMaker traffic is through the specified Amazon VPC and subnets. You must use a subnet that does not have direct internet access in VPC only mode. Internet access is disabled by default.
4. Choose the security groups. If you chose Public internet only, this step is optional. If you chose VPC only, this step is required.

   **Note**
   For the maximum number of allowed security groups, see UserSettings.

For Amazon VPC requirements in VPC only mode, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522).

**Supported Regions and Quotas**

For the AWS Regions supported by Amazon SageMaker and the Amazon Elastic Compute Cloud (Amazon EC2) instance types that are available in each Region, see Amazon SageMaker Pricing.

For a list of the SageMaker service endpoints for each Region, see Amazon SageMaker endpoints and quotas in the AWS General Reference.

**Quotas**

For a list of SageMaker quotas, see Amazon SageMaker endpoints and quotas in the AWS General Reference.

The Service Quotas console provides information about your service quotas. You can use the Service Quotas console to view your default service quotas or to request quota increases. To request a quota increase for adjustable quotas, see Requesting a quota increase.

You can set up a quota request template for your AWS Organization that automatically requests quota increases during account creation. For more information, see Using Service Quotas request templates.
Use automated ML, no-code, or low-code

Amazon SageMaker offers the following features to automate key machine learning tasks and use no-code or low-code solutions.

- **Amazon SageMaker Autopilot** is a feature-set that automates key tasks of an automatic machine learning (AutoML) process. It explores your data, selects the algorithms relevant to your problem type, and prepares the data to facilitate model training and tuning.
- **SageMaker JumpStart** provides pretrained, open-source models for a wide range of problem types to help you get started with machine learning. You can incrementally train and tune these models before deployment. JumpStart also provides solution templates that set up infrastructure for common use cases, and executable example notebooks for machine learning with SageMaker.

**Topics**
- [SageMaker Autopilot](#) (p. 44)
- [SageMaker JumpStart](#) (p. 161)

**SageMaker Autopilot**

Amazon SageMaker Autopilot is a feature-set that simplifies and accelerates various stages of the machine learning workflow by automating the process of building and deploying machine learning models (AutoML).

Autopilot performs the following key tasks that you can use on autopilot (hence the name) or with various degrees of human guidance:

- **Data analysis and preprocessing**: Autopilot identifies your specific problem type, handles missing values, normalizes your data, selects features, and overall prepares the data for model training.
- **Model selection**: Autopilot explores a variety of algorithms and uses a cross-validation resampling technique to generate metrics that evaluate the predictive quality of the algorithms based on predefined objective metrics.
- **Hyperparameter Optimization**: Autopilot automates the search for optimal hyperparameter configurations.
- **Model Training and Evaluation**: Autopilot automates the process of training and evaluating various model candidates. It splits the data into training and validation sets, trains the selected model candidates using the training data, and evaluates their performance on the unseen data of the validation set. Lastly, it ranks the optimized model candidates based on their performance and identifies the best performing model.
- **Model Deployment**: Once Autopilot has identified the best performing model, it provides the option to deploy the model automatically by generating the model artifacts and the endpoint exposing an API (Application Programming Interface). External applications can send data to the endpoint and receive the corresponding predictions or inferences.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs.
The following outlines the tasks of this AutoML process managed by Autopilot.

Depending on your comfort level with the machine learning process and coding experience, you can use Autopilot in different ways:

- **Fully automated mode** without any additional human input with Amazon SageMaker Studio UI. This approach requires minimal coding or technical knowledge. Only experiments created from tabular data for problem types such as regression or classification are available via the Studio UI.

- **Human input** with specific option and parameter selection in Amazon SageMaker Studio UI. Users can better customize and control the creation of their machine learning experiment by selecting specific options and parameter values.

- **Code implementation** using SDKs. If you have coding experience, you can use available software development kits (SDKs) to create an Autopilot experiment into your own code. This approach provides greater flexibility and customization options.

Autopilot currently supports the following problem types:

- **Regression, binary, and multiclass classification** with tabular data formatted as CSV or Parquet files in which each column contains a feature with a specific data type and each row contains an observation. The column data types accepted include numerical, categorical, text, and time series that consists of strings of comma-separated numbers.

- **Text classification** with data formatted as CSV or Parquet files in which a column provides the sentences to be classified, while another column should provide the corresponding class label.

- **Image classification** with images formats such as PNG, JPEG or a combination of both.

- **Time-series forecasting** with time-series data formatted as CSV or as Parquet files.

- **Text generation** fine-tuning of Large Language Models (LLMs) with data formatted as CSV or as Parquet files.

**Note**
For regression or classification problems involving tabular data, users can choose between two options: using the Studio user interface or the API Reference. Tasks such as text and image classification, time-series forecasting, or LLMs fine-tuning are exclusively available through the latest version of the SageMaker API. Users who prefer the convenience of a user interface can use Amazon SageMaker Canvas to access pre-trained models or create custom models tailored for specific text, image classification, or forecasting needs.

Additionally, Autopilot helps users understand how models make predictions by automatically generating reports that show the importance of each individual feature. This provides transparency and insights into the factors influencing the predictions, which can be used by risk and compliance teams and external regulators. Autopilot also provides a model performance report, which encompasses a summary of evaluation metrics, a confusion matrix, various visualizations such as receiver operating characteristic curves and precision-recall curves, and more. The specific content of each report vary depending on the problem type of the Autopilot experiment.

The explainability and performance reports of Autopilot are available for all problem types for the best model candidate.
For tabular data use cases such as regression or classification, Autopilot offers additional visibility into how the data was wrangled and how the model candidates were selected, trained, and tuned, by generating notebooks that contain the code used to explore the data and find the best performing model. These notebooks provide an interactive and exploratory environment to help you learn about the impact of various inputs or the trade-offs made in the experiments. You can experiment further with the higher performing model candidate by making your own modifications to the data exploration and candidate definition notebooks provided by Autopilot.

With Amazon SageMaker, you pay only for what you use. You pay for the underlying compute and storage resources within SageMaker or other AWS services, based on your usage. For more information about the cost of using SageMaker, see Amazon SageMaker Pricing.

Create an Amazon SageMaker Autopilot experiment for tabular data

In this guide, you learn how to create an Amazon SageMaker Autopilot experiment (that is, start an Autopilot job in SageMaker) to explore, pre-process, and train various model candidates on a tabular dataset.

You can use a user interface (Amazon SageMaker Studio UI) to help you specify the name of your experiment, provide locations for the input and output data, and specify which target data to predict or you can use the AWS Command Line Interface or any SDK supported by SageMaker API Reference. Optionally, you can also specify the type of machine learning problem that you want to solve, choose your modeling strategy (stacked ensembles or hyperparameters optimization), select the list of algorithms used by the Autopilot job to train the data, and more.

The UI has descriptions, toggle switches, dropdown menus, radio buttons, and more to help you navigate creating your model candidates. You can view statistics while the experiment is running. After it runs, you can compare trials and delve into the details of the pre-processing steps, algorithms, and hyperparameter ranges of each model. You also have the option to download their explainability and performance reports. Use the provided notebooks to see the results of the automated data exploration or the candidate model definitions.

- To create an Autopilot job as a pilot experiment using Studio UI, see Create an Autopilot experiment using Studio (p. 47).
- To create an Autopilot job as a pilot experiment using SageMaker API reference, see Create an Autopilot experiment programmatically (p. 53).
- If you are an administrator looking to pre-configure default infrastructure, networking, or security parameters of Autopilot experiments in Studio UI, see Configure the default parameters of an Autopilot experiment (for administrators) (p. 47).
Create an Autopilot experiment using Studio

Configure the default parameters of an Autopilot experiment (for administrators)

Autopilot supports setting default values to simplify the configuration of Amazon SageMaker Autopilot when you create an Autopilot experiment using the Studio UI. Administrators can use Studio lifecycle configurations (p. 271) (LCC) to set infrastructure, networking, and security values in configuration files and pre-populate the advanced settings (p. 52) of AutoML jobs.

By doing so, they can fully control network connectivity and access permissions for the resources associated with Amazon SageMaker Studio, including SageMaker instances, data sources, output data, and other related services. Specifically, administrators can configure a desired network architecture, such as Amazon VPC, subnets, and security groups, for a Studio Domain or individual user profiles. Data scientists can focus on data science specific parameters when creating their Autopilot experiments using the Studio UI. Furthermore, administrators can manage the encryption of data on the instance in which Autopilot experiments run by setting default encryption keys.

**Note**
This feature is currently not available in the Asia Pacific (Hong Kong) and Middle East (Bahrain) opt-in Regions.

In the following sections, you can find the full list of parameters supporting the setting of defaults when creating an Autopilot experiment using the Studio UI, and learn how to set those default values.

**Topics**
- List of default parameters supported (p. 47)
- Set default Autopilot experiment parameters (p. 47)

**List of default parameters supported**

The following parameters support setting default values with a configuration file for creating an Autopilot experiment using the Studio UI. Once set, the values automatically fill in their corresponding field in the Autopilot' Create Experiment tab in the Studio UI. See Advanced settings (optional) (p. 52) for a full description of each field.

- **Security**: Amazon VPC, subnets, and security groups.
- **Access**: AWS IAM role ARNs.
- **Encryption**: AWS KMS key IDs.
- **Tags**: Key-value pairs used to label and organize SageMaker resources.

**Set default Autopilot experiment parameters**

Administrators can set default values in a configuration file, then manually place the file in a recommended location within the Studio environment of specific users, or they can pass the file to a lifecycle configuration script (LCC) to automate the customization of the Studio environment for a given Domain or user profile.

- To set up the configuration file, start by filling in its default parameters.

  To configure any or all default values listed in List of default parameters supported (p. 47), administrators can create a configuration file named config.yaml, the structure of which should adhere to this sample configuration file. The following snippet shows a sample configuration file with all the supported AutoML parameters. For more information on the format of this file, refer to the full schema.
Then, place the configuration file in the recommended location by either manually copying the file (p. 49) to its recommended paths or using a lifecycle configuration (p. 49) (LCC).

The configuration file needs to be present in at least one of the following locations in the user's Studio environment. By default, SageMaker searches for a configuration file in two locations:

- First, in `/etc/xdg/sagemaker/config.yaml`. We refer to this file as the administrator configuration file.
- Then, in `/root/.config/sagemaker/config.yaml`. We refer to this file as the user configuration file.

Using the administrator configuration file, administrators can define a set of default values. Optionally, they can use the user configuration file to override values set in the administrator configuration file, or set additional default parameter values.

The following snippet shows a sample script which writes the default parameters configuration file to the administrator location in the user's Studio environment. You can replace `/etc/xdg/sagemaker` with `/root/.config/sagemaker` to write the file to the user location.

```bash
#!/bin/bash

sudo mkdir -p /etc/xdg/sagemaker

echo 'SchemaVersion: '1.0'
CustomParameters:
  AnyStringKey: 'AnyStringValue'
SageMaker:
  AutoMLJob:
    # https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_CreateAutoMLJob.html
    AutoMLJobConfig:
      SecurityConfig:
        EnableInterContainerTrafficEncryption: true
        VolumeKmsKeyId: 'kms-key-id'
      VpcConfig:
        SecurityGroupIds:
          - 'security-group-id-1'
          - 'security-group-id-2'
        Subnets:
          - 'subnet-1'
          - 'subnet-2'
      OutputDataConfig:
        KmsKeyId: 'kms-key-id'
        RoleArn: 'arn:aws:iam::111222333444:role/Admin'
      Tags:
        - Key: 'tag_key'
          Value: 'tag_value'
```

48
Amazon SageMaker Developer Guide
Create an Autopilot Experiment for Tabular Data

```
- subnet-2
OutputDataConfig:
  KmsKeyId: 'kms-key-id'
  RoleArn: 'arn:aws:iam::1112233444:role/Admin'
Tags:
- Key: 'tag_key'
  Value: 'tag_value'
```

```
| sudo tee /etc/xdg/sagemaker/config.yaml
```

- **Copy the files manually** – To copy the configuration files manually, run the [script](p. 49) created in the previous step from a Studio terminal. In this case, the user profile that executed the script can create Autopilot experiments with the default values applicable only to them.

- **Create a SageMaker lifecycle configuration** – Alternatively, you can use a [lifecycle configuration](LCC) to automate the customization of your Studio environment. LCC are shell scripts triggered by Amazon SageMaker Studio lifecycle events such as starting a Studio application. This customization includes installing custom packages, configuring notebook extensions, pre-loading datasets, setting up source code repositories, or, in our case, pre-populating default parameters. Administrators can attach the LCC to a Studio Domain to automate the configuration of default values for each user profile within that Domain.

The following sections detail how to create a lifecycle configuration so users can load Autopilot default parameters automatically when launching Studio. You can choose to create an LCC using the SageMaker Console or the AWS CLI.

Create a LCC from the SageMaker Console

Use the following steps to create an LCC containing your default parameters, attach the LCC to a Domain or a user profile, then launch a Studio application pre-populated with the default parameters set by the LCC using the SageMaker Console.

- **To create a lifecycle configuration that runs the script containing your default values using the SageMaker Console**
  
  
  - On the left side, under the SageMaker dashboard, choose **Lifecycle configurations**.
  
  - From the **Lifecycle configurations** page, on the **Domain** tab, choose **Create configuration**.
  
  - For **Name**, type a name using alphanumeric characters and "-", but no spaces. The name can have a maximum of 63 characters.
  
  - Paste your [script](p. 48) in the **Scripts** section.
  
  - Choose **Submit** to create the lifecycle configuration.

- **To attach the lifecycle configuration to a Studio Domain or a user profile**

  Follow the steps in [Attach the lifecycle configuration to Studio Domain or user profile](Attach the lifecycle configuration to Studio Domain or user profile) to attach your LCC to a Studio Domain or a specific user profile.

- **To launch your Studio application with the lifecycle configuration**

  Once the LCC is attached to a Domain or a user profile, impacted users can start a Studio application from the AWS Console to pick up the defaults set by the LCC automatically. This auto-populates the Studio UI when creating an Autopilot experiment.

Create a LCC from the AWS CLI

Use the following snippets to launch a Studio application that runs your [script](p. 49) using the AWS CLI. Note that `lifecycle_config.sh` is the name given to your script in this example.

Before getting started:

- Ensure that you have updated and configured AWS CLI by completing the prerequisites described in [Create a lifecycle configuration from the AWS CLI](Create a lifecycle configuration from the AWS CLI).
• Install OpenSSL documentation. The AWS CLI command uses the open-source library OpenSSL to encode your script in Base64 format. This requirement prevents errors that occur from spacing and line break encoding.

You can now follow these three steps:

• Create a new lifecycle configuration referencing the configuration script lifecycle_config.sh

```
LCC_CONTENT=`openssl base64 -A -in lifecycle_config.sh`
```

```
## Create a new lifecycle config
aws sagemaker create-studio-lifecycle-config --region region 
--studio-lifecycle-config-name lcc-name 
--studio-lifecycle-config-content $LCC_CONTENT 
--studio-lifecycle-config-app-type default
```

Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

• Attach the lifecycle configuration to your JupyterServerApp

The following example shows how to create a new user profile with a lifecycle configuration attached. To update an existing user profile, use the AWS CLI update-user-profile command. To create or update a Domain, see create-domain and update-domain. Add the lifecycle configuration ARN from the previous step to the settings of the JupyterServerAppSettings application type. You can add multiple lifecycle configurations at the same time by using a list of lifecycle configurations.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id 
--user-profile-name user-profile-name 
--region region 
--user-settings '{"JupyterServerAppSettings": {
"LifecycleConfigArns": [
"lifecycle-configuration-arn"
]}

Once the LCC is attached to a Domain or a user profile, impacted users can shut down and update their existing Studio application by following the steps in Shut down and Update Amazon SageMaker Studio, or start a new Studio application from the AWS Console to pick up the defaults set by the LCC automatically. This auto-populates the Studio UI when creating an Autopilot experiment. Alternatively, they can launch a new Studio application using the AWS CLI as follows.

• Launch your Studio application with the lifecycle configuration using the AWS CLI

```
# Create a Jupyter Server application
aws sagemaker create-app --domain-id domain-id 
--user-profile-name user-profile-name 
--region region 
--app-type JupyterServer 
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn 
--app-name default
```

For more information on creating a lifecycle configuration using the AWS CLI, see Create a Lifecycle Configuration from the AWS CLI.
To create an Autopilot experiment using Studio

1. Sign in at https://console.aws.amazon.com/sagemaker/, select Studio from the left navigation pane, then choose Open Studio.
2. In Studio, choose the home icon (🏠) from the left navigation pane to view the Studio top-level navigation menu.
3. On the Home tab, choose the AutoML card. This opens a new AutoML tab.
4. Choose Create an AutoML experiment. This opens a new Create experiment tab.
5. In the Experiment and data details section, enter the following information:
   a. **Experiment name** – Must be unique to your account in the current AWS Region and contain a maximum of 63 alphanumeric characters. Can include hyphens (-) but not spaces.
   b. **Input data** – Provide the Amazon Simple Storage Service (Amazon S3) bucket location of your input data. This S3 bucket must be in your current AWS Region. The URL must be in an s3:// format where Amazon SageMaker has write permissions. The file must be in CSV or Parquet format and contain at least 500 rows. Select Browse to scroll through available paths and Preview to see a sample of your input data.
   c. **Is your S3 input a manifest file?** – A manifest file includes metadata with your input data. The metadata specifies the location of your data in Amazon S3. It also specifies how the data is formatted and which attributes from the dataset to use when training your model. You can use a manifest file as an alternative to preprocessing when your labeled data is being streamed in Pipe mode.
   d. **Auto split data?** – Autopilot can split your data into an 80-20% split for training and validation data. If you prefer a custom split, you can choose the Specify split ratio. To use a custom dataset for validation, choose Provide a validation set.
   e. **Output data location (S3 bucket)** – The name of the S3 bucket location where you want to store the output data. The URL for this bucket must be in an Amazon S3 format where Amazon SageMaker has write permissions. The S3 bucket must be in the current AWS Region. Autopilot can also create this for you in the same location as your input data.
6. Choose Next: Target and features. The Target and features tab opens.
7. In the Target and features section:
   - Select a column to set as a target for model predictions.
   - Optionally, you can pass the name of a sample weights column in the Sample weight section to request your dataset rows to be weighted during training and evaluation. For more information on the available objective metrics, see Autopilot weighted metrics (p. 66).

   **Note**
   Support for sample weights is available in ensembling mode only.
   - You can also select features for training and change their data type. The following data types are available: Text, Numerical, Categorical, Datetime, Sequence, and Auto. All features are selected by default.
9. In the Training method section, select your training option: Ensembling, Hyperparameter optimization (HPO), or Auto to let Autopilot choose the training method automatically based on the dataset size. Each training mode runs a pre-defined set of algorithms on your dataset to train model candidates. By default, Autopilot pre-selects all the available algorithms for the given training mode. You can run an Autopilot training experiment with all the algorithms or choose your own subset.

For more information on the training modes and the available algorithms, see the Autopilot training modes section in the Training modes and algorithms page.
10. Choose **Next: Deployment and advanced settings** to open the **Deployment and advanced settings** tab. Settings include the auto-display endpoint name, machine learning problem type, and additional choices for running your experiment.

a. **Deployment settings** – Autopilot can automatically create an endpoint and deploy your model for you.

To auto-deploy to an automatically generated endpoint, or to provide an endpoint name for custom deployment, set the toggle to **Yes** under **Auto deploy**? If you are importing data from Amazon SageMaker Data Wrangler, you have additional options to auto-deploy the best model with or without the transforms from Data Wrangler.

**Note**
If your Data Wrangler flow contains multi-row operations such as `groupby`, `join`, or `concatenate`, you can't auto-deploy with these transforms. For more information, see [Automatically Train Models on Your Data Flow](#).

b. **Advanced settings (optional)** – Autopilot provides additional controls to manually set experimental parameters such as defining your problem type, time constraints on your Autopilot job and trials, security, and encryption settings.

**Note**
Autopilot supports the setting of default values to simplify the configuration of Autopilot experiments using Studio UI. Administrators can use Studio **lifecycle configurations** (LCC) to set infrastructure, networking, and security values in configuration files and pre-populate the **advanced settings** of AutoML jobs. To learn about how administrators can automate the customization of an Autopilot experiment, see [Configure the default parameters of an Autopilot experiment (for administrators)](p. 47).

i. **Machine learning problem type** – Autopilot can automatically infer the type of supervised learning problem from your dataset. If you prefer to choose it manually, you can use the **Select the machine learning problem type** dropdown menu. Note that it defaults to **Auto**.

   In some cases, SageMaker is unable to infer accurately. When that happens, you must provide the value for the job to succeed. In particular, you can choose from the following types:

   - **Binary classification** – Binary classification assigns input data to one of two predefined and mutually exclusive classes, based on their attributes, such as medical diagnosis based on results of diagnostic tests that determine if someone has a disease.

   - **Regression** – Regression establishes a relationship between the input variables (also known as independent variables or features) and the target variable (also known as the dependent variable). This relationship is captured through a mathematical function or model that maps the input variables to a continuous output. It is commonly used for tasks such as predicting house prices based on features like square footage and the number of bathrooms, stock market trends, or estimating sales figures.

   - **Multiclass classification** – Multiclass classification assigns input data to one of several classes based on their attributes, like the prediction of the topic most relevant to a text document, such as politics, finance, or philosophy.

ii. **Runtime** – You can define a maximum time limit. Upon reaching the time limit, trials and jobs that exceed the time constraint automatically stop.

iii. **Access** – You can choose the role that Amazon SageMaker Studio assumes to gain temporary access to AWS services (in particular, SageMaker and Amazon S3) on your behalf. If no role is explicitly defined, Studio automatically uses the default SageMaker execution role attached to your user profile.

iv. **Encryption** – To enhance the security of your data at rest and protect it against unauthorized access, you can specify encryption keys to encrypt data in your Amazon S3...
buckets and in the Amazon Elastic Block Store (Amazon EBS) volume attached to your Studio Domain.

v. **Security** – You can choose the virtual private cloud (Amazon VPC) in which your SageMaker job runs. Ensure that the Amazon VPC has access to your input and output Amazon S3 buckets.

vi. **Project** – Specify the name of the SageMaker project to associate with this Autopilot experiment and model outputs. When you specify a project, Autopilot tags the project to an experiment. This lets you know which model outputs are associated with this project.

vii. **Tags** – Tags are an array of key-value pairs. Use tags to categorize your resources from AWS services, such as their purpose, owner, or environment.

c. Choose **Next: Review and create** to get a summary of your Autopilot experiment before you create it.

11. Select **Create experiment**. The creation of the experiment starts an Autopilot job in SageMaker. Autopilot provides the status of the experiment, information on the data exploration process and model candidates in notebooks, a list of generated models and their reports, and the job profile used to create them.

For information on the notebooks generated by an Autopilot job, see Amazon SageMaker Autopilot notebooks generated to manage AutoML tasks (p. 94). For information on the details of each model candidate and their reports, see Models generated by Amazon SageMaker Autopilot (p. 82).

**Note**
To avoid incurring unnecessary charges: If you deploy a model that is no longer needed, delete the endpoints and resources that were created during that deployment. Information about pricing instances by Region is available at Amazon SageMaker Pricing.

### Create an Autopilot experiment programmatically

You can create an Autopilot experiment for tabular data programmatically by calling the CreateAutoMLJobV2 API action in any language supported by Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the See Also section of CreateAutoMLJobV2 and choose an SDK. As an example, for Python users, see the full request syntax of create_auto_ml_job_v2 in AWS SDK for Python (Boto3).

**Note**
CreateAutoMLJobV2 and DescribeAutoMLJobV2 are new versions of CreateAutoMLJob and DescribeAutoMLJob which offer backward compatibility.

We recommend using the CreateAutoMLJobV2. CreateAutoMLJobV2 can manage tabular problem types identical to those of its previous version CreateAutoMLJob, as well as non-tabular problem types such as image or text classification, or time-series forecasting.

The following is a collection of mandatory and optional input request parameters for the CreateAutoMLJobV2 API action. You can find the alternative information for the previous version of this action, CreateAutoMLJob. However, we recommend using CreateAutoMLJobV2.

Find guidelines on how to migrate a CreateAutoMLJob to CreateAutoMLJobV2 in Migrate a CreateAutoMLJob to CreateAutoMLJobV2 (p. 58).

### Required parameters

CreateAutoMLJobV2

When calling CreateAutoMLJobV2 to create an Autopilot experiment for tabular data, you must provide the following values:
• An **AutoMLJobName** to specify the name of your job.

• At least one **AutoMLJobChannel** in **AutoMLJobInputDataConfig** to specify your data source.

• Both an **AutoMLJobObjective** metric and your chosen type of supervised learning problem (binary classification, multiclass classification, regression) in **AutoMLProblemTypeConfig**, or none at all. For tabular data, you must choose **TabularJobConfig** as the type of **AutoMLProblemTypeConfig**. You set the supervised learning problem in the **ProblemType** attribute of **TabularJobConfig**.

• An **OutputDataConfig** to specify the Amazon S3 output path to store the artifacts of your AutoML job.

• A **RoleArn** to specify the ARN of the role used to access your data.

CreateAutoMLJob

When calling **CreateAutoMLJob** to create an AutoML experiment, you must provide the following four values:

• An **AutoMLJobName** to specify the name of your job.

• At least one **AutoMLChannel** in **InputDataConfig** to specify your data source.

• An **OutputDataConfig** to specify the Amazon S3 output path to store the artifacts of your AutoML job.

• A **RoleArn** to specify the ARN of the role used to access your data.

All other parameters are optional.

**Optional parameters**

The following sections provide details of some optional parameters that you can pass to your **CreateAutoMLJobV2** API action when using tabular data. You can find the alternative information for the previous version of this action, **CreateAutoMLJob**. However, we recommend using **CreateAutoMLJobV2**.

**How to set the training mode of an AutoML job**

For tabular data, the set of algorithms run on your data to train your model candidates is dependent on your modeling strategy (*ENSEMBLING* or *HYPERPARAMETER_TUNING*). The following details how to set this training mode.

If you keep blank (or null), the **Mode** is inferred based on the size of your dataset.

For information on Autopilot’s *stacked ensembles* and *hyperparameters optimization* training methods, see [Training modes and algorithm support](p. 62)

**CreateAutoMLJobV2**

For tabular data, you must choose **TabularJobConfig** as the type of **AutoMLProblemTypeConfig**.

You can set the **training method** of an AutoML job V2 with the **TabularJobConfig.Mode** parameter.

**CreateAutoMLJob**

You can set the **training method** of an AutoML job with the **AutoMLJobConfig.Mode** parameter.
How to select features and algorithms for training an AutoML job

Features selection

Autopilot provides automatic data-preprocessing steps including feature selection and feature extraction. However, you can manually provide the features to be used in training with the FeatureSpecificatioS3Uri attribute.

Selected features should be contained within a JSON file in the following format:

```
{ "FeatureAttributeNames":["col1", "col2", ...] }
```

The values listed in ["col1", "col2", ...] are case sensitive. They should be a list of strings containing unique values that are subsets of the column names in the input data.

**Note**

The list of columns provided as features cannot include the target column.

CreateAutoMLJobV2

For tabular data, you must choose TabularJobConfig as the type of AutoMLProblemTypeConfig.

You can set the URL to your selected features with the TabularJobConfig.FeatureSpecificatioS3Uri parameter.

CreateAutoMLJob

You can set the FeatureSpecificatioS3Uri attribute of AutoMLCandidateGenerationConfig within the CreateAutoMLJob API with the following format:

```
{
    "AutoMLJobConfig": {
        "CandidateGenerationConfig": {
            "FeatureSpecificationS3Uri": "string"
        },
    }  
}
```

Algorithms selection

By default, your Autopilot job runs a pre-defined list of algorithms on your dataset to train model candidates. The list of algorithms depends on the training mode (ENSEMBLING or HYPERPARAMETER_TUNING) used by the job.

You can provide a subset of the default selection of algorithms.

CreateAutoMLJobV2

For tabular data, you must choose TabularJobConfig as the type of AutoMLProblemTypeConfig.

You can specify an array of selected AutoMLAlgorithms in the AlgorithmsConfig attribute of CandidateGenerationConfig.

The following is an example of an AlgorithmsConfig attribute listing exactly three algorithms ("xgboost", "fastai", "catboost") in its AutoMLAlgorithms field for the ensembling training mode.

```
{
    "AutoMLProblemTypeConfig": {
        "TabularJobConfig": {
```
Create an Autopilot Experiment for Tabular Data

CreateAutoMLJob

You can specify an array of selected AutoMLAlgorithms in the AlgorithmsConfig attribute of AutoMLCandidateGenerationConfig.

The following is an example of an AlgorithmsConfig attribute listing exactly three algorithms ("xgboost", "fastai", "catboost") in its AutoMLAlgorithms field for the ensembling training mode.

```
{
  "AutoMLJobConfig": {
    "CandidateGenerationConfig": {
      "AlgorithmsConfig": [{
        "AutoMLAlgorithms": ["xgboost", "fastai", "catboost"]
      }]
    },
    "Mode": "ENSEMBLING"
  }
```

For the list of available algorithms per training Mode, see AutoMLAlgorithms. For details on each algorithm, see Training modes and algorithm support (p. 62).

How to specify the training and validation datasets of an AutoML job

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

CreateAutoMLJobV2

Each AutoMLJobChannel object (see the required parameter AutoMLJobInputDataConfig) has a ChannelType, which can be set to either training or validation values that specify how the data is to be used when building a machine learning model. At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have one data source, the ChannelType is set to training by default and must have this value.
- If the ValidationFraction value in AutoMLDataSplitConfig is not set, 0.2 (20%) of the data from this source is used for validation by default.
- If the ValidationFraction is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have two data sources, the ChannelType of one of the AutoMLJobChannel objects must be set to training, the default value. The ChannelType of the other data source must be set to validation. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the ValidationFraction in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.
CreateAutoMLJob

Each AutoMLChannel object (see the required parameter InputDataConfig) has a ChannelType, which can be set to either training or validation values that specify how the data is to be used when building a machine learning model. At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- **If you only have one data source**, the ChannelType is set to training by default and must have this value.
  - If the ValidationFraction value in AutoMLDataSplitConfig is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the ValidationFraction is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- **If you have two data sources**, the ChannelType of one of the AutoMLChannel objects must be set to training, the default value. The ChannelType of the other data source must be set to validation. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the ValidationFraction in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

For information on split and cross-validation in Autopilot see [Cross-validation in Autopilot](p. 66).

How to set the problem type of an AutoML job

CreateAutoMLJobV2

For tabular data, you must choose TabularJobConfig as the type of AutoMLProblemTypeConfig.

You can further specify the type of supervised learning problem (binary classification, multiclass classification, regression) available for the model candidates of your AutoML job V2 with the TabularJobConfig.ProblemType parameter.

CreateAutoMLJob

You can set the type of problem on an AutoML job with the CreateAutoPilot.ProblemType parameter. This limits the kind of preprocessing and algorithms that Autopilot tries. After the job is finished, if you had set the CreateAutoPilot.ProblemType, then the ResolvedAttribute.ProblemType matches the ProblemType you set. If you keep it blank (or null), the ProblemType is inferred on your behalf.

**Note**
In some cases, Autopilot is unable to infer the ProblemType with high enough confidence, in which case you must provide the value for the job to succeed.

How to add sample weights to an AutoML job

You can add a sample weights column to your tabular dataset and then pass it to your AutoML job to request dataset rows to be weighted during training and evaluation.

Support for sample weights is available in ensembling mode only. Your weights should be numeric and non-negative. Data points with invalid or no weight value are excluded. For more information on the available objective metrics, see [Autopilot weighted metrics](p. 66).
CreateAutoMLJobV2

For tabular data, you must choose TabularJobConfig as the type of AutoMLProblemTypeConfig.

To set sample weights when creating an experiment (see CreateAutoMLJobV2), you can pass the name of your sample weights column in the SampleWeightAttributeName attribute of the TabularJobConfig object. This ensures that your objective metric uses the weights for the training, evaluation, and selection of model candidates.

CreateAutoMLJob

To set sample weights when creating an experiment (see CreateAutoMLJob), you can pass the name of your sample weights column in the SampleWeightAttributeName attribute of the AutoMLChannel object. This ensures that your objective metric uses the weights for the training, evaluation, and selection of model candidates.

Migrate a CreateAutoMLJob to CreateAutoMLJobV2

We recommend users of CreateAutoMLJob to migrate to CreateAutoMLJobV2.

This section explains the differences in the input parameters between CreateAutoMLJob and CreateAutoMLJobV2 by highlighting the changes in the position, name, or structure of the objects and attributes of the input request between the two versions.

- **Request attributes that did not change between versions.**

```json
{
    "AutoMLJobName": "string",
    "AutoMLJobObjective": {
        "MetricName": "string"
    },
    "ModelDeployConfig": {
        "AutoGenerateEndpointName": boolean,
        "EndpointName": "string"
    },
    "OutputDataConfig": {
        "KmsKeyId": "string",
        "S3OutputPath": "string"
    },
    "RoleArn": "string",
    "Tags": [
        {
            "Key": "string",
            "Value": "string"
        }
    ]
}
```

- **Request attributes that changed position and structure between versions.**

The following attributes changed position: DataSplitConfig, Security Config, CompletionCriteria, Mode, FeatureSpecificationS3Uri, SampleWeightAttributeName, TargetAttributeName.

CreateAutoMLJob

            "ContentType": "string",
            "DataSource": {
                "S3DataSource": {
                    "S3DataType": "string",
                    "S3Uri": "string"
                }
            }
        }
    ]
}
```
Autopilot datasets and problem types

For tabular data (that is data in which each column contains a feature with a specific data type and each row contains an observation), Autopilot gives you the option of specifying the type of supervised learning problem available for the model candidates of the AutoML job, such as binary classification or regression, or of detecting it on your behalf based on the data you provide.

Topics
- Autopilot datasets, data types, and formats (p. 61)
- Autopilot problem types (p. 61)

Autopilot datasets, data types, and formats

Autopilot supports tabular data formatted as CSV files or as Parquet files: each column contains a feature with a specific data type and each row contains an observation. The properties of these two file formats differ considerably.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

The **data types** accepted for columns include numerical, categorical, text, and time series that consists of strings of comma-separated numbers. If Autopilot detects it is dealing with **time series** sequences, it processes them through specialized feature transformers provided by the tsfresh library. This library takes the time series as an input and outputs a feature such as the highest absolute value of the time series or descriptive statistics on autocorrelation. These outputted features are then used as inputs to one of the three problem types.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs. For details on the default resource limits for input datasets and how to increase them, see Autopilot quotas.

Autopilot problem types

For the tabular data, you further specify the type of supervised learning problems available for the model candidates as follows:

**Regression**

Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms, square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

**Binary classification**

Binary classification is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on their attributes. It is supervised because the models are trained
using examples where the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

**Multiclass classification**

Multiclass classification is a type of supervised learning that assigns an individual to one of several classes based on their attributes. It is supervised because the models are trained using examples where the attributes are provided with correctly labelled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about, say, religion or politics or finance, or about one of several other predefined topic classes.

**Training modes and algorithm support**

Autopilot supports different training modes and algorithms to address machine learning problems, report on quality and objective metrics, and to use cross-validation automatically, when needed.

**Training modes**

SageMaker Autopilot can automatically select the training method based on the dataset size, or you can select it manually. The choices are as follows:

- **Ensembling** – Autopilot uses the AutoGluon library to train several base models. To find the best combination for your dataset, ensemble mode runs 10 trials with different model and meta parameter settings. Then Autopilot combines these models using a stacking ensemble method to create an optimal predictive model. For a list of algorithms that Autopilot supports in ensembling mode for tabular data, see the following Algorithms support section.

- **Hyperparameter optimization (HPO)** – Autopilot finds the best version of a model by tuning hyperparameters using Bayesian optimization or multi-fidelity optimization while running training jobs on your dataset. HPO mode selects the algorithms that are most relevant to your dataset and selects the best range of hyperparameters to tune your models. To tune your models, HPO mode runs up to 100 trials (default) to find the optimal hyperparameters settings within the selected range. If your dataset size is less than 100 MB, Autopilot uses Bayesian optimization. Autopilot chooses multi-fidelity optimization if your dataset is larger than 100 MB.

In multi-fidelity optimization, metrics are continuously emitted from the training containers. A trial that is performing poorly against a selected objective metric is stopped early. A trial that is performing well is allocated more resources.

For a list of algorithms that Autopilot supports in HPO mode, see the following Algorithm support section.

- **Auto** – Autopilot automatically chooses either ensembling mode or HPO mode based on your dataset size. If your dataset is larger than 100 MB, Autopilot chooses HPO. Otherwise, it chooses ensembling mode. Autopilot can fail to read the size of your dataset in the following cases.

  - If you enable Virtual Private Cloud (VPC) mode, for an AutoML job but the S3 bucket containing the dataset only allows access from the VPC.
  - The input S3DataType of your dataset is a ManifestFile.
  - The input S3Uri contains more than 1000 items.

If Autopilot is unable to read your dataset size, it defaults to choosing HPO mode.

**Note**

For optimal runtime and performance, use ensemble training mode for datasets that are smaller than 100 MB.
Algorithms support

In **HPO mode**, Autopilot supports the following types of machine learning algorithms:

- **Linear learner** – A supervised learning algorithm that can solve either classification or regression problems.
- **XGBoost** – A supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.
- Deep learning algorithm – A multilayer perceptron (MLP) and feedforward artificial neural network. This algorithm can handle data that is not linearly separable.

**Note**
You don’t need to specify an algorithm to use for your machine learning problem. Autopilot automatically selects the appropriate algorithm to train.

In **ensembling mode**, Autopilot supports the following types of machine learning algorithms:

- **LightGBM** – An optimized framework that uses tree-based algorithms with gradient boosting. This algorithm uses trees that grow in breadth, rather than depth, and is highly optimized for speed.
- **CatBoost** – A framework that uses tree-based algorithms with gradient boosting. Optimized for handling categorical variables.
- **XGBoost** – A framework that uses tree-based algorithms with gradient boosting that grows in depth, rather than breadth.
- **Random Forest** – A tree-based algorithm that uses several decision trees on random sub-samples of the data with replacement. The trees are split into optimal nodes at each level. The decisions of each tree are averaged together to prevent overfitting and improve predictions.
- **Extra Trees** – A tree-based algorithm that uses several decision trees on the entire dataset. The trees are split randomly at each level. The decisions of each tree are averaged to prevent overfitting and to improve predictions. Extra trees add a degree of randomization in comparison to the random forest algorithm.
- **Linear Models** – A framework that uses a linear equation to model the relationship between two variables in observed data.
- Neural network torch – A neural network model that's implemented using Pytorch.
- Neural network fast.ai – A neural network model that's implemented using fast.ai.

Metrics and validation

This guide shows metrics and validation techniques that you can use to measure machine learning model performance. Amazon SageMaker Autopilot produces metrics that measure the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of **MetricDatum** types.

**Autopilot metrics**

The following list contains the names of the metrics that are currently available to measure model performance within Autopilot.

**Note**
Autopilot supports sample weights. To learn more about sample weights and the available objective metrics, see **Autopilot weighted metrics** (p. 66).

The following are the available metrics.
Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. It is used for both binary and multiclass classification. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

AUC

The area under the curve (AUC) metric is used to compare and evaluate binary classification by algorithms that return probabilities, such as logistic regression. To map the probabilities into classifications, these are compared against a threshold value.

The relevant curve is the receiver operating characteristic curve. The curve plots the true positive rate (TPR) of predictions (or recall) against the false positive rate (FPR) as a function of the threshold value, above which a prediction is considered positive. Increasing the threshold results in fewer false positives, but more false negatives.

AUC is the area under this receiver operating characteristic curve. Therefore, AUC provides an aggregated measure of the model performance across all possible classification thresholds. AUC scores vary between 0 and 1. A score of 1 indicates perfect accuracy, and a score of one half (0.5) indicates that the prediction is not better than a random classifier.

BalancedAccuracy

BalancedAccuracy is a metric that measures the ratio of accurate predictions to all predictions. This ratio is calculated after normalizing true positives (TP) and true negatives (TN) by the total number of positive (P) and negative (N) values. It is used in both binary and multiclass classification and is defined as follows: 0.5*(TP/P)+(TN/N)), with values ranging from 0 to 1. BalancedAccuracy gives a better measure of accuracy when the number of positives or negatives differ greatly from each other in an imbalanced dataset, such as when only 1% of email is spam.

F1

The F1 score is the harmonic mean of the precision and recall, defined as follows: F1 = 2 * (precision * recall) / (precision + recall). It is used for binary classification into classes traditionally referred to as positive and negative. Predictions are said to be true when they match their actual (correct) class, and false when they do not.

Precision is the ratio of the true positive predictions to all positive predictions, and it includes the false positives in a dataset. Precision measures the quality of the prediction when it predicts the positive class.

Recall (or sensitivity) is the ratio of the true positive predictions to all actual positive instances. Recall measures how completely a model predicts the actual class members in a dataset.

F1 scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

F1macro

The F1macro score applies F1 scoring to multiclass classification problems. It does this by calculating the precision and recall, and then taking their harmonic mean to calculate the F1 score for each class. Lastly, the F1macro averages the individual scores to obtain the F1macro score. F1macro scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

InferenceLatency

Inference latency is the approximate amount of time between making a request for a model prediction to receiving it from a real time endpoint to which the model is deployed. This metric is measured in seconds and only available in ensembling mode.
LogLoss

Log loss, also known as cross-entropy loss, is a metric used to evaluate the quality of the probability outputs, rather than the outputs themselves. It is used in both binary and multiclass classification and in neural nets. It is also the cost function for logistic regression. Log loss is an important metric to indicate when a model makes incorrect predictions with high probabilities. Values range from 0 to infinity. A value of 0 represents a model that perfectly predicts the data.

MAE

The mean absolute error (MAE) is a measure of how different the predicted and actual values are, when they're averaged over all values. MAE is commonly used in regression analysis to understand model prediction error. If there is linear regression, MAE represents the average distance from a predicted line to the actual value. MAE is defined as the sum of absolute errors divided by the number of observations. Values range from 0 to infinity, with smaller numbers indicating a better model fit to the data.

MSE

The mean squared error (MSE) is the average of the squared differences between the predicted and actual values. It is used for regression. MSE values are always positive. The better a model is at predicting the actual values, the smaller the MSE value is.

Precision

Precision measures how well an algorithm predicts the true positives (TP) out of all of the positives that it identifies. It is defined as follows: Precision = TP/(TP+FP), with values ranging from zero (0) to one (1), and is used in binary classification. Precision is an important metric when the cost of a false positive is high. For example, the cost of a false positive is very high if an airplane safety system is falsely deemed safe to fly. A false positive (FP) reflects a positive prediction that is actually negative in the data.

PrecisionMacro

The precision macro computes precision for multiclass classification problems. It does this by calculating precision for each class and averaging scores to obtain precision for several classes. PrecisionMacro scores range from zero (0) to one (1). Higher scores reflect the model's ability to predict true positives (TP) out of all of the positives that it identifies, averaged across multiple classes.

R2

R², also known as the coefficient of determination, is used in regression to quantify how much a model can explain the variance of a dependent variable. Values range from one (1) to negative one (-1). Higher numbers indicate a higher fraction of explained variability. R2 values close to zero (0) indicate that very little of the dependent variable can be explained by the model. Negative values indicate a poor fit and that the model is outperformed by a constant function. For linear regression, this is a horizontal line.

Recall

Recall measures how well an algorithm correctly predicts all of the true positives (TP) in a dataset. A true positive is a positive prediction that is also an actual positive value in the data. Recall is defined as follows: Recall = TP/(TP+FN), with values ranging from 0 to 1. Higher scores reflect a better ability of the model to predict true positives (TP) in the data. It is used in binary classification.

Recall is important when testing for cancer because it's used to find all of the true positives. A false positive (FP) reflects a positive prediction that is actually negative in the data. It is often insufficient to measure only recall, because predicting every output as a true positive yields a perfect recall score.

RecallMacro

The RecallMacro computes recall for multiclass classification problems by calculating recall for each class and averaging scores to obtain recall for several classes. RecallMacro scores range from
0 to 1. Higher scores reflect the model's ability to predict true positives (TP) in a dataset, whereas a true positive reflects a positive prediction that is also an actual positive value in the data. It is often insufficient to measure only recall, because predicting every output as a true positive will yield a perfect recall score.

**RMSE**

Root mean squared error (RMSE) measures the square root of the squared difference between predicted and actual values, and is averaged over all values. It is used in regression analysis to understand model prediction error. It's an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different sizes.

Metrics that are automatically calculated for a model candidate are determined by the type of problem being addressed.

- **Regression:** InferenceLatency, MAE, MSE, R2, RMSE
- **Binary classification:** Accuracy, AUC, BalancedAccuracy, F1, InferenceLatency, LogLoss, Precision, Recall
- **Multiclass classification:** Accuracy, BalancedAccuracy, F1macro, InferenceLatency, LogLoss, PrecisionMacro, RecallMacro

**Autopilot weighted metrics**

*Note*

Autopilot supports sample weights in ensembling mode only for all available metrics with the exception of Balanced Accuracy and InferenceLatency. Balanced Accuracy comes with its own weighting scheme for imbalanced datasets that does not require sample weights. InferenceLatency does not support sample weights. Both objective Balanced Accuracy and InferenceLatency metrics ignore any existing sample weights when training and evaluating a model.

Users can add a sample weights column to their data to ensure that each observation used to train a machine learning model is given a weight corresponding to its perceived importance to the model. This is especially useful in scenarios in which the observations in the dataset have varying degrees of importance, or in which a dataset contains a disproportionate number of samples from one class compared to others. Assigning a weight to each observation based on its importance or greater importance to a minority class can help a model's overall performance, or ensure that a model is not biased toward the majority class.

For information about how to pass sample weights when creating an experiment in the Studio UI, see *Step 7* in [Create an Autopilot experiment using Studio](#).

For information about how to pass sample weights programmatically when creating an Autopilot experiment using the API, see [How to add sample weights to an AutoML job](#) in [Create an Autopilot experiment programmatically](#).

**Cross-validation in Autopilot**

Cross-validation is used to reduce overfitting and bias in model selection. It is also used to assess how well a model can predict the values of an unseen validation dataset, if the validation dataset is drawn from the same population. This method is especially important when training on datasets that have a limited number of training instances.

Autopilot uses cross-validation to build models in hyperparameter optimization (HPO) and ensemble training mode. The first step in the Autopilot cross-validation process is to split the data into k-folds.
K-fold splitting

K-fold splitting is a method that separates an input training dataset into multiple training and validation datasets. The dataset is split into \( k \) equally-sized sub-samples called folds. Models are then trained on \( k-1 \) folds and tested against the remaining \( k \)-th fold, which is the validation dataset. The process is repeated \( k \) times using a different data set for validation.

The following image depicts k-fold splitting with \( k = 4 \) folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

<table>
<thead>
<tr>
<th>(train=2,3,4. val=1)</th>

<td>(train=1,2,3. val=4)</td>
<td></td>
<td>♦</td>
<td>♦</td>
<td>♦</td>
</tr>
</tbody>
</table>

4-fold splitting

Autopilot uses k-fold cross-validation for both hyperparameter optimization (HPO) mode and ensembling mode.

You can deploy Autopilot models that are built using cross-validation like you would with any other Autopilot or SageMaker model.

HPO mode

K-fold cross-validation uses the k-fold splitting method for cross-validation. In HPO mode, Autopilot automatically implements k-fold cross-validation for small datasets with 50,000 or fewer training instances. Performing cross-validation is especially important when training on small datasets because it protects against overfitting and selection bias.

HPO mode uses a \( k \) value of 5 on each of the candidate algorithms that are used to model the dataset. Multiple models are trained on different splits, and the models are stored separately. When training is complete, validation metrics for each of the models are averaged to produce a single estimation metric. Lastly, Autopilot combines the models from the trial with the best validation metric into an ensemble model. Autopilot uses this ensemble model to make predictions.

The validation metric for the models trained by Autopilot is presented as the objective metric in the model leaderboard. Autopilot uses the default validation metric for each problem type that it handles, unless you specify otherwise. For the list of all metrics that Autopilot uses, see Autopilot metrics (p. 63).

For example, the Boston Housing dataset contains only 861 samples. If you build a model to predict house sale prices using this dataset without cross-validation, you risk training on a dataset that is not representative of the Boston housing stock. If you split the data only once into training and validation subsets, the training fold may only contain data mainly from the suburbs. As a result, you would train on data that isn’t representative of the rest of the city. In this example, your model would likely overfit on this biased selection. K-fold cross-validation can reduce the risk of this kind of error by making full and randomized use of the available data for both training and validation.

Cross-validation can increase training times by an average of 20%. Training times may also increase significantly for complex datasets.
**Note**

In HPO mode, you can see the training and validation metrics from each fold in your /aws/sagemaker/TrainingJobs CloudWatch Logs. For more information about CloudWatch Logs, see [Log Amazon SageMaker Events with Amazon CloudWatch](p. 3591).

**Ensembling mode**

**Note**

Autopilot supports sample weights in ensembling mode. For the list of available metrics supporting sample weights, see [Autopilot metrics](p. 63).

In ensembling mode, cross-validation is performed regardless of dataset size. Customers can either provide their own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically into an 80-20% split ratio. The training data is then split into k-folds for cross-validation, where the value of k is determined by the AutoGluon engine. An ensemble consists of multiple machine learning models, where each model is known as the base model. A single base model is trained on (k-1) folds and makes out-of-fold predictions on the remaining fold. This process is repeated for all k folds, and the out-of-fold (OOF) predictions are concatenated to form a single set of predictions. All base models in the ensemble follow this same process of generating OOF predictions.

The following image depicts k-fold validation with k = 4 folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

In the upper part of the image, in each fold, the first base model makes predictions on the validation dataset after training on the training datasets. At each subsequent fold, the datasets change roles. A dataset that was previously used for training is now used for validation, and this also applies in reverse. At the end of k folds, all of the predictions are concatenated to form a single set of predictions called an out-of-fold (OOF) prediction. This process is repeated for each n base models.

The OOF predictions for each base model are then used as features to train a stacking model. The stacking model learns the importance weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. Performance on the validation dataset determines which base or stacking model is the best, and this model is returned as the final model.

In ensemble mode, you can either provide your own validation dataset or let Autopilot split the input dataset automatically into 80% train and 20% validation datasets. The training data is then split into k-folds for cross-validation and produces an OOF prediction and a base model for each fold.

These OOF predictions are used as features to train a stacking model, which simultaneously learns weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. The validation datasets for each fold are used for hyperparameter tuning of all base models and the stacking model. Performance on the validation datasets determines which base or stacking model is the best model, and this model is returned as the final model.
Amazon SageMaker Autopilot model deployment and prediction

This Amazon SageMaker Autopilot guide includes steps for model deployment, setting up real-time inference, and running inference with batch jobs.

After you train your Autopilot models, you can deploy them to get predictions in one of two ways:

1. Use Real-time inferencing (p. 69) to set up an endpoint and obtain predictions interactively.
2. Use Batch inferencing (p. 76) to make predictions in parallel on batches of observations on an entire dataset.

**Note**

To avoid incurring unnecessary charges: After the endpoints and resources that were created from model deployment are no longer needed, you can delete them. For information about pricing of instances by Region, see Amazon SageMaker Pricing.

Real-time inferencing

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

To deploy the model that produced the best validation metric in an Autopilot experiment, you have several options. For example, when using Autopilot in SageMaker Studio, you can deploy the model automatically or manually. You can also use SageMaker APIs to manually deploy an Autopilot model.

The following tabs show three options for deploying your model. These instructions assume that you have already created a model in Autopilot. If you don't have a model, see Create an Amazon SageMaker Autopilot experiment for tabular data (p. 46). To see examples for each option, open each tab.

Deploy using the Autopilot User Interface (UI)

The Autopilot UI contains helpful dropdown menus, toggles, tooltips, and more to help you navigate through model deployment. You can deploy using either one of the following procedures: Automatic or Manual.

- **Automatic Deployment**: To automatically deploy the best model from an Autopilot experiment to an endpoint
  2. Toggle the Auto deploy value to Yes.

  **Note**
  Automatic deployment will fail if either the default resource quota or your customer quota for endpoint instances in a Region is too limited. In hyperparameter optimization (HPO) mode, you are required to have at least two ml.m5.2xlarge instances. In ensembling mode, you are required to have at least one ml.m5.12xlarge instance. If you encounter a failure related to quotas, you can request a service limit increase for SageMaker endpoint instances.

- **Manual Deployment**: To manually deploy the best model from an Autopilot experiment to an endpoint
  2. Toggle the Auto deploy value to No.
  3. Select the model that you want to deploy under Model name.
  4. Select the orange Deployment and advanced settings button located on the right of the leaderboard. This opens a new tab.
  5. Configure the endpoint name, instance type, and other optional information.
6. Select the orange **Deploy model** to deploy to an endpoint.

7. Check the progress of the endpoint creation process in the [https://console.aws.amazon.com/sagemaker/](https://console.aws.amazon.com/sagemaker/) by navigating to the Endpoints section. That section is located in the **Inference** dropdown menu in the navigation panel.

8. After the endpoint status changes from **Creating** to **InService**, as shown below, return to Studio and invoke the endpoint.

![Endpoint Creation Progress](image)

---

**Deploy using SageMaker APIs**

You can also obtain real-time inference by deploying your model using **API calls**. This section shows the five steps of this process using AWS Command Line Interface (AWS CLI) code snippets.

For complete code examples for both AWS CLI commands and AWS SDK for Python (boto3), open the tabs directly following these steps.

1. **Obtain candidate definitions**

   Obtain the candidate container definitions from **InferenceContainers**. These candidate definitions are used to create a SageMaker model.

   The following example uses the **DescribeAutoMLJob** API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

   ```
   aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

2. **List candidates**

   The following example uses the **ListCandidatesForAutoMLJob** API to list all candidates. See the following AWS CLI command as an example.

   ```
   aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

3. **Create a SageMaker model**

   Use the container definitions from the previous steps to create a SageMaker model by using the **CreateModel** API. See the following AWS CLI command as an example.

   ```
   aws sagemaker create-model --model-name '<your-custom-model-name>' \
   --containers ['<container-definition1>', '<container-definition2>', '<container-definition3>'] \
   --execution-role-arn '<execution-role-arn>' --region '<region>'
   ```

4. **Create an endpoint configuration**

   The following example uses the **CreateEndpointConfig** API to create an endpoint configuration. See the following AWS CLI command as an example.

   ```
   aws sagemaker create-endpoint-config --endpoint-config-name '<your-custom-endpoint-config-name>' \
   --production-variants '<list-of-production-variants>' \
   --region '<region>'
   ```
5. Create the endpoint

The following AWS CLI example uses the **CreateEndpoint** API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-custom-endpoint-name>' \
    --endpoint-config-name '<endpoint-config-name-you-just-created>' \
    --region '<region>'
```

Check the progress of your endpoint deployment by using the **DescribeEndpoint** API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region '<region>'
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready to use for real-time inference.

6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \
    --region '<region>' --body '<your-data>' [--content-type] '<content-type>' <outfile>
```

The following tabs contain complete code examples for deploying a model with AWS SDK for Python (boto3) or the AWS CLI.

**AWS SDK for Python (boto3)**

1. **Obtain the candidate definitions** by using the following code example.

   ```python
   import sagemaker
   import boto3

   session = sagemaker.session.Session()
   sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')
   job_name = 'test-auto-ml-job'
   describe_response = sagemaker_client.describe_auto_ml_job(AutoMLJobName=job_name)
   # extract the best candidate definition from DescribeAutoMLJob response
   best_candidate = describe_response['BestCandidate']
   # extract the InferenceContainers definition from the caandidate definition
   inference_containers = best_candidate['InferenceContainers']
   ```

2. **Create the model** by using the following the code example.

   ```python
   # Create Model
   model_name = 'test-model'
   sagemaker_role = 'arn:aws:iam:444455556666:role/sagemaker-execution-role'
   create_model_response = sagemaker_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = sagemaker_role,
       Containers = inference_containers
   )
   ```

3. **Create the endpoint configuration** by using the following the code example.
Create an Autopilot Experiment for Tabular Data

```
endpoint_config_name = 'test-endpoint-config'
instance_type = 'ml.m5.2xlarge'
# for all supported instance types, see
# https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html#sagemaker-Type-ProductionVariant-InstanceType

# Create endpoint config
endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": "variant1",
            "ModelName": model_name,
            "InstanceType": instance_type,
            "InitialInstanceCount": 1
        }
    ]
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")

4. Create the endpoint and deploy the model with the following code example.

```python
# create endpoint and deploy the model
endpoint_name = 'test-endpoint'
create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response)

Check the status of creating the endpoint by using the following the code example.

```python
# describe endpoint creation status
status = sagemaker_client.describe_endpoint(EndpointName=endpoint_name)
["EndpointStatus"]

5. Invoke the endpoint for real-time inferencing by using the following command structure.

```python
# once endpoint status is InService, you can invoke the endpoint for inferencing
if status == "InService":
    sm_runtime = boto3.Session().client('sagemaker-runtime')
    inference_result = sm_runtime.invoke_endpoint(EndpointName='test-endpoint',
        ContentType='text/csv', Body='1,2,3,4,class')
```

AWS Command Line Interface (AWS CLI)

1. Obtain the candidate definitions by using the following code example.

```bash
aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --region us-west-2
```

2. Create the model by using the following code example.

```bash
aws sagemaker create-model --model-name 'test-sagemaker-model'
    --containers '[[
```
"Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3", "ModelDataUrl": "s3://DOC-EXAMPLE-BUCKET/output/model.tar.gz", "Environment": {
  "AUTOML_SPARSE_ENCODE_RECORDIO_PROTobuf": "1",
  "AUTOML_TRANSFORM_MODE": "feature-transform",
  "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
  "SAGEMAKER_PROGRAM": "sagemaker_server",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-xgboost:1.3-1-cpu-py3",
  "ModelDataUrl": "s3://DOC-EXAMPLE-BUCKET/output/model.tar.gz",
  "Environment": {
    "MAX_CONTENT_LENGTH": "20971520",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,probabilities"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3", "aws-region"
  "ModelDataUrl": "s3://DOC-EXAMPLE-BUCKET/output/model.tar.gz",
  "Environment": {
    "AUTOML_TRANSFORM_MODE": "inverse-label-transform",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,labels,probabilities",
    "SAGEMAKER_PROGRAM": "sagemaker_server",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}
|--execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role' 
|--region 'us-west-2'

For additional details, see [creating a model](#).

The `create_model` command will return a response in the following format.

```
{
}
```

3. **Create an endpoint configuration** by using the following code example.

```
aws sagemaker create-endpoint-config --endpoint-config-name 'test-endpoint-config' 
--production-variants '[]' --region us-west-2
```

The `create_endpoint_configuration` command will return a response in the following format.

```
{
}
```
4. **Create an endpoint** by using the following code example.

```bash
aws sagemaker create-endpoint --endpoint-name 'test-endpoint' \
--endpoint-config-name 'test-endpoint-config' \
--region us-west-2
```

The `create endpoint` command will return a response in the following format.

```json
{
}
```

Check the progress of the endpoint deployment by using the following `describe-endpoint` CLI code example.

```bash
aws sagemaker describe-endpoint --endpoint-name 'test-endpoint' --region us-west-2
```

The previous progress check will return a response in the following format.

```json
{
  "EndpointName": "test-endpoint",
  "EndpointConfigName": "test-endpoint-config",
  "EndpointStatus": "Creating",
  "CreationTime": 1660251167.595,
  "LastModifiedTime": 1660251167.595
}
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready for use in real-time inference.

5. **Invoke the endpoint** for real-time inferencing by using the following command structure.

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'test-endpoint' \
--region 'us-west-2' \
--body '1,51,3.5,1.4,0.2' \
--content-type 'text/csv' \
'/tmp/inference_output'
```

For more options, see [invoking an endpoint](#).

---

**Deploy models from different accounts**

You can deploy an Autopilot model from a different account than the original account that a model was generated in. To implement cross-account model deployment, this section shows how to do the following:

1. **Grant permission to the deploying account**

   To assume the role in the generating account, you must grant permission to the deploying account. This allows the deploying account to describe Autopilot jobs in the generating account.

   The following example uses a generating account with a trusted `sagemaker-role` entity. The example shows how to give a deploying account with the ID 111122223333 permission to assume the role of the generating account.
The new account with the ID 111122223333 can now assume the role for the generating account.

Next, call the DescribeAutoMLJob API from the deploying account to obtain a description of the job created by the generating account.

The following code example describes the model from the deploying account.

```python
import sagemaker
import boto3

session = sagemaker.session.Session()

sts_client = boto3.client('sts')
sts_client.assume_role

role = 'arn:aws:iam::111122223333:role/sagemaker-role'
role_session_name = '
_assumed_role = sts_client.assume_role(RoleArn=role, RoleSessionName=role_session_name)

credentials = _assumed_role['Credentials']
access_key = credentials['AccessKeyId']
secret_key = credentials['SecretAccessKeyId']
session_token = credentials['SessionToken']

session = boto3.session.Session()

sm_client = sagemaker.client('sagemaker', region_name='us-west-2',
aws_access_key_id=access_key,
aws_secret_access_key=secret_key,
aws_session_token=session_token)

# now you can call describe automl job created in account A

job_name = "test-job"
response= sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
```

2. **Grant access to the deploying account** to the model artifacts in the generating account.

   The deploying account only needs access to the model artifacts in the generating account to deploy it. These are located in the S3OutputPath that was specified in the original CreateAutoMLJob API call during model generation.

   To give the deploying account access to the model artifacts, choose one of the following options:
   a. **Give access** to the ModelDataUrl from the generating account to the deploying account.
   b. **Copy model artifacts** from the generating account's original S3OutputPath to the generating account.
To grant access to the model artifacts, you must define a best_candidate model and reassign model containers to the new account.

The following example shows how to define a best_candidate model and reassign the ModelDataUrl.

```python
best_candidate = automl.describe_auto_ml_job()['BestCandidate']

# reassigning ModelDataUrl for best_candidate containers below
new_model_locations = ['new-container-1-ModelDataUrl', 'new-container-2-ModelDataUrl', 'new-container-3-ModelDataUrl']
new_model_locations_index = 0
for container in best_candidate['InferenceContainers']:
    container['ModelDataUrl'] = new_model_locations[new_model_locations_index++]
```

After this assignment of containers, follow the steps in Deploy using SageMaker APIs (p. 70) to deploy.

To build a payload in real-time inferencing, see the notebook example to define a test payload. To create the payload from a CSV file and invoke an endpoint, see the Predict with your model section in Create a machine learning model automatically.

**Batch inferencing**

Batch inferencing, also known as offline inferencing, generates model predictions on a batch of observations. Batch inference is a good option for large datasets or if you don't need an immediate response to a model prediction request.

By contrast, online inference (real-time inferencing) generates predictions in real time.

You can make batch inferences from an Autopilot model using the SageMaker Python SDK, the Autopilot user interface (UI), the AWS SDK for Python (boto3), or the AWS Command Line Interface (AWS CLI).

The following tabs show three options for deploying your model: Using APIs, Autopilot UI, or using APIs to deploy from different accounts. These instructions assume that you have already created a model in Autopilot. If you don't have a model, see Create an Amazon SageMaker Autopilot experiment for tabular data (p. 46). To see examples for each option, open each tab.

**Deploy a model using Autopilot UI**

The Autopilot UI contains helpful dropdown menus, toggles, tooltips, and more to help you navigate through model deployment.

The following steps show how to deploy a model from an Autopilot experiment for batch predictions.

1. Sign in at https://console.aws.amazon.com/sagemaker/ and select **Studio** from the navigation pane.
2. On the left navigation pane, choose **Studio**.
3. Under **Get started**, select the Domain that you want to launch the Studio application in. If your user profile only belongs to one Domain, you do not see the option for selecting a Domain.
4. Select the user profile that you want to launch the Studio application for. If there is no user profile in the Domain, choose **Create user profile**. For more information, see Add and Remove User Profiles.
5. Choose **Launch Studio**. If the user profile belongs to a shared space, choose **Open Spaces**.
6. When the SageMaker Studio console opens, choose the **Launch SageMaker Studio** button.
7. Select **AutoML** from the left navigation pane.
8. Under **Name**, select the Autopilot experiment corresponding to the model that you want to deploy. This opens a new **AUTOPILOT JOB** tab.

9. In the **Model name** section, select the model that you want to deploy.

10. Choose **Deploy model**. This opens a new tab.

11. Choose **Make batch predictions** at the top of the page.

12. For **Batch transform job configuration**, input the **Instance type**, **Instance count** and other optional information.

13. In the **Input data configuration** section, open the dropdown menu.
   
   a. For **S3 data type**, choose **ManifestFile** or **S3Prefix**.
   
   b. For **Split type**, choose **Line**, **RecordIO**, **TFRecord** or **None**.
   
   c. For **Compression**, choose **Gzip** or **None**.

14. For **S3 location**, enter the Amazon S3 bucket location of the input data and other optional information.

15. Under **Output data configuration**, enter the S3 bucket for the output data, and choose how to assemble the output of your job.
   
   a. For **Additional configuration (optional)**, you can enter a MIME type and an **S3 Encryption key**.

16. For **Input/output filtering and data joins (optional)**, you enter a JSONpath expression to filter your input data, join the input source data with your output data, and enter a JSONpath expression to filter your output data.
   
   a. For examples for each type of filter, see the **DataProcessing API**.

17. To perform batch predictions on your input dataset, select **Create batch transform job**. A new **Batch Transform Jobs** tab appears.

18. In the **Batch Transform Jobs** tab: Locate the name of your job in **Status** section. Then check the progress of the job.

**Deploy using SageMaker APIs**

To use the SageMaker APIs for batch inferencing, there are three steps:

1. **Obtain candidate definitions**

   Candidate definitions from **InferenceContainers** are used to create a SageMaker model.

   The following example shows how to use the **DescribeAutoMLJob** API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

   Use the **ListCandidatesForAutoMLJob** API to list all candidates. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

2. **Create a SageMaker model**

   To create a SageMaker model using the **CreateModel** API, use the container definitions from the previous steps. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker create-model --model-name '<your-custom-model-name>' --containers ['<container-definition1>', '<container-definition2>', '<container-definition3>'] --execution-role-arn '<execution-role-arn>' --region '<region>'
   ```
3. Create a SageMaker transform job

The following example creates a SageMaker transform job with the `CreateTransformJob` API. See the following AWS CLI command as an example.

```
aws sagemaker create-transform-job --transform-job-name '<your-custom-transform-job-name>' --model-name '<your-custom-model-name-from-last-step>'
  --transform-input '{
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "<your-input-data>"
      }
    },
    "ContentType": "text/csv",
    "SplitType": "Line"
  }'
  --transform-output '{
    "S3OutputPath": "<your-output-path>",
    "AssembleWith": "Line"
  }'
  --transform-resources '{
    "InstanceType": "<instance-type>",
    "InstanceCount": 1
  }' --region '<region>'
```

Check the progress of your transform job using the `DescribeTransformJob` API. See the following AWS CLI command as an example.

```
aws sagemaker describe-transform-job --transform-job-name '<your-custom-transform-job-name>' --region '<region>'
```

After the job is finished, the predicted result will be available in `<your-output-path>`.

The output file name has the following format: `<input_data_file_name>.out`. As an example, if your input file is `text_x.csv`, the output name will be `text_x.csv.out`.

The following tabs show code examples for SageMaker Python SDK, AWS SDK for Python (boto3), and the AWS CLI.

SageMaker Python SDK

The following example uses the **SageMaker Python SDK** to make predictions in batches.

```
from sagemaker import AutoML
sagemaker_session= sagemaker.session.Session()

job_name = 'test-auto-ml-job' # your autopilot job name
automl = AutoML.attach(auto_ml_job_name=job_name)
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

# call DescribeAutoMLJob API to get the best candidate definition
best_candidate = automl.describe_auto_ml_job()['BestCandidate']
best_candidate_name = best_candidate['CandidateName']

# create model
model = automl.create_model(name=best_candidate_name,
    candidate=best_candidate)
```
# create transformer
transformer = model.transformer(instance_count=1,
       instance_type='ml.m5.2xlarge',
       assemble_with='Line',
       output_path=output_path)

# do batch transform
transformer.transform(data=input_data,
                      split_type='Line',
                      content_type='text/csv',
                      wait=True)

AWS SDK for Python (boto3)

The following example uses **AWS SDK for Python (boto3)** to make predictions in batches.

```python
import sagemaker
import boto3

session = sagemaker.session.Session()

sm_client = boto3.client('sagemaker', region_name='us-west-2')
role = 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

# create model
response = sm_client.create_model(
    ModelName = best_candidate_name,
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName=f'{best_candidate_name}-transform-job',
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/csv",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m5.2xlarge',
        'InstanceCount': 1,
    }
)
```

The batch inference job returns a response in the following format.
AWS Command Line Interface (AWS CLI)

1. **Obtain the candidate definitions** by using the following code example.

   ```bash
   aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --region us-west-2
   ```

2. **Create the model** by using the following code example.

   ```bash
   aws sagemaker create-model --model-name 'test-sagemaker-model' --containers '[[
     "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
     "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569ff7ad77f4e55a7e549a/output/model.tar.gz",
     "Environment": {
       "AUTOML_SPARSE_ENCODE_RECORDIO_PROTOBUF": "1",
       "AUTOML_TRANSFORM_MODE": "feature-transform",
       "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
       "SAGEMAKER_PROGRAM": "sagemaker_serve",
       "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
     }
   ]],
   ["Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-xgboost:1.3-1-cpu-py3",

    "Environment": {
      "MAX_CONTENT_LENGTH": "20971520",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,labels,probabilities",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
   ],
   ["Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
    "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569ff7ad77f4e55a7e549a/output/model.tar.gz",
    "Environment": {
      "AUTOML_TRANSFORM_MODE": "inverse-label-transform",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,labels,probabilities",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
   ]
   ]
   --execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role' \
   --region 'us-west-2'
   ```

3. **Create the transform job** by using the following code example.
aws sagemaker create-transform-job --transform-job-name 'test-transform-job'\
--model-name 'test-sagemaker-model'\
--transform-input '{
  "DataSource": {
    "S3DataSource": {
      "S3DataType": "S3Prefix",
      "S3Uri": "s3://test-bucket/data.csv"
    }
  },
  "ContentType": "text/csv",
  "SplitType": "Line"
}'
--transform-output '{
  "S3OutputPath": "s3://test-bucket/output/",
  "AssembleWith": "Line"
}'
--transform-resources '{
  "InstanceType": "ml.m5.2xlarge",
  "InstanceCount": 1
}'
--region 'us-west-2'

4. Check the progress of the transform job by using the following the code example.

aws sagemaker describe-transform-job --transform-job-name 'test-transform-job' --region us-west-2

The following is the response from the transform job.

```json
{
  "TransformJobName": "test-transform-job",
  "TransformJobStatus": "InProgress",
  "ModelName": "test-model",
  "TransformInput": {
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "s3://test-bucket/data.csv"
      }
    },
    "ContentType": "text/csv",
    "CompressionType": "None",
    "SplitType": "Line"
  },
  "TransformOutput": {
    "S3OutputPath": "s3://test-bucket/output/",
    "AssembleWith": "Line",
    "KmsKeyId": ""
  },
  "TransformResources": {
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
  },
  "CreationTime": 1662495635.679,
  "TransformStartDateTime": 1662495847.496,
  "DataProcessing": {
    "InputFilter": "$",
    "OutputFilter": "$",
    "JoinSource": "None"
  }
}
```
After the TransformJobStatus changes to Completed, you can check the inference result in the S3OutputPath.

Deploy models from different accounts

To create a batch inferencing job in a different account than the one that the model was generated in, follow the instructions in Deploy models from different accounts (p. 74). Then you can create models and transform jobs by following the Deploy using SageMaker APIs (p. 77).

Models generated by Amazon SageMaker Autopilot

This procedure describes how to share a model that you created in Amazon SageMaker Autopilot with another user in SageMaker Canvas. It also shows how to view details about jobs that you've run.

Prerequisites

Before you begin this procedure, you must have created and run an Autopilot experiment. For instructions, see Create an Amazon SageMaker Autopilot experiment for tabular data (p. 46).

Share your Autopilot model

You can share your Autopilot model with another user in SageMaker Canvas. The other user can then import your model and use it to generate predictions.

To share the model in the Autopilot user interface using a button, see the following section View model details. The Share Model button is discussed in Step 6.

For more information about how to share a model, see Bring Your Own Model Into Canvas.

View model details

Autopilot generates details about the candidate models that you can obtain. These details include the following:

- A plot of the aggregated SHAP values that indicate the importance of each feature. This helps explain your models predictions.
- The summary statistics for various training and validation metrics, including the objective metric.
- A list of the hyperparameters used to train and tune the model.

To view model details after running an Autopilot job, follow these steps:

1. Choose the Home icon from the left navigation pane to view the top-level Amazon SageMaker Studio navigation menu.
2. Select the AutoML card from the main working area. This opens a new Autopilot tab.
3. In the Name section, select the Autopilot job that has the details that you want to examine. This opens a new Autopilot job tab.
4. The Autopilot job panel lists the metric values including the Objective metric for each model under Model name. The Best model is listed at the top of the list under Model name and is also highlighted in the Models tab.
   - To review model details, select the model that you are interested in and select View model details. This opens a new Model Details tab.
5. The **Model Details** tab is divided into four subsections.

   1. The top of the **Explainability** tab contains a plot of aggregated SHAP values that indicate the importance of each feature. Following that are the metrics and hyperparameter values for this model.
   2. The **Performance** tab contains metrics statistics a confusion matrix.
   3. The **Artifacts** tab contains information about model inputs, outputs, and intermediate results.
   4. The **Network** tab summarizes your network isolation and encryption choices.

   **Note**
   Feature importance and information in the **Performance** tab is only generated for the **Best model**.

   For more information about how the SHAP values help explain predictions based on feature importance, see the whitepaper **Understanding the model explainability**. Additional information is also available in the Amazon SageMaker Clarify Model Explainability (p. 3241) topic in the SageMaker Developer Guide.

6. To share your Autopilot model with another SageMaker Canvas user, choose **Share Model**. That button is located at the top right of the **Model Details** tab.

   - In the **Add Canvas users** section, use the down arrow to select a SageMaker Canvas user.

### View an Autopilot Model Performance Report

An Amazon SageMaker model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and other information related to the problem type. This guide shows how to view Amazon SageMaker Autopilot performance metrics graphically, or view metrics as raw data in a JSON file.

For example, in classification problems, the model quality report includes the following:

- Confusion matrix
- Area under the receiver operating characteristic curve (AUC)
- Information to understand false positives and false negatives
- Tradeoffs between true positives and false positives
- Tradeoffs between precision and recall

Autopilot also provides performance metrics for all of your candidate models. These metrics are calculated using all of the training data and are used to estimate model performance. The main working area includes these metrics by default. The type of metric is determined by the type of problem being addressed.

The following performance metrics are associated with the corresponding problem type:

- Regression: MAE, MSE, R2, RMSE
- Binary classification: Accuracy, AUC2, BalancedAccuracy, F1, LogLoss, Precision, Recall
- Multiclass classification: Accuracy, BalancedAccuracy, F1macro, LogLoss, PrecisionMacro, RecallMacro

You can sort your model candidates with the relevant metric to help you select and deploy the model that addresses your business needs. For definitions of these metrics, see the [Autopilot candidate metrics](#) topic.
To view a performance report from an Autopilot job, follow these steps:

1. Choose the **Home** icon 🏡 from the left navigation pane to view the top-level **Amazon SageMaker Studio** navigation menu.
2. Select the **AutoML** card from the main working area. This opens a new **Autopilot** tab.
3. In the **Name** section, select the Autopilot job that has the details that you want to examine. This opens a new **Autopilot job** tab.
4. The **Autopilot job** panel lists the metric values including the **Objective** metric for each model under **Model name**. The **Best model** is listed at the top of the list under **Model name** and it is highlighted in the **Models** tab.
   - To review model details, select the model that you are interested in and select **View in model details**. This opens a new **Model Details** tab.
5. Choose the **Performance** tab between the **Explainability** and **Artifacts** tab.
   a. On the top right section of the tab, select the down arrow on the **Download Performance Reports** button.
   b. The down arrow provides two options to view Autopilot performance metrics:
      i. You can download a PDF of the performance report to view the metrics graphically.
      ii. You can view metrics as raw data and download it as a JSON file.

For instructions on how to create and run an AutoML job in SageMaker Studio, see [Create an Amazon SageMaker Autopilot experiment for tabular data (p. 46)](https://docs.aws.amazon.com/sagemaker/latest/dg/autopilot-create-run.html).

The performance report contains two sections. The first contains details about the Autopilot job that produced the model. The second section contains a model quality report.

**Autopilot Job details**

This first section of the report gives some general information about the Autopilot job that produced the model. These job details include the following information:

- Autopilot candidate name
- Autopilot job name
- Problem type
- Objective metric
- Optimization direction

**Model quality report**

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed: regression, binary classification, or multiclass classification. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

**Metrics tables**

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.

The following image is an example of a metrics table that Autopilot generates for a regression problem. It shows the metric name, value, and standard deviation.
Create an Autopilot Experiment for Tabular Data

The following image is an example of a metrics table generated by Autopilot for a multiclass classification problem. It shows the metric name, value, and standard deviation.

**Graphical model performance information**

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the problem type used in modeling.

**The area under the receiver operating characteristic curve**

The area under the receiver operating characteristic curve represents the trade-off between true positive and false positive rates. It is an industry-standard accuracy metric used for binary classification models. AUC (area under the curve) measures the ability the model to predict a higher score for positive examples, as compared to negative examples. The AUC metric provides an aggregated measure of the model performance across all possible classification thresholds.

The AUC metric returns a decimal value from 0 to 1. AUC values near 1 indicate that the machine learning model is highly accurate. Values near 0.5 indicate that the model is performing no better than guessing at random. AUC values close to 0 indicate that the model has learned the correct patterns, but is making predictions that are as inaccurate as possible. Values near zero can indicate a problem with the data. For more information about the AUC metric, see the [Receiver operating characteristic](https://en.wikipedia.org/wiki/Receiver_operating_characteristic) article on Wikipedia.

The following is an example of an area under the receiver operating characteristic curve graph to evaluate predictions made by a binary classification model. The dashed thin line represents the area under the receiver operating characteristic curve that a model which classifies no-better-than-random guessing would score, with an AUC score of 0.5. The curves of more accurate classification models lie above this random baseline, where the rate of true positives exceeds the rate of false positives. The area under the receiver operating characteristic curve representing the performance of the binary classification model is the thicker solid line.
A summary of the graph's components of **false positive rate** (FPR) and **true positive rate** (TPR) are defined as follows.

- **Correct predictions**
  - **True positive** (TP): The predicted the value is 1, and the true value is 1.
  - **True negative** (TN): The predicted the value is 0, and the true value is 0.
- **Erroneous predictions**
  - **False positive** (FP): The predicted the value is 1, but the true value is 0.
  - **False negative** (FN): The predicted the value is 0, but the true value is 1.

The false positive rate (FPR) measures the fraction of true negatives (TN) that were falsely predicted as positives (FP), over the sum of FP and TN. The range is 0 to 1. A smaller value indicates better predictive accuracy.

- \[ FPR = \frac{FP}{FP+TN} \]

The true positive rate (TPR) measures the fraction true positives that were correctly predicted as positives (TP) over the sum of TP and false negatives (FN). The range is 0 to 1. A larger value indicates better predictive accuracy.

- \[ TPR = \frac{TP}{TP+FN} \]

**Confusion matrix**

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems. The confusion matrix in the model quality report contains the following.

- The number and percentage of correct and incorrect predictions for the actual labels
- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a binary classification problem. It contains the following information:

- The vertical axis is divided into two rows containing true and false actual labels.
- The horizontal axis is divided into two columns containing true and false labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In this example, the model predicted actual 2817 false values correctly, and 353 actual true values correctly. The model incorrectly predicted 130 actual true values to be false and 33 actual false values to be true. The difference in tone indicates that the dataset is not balanced. The imbalance is because there are many more actual false labels than actual true labels.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following.

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.
In the example below, the model correctly predicted actual 354 values for label f, 1094 values for label i and 852 values for label m. The difference in tone indicates that the dataset is not balanced because there are many more labels for the value i than for f or m.

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a Nan value, it means that the validation dataset used to check model predictions does not contain data with that label.

**Gain curve**

In binary classification, a gain curve predicts the cumulative benefit of using a percentage of the dataset to find a positive label. The gain value is calculated during training by dividing the cumulative number of positive observations by the total number of positive observations in the data, at each decile. If the classification model created during training is representative of the unseen data, you can use the gain curve to predict the percentage of data that you must target to obtain a percentage of positive labels. The greater the percentage of the dataset used, the higher the percentage of positive labels found.

In the following example graph, the gain curve is the line with changing slope. The straight line is the percentage of positive labels found by selecting a percentage of data from the dataset at random. Upon targeting 20% of the dataset, you would expect to find larger than 40% of the positive labels. As an example, you might consider using a gain curve to determine your efforts in a marketing campaign. Using our gain curve example, for 83% of people in a neighborhood to purchase cookies, you'd send an advertisement to about 60% of the neighborhood.
Lift curve

In binary classification, the lift curve illustrates the uplift of using a trained model to predict the likelihood of finding a positive label compared to a random guess. The lift value is calculated during training using the ratio of percentage gain to the ratio of positive labels at each decile. If the model created during training is representative of the unseen data, use the lift curve to predict the benefit of using the model over randomly guessing.

In the following example graph, the lift curve is the line with changing slope. The straight line is the lift curve associated with selecting the corresponding percentage randomly from the dataset. Upon targeting 40% of the dataset with your model's classification labels, you would expect to find about 1.7 times the number of the positive labels that you would have found by randomly selecting 40% of the unseen data.
Precision-recall curve

The precision-recall curve represents the tradeoff between precision and recall for binary classification problems.

**Precision** measures the fraction of actual positives that are predicted as positive (TP) out of all positive predictions (TP and false positive). The range is 0 to 1. A larger value indicates better accuracy in the predicted values.

- \[ \text{Precision} = \frac{TP}{TP + FP} \]

**Recall** measures the fraction of actual positives (TP) that are predicted as positive out of all positive predictions (TP and false negative). This is also known as the sensitivity and as the true positive rate. The range is 0 to 1. A larger value indicates better detection of positive values from the sample.

- \[ \text{Recall} = \frac{TP}{TP + FN} \]

The objective of a classification problem is to correctly label as many elements as possible. A system with high recall but low precision returns a high percentage of false positives.

The following graphic depicts a spam filter that marks every email as spam. It has high recall, but low precision, because recall doesn't measure false positives.

Give more weight to recall over precision if your problem has a low penalty for false positive values, but a high penalty for missing a true positive result. For example, detecting an impending collision in a self-driving vehicle.
By contrast, a system with high precision, but low recall, returns a high percentage of false negatives. A spam filter that marks every email as desirable (not spam) has high precision but low recall because precision doesn’t measure false negatives.

If your problem has a low penalty for false negative values, but a high penalty for missing a true negative results, give more weight to precision over recall. For example, flagging a suspicious filter for a tax audit.

The following graphic depicts a spam filter that has high precision but low recall, because precision doesn’t measure false negatives.

A model that makes predictions with both high precision and high recall produces a high number of correctly labeled results. For more information, see [Precision and recall](#) article in Wikipedia.

**Area under precision-recall curve (AUPRC)**

For binary classification problems, Amazon SageMaker Autopilot includes a graph of the area under the precision-recall curve (AUPRC). The AUPRC metric provides an aggregated measure of the model performance across all possible classification thresholds and uses both precision and recall. AUPRC does not take the number of true negatives into account. Therefore, it can be useful to evaluate model performance in cases where there’s a large number of true negatives in the data. For example, to model a gene containing a rare mutation.

The following graphic is an example of an AUPRC graph. Precision at its highest value is 1, and recall is at 0. In the lower right corner of the graph, recall is its highest value (1) and precision is 0. In between these two points, the AUPRC curve illustrates the tradeoff between precision and recall at different thresholds.
Actual against predicted plot

The actual against predicted plot shows the difference between actual and predicted model values. In the following example graph, the solid line is a linear line of best fit. If the model were 100% accurate, each predicted point would equal its corresponding actual point and lie on this line of best fit. The distance away from the line of best fit is a visual indication of model error. The larger the distance away from the line of best fit, the higher the model error.

Standardized residual plot

A standardized residual plot incorporates the following statistical terms:
residual

A (raw) residual shows the difference between actual and values predicted by your model. The larger the difference, the larger the residual value.

standard deviation

The standard deviation is a measure of how much values vary from an average value. A high standard deviation indicates that many values are very different from their average value. A low standard deviation indicates that many values are close to their average value.

standardized residual

A standardized residual divides the raw residuals by their standard deviation. Standardized residuals have units of standard deviation and are useful in identifying outliers in data regardless of the difference in scale of the raw residuals. If a standardized residual is much smaller or larger than the other standardized residuals, it indicates that the model is not fitting these observations well.

The standardized residual plot measures the strength of the difference between observed and expected values. The actual predicted value is displayed on the x axis. A point with a value larger than an absolute value of 3 is commonly regarded as an outlier.

The following example graph shows that a large number of standardized residuals are clustered around 0 on the horizontal axis. The values close to zero indicate that the model is fitting these points well. The points towards the top and bottom of the plot are not predicted well by the model.

residual histogram

A residual histogram incorporates the following statistical terms:

residual

A (raw) residual shows the difference between actual and values predicted by your model. The larger the difference, the larger the residual value.

standard deviation

The standard deviation is a measure of how much values vary from an average value. A high standard deviation indicates that many values are very different from their average value. A low standard deviation indicates that many values are close to their average value.
standardized residual

A standardized residual divides the raw residuals by their standard deviation. Standardized residuals have units of standard deviation. These are useful in identifying outliers in data regardless of the difference in scale of the raw residuals. If a standardized residual is much smaller or larger than the other standardized residuals, it would indicate that the model is not fitting these observations well.

histogram

A histogram is a graph that shows how often a value occurred.

The residual histogram shows the distribution of standardized residual values. A histogram distributed in a bell shape and centered at zero indicates that the model does not systematically overpredict or underpredict any particular range of target values.

In the following graphic, the standardized residual values indicate that the model is fitting the data well. If the graph showed values far away from the center value, it would indicate that those values don't fit the model well.

Amazon SageMaker Autopilot notebooks generated to manage AutoML tasks

Amazon SageMaker Autopilot manages the key tasks in an automatic machine learning (AutoML) process using an AutoML job.

The AutoML job creates three notebook-based reports that describe the plan that Autopilot follows to generate candidate models. A candidate model consists of a (pipeline, algorithm) pair. First, there's a data exploration notebook that describes what Autopilot learned about the data that you provided. Second, there's a candidate definition notebook, which uses the information about the data to generate candidates. Third, a model insights report that can help detail the performance characteristics of the best model in the leaderboard of an Autopilot experiment.

Topics

- Amazon SageMaker Autopilot Data exploration report (p. 95)
- Candidate definition notebook (p. 101)
You can run these notebooks in Amazon SageMaker, or locally, if you have installed the Amazon SageMaker Python SDK. You can share the notebooks just like any other SageMaker Studio notebook. The notebooks are created for you to conduct experiments. For example, you could edit the following items in the notebooks:

- Preprocessors used on the data
- Amount of hyperparameter optimization (HPO) runs and their parallelism
- Algorithms to try
- Instance types used for the HPO jobs
- Hyperparameter ranges

Modifications to the candidate definition notebook are encouraged as a learning tool. With this capability, you learn how decisions made during the machine learning process impact your results.

**Note**
When you run the notebooks in your default instance, you incur baseline costs. However, when you run HPO jobs from the candidate notebook, these jobs use additional compute resources that incur additional costs.

**Amazon SageMaker Autopilot Data exploration report**

Amazon SageMaker Autopilot cleans and pre-processes your dataset automatically. High-quality data improves machine learning efficiency and produces models that make more accurate predictions.

There are issues with customer-provided datasets that cannot be fixed automatically without the benefit of some domain knowledge. Large outlier values in the target column for regression problems, for example, may cause suboptimal predictions for the non-outlier values. Outliers may need to be removed depending on the modeling objective. If a target column is included by accident as one of the input features, the final model will validate well, but be of little value for future predictions.

To help customers discover these sorts of issues, Autopilot provides a data exploration report that contains insights into potential issues with their data. The report also suggests how to handle the issues.

A data exploration notebook containing the report is generated for every Autopilot job. The report is stored in an Amazon S3 bucket and can be accessed from your output path. The path of the data exploration report usually adheres to the following pattern.

```
[s3 output path]/[name of the automl job]/sagemaker-automl-candidates/[name of processing job used for data analysis]/notebooks/SageMakerAutopilotDataExplorationNotebook.ipynb
```

The location of the data exploration notebook can be obtained from the Autopilot API using the DescribeAutoMLJob operation response, which is stored in DataExplorationNotebookLocation.

When running Autopilot from SageMaker Studio, you can open the data exploration report using the following steps:

1. Choose the Home icon from the left navigation pane to view the top-level Amazon SageMaker Studio navigation menu.
2. Select the AutoML card from the main working area. This opens a new Autopilot tab.
3. In the Name section, select the Autopilot job that has the data exploration notebook that you want to examine. This opens a new Autopilot job tab.
4. Select Open data exploration notebook from the top right section of the Autopilot job tab.

The data exploration report is generated from your data before the training process begins. This allows you to stop Autopilot jobs that might lead to meaningless results. Likewise, you can address any issues
or improvements with your dataset before rerunning Autopilot. This way, you can use your domain expertise to improve the data quality manually, before you train a model on a better-curated dataset.

The data report contains only static markdown and can be opened in any Jupyter environment. The notebook that contains the report can be converted to other formats, such as PDF or HTML. For more information about conversions, see Using the nbconvert script to convert Jupyter notebooks to other formats.

Topics
- **Dataset Summary** (p. 96)
- **Target Analysis** (p. 96)
- **Data Sample** (p. 98)
- **Duplicate rows** (p. 99)
- **Cross column correlations** (p. 99)
- **Anomalous Rows** (p. 100)
- **Missing values, cardinality, and descriptive statistics** (p. 100)

Dataset Summary

This **Dataset Summary** provides key statistics characterizing your dataset including the number of rows, columns, percent duplicate rows and missing target values. It is intended to provide you with a quick alert when there are issue with your dataset that Amazon SageMaker Autopilot has detected and that are likely to require your intervention. The insights are surfaced as warnings that are classified as being of either “high” or “low” severity. The classification depends on the level of confidence that the issue will adversely impact the performance of the model.

The high and low severity insights appear in the summary as pop-ups. For most of the insights, recommendations are offered for how to confirm that there is an issue with the dataset that requires your attention. Proposals are also provided for how to resolve the issues.

Autopilot provides additional statistics about missing or not valid target values in our dataset to help you detect other issues that may not be captured by high severity insights. An unexpected number of columns of a particular type might indicate that some columns that you want to use may be missing from the dataset. It could also indicate that there was an issue with how the data was prepared or stored. Fixing these data problems brought to your attention by Autopilot can improve the performance of the machine learning models trained on your data.

High severity insights are shown in the summary section and in other relevant sections in the report. Examples of high and low-severity insights are usually given depending on the section of the data report.

Target Analysis

Various high and low-severity insights are shown in this section related to the distribution of values in the target column. Check that target column contains the correct values. Incorrect values in target column will likely result in a machine learning model that doesn’t serve the intended business purpose. Several data insights of high and low severity are present in this section. Here are several examples.

- **Outlier target values** - Skewed or unusual target distribution for regression, such as heavy tailed targets.
- **High or low target cardinality** - Infrequent number of class labels or a large number of unique classes for classification.

For both regression and classification problem types, not valid values such as numeric infinity, NaN or empty space in target column are surfaced. Depending on the problem type, different dataset statistics
are presented. A distribution of target column values for a regression problem allows you to verify if the distribution is what you expected.

The following screenshot shows an Autopilot data report, which includes statistics such as the mean, median, minimum, maximum, percentage of outliers in your dataset. The screenshot also includes a histogram showing the distribution of labels in the target column. The histogram shows **Target Column Values** on the horizontal axis and **Count** on the vertical axis. A box highlights the **Outliers Percentage** section of the screenshot to indicate where this statistic appears.

Multiple statistics are shown regarding target values and their distribution. If any of the outliers, not valid values, or missing percentages are greater than zero, these values are surfaced so you can investigate why your data contains unusable target values. Some unusable target values are highlighted as a low severity insight warning.

In the following screenshot, a ` symbol was added accidentally to the target column, which prevented the numeric value of the target from being parsed. A **Low severity insight: "Invalid target values"** warning appears. The warning in this example states "0.14% of the labels in the target column could not be converted to numeric values. The most common non-numeric values are: [-3.8e-05,-9.05,-4.7e-05,-1.4999999999999999e-05,-4.3e-05]. That usually indicates that there are problems with data collection or processing. Amazon SageMaker Autopilot ignores all observations with invalid target label."

Autopilot also provides a histogram showing the distribution of labels for classification.

The following screenshot shows an example of statistics given for your target column including the number of classes, missing or not valid values. A histogram with **Target Label** on the horizontal axis and **Frequency** on the vertical axis shows the distribution of each label category.
Note
You can find definitions of all the terms presented in this and other sections in Definitions section at the bottom of the report notebook.

Data Sample

Autopilot presents an actual sample of your data to help you spot issues with your dataset. The sample table scrolls horizontally. Inspect the sample data to verify that all the necessary columns are present in the dataset.

Autopilot also calculates a measure of prediction power, that can be used to identify a linear or nonlinear relationship between a feature and the target variable. A value of 0 indicates that the feature has no predictive value in predicting the target variable. A value of 1 indicates the highest predictive power for the target variable. For more information on predictive power, see the Definitions section.

Note
It is not recommended that you use prediction power as a substitute for feature importance. Only use it if you're certain that prediction power is an appropriate measure for your use case.

The following screenshot shows example data sample. The top row contains the prediction power of each column in your dataset. The second row contains the column data type. Subsequent rows contain the labels. The columns contain the target column followed by each feature column. Each feature column has an associated prediction power, highlighted in this screenshot, with a box. In this example, the column containing the feature x51 has a predictive power of 0.68 for the target variable y. The feature x55 is slightly less predictive with a prediction power of 0.59.
Duplicate rows

If duplicate rows are present in the dataset, Amazon SageMaker Autopilot displays a sample of them.

**Note**
It is not recommended to balance a dataset by up-sampling before providing it to Autopilot. This may result in inaccurate validation scores for the models trained by Autopilot, and the models that are produced may be unusable.

Cross column correlations

Autopilot uses the Pearson's correlation coefficient, a measure of linear correlation between two features, to populate a correlation matrix. In the correlation matrix, numeric features are plotted on both the horizontal and vertical axes, with the Pearson's correlation coefficient plotted at their intersections. The higher the correlation between two features, the higher the coefficient, with a maximum value of $|1|$.

- A value of -1 indicates that the features are perfectly negatively correlated.
- A value of 1, which occurs when a feature is correlated with itself, indicates perfect positive correlation.

You can use the information in the correlation matrix to remove highly correlated features. A smaller number of features reduces chances of overfitting a model and can reduce the costs of production in two ways. It lessens the Autopilot runtime needed and, for some applications, can make data collection procedures cheaper.

The following screenshot shows an example of a correlation matrix between 7 features. Each feature is displayed in a matrix on both the horizontal and vertical axes. The Pearson's correlation coefficient is displayed at the intersection between two features. Each feature intersection has a color tone associated with it. The higher the correlation, the darker the tone. The darkest tones occupy the diagonal of the matrix, where each feature is correlated with itself, representing perfect correlation.
Anomalous Rows

Amazon SageMaker Autopilot detects which rows in your dataset might be anomalous. It then assigns an anomaly score to each row. Rows with negative anomaly scores are considered anomalous.

The following screenshot shows the output from an Autopilot analysis for rows containing anomalies. A column containing an anomalous score appears next to the dataset columns for each row.

Missing values, cardinality, and descriptive statistics

Amazon SageMaker Autopilot examines and reports on properties of the individual columns of your dataset. In each section of the data report that presents this analysis, the content is arranged in order.
This is so you can check the most “suspicious” values first. Using these statistics you can improve contents of individual columns, and improve the quality of the model produced by Autopilot.

Autopilot calculates several statistics on the categorical values in columns that contain them. These include the number of unique entries and, for text, the number of unique words.

Autopilot calculates several standard statistics on the numerical values in columns that contain them. The following image depicts these statistics, including the mean, median, minimum and maximum values, and the percentages of numerical types and of outlier values.

Candidate definition notebook

The candidate definition notebook contains each suggested preprocessing step, algorithm, and hyperparameter ranges.

You can choose which candidate to train and tune in two ways. The first, by running sections of the notebook. The second, by running the entire notebook to optimize all candidates to identify a best candidate. If you run the entire notebook, only the best candidate is displayed after job completion.

To run Autopilot from SageMaker Studio, open the candidate definition notebook by following these steps:

1. Choose the Home icon 🏡 from the left navigation pane to view the top-level Amazon SageMaker Studio navigation menu.
2. Select the AutoML card from the main working area. This opens a new Autopilot tab.
3. In the Name section, select the Autopilot job that has the candidate definition notebook that you want to examine. This opens a new Autopilot job tab.
4. Choose Open candidate generation notebook from the top right section of the Autopilot job tab. This opens a new read-only preview of the Amazon SageMaker Autopilot Candidate Definition Notebook.

To run the candidate definition notebook, follow these steps:

1. Choose Import notebook at the top right of the Amazon SageMaker Autopilot Candidate Definition Notebook tab. This opens a tab to set up a new notebook environment to run the notebook.
2. Select an existing SageMaker Image or use a Custom Image.
3. Select a Kernel, an Instance type, and an optional Start-up script.

You can now run the notebook in this new environment.
Configure inference output in generated containers

Autopilot generates an ordered `ContainerDefinition` list. This can be used to build a model to deploy in a machine learning pipeline. This model can be used for online hosting and inference.

Customers can list inference container definitions with the `ListCandidateForAutoMLJob` API. The list of inference container definitions that represent the best candidate is also available in the `DescribeAutoMLJob` response.

Inference container definitions for regression and classification problem types

Autopilot generates inference containers specific to the training mode and the problem type of the job.

Container definitions for hyperparameter optimization (HPO) mode

- **Regression**: HPO generates two containers:
  1. A feature engineering container that transforms the original features into features that the regression algorithms can train on.
  2. An algorithm container that transforms features and generates a regression score for the dataset.

- **Classification**: HPO generates three containers:
  1. A feature engineering container that transforms the original features into features that the classification algorithms can train on.
  2. An algorithm container that generates the `predicted_label` with the highest probability. This container can also produce the various probabilities associated with the classification outcomes in the inference response.
  3. A feature engineering container that performs post-processing of the algorithm prediction. For example, it can perform an inverse transform on the predicted label and change it to the original label.

Container definitions for ensembling mode

In ensembling mode, both regression and classification problem types have only one inference container. This inference container transforms the features and generates the predictions based on problem type.

Inference responses per problem type

Inference responses for classification models

For classification inference containers, you can select the content of the inference response by using four predefined keys:

- `predicted_label`: The label with the highest probability of predicting the correct label, as determined by Autopilot.
- `probability`:
  - **HPO models**: The probability of the True class for binary classification. The probability of the `predicted_label` for multiclass classification.
  - **Ensemble models**: The probability of the `predicted_label` for binary and multiclass classification.
- `probabilities`: The list of probabilities for all corresponding classes.
- `labels`: The list of all labels.

For example, for a binary classification problem, if you pass the inference response keys `['predicted_label', 'probability', 'probabilities', 'labels']` and the output response appears as `[1, 0.1, ['0.9', '0.1'], ['1', '0']]`, you should interpret it as follows:
1. predicted_label equals 1 because label "1" has a higher probability (0.9 in this case).
2. For HPO models, probability equals 0.1 which is the probability of the positive_class (0 in this case) selected by Autopilot.

   For Ensemble models, probability equals 0.9 which is the probability of the predicted_label.
3. probabilities lists the probability of each label in labels.
4. labels are the unique labels in the dataset, where the second label ("0" in this case) is the positive_class selected by Autopilot.

By default, inference containers are configured to generate only the predicted_label. To select additional inference content, you can update the inference_response_keys parameter to include up to these three environment variables:

- SAGEMAKER_INFERENCE_SUPPORTED: This is set to provide hints to you about what content each container supports.
- SAGEMAKER_INFERENCE_INPUT: This should be set to the keys that the container expects in input payload.
- SAGEMAKER_INFERENCE_OUTPUT: This should be populated with the set of keys that the container outputs.

**Inference responses for classification models in HPO mode**

This section shows how to configure the inference response from classification models using hyperparameter optimization (HPO) mode.

To choose the inference response content in HPO mode: Add the SAGEMAKER_INFERENCE_INPUT and SAGEMAKER_INFERENCE_OUTPUT variables to the second and third containers that are generated in HPO mode for classification problems.

The keys supported by the second container (algorithm) are predicted_label, probability, and probabilities. Note that labels is deliberately not added to SAGEMAKER_INFERENCE_SUPPORTED.

The keys supported by the third classification model container are predicted_label, labels, probability, and probabilities. Therefore, the SAGEMAKER_INFERENCE_SUPPORTED environment includes the names of these keys.

To update the definition of the inference containers to receive predicted_label and probability, use the following code example.

```python
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
```

The following code example updates the definition of the inference containers to receive predicted_label, probabilities, and labels. Do not pass the labels to the second container (the algorithm container), because it is generated by the third container independently.

```python
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probabilities'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label, probabilities'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probabilities, labels'})
```
The following collapsible sections provide code examples for AWS SDK for Python (Boto3) and for SageMaker SDK for Python. Each section shows how to select the content of the inference responses in HPO mode for the respective code example.

AWS SDK for Python (Boto3)

```python
import boto3
sm_client = boto3.client('sagemaker', region_name= '<Region>

role = '<IAM role>'
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName= '<AutoML Job Name>'

['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

best_candidate_containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
'predicted_label, probability'})
best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT':
'predicted_label, probability'})
best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
'predicted_label, probability'})

# create model
response = sm_client.create_model(
    ModelName = '<Model Name>',
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName='<Transform Job Name>',
    ModelName='<Model Name>',
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/CSV",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m4.xlarge',
        'InstanceCount': 1,
    }
)
```

SageMaker SDK for Python

```python
from sagemaker import AutoML

aml = AutoML.attach(auto_ml_job_name='<AutoML Job Name>')</naml_best_model = aml.create_model(name='<Model Name>',
```
Inference responses for classification models in ensembling mode

This section shows how to configure the inference response from classification models using ensembling mode.

In **ensembling mode**, to choose the content of the inference response, update the SAGEMAKER_INFERENCE_OUTPUT environment variable.

The keys supported by the classification model container are `predicted_label`, `labels`, `probability`, and `probabilities`. These keys are included in the SAGEMAKER_INFERENCE_SUPPORTED environment.

To update the inference container definition to receive `predicted_label` and `probability`, refer to the following code example.

```python
containers[0]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
```

The following collapsible section provides a code example for selecting the content of the inference responses in ensembling mode. The example uses AWS SDK for Python (Boto3).

**AWS SDK for Python (Boto3)**

```python
import boto3
sm_client = boto3.client('sagemaker', region_name='<Region>')</code>
```

```python
role = '<IAM role>'
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName='<AutoML Job Name>')
["BestCandidate"]
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

*best_candidate_containers[0]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
*# create model
response = sm_client.create_model(
  ModelName = '<Model Name>',
  ExecutionRoleArn = role,
  Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
```
The following collapsible section provides a code example that is identical to the SageMaker SDK for Python example for HPO. It is included for your convenience.

### SageMaker SDK for Python

The following HPO code example uses SageMaker SDK for Python.

```python
from sagemaker import AutoML

aml = AutoML.attach(auto_ml_job_name='<AutoML Job Name>')
aml_best_model = aml.create_model(name='<Model Name>',
                                   candidate=None,
                                   *inference_response_keys**=['probabilities', 'labels'])*

aml_transformer = aml_best_model.transformer(accept='text/csv',
                                             assemble_with='Line',
                                             instance_type='ml.m5.xlarge',
                                             instance_count=1,)

aml_transformer.transform('<S3 input uri>',
                          content_type='text/csv',
                          split_type='Line',
                          job_name='<Transform Job Name>',
                          wait=True)
```

### Tutorials and example notebooks

Example notebooks, tutorial videos, and walkthroughs to get started with Amazon SageMaker Autopilot.

**Topics**

- Example notebooks: Explore modeling with Amazon SageMaker Autopilot (p. 106)
- Videos: Use Autopilot to automate and explore the machine learning process (p. 107)
- Tutorials: Get started with Amazon SageMaker Autopilot (p. 108)

**Example notebooks: Explore modeling with Amazon SageMaker Autopilot**

Amazon SageMaker Autopilot provides the following example notebooks.
• **Direct marketing with Amazon SageMaker Autopilot:** This notebook demonstrates how uses the Bank Marketing Data Set to predict whether a customer will enroll for a term deposit at a bank. You can use Autopilot on this dataset to get the most accurate ML pipeline by exploring options contained in various candidate pipelines. Autopilot generates each candidate in a two-step procedure. The first step performs automated feature engineering on the dataset. The second step trains and tunes an algorithm to produce a model. The notebook contains instructions on how to train the model and how to deploy the model to perform batch inference using the best candidate.

• **Customer Churn Prediction with Amazon SageMaker Autopilot:** This notebook describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. The example shows how to analyze a publicly available dataset and perform feature engineering on it. Next it shows how to tune a model by selecting the best performing pipeline along with the optimal hyperparameters for the training algorithm. Finally, it shows how to deploy the model to a hosted endpoint and how to evaluate its predictions against ground truth. However, ML models rarely give perfect predictions. That's why this notebook also shows how to incorporate the relative costs of prediction mistakes when determining the financial outcome of using ML.

• **Top Candidates Customer Churn Prediction with Amazon SageMaker Autopilot and Batch Transform (Python SDK):** This notebook also describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. This notebook demonstrates how to configure the model to obtain the inference probability, select the top N models, and make Batch Transform on a hold-out test set for evaluation.

**Note**
This notebook works with SageMaker Python SDK >= 1.65.1 released on 6/19/2020.

• **Bringing your own data processing code to Amazon SageMaker Autopilot:** This notebook demonstrates how to incorporate and deploy custom data processing code when using Amazon SageMaker Autopilot. It adds a custom feature selection step to remove irrelevant variables to an Autopilot job. It then shows how to deploy both the custom processing code and models generated by Autopilot on a real-time endpoint and, alternatively, for batch processing.

**Videos: Use Autopilot to automate and explore the machine learning process**

Here is a video series that provides a tour of Amazon SageMaker Autopilot capabilities using Studio. They show how to start an AutoML job, analyze and preprocess data, how to do feature engineering and hyperparameter optimization on candidate models, and how to visualize and compare the resulting model metrics.

**Topics**

- Start an AutoML job with Amazon SageMaker Autopilot (p. 107)
- Review data exploration and feature engineering automated in Autopilot. (p. 107)
- Tune models to optimize performance (p. 108)
- Choose and deploy the best model (p. 108)
- Amazon SageMaker Autopilot tutorial (p. 108)

**Start an AutoML job with Amazon SageMaker Autopilot**

This video shows you how to start an AutoML job with Autopilot. (Length: 8:41)

[Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 1)]

**Review data exploration and feature engineering automated in Autopilot.**

This video shows you how to review the data exploration and candidate definition notebooks generated by Amazon SageMaker Autopilot. (Length: 10:04)

[Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 2)]
Tune models to optimize performance
This video shows you how to optimize model performance during training using hyperparameter tuning. (Length: 4:59)

SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 3)

Choose and deploy the best model
This video shows you how to use job metrics to choose the best model and then how to deploy it. (Length: 5:20)

SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 4)

Amazon SageMaker Autopilot tutorial
This video walks you through an end to end demo where we first build a binary classification model automatically with Amazon SageMaker Autopilot. We see how candidate models have been built and optimized using auto-generated notebooks. We also look at the top candidates with Amazon SageMaker Experiments. Finally, we deploy the top candidate (based on XGBoost), and configure data capture with SageMaker Model Monitor.

End to end demo with AutoML on SageMaker

Tutorials: Get started with Amazon SageMaker Autopilot
Get started tutorials for Autopilot demonstrate how to create a machine learning model automatically without writing code. They show you how Autopilot simplifies the machine learning experience by helping you explore your data and try different algorithms. Autopilot builds the best machine learning model for the problem type using AutoML capabilities while allowing full control and visibility.

- Create a machine learning model automatically with Autopilot: You assume the role of a developer working at a bank in this tutorial. You have been asked to develop a machine learning model to predict if a customer will enroll for a certificate of deposit (CD). This is a binary classification problem. The model is trained on the marketing dataset that contains information on customer demographics, responses to marketing events, and external factors.

Create an Amazon SageMaker Autopilot experiment for image classification
The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for image classification problem types using SageMaker API Reference.

Note
Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the latest version of the SageMaker API. Users who prefer the convenience of a user interface can use Amazon SageMaker Canvas to access pre-trained models, generative AI foundation models, or create custom models tailored for specific text, image classification, or forecasting needs.

Create an Autopilot experiment programmatically
You can create an Autopilot image classification experiment programmatically by calling the CreateAutoMLJobV2 API action in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the See Also section of CreateAutoMLJobV2 and choose an SDK. As an example, for Python users, see the full request syntax of create_auto_ml_job_v2 in AWS SDK for Python (Boto3).
The following is a collection of mandatory and optional input request parameters for the CreateAutoMLJobV2 API action used in image classification.

**Required parameters**

When calling `CreateAutoMLJobV2` to create an Autopilot experiment for image classification, you must provide the following values:

- An `AutoMLJobName` to specify the name of your job.
- At least one `AutoMLJobChannel` in `AutoMLJobInputDataConfig` to specify your data source.
- An `AutoMLProblemTypeConfig` of type `ImageClassificationJobConfig`.
- An `OutputDataConfig` to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A `RoleArn` to specify the ARN of the role used to access your data.

All other parameters are optional.

**Optional parameters**

The following sections provide details of some optional parameters that you can pass to your image classification AutoML job.

**How to specify the training and validation datasets of an AutoML job**

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each `AutoMLJobChannel` object (see the required parameter `AutoMLJobInputDataConfig`) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in `AutoMLDataSplitConfig` is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

**How to specify the automatic model deployment configuration for an AutoML job**

To enable automatic deployment for the best model candidate of an AutoML job, include a `ModelDeployConfig` in the AutoML job request. This will allow the deployment of the best model to a SageMaker endpoint. Below are the available configurations for customization.
• To let Autopilot generate the endpoint name, set `AutoGenerateEndpointName` to True.
• To provide your own name for the endpoint, set `AutoGenerateEndpointName` to False and provide a name of your choice in `EndpointName`.

Datasets format and objective metric for image classification

In this section we learn about the available formats for datasets used in image classification as well as the objective metric used to evaluate the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of `MetricDatum` types.

Datasets formats

Autopilot supports .png, .jpg, and .jpeg image formats. If your dataset contains all .png images use `image/png`, if it contains all .jpg or .jpeg images use `image/jpeg`, and if your dataset contains a mix of image formats use `image/*`.

Objective metric

The following list contains the names of the metrics that are currently available to measure the performance of models for image classification.

Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

Autopilot model deployment and prediction

This Autopilot guide includes steps for model deployment and setting up real-time inference.

After you train your Autopilot models, you can set up an endpoint and obtain predictions interactively.

Real-time inferencing

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

You can use SageMaker APIs to manually deploy the model that produced the best validation metric in an Autopilot experiment as follows.

Alternatively, you can chose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see `ModelDeployConfig` in the request parameters of `CreateAutoMLJobV2`. This creates an endpoint automatically.

**Note**

To avoid incurring unnecessary charges, you can delete unneeded endpoint and resources created from model deployment. For information about pricing of instances by Region, see `Amazon SageMaker Pricing`.

1. **Obtain the candidate container definitions**

Obtain the candidate container definitions from `InferenceContainers`. A container definition for inference refers to the containerized environment designed for deploying and running your trained SageMaker model to make predictions.
The following AWS CLI command example uses the `DescribeAutoMLJobV2` API to obtain candidate definitions for the best model candidate.

```bash
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

2. List candidates

The following AWS CLI command example uses the `ListCandidatesForAutoMLJob` API to list all model candidates.

```bash
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
```

3. Create a SageMaker model

Use the container definitions from the previous steps and a candidate of your choice to create a SageMaker model by using the `CreateModel` API. See the following AWS CLI command as an example.

```bash
aws sagemaker create-model --model-name '<your-candidate-name>' \
--containers ['<container-definition1>', '<container-definition2>', '<container-definition3>'] \
--execution-role-arn '<execution-role-arn>' --region '<region>
```

4. Create an endpoint configuration

The following AWS CLI command example uses the `CreateEndpointConfig` API to create an endpoint configuration.

```bash
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>' \
--production-variants '<list-of-production-variants>' \
--region '<region>'
```

5. Create the endpoint

The following AWS CLI example uses the `CreateEndpoint` API to create the endpoint.

```bash
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>' \
--endpoint-config-name '<endpoint-config-name-you-just-created>' \
--region '<region>'
```

Check the progress of your endpoint deployment by using the `DescribeEndpoint` API. See the following AWS CLI command as an example.

```bash
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region '<region>'
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```bash
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \
--region '<region>' --body '<your-data>' [--content-type] '<content-type>' <outfile>
```
Explainability report

Amazon SageMaker Autopilot provides an explainability report to help explain how a best model candidate makes predictions for image classification problems. This report can assist ML engineers, product managers, and other internal stakeholders in understanding the characteristics of the model. Both consumers and regulators rely on transparency in machine learning to trust and interpret decisions made on model predictions. You can use these explanations for auditing and meeting regulatory requirements, establishing trust in the model, supporting human decision-making, and debugging and improving model performance.

The Autopilot explanatory functionality for image classification uses a visual class activation map (CAM) approach that produces a heatmap where the distribution and intensity of each color highlights the areas of an image that contribute the most to a specific prediction. This approach relies on principal components derived from an implementation of Eigen-CAM.

Autopilot generates the explainability report as a JSON file. The report includes analysis details that are based on the validation dataset. Each image used to generate the report contains the following information:

- **input_image_uri**: The Amazon S3 URI to the input image taken as input for the heatmap.
- **heatmap_image_uri**: The Amazon S3 URL to the heatmap image generated by Autopilot.
- **predicted_label**: The label class predicted by best model trained by Autopilot.
- **probability**: The confidence with which the predicted_label is predicted.

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to `DescribeAutoMLJobV2` at `BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability`.

The following examples illustrate what the heatmaps look like on a few samples from Oxford-IIIT Pet Dataset. The heatmap image displays color gradients that indicate the relative importance of different features within the image. The red color represents regions with greater importance in predicting the "predicted_label" of the input image compared to the features represented by the blue color.

<table>
<thead>
<tr>

Model performance report

An Amazon SageMaker model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and various metrics. This section details the content of a performance report for image classification problems and explains how to access the metrics as raw data in a JSON file.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to DescribeAutoMLJobV2 at BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights.

The performance report contains two sections:

- The first section contains details about the Autopilot job that produced the model.
- The second section contains a model quality report with various performance metrics.

Autopilot job details

This first section of the report gives some general information about the Autopilot job that produced the model. These details include the following information:

- Autopilot candidate name: The name of the best model candidate.
- Autopilot job name: The name of the job.
- Problem type: The problem type. In our case, image classification.
- Objective metric: The objective metric used to optimize the performance of the model. In our case, Accuracy.
- Optimization direction: Indicates whether to minimize or maximize the objective metric.

Model quality report

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

Metrics tables

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.
The following image is an example of a metrics table generated by Autopilot for an image or text classification problem. It shows the metric name, value, and standard deviation.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Value</th>
<th>Standard Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>weighted_recall</td>
<td>0.597104</td>
<td>0.005410</td>
</tr>
<tr>
<td>weighted_precision</td>
<td>0.591693</td>
<td>0.005729</td>
</tr>

<td>0.003808</td>
</tr>
</tbody>
</table>

Graphical model performance information

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the selected problem type.

Confusion matrix

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems.

A summary of the graph's components of false positive rate (FPR) and true positive rate (TPR) are defined as follows.

- Correct predictions
  - True positive (TP): The predicted the value is 1, and the true value is 1.
  - True negative (TN): The predicted the value is 0, and the true value is 0.
- Erroneous predictions
  - False positive (FP): The predicted the value is 1, but the true value is 0.
  - False negative (FN): The predicted the value is 0, but the true value is 1.

The confusion matrix in the model quality report contains the following.

- The number and percentage of correct and incorrect predictions for the actual labels
- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following.

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.
In the example below, the model correctly predicted actual 354 values for label \( f \), 1094 values for label \( i \) and 852 values for label \( m \). The difference in tone indicates that the dataset is not balanced because there are many more labels for the value \( i \) than for \( f \) or \( m \).

![Confusion Matrix](image)

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a \textit{NaN} value, it means that the validation dataset used to check model predictions does not contain data with that label.

**Create an Amazon SageMaker Autopilot experiment for text classification**

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for text classification problem types using SageMaker API Reference.

**Note**

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the latest version of the SageMaker API. Users who prefer the convenience of a user interface can use Amazon SageMaker Canvas to access pre-trained models, generative AI foundation models, or create custom models tailored for specific text, image classification, or forecasting needs.

**Create an Autopilot experiment programmatically**

You can create an Autopilot text classification experiment programmatically by calling the `CreateAutoMLJobV2` API action in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the See Also section of `CreateAutoMLJobV2` and choose an SDK. As an example, for Python users, see the full request syntax of `create_auto_ml_job_v2` in AWS SDK for Python (Boto3).
The following is a collection of mandatory and optional input request parameters for the `CreateAutoMLJobV2` API action used in text classification.

**Required parameters**

When calling `CreateAutoMLJobV2` to create an Autopilot experiment for text classification, you must provide the following values:

- An `AutoMLJobName` to specify the name of your job.
- At least one `AutoMLJobChannel` in `AutoMLJobInputDataConfig` to specify your data source.
- An `AutoMLProblemTypeConfig` of type `TextClassificationJobConfig`.
- An `OutputDataConfig` to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A `RoleArn` to specify the ARN of the role used to access your data.

All other parameters are optional.

**Optional parameters**

The following sections provide details of some optional parameters that you can pass to your text classification AutoML job.

**How to specify the training and validation datasets of an AutoML job**

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each `AutoMLJobChannel` object (see the required parameter `AutoMLJobInputDataConfig`) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in `AutoMLDataSplitConfig` is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

**How to specify the automatic model deployment configuration for an AutoML job**

To enable automatic deployment for the best model candidate of an AutoML job, include a `ModelDeployConfig` in the AutoML job request. This will allow the deployment of the best model to a SageMaker endpoint. Below are the available configurations for customization.
• To let Autopilot generate the endpoint name, set `AutoGenerateEndpointName` to True.
• To provide your own name for the endpoint, set `AutoGenerateEndpointName` to False and provide a name of your choice in `EndpointName`.

Datasets format and objective metric for text classification

In this section we learn about the available formats for datasets used in text classification as well as the metric used to evaluate the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of `MetricDatum` types.

Datasets formats

Autopilot supports tabular data formatted as CSV files or as Parquet files. For tabular data, each column contains a feature with a specific data type and each row contains an observation. The properties of these two file formats differ considerably.

• **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
• **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

The data types accepted for columns include numerical, categorical, text.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs. For details on the default resource limits for input datasets and how to increase them, see [Amazon SageMaker Autopilot quotas](#).

Objective metric

The following list contains the names of the metrics that are currently available to measure the performance of models for text classification.

**Accuracy**

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

Autopilot model deployment and prediction

This Autopilot guide includes steps for model deployment and setting up real-time inference.

After you train your Autopilot models, you can set up an endpoint and obtain predictions interactively.

**Real-time inferencing**

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

You can use SageMaker APIs to manually deploy the model that produced the best validation metric in an Autopilot experiment as follows.
Alternatively, you can choose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see `ModelDeployConfig` in the request parameters of `CreateAutoMLJobV2`. This creates an endpoint automatically.

**Note**
To avoid incurring unnecessary charges, you can delete unneeded endpoint and resources created from model deployment. For information about pricing of instances by Region, see Amazon SageMaker Pricing.

1. **Obtain the candidate container definitions**

Obtain the candidate container definitions from `InferenceContainers`. A container definition for inference refers to the containerized environment designed for deploying and running your trained SageMaker model to make predictions.

The following AWS CLI command example uses the `DescribeAutoMLJobV2` API to obtain candidate definitions for the best model candidate.

```bash
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

2. **List candidates**

The following AWS CLI command example uses the `ListCandidatesForAutoMLJob` API to list all model candidates.

```bash
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
```

3. **Create a SageMaker model**

Use the container definitions from the previous steps and a candidate of your choice to create a SageMaker model by using the `CreateModel` API. See the following AWS CLI command as an example.

```bash
aws sagemaker create-model --model-name '<your-candidate-name>' \ 
--containers ['<container-definition1>, <container-definition2>, <container-definition3>'] \ 
--execution-role-arn '<execution-role-arn>' --region '<region>
```

4. **Create an endpoint configuration**

The following AWS CLI command example uses the `CreateEndpointConfig` API to create an endpoint configuration.

```bash
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>' \ 
--production-variants '<list-of-production-variants>' \ 
--region '<region>
```

5. **Create the endpoint**

The following AWS CLI example uses the `CreateEndpoint` API to create the endpoint.

```bash
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>' \ 
--endpoint-config-name '<endpoint-config-name-you-just-created>' \ 
--region '<region>
```

Check the progress of your endpoint deployment by using the `DescribeEndpoint` API. See the following AWS CLI command as an example.
After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

6. **Invoke the endpoint**

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' --region '<region>' --body '<your-data>' [--content-type] '<content-type>' <outfile>
```

### Explainability report

Amazon SageMaker Autopilot provides an explainability report to help explain how a best model candidate makes predictions for text classification problems. This report can assist ML engineers, product managers, and other internal stakeholders in understanding the characteristics of the model. Both consumers and regulators rely on transparency in machine learning to trust and interpret decisions made on model predictions. You can use these explanations for auditing and meeting regulatory requirements, establishing trust in the model, supporting human decision-making, and debugging and improving model performance.

The Autopilot explanatory functionality for text classification uses the axiomatic attribution method **Integrated Gradients**. This approach relies on an implementation of [Axiomatic Attribution for Deep Network](https://arxiv.org/abs/1611.07702).

Autopilot generates the explainability report as a JSON file. The report includes analysis details that are based on the validation dataset. Each sample used to generate the report contains the following information:

- **text**: The input text content explained.
- **token_scores**: The list of scores for every token in the text.
- **attribution**: The score depicting the importance of the token.
- **description.partial_text**: The partial substring that represents the token.
- **predicted_label**: The label class predicted by the best model candidate.
- **probability**: The confidence with which the predicted_label was predicted.

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to `DescribeAutoMLJobV2` at `BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability`.

The following is an example of analysis content that you could find in the explainability artifacts.

```json
{
    "text": "It was a fantastic movie!",
    "predicted_label": 2,
    "probability": 0.9984835,
    "token_scores": [
        {
            "attribution": 0,
            "description": {
                "partial_text": "It"
            }
        },
        
    ]
}
```
In this sample of the JSON report, the explanatory functionality evaluates the text “It was a fantastic movie!” and scores the contribution of each of its token to the overall predicted label. The predicted label is 2, which is a strong positive sentiment, with a probability of 99.85%. The JSON sample then details the contribution of each individual token to this prediction. For example, the token “fantastic” has a stronger attribution than the token “was”. It is the token that contributed the most to the final prediction.

Model performance report

An Amazon SageMaker model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and various metrics. This section details the content of a performance report for text classification problems and explains how to access the metrics as raw data in a JSON file.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to DescribeAutoMLJobV2 at BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights.

The performance report contains two sections:

- The first section contains details about the Autopilot job that produced the model.
- The second section contains a model quality report with various performance metrics.

Autopilot job details

This first section of the report gives some general information about the Autopilot job that produced the model. These details include the following information:

- Autopilot candidate name: The name of the best model candidate.
- Autopilot job name: The name of the job.
- Problem type: The problem type. In our case, text classification.
• Objective metric: The objective metric used to optimize the performance of the model. In our case, *Accuracy*.

• Optimization direction: Indicates whether to minimize or maximize the objective metric.

**Model quality report**

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

**Metrics tables**

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.

The following image is an example of a metrics table generated by Autopilot for an image or text classification problem. It shows the metric name, value, and standard deviation.

**Metrics table**

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Value</th>
<th>Standard Deviation</th>
</tr>
</thead>

<td>0.003808</td>
</tr>
</tbody>
</table>

**Graphical model performance information**

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the selected problem type.

**Confusion matrix**

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems.

A summary of the graph's components of **false positive rate** (FPR) and **true positive rate** (TPR) are defined as follows.

• Correct predictions
  • **True positive** (TP): The predicted the value is 1, and the true value is 1.
  • **True negative** (TN): The predicted the value is 0, and the true value is 0.

• Erroneous predictions
  • **False positive** (FP): The predicted the value is 1, but the true value is 0.
  • **False negative** (FN): The predicted the value is 0, but the true value is 1.

The confusion matrix in the model quality report contains the following.
The number and percentage of correct and incorrect predictions for the actual labels

- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following:

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In the example below, the model correctly predicted actual 354 values for label $f$, 1094 values for label $i$ and 852 values for label $m$. The difference in tone indicates that the dataset is not balanced because there are many more labels for the value $i$ than for $f$ or $m$.

![Confusion Matrix](image)

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a Nan value, it means that the validation dataset used to check model predictions does not contain data with that label.

Create an Amazon SageMaker Autopilot experiment for time-series forecasting

Forecasting in machine learning refers to the process of predicting future outcomes or trends based on historical data and patterns. By analyzing past time-series data and identifying underlying patterns,
machine learning algorithms can make predictions and provide valuable insights into future behavior. In forecasting, the goal is to develop models that can accurately capture the relationship between input variables and the target variable over time. This involves examining various factors such as trends, seasonality, and other relevant patterns within the data. The collected information is then used to train a machine learning model. The trained model is capable of generating predictions by taking new input data and applying the learned patterns and relationships. It can provide forecasts for a wide range of use cases, such as sales projections, stock market trends, weather forecasts, demand forecasting, and many more.

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for time-series forecasting problem types using SageMaker API Reference.

**Note**
Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the latest version of the SageMaker API. Users who prefer the convenience of a user interface can use Amazon SageMaker Canvas to access pre-trained models, generative AI foundation models, or create custom models tailored for specific text, image classification, or forecasting needs.

Before using Autopilot to create a time-series forecasting experiment in SageMaker, make sure to:

- Prepare your time-series dataset. Dataset preparation involves collecting relevant data from various sources, cleaning and filtering it to remove noise and inconsistencies, and organizing it into a structured format. See Time-series datasets format and missing values filling methods (p. 127) to learn more about time-series formats requirements in Autopilot. Optionally, you can supplement your dataset with the public holiday calendar of the country of your choice to capture associated patterns. For more information on holiday calendars, see National holiday calendars (p. 129).
- Place your time-series data in an Amazon S3 bucket.
- Grant full access to the Amazon S3 bucket containing your input data for the SageMaker execution role used to run your experiment. Once this is done, you can use the ARN of this execution role in Autopilot API requests.
- For information on retrieving your SageMaker execution role, see Get execution role (p. 3390).
- For information on granting your SageMaker execution role permissions to access one or more specific buckets in Amazon S3, see Add Additional Amazon S3 Permissions to a SageMaker Execution Role in Create execution role (p. 3387).

**Create an Autopilot experiment programmatically**

You can create an Autopilot time-series forecasting experiment programmatically by calling the CreateAutoMLJobV2 API in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the See Also section of CreateAutoMLJobV2 and choose an SDK. As an example, for Python users, see the full request syntax of create_auto_ml_job_v2 in AWS SDK for Python (Boto3).

Autopilot trains several model candidates with your target time-series, then selects an optimal forecasting model for a given objective metric. When your model candidates have been trained, you can find the best candidate metrics in the response to DescribeAutoMLJobV2 at BestCandidate.

The following sections define the mandatory and optional input request parameters for the CreateAutoMLJobV2 API used in time-series forecasting.

**Note**
Refer to the notebook Time-Series Forecasting with Amazon SageMaker Autopilot for a practical, hands-on time-series forecasting example. In this notebook, you use Amazon SageMaker Autopilot to train a time-series model and produce predictions using the trained model. The notebook provides instructions for retrieving a ready-made dataset of tabular historical data on Amazon S3.
Required parameters

When calling `CreateAutoMLJobV2` to create an Autopilot experiment for time-series forecasting, you must provide the following values:

- An `AutoMLJobName` to specify the name of your job. The name should be of type `string`, and should have a minimum length of 1 character and a maximum length of 32.
- At least one `AutoMLJobChannel` in `AutoMLJobInputDataConfig` in which you specify the name of the Amazon S3 bucket that contains your data. Optionally, you can specify the content (CSV or Parquet files) and compression (GZip) types.
- An `AutoMLProblemTypeConfig` of type `TimeSeriesForecastingJobConfig` to configure the settings of your time-series forecasting job. In particular, you must specify:
  - The `frequency` of predictions, which refers to the desired granularity (hourly, daily, monthly, etc) of your forecast.

Valid intervals are an integer followed by Y (Year), M (Month), W (Week), D (Day), H (Hour), and min (Minute). For example, 1D indicates every day and 15min indicates every 15 minutes. The value of a frequency must not overlap with the next larger frequency. For example, you must use a frequency of 1H instead of 60min.

The valid values for each frequency are the following:
- Minute - 1-59
- Hour - 1-23
- Day - 1-6
- Week - 1-4
- Month - 1-11
- Year - 1
- The `horizon` of predictions in your forecast, which refers to the number of time-steps that the model predicts. The forecast horizon is also called the prediction length. The maximum forecast horizon is the lesser of 500 time-steps or 1/4 of the time-steps in the dataset.
- A `TimeSeriesConfig` in which you define the schema of your dataset to map the column headers to your forecast by specifying:
  - A `TargetAttributeName`: The column that contains historical data of the target field to forecast.
  - A `TimestampAttributeName`: The column that contains a point in time at which the target value of a given item is recorded.
  - A `ItemIdentifierAttributeName`: The column that contains the item identifiers for which you want to predict the target value.

The following is an example of those request parameters. In this example, you are setting up a daily forecast for the expected quantity or level of demand of specific items over a period of 20 days.

```json
"AutoMLProblemTypeConfig": {
    "ForecastFrequency": "D",
    "ForecastHorizon": 20,
    "TimeSeriesConfig": {
        "TargetAttributeName": "demand",
        "TimestampAttributeName": "timestamp",
        "ItemIdentifierAttributeName": "item_id"
    }
},
```

- An `OutputDataConfig` to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A `RoleArn` to specify the ARN of the role used to access your data. You can use the ARN of the execution role to which you have granted access to your data.
All other parameters are optional. For example, you can set specific forecast quantiles, choose a filling method for missing values in the dataset, or define how to aggregate data that does not align with forecast frequency. To learn how to set those additional parameters, see Optional parameters (p. 125).

Optional parameters

The following sections provide details of some optional parameters that you can pass to your time-series forecasting AutoML job.

How to specify custom quantiles

Autopilot trains 6 models candidates with your target time-series, then combines these models using a stacking ensemble method to create an optimal forecasting model for a given objective metric. Each Autopilot forecasting model generates a probabilistic forecast by producing forecasts at quantiles between P1 and P99. These quantiles are used to account for forecast uncertainty. By default, forecasts will be generated for the 0.1 (p10), 0.5 (p50), and 0.9 (p90). You can choose to specify your own quantiles.

In Autopilot, you can specify up to five forecast quantiles from 0.01 (p1) to 0.99 (p99), by increments of 0.01 or higher in the ForecastQuantiles attribute of TimeSeriesForecastingJobConfig.

In the following example, you are setting up a daily 10th, 25th, 50th, 75th, and 90th percentile forecast for the expected quantity or level of demand of specific items over a period of 20 days.

```
"AutoMLProblemTypeConfig": {
  "ForecastFrequency": "D",
  "ForecastHorizon": 20,
  "ForecastQuantiles": ["p10", "p25", "p50", "p75", "p90"],
  "TimeSeriesConfig": {
    "TargetAttributeName": "demand",
    "TimestampAttributeName": "timestamp",
    "ItemIdentifierAttributeName": "item_id"
  }
}
```

How to aggregate data for different forecast frequencies

To create a forecast model (also referred to as the best model candidate from your experiment), you must specify a forecast frequency. The forecast frequency determines the frequency of predictions in your forecasts. For example, monthly sales forecasts. Autopilot best model can generate forecasts for data frequencies that are higher than the frequency at which your data is recorded.

During training, Autopilot aggregates any data that does not align with the forecast frequency you specify. For example, you might have some daily data but specify a weekly forecast frequency. Autopilot aligns the daily data based on the week that it belongs in. Autopilot then combines it into single record for each week.

During aggregation, the default transformation method is to sum the data. You can configure the aggregation when you create your AutoML job in the Transformations attribute of TimeSeriesForecastingJobConfig. The supported aggregation methods are sum (default), avg, first, min, max. Aggregation is only supported for the target column.

In the following example, you configure the aggregation to calculate the average of the individual promo forecasts to provide the final aggregated forecast values.

```
"Transformations": {
  "Aggregation": {
    "promo": "avg"
  }
}
```
How to handle missing values in your input datasets

Autopilot provides a number of filling methods to handle missing values in the target and other numeric columns of your time-series datasets. For information on the list of supported filling methods and their available filling logic, see Handle missing values (p. 128).

You configure your filling strategy in the Transformations attribute of TimeSeriesForecastingJobConfig when creating your AutoML job.

To set a filling method, you need to provide a key-value pair:

- The key is the name of the column for which you want to specify the filling method.
- The value associated with the key is an object that defines the filling strategy for that column.

You can specify multiple filling methods for a single column.

To set a specific value for the filling method, you should set the fill parameter to the desired filling method value (for example "backfill" : "value"), and define the actual filling value in an additional parameter suffixed with ".value". For example, to set backfill to a value of 2, you must include two parameters: "backfill": "value" and "backfill_value": "2".

In the following example, you specify the filling strategy for the incomplete data column, "price" as follows: All missing values between the first data point of an item and the last are set to 0 after which all missing values are filled with the value 2 until the end date of the dataset.

```
"Transformations": {  
  "Filling": {  
    "price": {  
      "middlefill": "zero",  
      "backfill": "value",  
      "backfill_value": "2"  
    }  
  }  
}
```

How to specify an objective metric

Autopilot produces accuracy metrics to evaluate the model candidates and help you choose which to use to generate forecasts. When you run a time-series forecasting experiment, you can either choose AutoML to let Autopilot optimize the predictor for you, or you can manually choose an algorithm for your predictor.

By default, Autopilot uses the Average Weighted Quantile Loss. However, you can configure the objective metric when you create your AutoML job in the MetricName attribute of AutoMLJobObjective.

For the list of available algorithms, see Algorithms support for time-series forecasting (p. 139).

How to incorporate national holiday information to your dataset

In Autopilot, you can incorporate a feature-engineered dataset of national holiday information to your time-series. Autopilot provide native support for the holiday calendars of over 250 countries. After you choose a country, Autopilot applies that country's holiday calendar to every item in your dataset during training. This allows the model to identify patterns associated with specific holidays.

You can enable the holiday featurization when you create your AutoML job by passing an HolidayConfigAttributes object to the HolidayConfig attribute of TimeSeriesForecastingJobConfig. The HolidayConfigAttributes object contains the two letters CountryCode attribute that determines the country of the public national holiday calendar used to augment your time-series dataset.
Refer to Country Codes (p. 130) for the list of supported calendars and their corresponding country code.

How to enable automatic deployment

Autopilot allows you to automatically deploy your forecast model to an endpoint. To enable automatic deployment for the best model candidate of an AutoML job, include a ModelDeployConfig in the AutoML job request. This allows the deployment of the best model to a SageMaker endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set AutoGenerateEndpointName to True.
- To provide your own name for the endpoint, set AutoGenerateEndpointName to False and provide a name of your choice in EndpointName.

Time-series datasets format and missing values filling methods

Time-series data refers to a collection of observations or measurements recorded over regular intervals of time. In this type of data, each observation is associated with a specific timestamp or time period, creating a sequence of data points ordered chronologically.

The specific columns you include in your time-series dataset depend on the goals of your analysis and the data available to you. At a minimum, the time-series data is composed of a 3-column table where:

- One column contains unique identifiers assigned to individual items to refer to their value at a specific moment.
- Another column represents the point-in-time value or target to log the value of a given item at a specific moment. After the model is trained on those target values, this target column contains the values that the model predicts at a specified frequency within a defined horizon.
- And a timestamp column is included to record the date and time when the value was measured.
- Additional columns can contain other factors that may influence the forecast performance. For example, in a time-series dataset for retail where the target is the sales or revenue, you might include features that provide information about units sold, product ID, store location, customer count, inventory levels, as well as covariate indicators such as weather data or demographic information.

Note
You can add a feature-engineered dataset of national holiday information to your time-series. By including holidays in your time series model, you can capture the periodic patterns that holidays create. This helps your forecasts better reflect the underlying seasonality of your data. For information on the available calendars per country, see National holiday calendars (p. 129).

Datasets format for time-series forecasting

Autopilot supports numeric, categorical, text, and datetime data types. The data type of the target column must be numeric.

Autopilot supports time-series data formatted as CSV (default) files or as Parquet files.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

For more information about the resource limits on time-series datasets for forecasting in Autopilot, see Amazon SageMaker Autopilot time-series forecasting resource limits (p. 147).
Handle missing values

A common issue in time-series forecasting data is the presence of missing values. Your data might contain missing values for a number of reasons, including measurement failures, formatting problems, human errors, or a lack of information to record. For instance, if you are forecasting product demand for a retail store and an item is sold out or unavailable, there would be no sales data to record while that item is out of stock. If prevalent enough, missing values can significantly impact a model's accuracy.

Autopilot provides a number of filling methods to handle missing values, with distinct approaches for the target column and other additional columns. Filling is the process of adding standardized values to missing entries in your dataset.

Refer to How to handle missing values in your input datasets (p. 126) to learn how to set the method for filling missing values in your time-series dataset.

Autopilot supports the following filling methods:

- **Front filling:** Fills any missing values between the earliest recorded data point among all items and the starting point of each item (each item can start at a different time). This ensures that the data for each item is complete and spans from the earliest recorded data point to its respective starting point.
- **Middle filling:** Fills any missing values between the start and end dates of the items in the dataset.
- **Back filling:** Fills any missing values between the last data point of each item (each item can stop at a different time) and the last recorded data point among all items.
- **Future filling:** Fills any missing values between the last recorded data point among all items and the end of the forecast horizon.

The following image provides a visual representation of the different filling methods.

![Filling methods diagram]

Choose a filling logic

When choosing a filling logic, you should consider how the logic will be interpreted by your model. For instance, in a retail scenario, recording 0 sales of an available item is different from recording 0 sales of an unavailable item, as the latter does not imply a lack of customer interest in the item. Because of this, 0 filling in the target column of the time-series might cause the predictor to be under-biased in its predictions, while NaN filling might ignore actual occurrences of 0 available items being sold and cause the predictor to be over-biased.

**Filling logic**

You can perform filling on the target column and other numeric columns in your datasets. Target columns have different filling guidelines and restrictions than the rest of the numeric columns.

**Filling Guidelines**

<table>
<thead>
<tr>
<th>Column type</th>
<th>Filling by default?</th>
<th>Supported filling methods</th>
<th>Default filling logic</th>
<th>Accepted filling logic</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Target column</strong></td>
<td>Yes</td>
<td>Middle and back filling</td>
<td>0</td>
<td>• zero - 0 filling.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• value - an integer or float number.</td>
</tr>
<tr>
<td>Column type</td>
<td>Filling by default?</td>
<td>Supported filling methods</td>

<td></td>
<td>• min - the minimum value from the data series.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• max - the maximum value from the data series.</td>
</tr>
</tbody>
</table>

**Note**
For both the target and other numeric columns, mean, median, min, and max are calculated based on a rolling window of the 64 most recent data entries before the missing values.

**National holiday calendars**

Autopilot supports a feature-engineered dataset of national holiday information that provides access to the holiday calendars of over 250 countries.

Holiday calendar features are especially useful in the retail domain, where public holidays can significantly affect demand.
Refer to How to incorporate national holiday information to your dataset (p. 126) to learn how to add a calendar to your dataset.

**Country Codes**

Autopilot provides native support for the public holiday calendars of the following countries. Use the Country Code when specifying a country with the API.

Objective metrics

Autopilot produces accuracy metrics to evaluate the model candidates and help you choose which to use to generate forecasts. You can either let Autopilot optimize the predictor for you, or you can manually choose an algorithm for your predictor. By default, Autopilot uses the Average Weighted Quantile Loss.

The following list contains the names of the metrics that are currently available to measure the performance of models for time-series forecasting.

**RMSE**

Root mean squared error (RMSE) – Measures the square root of the squared difference between predicted and actual values, and is averaged over all values. It’s an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different sizes.

**wQL**

Weighted Quantile Loss (wQL) – Assess the accuracy of the forecast by measuring the weighted absolute differences between predicted and actual P10, P50, and P90 quantiles with lower values indicating better performance.

**Average wQL (default)**

Average Weighted Quantile Loss (Average wQL) – Evaluates the forecast by averaging the accuracy at the P10, P50, and P90 quantiles. A lower value indicates a more accurate model.

**MASE**

Mean Absolute Scaled Error (MASE) – The mean absolute error of the forecast normalized by the mean absolute error of a simple baseline forecasting method. A lower value indicates a more accurate model, where MASE < 1 is estimated to be better than the baseline and MASE > 1 is estimated to be worse than the baseline.

**MAPE**

Mean Absolute Percent Error (MAPE) – The percentage error (percent difference of the mean forecasted value versus the actual value) averaged over all time points. A lower value indicates a more accurate model, where MAPE = 0 is a model with no errors.
WAPE

Weighted Absolute Percent Error (WAPE) – The sum of the absolute error normalized by the sum of the absolute target, which measure the overall deviation of forecasted values from observed values. A lower value indicates a more accurate model.

Algorithms support for time-series forecasting

Autopilot trains the following six built-in algorithms with your target time-series. Then, using a stacking ensemble method, it combines these model candidates to create an optimal forecasting model for a given objective metric.

• Convolutional Neural Network - Quantile Regression (CNN-QR) – CNN-QR is a proprietary machine learning algorithm for forecasting time-series using causal convolutional neural networks (CNNs). CNN-QR works best with large datasets containing hundreds of time-series.
• Prophet – Prophet is a popular local Bayesian structural time series model based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality. The Autopilot Prophet algorithm uses the Prophet class of the Python implementation of Prophet. It works best with time-series with strong seasonal effects and several seasons of historical data.
• Non-Parametric Time Series (NPTS) – The NPTS proprietary algorithm is a scalable, probabilistic baseline forecaster. It predicts the future value distribution of a given time-series by sampling from past observations. NPTS is especially useful when working with sparse or intermittent time series.
• Autoregressive Integrated Moving Average (ARIMA) – ARIMA is a commonly used statistical algorithm for time-series forecasting. The algorithm captures standard temporal structures (patterned organizations of time) in the input dataset. It is especially useful for simple datasets with under 100 time series.
• Exponential Smoothing (ETS) – ETS is a commonly used statistical algorithm for time-series forecasting. The algorithm is especially useful for simple datasets with under 100 time series, and datasets with seasonality patterns. ETS computes a weighted average over all observations in the time series dataset as its prediction, with exponentially decreasing weights over time.

Autopilot model deployment and forecasts

After you train your Autopilot predictor (best model), you can deploy a model to get predictions in one of two ways:

1. Use Real-time forecasting (p. 140) to set up an endpoint and obtain predictions interactively.
2. Use Batch forecasting (p. 141) to make predictions in parallel on batches of observations on an entire dataset.

When providing input data for forecasting, the schema of your data should remain the same as the one used to train your model, including the number of columns, column headers, and data types. You can forecast for existing or new item IDs within the same or different timestamp range to predict for a different time period.

Forecasting models predict for the forecast horizon points in the future specified in the input request at training, which is from the target end date to the target end date + forecast horizon. To use the model for predicting specific dates, you should provide the data in the same format as the original input data, extending up to a specified target end date. In this scenario, the model will start predicting from the new target end date.
For example, if your dataset had monthly data from January to June with a Forecast horizon of 2, then the model would predict the target value for the next 2 months, which would be July and August. If in August, you want to predict for the next 2 months, this time your input data should be from January to August and the model will predict for the next 2 months (September, October).

**Note**
We recommend using the following instance types for forecasting:

- For real-time forecasting, use `m5.12xlarge` instances.
- For batch forecasting, use `m5.12xlarge` instances for general-purpose workloads and `m5.24xlarge` instances for big data forecasting tasks.

**Real-time forecasting**

You can use real-time forecasting for inference workloads where you have real-time, interactive, low latency requirements.

**Note**
For real time forecasting, the dataset should be a subset of the input dataset. The real time endpoint has an input data size of approximately 6MB and a response timeout limitation of 60 seconds. We recommend bringing in one or few items at a time.

You can use SageMaker APIs to manually deploy the model that produced the best validation metric in an Autopilot experiment as follows.

Alternatively, you can chose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see How to enable automatic deployment (p. 127).

1. **Obtain the candidate container definitions**

   Obtain the candidate container definitions from `InferenceContainers`. A container definition for inference refers to the containerized environment designed for deploying and running your trained SageMaker model to make predictions.

   The following AWS CLI command example uses the `DescribeAutoMLJobV2` API to obtain candidate definitions for the best model candidate.

   ```
   aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name <job-name> --region <region>
   ```

2. **List candidates**

   The following AWS CLI command example uses the `ListCandidatesForAutoMLJob` API to list all model candidates.

   ```
   aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

3. **Create a SageMaker model**

   Use the container definitions from the previous steps and a candidate of your choice to create a SageMaker model by using the `CreateModel` API. See the following AWS CLI command as an example.

   ```
   aws sagemaker create-model --model-name '<your-candidate-name>' \
   --containers ['<container-definition1>', '<container-definition2>', '<container-definition3>'] \
   --execution-role-arn '<execution-role-arn>' --region '<region>'
   ```

4. **Create an endpoint configuration**
The following AWS CLI command example uses the **CreateEndpointConfig** API to create an endpoint configuration.

```bash
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>'
   --production-variants '<list-of-production-variants>'
   --region '<region>'
```

### 5. Create the endpoint

The following AWS CLI example uses the **CreateEndpoint** API to create the endpoint.

```bash
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>'
   --endpoint-config-name '<endpoint-config-name-you-just-created>'
   --region '<region>'
```

Check the progress of your endpoint deployment by using the **DescribeEndpoint** API. See the following AWS CLI command as an example.

```bash
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region '<region>'
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

### 6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```bash
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>'
   --region '<region>' --body '<your-data-in-bytes>' [--content-type]

   '<content-type>' '<outfile>'
```

### Batch forecasting

Batch forecasting, also known as offline inferencing, generates model predictions on a batch of observations. Batch inference is a good option for large datasets or if you don't need an immediate response to a model prediction request.

By contrast, online inference (real-time inferencing) generates predictions in real time.

You can make batch inferences from an Autopilot model using the API reference.

To use the SageMaker APIs for batch inferencing:

1. **Obtain candidate definitions**

   Candidate definitions from **InferenceContainers** are used to create a SageMaker model.

   The following example shows how to use the **DescribeAutoMlJobV2** API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name <job-name> --region <region>
   ```

   Use the **ListCandidatesForAutoMlJob** API to list all candidates. See the following AWS CLI command as an example.
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>

2. Create a SageMaker model

To create a SageMaker model using the CreateModel API, use the container definitions from the previous steps. See the following AWS CLI command as an example.

aws sagemaker create-model --model-name '<your-custom-model-name>' --containers ['<container-definition1>', '<container-definition2>', '<container-definition3>'] --execution-role-arn '<execution-role-arn>' --region '<region>'

3. Create a SageMaker transform job

The following example creates a SageMaker transform job with the CreateTransformJob API. See the following AWS CLI command as an example.

aws sagemaker create-transform-job --transform-job-name '<your-custom-transform-job-name>' --model-name '<your-custom-model-name-from-last-step>' --transform-input '{
    "DataSource": {
        "S3DataSource": {
            "S3DataType": "S3Prefix",
            "S3Uri": "<your-input-data>"
        }
    },
    "ContentType": "text/csv",
    "SplitType": "None"
}"
--transform-output '{
    "S3OutputPath": "<your-output-path>",
    "AssembleWith": "Line"
}"
--transform-resources '{
    "InstanceType": "<instance-type>",
    "InstanceCount": 1
}' --region '<region>'

Check the progress of your transform job using the DescribeTransformJob API. See the following AWS CLI command as an example.

aws sagemaker describe-transform-job --transform-job-name '<your-custom-transform-job-name>' --region <region>

After the job is finished, the predicted result is available in <your-output-path>.

The output file name has the following format: <input_data_file_name>.out. As an example, if your input file is text_x.csv, the output name will be text_x.csv.out.

The following tabs show code examples for the AWS SDK for Python (boto3), and the AWS CLI.

AWS SDK for Python (boto3)

The following example uses AWS SDK for Python (boto3) to make predictions in batches.

```python
import sagemaker
import boto3
```
session = sagemaker.session.Session()

sm_client = boto3.client('sagemaker', region_name='us-west-2')
role = 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

best_candidate = sm_client.describe_auto_ml_job_v2(AutoMLJobName=job_name)
best_candidate['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

# create model
response = sm_client.create_model(
    ModelName = best_candidate_name,
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName=f'{best_candidate_name}-transform-job',
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/csv",
        'SplitType': 'None'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m5.2xlarge',
        'InstanceCount': 1,
    }
)

The batch inference job returns a response in the following format.

 'ResponseMetadata': {'RequestId': '659f97fc-28c4-440f-b957-a49733f7c2f2',
 'HTTPStatusCode': 200,
 'HTTPHeaders': {'x-amzn-requestid': '659f97fc-28c4-440f-b957-a49733f7c2f2',
 'content-type': 'application/x-amz-json-1.1',
 'content-length': '96',
 'date': 'Thu, 11 Aug 2022 22:23:49 GMT'},
'RetryAttempts': 0})

AWS Command Line Interface (AWS CLI)

1. Obtain the candidate definitions by using the following code example.

aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name "test-automl-job" --region us-west-2

2. Create the model by using the following code example.
Create an Autopilot Experiment for Time-series Forecasting

```
aws sagemaker create-model --model-name 'test-sagemaker-model'
--containers '[{
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
  "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569f7ad77f4e55a7e549a/output/model.tar.gz",
  "Environment": {
    "AUTOML_SPARSE_ENCODE_RECORDIO_PROTobuf": "1",
    "AUTOML_TRANSFORM_MODE": "feature-transform",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
    "SAGEMAKER_PROGRAM": "sagemaker_server",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-xgboost:1.3-1-cpu-py3",
  "ModelDataUrl": "s3://test-bucket/out/test-job1/tuning/flicdf10v2-dpp0-xgb/test-job1E9-244-7490a1c0/output/model.tar.gz",
  "Environment": {
    "MAX_CONTENT_LENGTH": "20971520",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,probabilities"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
  "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569f7ad77f4e55a7e549a/output/model.tar.gz",
  "Environment": {
    "AUTOML_TRANSFORM_MODE": "inverse-label-transform",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,labels,probabilities",
    "SAGEMAKER_PROGRAM": "sagemaker_server",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}]

--execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
--region 'us-west-2'
```

3. Create the transform job by using the following code example.

```
aws sagemaker create-transform-job --transform-job-name 'test-tranform-job'
--model-name 'test-sagemaker-model'
--transform-input '{
  "DataSource": {
    "S3DataSource": {
      "S3DataType": "S3Prefix",
      "S3Uri": "s3://test-bucket/data.csv"
    }
  },
  "ContentType": "text/csv",
  "SplitType": "None"
}
--transform-output '{
  "S3OutputPath": "s3://test-bucket/output/",
  "AssembleWith": "Line"
}
--transform-resources '{
  "InstanceType": "ml.m5.2xlarge",
```

144
4. **Check the progress of the transform job** by using the following the code example.

```bash
aws sagemaker describe-transform-job --transform-job-name 'test-transform-job' --region us-west-2
```

The following is the response from the transform job.

```json
{
  "TransformJobName": "test-transform-job",
  "TransformJobStatus": "InProgress",
  "ModelName": "test-model",
  "TransformInput": {
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "s3://test-bucket/data.csv"
      }
    },
    "ContentType": "text/csv",
    "CompressionType": "None",
    "SplitType": "None"
  },
  "TransformOutput": {
    "S3OutputPath": "s3://test-bucket/output/",
    "AssembleWith": "Line",
    "KmsKeyId": ""
  },
  "TransformResources": {
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
  },
  "CreationTime": 1662495635.679,
  "TransformStartTime": 1662495847.496,
  "DataProcessing": {
    "InputFilter": "$",
    "OutputFilter": "$",
    "JoinSource": "None"
  }
}
```

After the `TransformJobStatus` changes to **Completed**, you can check the inference result in the `S3OutputPath`.

## Amazon SageMaker Autopilot data exploration notebook

Amazon SageMaker Autopilot cleans and pre-processes your dataset automatically. To help users understand their data, uncover patterns, relationships, and anomalies about the time-series, Amazon SageMaker Autopilot generates a **data exploration** static report in the form of a notebook for users to reference.

The data exploration notebook is generated for every Autopilot job. The report is stored in an Amazon S3 bucket and can be accessed from the job output path.
Reports generated by Amazon SageMaker Autopilot

In addition to the data exploration notebook, Autopilot generates various reports for the best model candidate of each experiment.

- An explainability report provides insights into how the model makes forecasts.
- A performance report provides a quantitative assessment of the model's forecasting capabilities.
- A backtest results report is generated after testing the model's performance on historical data.

Explainability report

Autopilot explainability report helps you better understand how the attributes in your datasets impact forecasts for specific time-series (item and dimension combinations) and time points. Autopilot uses a metric called Impact scores to quantify the relative impact of each attribute and determine whether they increase or decrease forecast values.

For example, consider a forecasting scenario where the target is sales and there are two related attributes: price and color. Autopilot may find that the item's color has a high impact on sales for certain items, but a negligible effect for other items. It may also find that a promotion in the summer has a high impact on sales, but a promotion in the winter has little effect.

The explainability report is generated only when:

- The time series dataset includes additional feature columns or is associated with a holiday calendar.
- The base models CNN-QR and DeepAR+ are included in the final ensemble.

Interpret Impact scores

Impact scores measure the relative impact attributes have on forecast values. For example, if the price attribute has an impact score that is twice as large as the store location attribute, you can conclude that the price of an item has twice the impact on forecast values than the store location.

Impact scores also provide information on whether attributes increase or decrease forecast values.

The Impact scores range from -1 to 1, where the sign denotes the direction of the impact. A score of 0 indicates no impact, while scores close to 1 or -1 indicate a significant impact.

It is important to note that Impact scores measure the relative impact of attributes, not the absolute impact. Therefore, Impact scores cannot be used to determine whether particular attributes improve model accuracy. If an attribute has a low Impact score, that does not necessarily mean that it has a low impact on forecast values; it means that it has a lower impact on forecast values than other attributes used by the predictor.

Find the explainability report

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to DescribeAutoMLJobV2 at BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability.

Model performance report

Autopilot model quality report (also referred to as performance report) provides insights and quality information for the best model candidate (best predictor) generated by an AutoML job. This includes information about the job details, objective function, and accuracy metrics (wQL, MAPE, WAPE, RMSE, MASE).
You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to `DescribeAutoMLJobV2` at `BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights`.

**Backtests results report**

Backtests results provide insights into the performance of a time-series forecasting model by evaluating its predictive accuracy and reliability. It helps analysts and data scientists assess its performance on historical data and assists in understanding its potential performance on future, unseen data.

Autopilot uses backtesting to tune parameters and produce accuracy metrics. During backtesting, Autopilot automatically splits your time-series data into two sets, a training set and a testing set. The training set is used to train a model which is then used to generate forecasts for data points in the testing set. Autopilot uses this testing dataset to evaluate the model's accuracy by comparing forecasted values with observed values in the testing set.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to `DescribeAutoMLJobV2` at `BestCandidate.CandidateProperties.CandidateArtifactLocations.BacktestResults`.

**Create an Amazon SageMaker Autopilot experiment for text generation models fine-tuning**

Large language models (LLMs) excel in multiple generative tasks, including text generation, summarization, completion, question answering, and more. Their performance can be attributed to their significant size and extensive training on diverse datasets and various tasks. However, specific domains, such as healthcare and financial services, may require customized fine-tuning to adapt to unique data
and use cases. By tailoring their training to their particular domain, LLMs can improve their performance and provide more accurate outputs for targeted applications.

Autopilot offers the capability to fine-tune a selection of pre-trained generative text models. In particular, Autopilot supports the instruction-based fine tuning of a selection of general-purpose large language models (LLMs) powered by SageMaker JumpStart.

**Note**

The text generation models that support fine-tuning in Autopilot are currently accessible exclusively in regions supported by SageMaker Canvas. Refer to the documentation of SageMaker Canvas for the full list of its supported Regions.

Fine-tuning a pre-trained model requires a specific dataset of clear instructions that guide the model on how to generate output or behave for that task. The model learns from the dataset, adjusting its parameters to conform to the provided instructions. Instruction-based fine-tuning involves using labeled examples formatted as prompt, response pairs and phrased as instructions. For more information on fine-tuning, see [Fine-tune a foundation model](#).

The following guidelines outline the process of creating an Amazon SageMaker Autopilot job as a pilot experiment to fine-tune text generation LLMs using the SageMaker [API Reference](#).

**Note**

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the latest version of the SageMaker API. Users who prefer the convenience of a user interface can use Amazon SageMaker Canvas to access pre-trained models, generative AI foundation models, or create custom models tailored for specific text, image classification, or forecasting needs.

Before using Autopilot to create a fine-tuning experiment in SageMaker, make sure to:

- (Optional) Choose the pre-trained model you want to fine-tune.
  
  For the list of pre-trained models available for fine-tuning in Amazon SageMaker Autopilot, see [Supported large language models for fine-tuning](p. 151). The selection of a model is not mandatory; if no model is specified, Autopilot automatically defaults to the model *Falcon-7B-Instruct*.

- Create a dataset of instructions. See [Dataset file types and input data format](p. 152) to learn about the format requirements of your instruction-based dataset.

- Place your dataset in an Amazon S3 bucket.

- Grant full access to the Amazon S3 bucket containing your input data for the SageMaker execution role used to run your experiment.
  - For information on retrieving your SageMaker execution role, see [Get execution role](p. 3390).
  - For information on granting your SageMaker execution role permissions to access one or more specific buckets in Amazon S3, see [Add Additional Amazon S3 Permissions to a SageMaker Execution Role](p. 3387).

- Additionally, you should provide your execution role with the necessary permissions to access the default storage Amazon S3 bucket used by SageMaker JumpStart. This access is required for storing and retrieving SageMaker JumpStart pre-trained Language Model (LLM) artifacts. To grant access to this Amazon S3 bucket, you must create a new inline custom policy on your execution role.

Here's an example policy that you can use in your JSON editor when setting up AutoML fine-tuning jobs in *us-west-2*:

```
{
  "Sid": "Statement1",
  "Effect": "Allow",
```
Create an Autopilot Experiment for Text Generation Models Fine-Tuning

Once this is done, you can use the ARN of this execution role in Autopilot API requests.

Create an Autopilot experiment programmatically

To create an Autopilot experiment programmatically for fine-tuning a large language model, you can call the `CreateAutoMLJobV2` API in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the See Also section of CreateAutoMLJobV2 and choose an SDK. As an example, for Python users, see the full request syntax of `create_auto_ml_job_v2` in AWS SDK for Python (Boto3).

Note

Autopilot fine-tunes large language models without requiring multiple candidates to be trained and evaluated. Instead, using your dataset, Autopilot directly fine-tunes your target model to enhance a default objective metric, the cross-entropy loss. Fine-tuning language models in Autopilot does not require setting the `AutoMLJobObjective` field.

Once your LLM is fine-tuned, you can evaluate its performance by accessing various Rouge scores through the `BestCandidate` when making a `DescribeAutoMLJobV2` API call. The model also provides information about its training and validation loss as well as perplexity. For a comprehensive list of metrics for evaluating the quality of the text generated by the fine-tuned models, see Metrics for fine-tuning large language models in Autopilot (p. 153).

Required parameters

When calling `CreateAutoMLJobV2` to create an Autopilot experiment for LLMs fine-tuning, you must provide the following values:

- An `AutoMLJobName` to specify the name of your job. The name should be of type string, and should have a minimum length of 1 character and a maximum length of 32.
- At least one `AutoMLJobChannel` of the training type within the `AutoMLJobInputDataConfig`. This channel specifies the name of the Amazon S3 bucket where your fine-tuning dataset is located. You have the option to define a validation channel. If no validation channel is provided, and a `ValidationFraction` is configured in the `AutoMLDataSplitConfig`, this fraction is utilized to randomly divide the training dataset into training and validation sets. Additionally, you can specify the type of content (CSV or Parquet files) for the dataset.
- An `AutoMLProblemTypeConfig` of type `TextGenerationJobConfig` to configure the settings of your fine-tuning training job.

In particular, you can specify the name of the base model to fine-tune in the `BaseModelName` field. For the list of pre-trained models available for fine-tuning in Amazon SageMaker Autopilot, see Supported large language models for fine-tuning (p. 151).
- An `OutputDataConfig` to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A `RoleArn` to specify the ARN of the role used to access your data.
The following is an example of the full request format used when making an API call to CreateAutoMLJobV2 for fine-tuning a Falcon-7B-Instruct (Falcon7B) model.

```json
{
  "AutoMLJobName": "<job_name>",
  "AutoMLJobInputDataConfig": [
    {
      "ChannelType": "training",
      "CompressionType": "None",
      "ContentType": "text/csv",
      "DataSource": {
        "S3DataSource": {
          "S3DataType": "S3Prefix",
          "S3Uri": "s3://<bucket_name>/<input_data>.csv"
        }
      }
    }
  ],
  "OutputDataConfig": {
    "S3OutputPath": "s3://<bucket_name>/output",
    "KmsKeyId": "arn:aws:kms:<region>:<account_id>:key/<key_value>"
  },
  "RoleArn": "arn:aws:iam::<account_id>:role/<sageMaker_execution_role_name>",
  "AutoMLProblemTypeConfig": {
    "TextGenerationJobConfig": {
      "BaseModelName": "Falcon7B"
    }
  }
}
```

All other parameters are optional.

**Optional parameters**

The following sections provide details of some optional parameters that you can pass to your fine-tuning AutoML job.

**How to specify the training and validation datasets of an AutoML job**

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each `AutoMLJobChannel` object (see the required parameter `AutoMLJobInputDataConfig`) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

- **If you only have one data source**, the `ChannelType` is set to `training` by default and must have this value.
- **If the ValidationFraction value in `AutoMLDataSplitConfig` is not set**, 0.2 (20%) of the data from this source is used for validation by default.
- **If the ValidationFraction is set to a value between 0 and 1**, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- **If you have two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.
How to enable automatic deployment

Autopilot allows you to automatically deploy your fine-tuned model to an endpoint. To enable automatic deployment for your fine-tuned model, include a `ModelDeployConfig` in the AutoML job request. This allows the deployment of your fine-tuned model to a SageMaker endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set `AutoGenerateEndpointName` to True.
- To provide your own name for the endpoint, set `AutoGenerateEndpointName` to False and provide a name of your choice in `EndpointName`.

Supported large language models for fine-tuning

Text generation models supporting fine-tuning in Autopilot

Using Autopilot API, users can fine-tune the following large language models (LLMs). Those models are powered by Amazon SageMaker JumpStart.

<table>
<thead>
<tr>
<th>Model</th>
<th>BaseModelName in API request</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon-7B-Instruct</td>
<td>Falcon7B</td>
<td>Falcon-7B-Instruct has 7 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-40B-Instruct, Falcon-7B-Instruct is a slightly smaller and more compact model.</td>
</tr>
<tr>
<td>Falcon-40B-Instruct</td>
<td>Falcon40B</td>
<td>Falcon-40B-Instruct has 40 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-7B-Instruct, Falcon-40B-Instruct is a slightly larger and more powerful model.</td>
</tr>
</tbody>
</table>
Create an Autopilot Experiment for Text Generation Models Fine-Tuning

<table>
<thead>
<tr>
<th>Model</th>
<th>BaseModelName in API request</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPT-7B-Instruct</td>
<td>MPT7B</td>
<td>MPT-7B-Instruct is a model for long-form instruction following tasks and can assist you with writing tasks including text summarization and question-answering to save you time and effort. This model was trained on large amounts of fine-tuned data and can handle larger inputs, such as complex documents. Use this model when you want to process large bodies of text or want the model to generate long responses.</td>
</tr>
</tbody>
</table>

**Dataset file types and input data format**

Instruction-based fine-tuning uses labeled datasets to improve the performance of pre-trained LLMs on specific NLP tasks. The labeled examples are formatted as prompt, response pairs and phrased as instructions.

To learn about the supported dataset file types, see [Datasets file supported types](p. 152).

To learn about input data format, see [Input data format for instruction-based fine-tuning](p. 152).

**Datasets file supported types**

Autopilot supports instruction-based fine-tuning datasets formatted as CSV (default) files or as Parquet files.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

**Note**

The dataset may consist of multiple files, each of which must adhere to a specific template. For information on how to format your input data, see [Input data format for instruction-based fine-tuning](p. 152).

**Input data format for instruction-based fine-tuning**

Each file of the dataset must adhere to the following format:

- The dataset must contain exactly two comma-separated and named columns, `input` and `output`. Autopilot ignores any additional columns.
- The `input` columns contain the prompts, and their corresponding `output` contains the expected answer. Both the `input` and `output` are in string format.

The following example illustrates the input data format for instruction-based fine-tuning in Autopilot.

```
input,output
```
"<prompt text>"","<expected generated text>"

**Note**
We recommend using datasets with a minimum of 1000 rows to ensure optimal learning and performance of the model.

Additionally, Autopilot sets a maximum limit on the number of rows in the dataset and the context length based on the type of model being used.

- The limits on the number of rows in a dataset apply to the cumulative count of lines across all files within the dataset, including multiple files. If there are two channel types defined (one for training and one for validation), the limit applies to each dataset separately. When the number of rows exceeds the threshold, the job fails with a validation error.

- When the length of the input or output of a row in the dataset exceeds the limit set on the context of the language model, it is automatically truncated. If more than 60% of the rows in the dataset are truncated, whether in their input or output, Autopilot fails the job with a validation error.

The following table presents those limits for each model.

<table>
<thead>
<tr>
<th>Model</th>
<th>BaseModelName in API request</th>
<th>Row Limit</th>
<th>Context Length Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon-7B-Instruct</td>
<td>Falcon7B</td>
<td>100,000 rows</td>
<td>1024 tokens</td>
</tr>
<tr>
<td>Falcon-40B-Instruct</td>
<td>Falcon40B</td>
<td>10,000 rows</td>
<td>2048 tokens</td>
</tr>
<tr>
<td>MPT-7B-Instruct</td>
<td>MPT7B</td>
<td>100,000 rows</td>
<td>1024 tokens</td>
</tr>
</tbody>
</table>

**Metrics for fine-tuning large language models in Autopilot**

Using your dataset, Autopilot directly fine-tunes a target language model (LLM) to enhance a default objective metric, the cross-entropy loss.

Cross-entropy loss is a widely used metric to assess the dissimilarity between the predicted probability distribution and the actual distribution of words in the training data. By minimizing cross-entropy loss, the model learns to make more accurate and contextually relevant predictions, particularly in tasks related to text generation.

After fine-tuning a language model, you can evaluate the quality of its generated text using a range of ROUGE scores. Additionally, you can analyze the perplexity and cross-entropy training and validation losses as part of the evaluation process.

- **Perplexity loss** measures how well the model can predict the next word in a sequence of text, with lower values indicating a better understanding of the language and context.

- **Recall-Oriented Understudy for Gisting Evaluation (ROUGE)** is a set of metrics used in the field of natural language processing (NLP) and machine learning to evaluate the quality of machine-generated text, such as text summarization, or text generation. It primarily assesses the similarities between the generated text and the ground truth reference (human-written) text of a validation dataset. ROUGE measures are designed to assess various aspects of text similarity, including the precision and recall of n-grams (contiguous sequences of words) in the system-generated and reference texts. The goal is to assess how well a model captures the information present in the reference text.

There are several variants of ROUGE metrics, depending on the type of n-grams used and the specific aspects of text quality being evaluated.
The following list contains the name and description of the ROUGE metrics available after the fine-tuning of large language models in Autopilot.

**Rouge-1, Rouge-2**

ROUGE-N, the primary ROUGE metric, measures the overlap of n-grams between the system-generated and reference texts. ROUGE-N can be adjusted to different values of ‘n’ (here 1, or 2) to evaluate how well the system-generated text captures the n-grams from the reference text.

**Rouge-L**

ROUGE-L (ROUGE-Longest Common Subsequence) calculates the longest common subsequence between the system-generated text and the reference text. This variant considers word order in addition to content overlap. This variant considers word order in addition to content overlap.

**Rouge-L-Sum**

ROUGE-L-SUM (Longest Common Subsequence for Summarization) is designed for the evaluation of text summarization systems. It focuses on measuring the longest common subsequence between the machine-generated summary and the reference summary. ROUGE-L-SUM takes into account the order of words in the text, which is important in text summarization tasks.

### Autopilot model deployment and predictions

After fine-tuning a large language model, you can deploy the model for real-time text generation by setting up an endpoint to obtain interactive predictions.

**Note**
We recommend running real-time inference jobs on `ml.g5.12xlarge` for better performances. Alternatively, `ml.g5.8xlarge` instances are suitable for Falcon-7B-Instruct and MPT-7B-Instruct text generation tasks. You can find the specifics of these instances within the [Accelerated Computing](https://aws.amazon.com/ec2/accelerated-computing/) category in the selection of instance types provided by Amazon EC2.

### Real time text generation

You can use SageMaker APIs to manually deploy your fine-tuned model to a SageMaker Hosting [real-time inference endpoint](https://docs.aws.amazon.com/sagemaker/latest/dg/real-time-inference-endpoint.html), then begin making predictions by invoking the endpoint as follows.

**Note**
Alternatively, you can chose the automatic deployment option when creating your fine-tuning experiment in Autopilot. For information on setting up the automatic deployment of models, see [How to enable automatic deployment](https://docs.aws.amazon.com/sagemaker/latest/dg/autopilot-automatic-deployment.html) (p. 151).

You can also use the SageMaker Python SDK and the `JumpStartModel` class to perform inferences with models fine-tuned by Autopilot. This can be done by specifying a custom location for the model's artifact in Amazon S3. For information on defining your model as a SageMaker JumpStart model and deploying your model for inference, see [Low-code deployment with the JumpStartModel class](https://docs.aws.amazon.com/sagemaker/latest/dg/low-code-jumpstart.html).

1. **Obtain the candidate inference container definitions**

You can find the `InferenceContainerDefinitions` within the `BestCandidate` object retrieved from the response to the `DescribeAutoMLJobV2` API call. A container definition for inference refers to the containerized environment designed for deploying and running your trained model to make predictions.

The following AWS CLI command example uses the `DescribeAutoMLJobV2` API to obtain recommended container definitions for your job name.
2. Create a SageMaker model

Use the container definitions from the previous step to create a SageMaker model by using the `CreateModel` API. See the following AWS CLI command as an example. Use the `CandidateName` for your model name.

```
aws sagemaker create-model --model-name '<your-candidate-name>'
  --primary-container '<container-definition>'
  --execution-role-arn '<execution-role-arn>'
  --region '<region>'
```

3. Create an endpoint configuration

The following AWS CLI command example uses the `CreateEndpointConfig` API to create an endpoint configuration.

**Note**
To prevent the endpoint creation from timing out due to a lengthy model download, we recommend setting `ModelDataDownloadTimeoutInSeconds = 3600` and `ContainerStartupHealthCheckTimeoutInSeconds = 3600`.

```
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>'
  --production-variants '<list-of-production-variants>'
  ModelDataDownloadTimeoutInSeconds=3600 ContainerStartupHealthCheckTimeoutInSeconds=3600
  --region '<region>'
```

4. Create the endpoint

The following AWS CLI example uses the `CreateEndpoint` API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>'
  --endpoint-config-name '<endpoint-config-name-you-just-created>'
  --region '<region>'
```

Check the progress of your endpoint deployment by using the `DescribeEndpoint` API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region '<region>'
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready to use for real-time inference.

5. Invoke the endpoint

The following command invokes the endpoint for real-time inferencing. Your prompt needs to be encoded in bytes.

**Note**
The format of your input prompt depends on the language model. For more information on the format of text generation prompts, see Text generation prompts format examples (p. 156).

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>'
  --region '<region>' --body '<your-prompt-in-bytes>' [--content-type]
  'application/json' <outfile>
```
Text generation prompts format examples

Different language models may have specific software dependencies, runtime environments, and hardware requirements influencing Autopilot's recommended container to host the model for inference. Additionally, each model dictates the required input data format and the expected format for predictions or outputs.

Here are example inputs for some models and recommended containers.

- For Falcon models with the recommended container huggingface-pytorch-tgi-inference:2.0.1-tgi1.0.3-gpu-py39-cu118-ubuntu20.04:

  ```json
  {
    "inputs": "Large language model fine-tuning is defined as",
    "parameters": {
      "do_sample": false,
      "top_p": 0.9,
      "temperature": 0.1,
      "max_new_tokens": 128,
      "stop": ["<endoftext>", "</s>"
    }
  }
  ```

- For the MPT model with the recommended container djl-inference:0.22.1-fastertransformer5.3.0-cu118:

  ```json
  {
    "text_inputs": "Large language model fine-tuning is defined as"
  }
  ```

Amazon SageMaker Autopilot example notebooks

The following notebooks serve as practical, hands-on examples that address various use cases of Autopilot.

You can find all of Autopilot's notebooks in the [autopilot](https://github.com/aws-samples/sagemaker-autopilot) directory of SageMaker GitHub examples repository.

We recommend cloning the full Git repository within Studio to access and run the notebooks directly. For information on how to clone a Git repository in Studio, see [Clone a Git Repository in SageMaker Studio](p. 287).

<table>
<thead>
<tr>
<th>Use case</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Serverless inference</strong></td>
<td>By default, Autopilot allows deploying generated models to real-time inference endpoints. In this repository, the notebook illustrates how to deploy Autopilot models trained with ENSEMBLING and HYPERPARAMETER OPTIMIZATION (HPO) modes to serverless endpoints. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies.</td>
</tr>
<tr>
<td><strong>Custom feature selection</strong></td>
<td>Autopilot inspects your data set, and runs a number of candidates to figure out the optimal</td>
</tr>
</tbody>
</table>
### Use case

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>combination of data preprocessing steps, machine learning algorithms, and hyperparameters. You can easily deploy either on a real-time endpoint or for batch processing.</td>
</tr>
</tbody>
</table>

In some cases, you might want to have the flexibility to bring custom data processing code to Autopilot. For example, your datasets might contain a large number of independent variables, and you may wish to incorporate a custom feature selection step to remove irrelevant variables first. The resulting smaller dataset can then be used to launch an Autopilot job. Ultimately, you would also want to include both the custom processing code and models from Autopilot for real-time or batch processing.

### Pipeline example

While Autopilot streamlines the process of building ML models, MLOps engineers are still responsible for creating, automating, and managing end-to-end ML workflows in production. SageMaker Pipelines can assist in automating various steps of the ML lifecycle, such as data preprocessing, model training, hyperparameter tuning, model evaluation, and deployment. This notebook serves as a demonstration of how to incorporate Autopilot into a SageMaker Pipelines end-to-end AutoML training workflow. To launch an Autopilot experiment within Pipelines, you must create a model-building workflow by writing custom integration code using Pipelines Lambda or Processing steps. For more information, refer to Move Amazon SageMaker Autopilot ML models from experimentation to production using Amazon SageMaker Pipelines.

Alternatively, when using Autopilot in Ensembling mode, you can refer to the notebook example that demonstrates how to use native AutoML step in SageMaker Pipeline's native AutoML step. With Autopilot supported as a native step within Pipelines, you can now add an automated training step (AutoMLStep) to your Pipelines and invoke an Autopilot experiment in Ensembling mode.

### More notebooks

You can find more notebooks illustrating other use cases such as batch transform, time-series forecasting and more in the root directory.

---

### Amazon SageMaker Autopilot quotas

There are quotas that limit the resources available to you when using Amazon SageMaker Autopilot. Some of these limits are increasable and some are not.
Quotas that you can increase

There are default limits for the size of the input datasets: file size of a single Parquet file (*), the target dataset size subsampling (**), and the number of concurrent jobs you can run with Amazon SageMaker Autopilot for each AWS account per AWS Region.

Resource limits

<table>
<thead>
<tr>
<th>Resource</th>
<th>Regions</th>
<th>Default limits</th>
<th>Can be increased up to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size of input dataset</td>
<td>All</td>
<td>100 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Size of a single Parquet file*</td>
<td>All</td>
<td>2 GB</td>
<td>Tens of GBs</td>
</tr>
<tr>
<td>Target dataset size for subsampling**</td>
<td>All</td>
<td>5 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Number of concurrent Autopilot jobs</td>
<td>us-east-1, us-east-2, us-west-2, ap-northeast-1, eu-west-1, eu-central-1</td>
<td>4</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>ap-northeast-2, ap-southeast-2, eu-west-2, ap-southeast-1</td>
<td>2</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>All other Regions</td>
<td>1</td>
<td>Tens</td>
</tr>
</tbody>
</table>

Note

*This 2 GB size limit is for a single compressed Parquet file. You can provide a Parquet dataset that includes multiple compressed Parquet files. After the files are decompressed, they may each expand to a larger size.

**Autopilot automatically subsamples input datasets that are larger than the target dataset size while accounting for class imbalance and preserving rare class labels.

You can increase these limits by contacting AWS Support.

To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
3. In the Case details panel, select SageMaker AutoML for the Limit Type.
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase, and the New Limit value that you are requesting. If you have additional requests for quota increases, select Add another request.
5. Provide your preferred Contact options and choose Submit.

Resource quotas

The following table contains the runtime resource limits for an Amazon SageMaker Autopilot job in an AWS Region.

<table>
<thead>
<tr>
<th>Resource limits per Autopilot job</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum runtime for an Autopilot job</td>
</tr>
</tbody>

API Reference guide for Amazon SageMaker Autopilot

This section provides a subset of the HTTP service APIs for creating and managing Amazon SageMaker Autopilot resources (AutoML jobs) programmatically.

For information on the entire SageMaker REST APIs and the available SDKs, see API and SDK Reference.

If your language of choice is Python, you can refer to AWS SDK for Python (Boto3) directly.

Actions
This list details the operations available in the Reference API to manage AutoML jobs programmatically.

- **CreateAutoMLJob**
- **CreateAutoMLJobV2**
- **DescribeAutoMLJob**
- **DescribeAutoMLJobV2**
- **ListAutoMLJobs**
- **ListCandidatesForAutoMLJob**
- **StopAutoMLJob**

**Note**

CreateAutoMLJobV2 and DescribeAutoMLJobV2 are new versions of CreateAutoMLJob and DescribeAutoMLJob which offer backward compatibility. We recommend using the CreateAutoMLJobV2. CreateAutoMLJobV2 can manage tabular problem types identical to those of its previous version CreateAutoMLJob, as well as non-tabular problem types such as image or text classification, or time-series forecasting. Find guidelines about how to migrate a CreateAutoMLJob to CreateAutoMLJobV2 in [Migrate a CreateAutoMLJob to CreateAutoMLJobV2](#).

**Data Types**

This list details the API AutoML objects used by the actions above as inbound requests or outbound responses.

- **AutoMLAlgorithmConfig**
- **AutoMLCandidate**
- **AutoMLCandidateGenerationConfig**
- **AutoMLCandidateStep**
- **AutoMLChannel**
- **AutoMLContainerDefinition**
- **AutoMLDataSource**

SageMaker JumpStart

SageMaker JumpStart provides pretrained, open-source models for a wide range of problem types to help you get started with machine learning. You can incrementally train and tune these models before deployment. JumpStart also provides solution templates that set up infrastructure for common use cases, and executable example notebooks for machine learning with SageMaker.

You can access the pretrained models, solution templates, and examples through the JumpStart landing page in Amazon SageMaker Studio. The following steps show how to access JumpStart models and solutions using Amazon SageMaker Studio.

You can also access JumpStart models using the SageMaker Python SDK. For information about how to use JumpStart models programmatically, see Use SageMaker JumpStart Algorithms with Pretrained Models.

Open and use JumpStart

The following sections give information on how to open, use, and manage JumpStart from the Amazon SageMaker Studio UI.

Open JumpStart

In Amazon SageMaker Studio, open the JumpStart landing page either through the Home page or the Home menu on the left-side panel.

- From the Home page you can either:
  - Choose JumpStart in the Prebuilt and automated solutions pane. This opens the SageMaker JumpStart landing page.
• Choose a model directly in the **SageMaker JumpStart** landing page, or choose the **Explore All** option to see available solutions or models of a specific type.

• From the **Home** menu in the left panel you can either:
  • Navigate to the **SageMaker JumpStart** node, then choose **Models, notebooks, solutions**. This opens the **SageMaker JumpStart** landing page.
  • Navigate to the **JumpStart** node, then choose **Launched JumpStart assets**.

The **Launched JumpStart assets** page lists your currently launched solutions, deployed model endpoints, and training jobs created with JumpStart. You can access the JumpStart landing page from this tab by clicking on the **Browse JumpStart** button at the top right of the tab.

The JumpStart landing page lists available end-to-end machine learning solutions, pretrained models, and example notebooks. From any individual solution or model page, you can choose the **Browse** button (上面) at the top right of the tab to return to the **SageMaker JumpStart** page.

---

**Important**

Before downloading or using third-party content: You are responsible for reviewing and complying with any applicable license terms and making sure that they are acceptable for your use case.
Use JumpStart

From the SageMaker JumpStart landing page, you can browse for solutions, models, notebooks, and other resources.

You can find JumpStart resources by using the search bar, or by browsing each category. Use the tabs to filter the available solutions by categories:

- **Solutions** – In one step, launch comprehensive machine learning solutions that tie SageMaker to other AWS services. Select *Explore All Solutions* to view all available solutions.
- **Resources** – Use example notebooks, blogs, and video tutorials to learn and head start your problem types.
- **Blogs** – Read details and solutions from machine learning experts.
- **Video tutorials** – Watch video tutorials for SageMaker features and machine learning use cases from machine learning experts.
- **Example notebooks** – Run example notebooks that use SageMaker features like Spot Instance training and experiments over a large variety of model types and use cases.
- **Data types** – Find a model by data type (e.g., Vision, Text, Tabular, Audio, Text Generation). Select *Explore All Models* to view all available models.
- **ML tasks** – Find a model by problem type (e.g., Image Classification, Image Embedding, Object Detection, Text Generation). Select *Explore All Models* to view all available models.
- **Notebooks** – Find example notebooks that use SageMaker features across multiple model types and use cases. Select *Explore All Notebooks* to view all available example notebooks.
- **Frameworks** – Find a model by framework (e.g., PyTorch, TensorFlow, Hugging Face).
Manage JumpStart

From the Home menu in the left panel, navigate to SageMaker JumpStart, then choose Launched JumpStart assets to list your currently launched solutions, deployed model endpoints, and training jobs created with JumpStart.

Topics

- Solution Templates (p. 164)
- JumpStart Foundation Models (p. 171)
- Task-Specific Models (p. 181)
- Shared Models and Notebooks (p. 195)
- Amazon SageMaker JumpStart Industry: Financial (p. 199)

Solution Templates

SageMaker JumpStart provides one-click, end-to-end solutions for many common machine learning use cases. Explore the following use cases for more information on available solution templates.

- Demand forecasting (p. 164)
- Credit rating prediction (p. 165)
- Fraud detection (p. 165)
- Computer vision (p. 166)
- Extract and analyze data from documents (p. 167)
- Predictive maintenance (p. 167)
- Churn prediction (p. 167)
- Personalized recommendations (p. 168)
- Reinforcement learning (p. 168)
- Healthcare and life sciences (p. 169)
- Financial pricing (p. 169)
- Causal inference (p. 169)

Choose the solution template that best fits your use case from the JumpStart landing page. When you choose a solution template, JumpStart opens a new tab showing a description of the solution and a Launch button. When you select Launch, JumpStart creates all of the resources that you need to run the solution, including training and model hosting instances. For more information on launching a JumpStart solution, see the section called “Launch a Solution” (p. 170).

After launching the solution, you can explore solution features and any generated artifacts in JumpStart. Use the Launched JumpStart assets menu to find your solution. In your solution's tab, select Open Notebook to use provided notebooks and explore the solution's features. When artifacts are generated during launch or after running the provided notebooks, they’re listed in the Generated Artifacts table.

You can delete individual artifacts with the trash icon (Trash). You can delete all of the solution's resources by choosing Delete solution resources.

Demand forecasting

Demand forecasting uses historical time series data in order to make future estimations in relation to customer demand over a specific period and streamline the supply-demand decision-making process across businesses.
Demand forecasting use cases include predicting ticket sales in the transportation industry, stock prices, number of hospital visits, number of customer representatives to hire for multiple locations in the next month, product sales across multiple regions in the next quarter, cloud server usage for the next day for a video streaming service, electricity consumption for multiple regions over the next week, number of IoT devices and sensors such as energy consumption, and more.

Time series data is categorized as univariate and multi-variate. For example, the total electricity consumption for a single household is a univariate time series over a period of time. When multiple univariate time series are stacked on each other, it’s called a multi-variate time series. For example, the total electricity consumption of 10 different (but correlated) households in a single neighborhood make up a multi-variate time series dataset.

Credit rating prediction

Use JumpStart's credit rating prediction solutions to predict corporate credit ratings or to explain credit prediction decisions made by machine learning models. Compared to traditional credit rating modeling methods, machine learning models can automate and improve the accuracy of credit prediction.

<table>
<thead>
<tr>
<th>Solution name</th>

Fraud detection

Many businesses lose billions annually to fraud. Machine learning based fraud detection models can help systematically identify likely fraudulent activities from a tremendous amount of data. The following solutions use transaction and user identity datasets to identify fraudulent transactions.
## Solution Templates

<table>
<thead>
<tr>
<th>Solution name</th>

</table>

### Computer vision

With the rise of business use cases such as autonomous vehicles, smart video surveillance, healthcare monitoring and various object counting tasks, fast and accurate object detection systems are rising in demand. These systems involve not only recognizing and classifying every object in an image, but localizing each one by drawing the appropriate bounding box around it. In the last decade, the rapid advances of deep learning techniques greatly accelerated the momentum of object detection.

<table>
<thead>

Churn prediction

Customer churn, or rate of attrition, is a costly problem faced by a wide range of companies. In an effort to reduce churn, companies can identify customers that are likely to leave their service in order to focus their efforts on customer retention. Use a JumpStart churn prediction solution to analyze data sources.
such as user behavior and customer support chat logs to identify customers that are at a high risk of cancelling a subscription or service.

<table>
<thead>
<tr>

<td>Train and deploy a custom recommender system that generates movie suggestions for a customer based on past behavior using Neural Collaborative Filtering in SageMaker.</td>
<td>Find in Amazon SageMaker Studio.</td>
</tr>
</tbody>
</table>

**Reinforcement learning**

Reinforcement learning (RL) is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles.

</tbody>
</table>
Launch a Solution

First, choose a solution through the SageMaker JumpStart landing page in the Amazon SageMaker Studio UI. For information on the onboarding steps to sign in to Amazon SageMaker Studio, see Onboard to Amazon SageMaker Domain. For details on getting to the SageMaker JumpStart landing page, see Open and use JumpStart (p. 161).

After you choose a solution, a solution's tab opens showing a description of the solution and a Launch button. To launch a solution, select Launch in the Launch Solution section. JumpStart then creates all of the resources needed to run the solution. This includes training and model hosting instances.

Advanced parameters

The solution that you choose may have advanced parameters that you can select. Choose Advanced Parameters to specify the AWS Identity and Access Management role for the solution.

Solutions are able to launch resources across 9 AWS services that interact with each other. For the solution to work as expected, newly created components from one service must be able to act on newly created components from another service. We recommend that you use the default IAM role to ensure that all needed permissions are added. For more information about IAM roles, see Identity and Access Management for Amazon SageMaker (p. 3349).

Default IAM role

If you select this option, the default IAM roles that are required by this solution are used. Each solution requires different resources. The following list describes the default roles that are used for the solutions based on the service needed. For a description of the permissions required for each service, see AWS Managed Policies for SageMaker projects and JumpStart (p. 3480).

- **API Gateway** – AmazonSageMakerServiceCatalogProductsApiGatewayRole
- **CloudFormation** – AmazonSageMakerServiceCatalogProductsCloudformationRole
- **CodeBuild** – AmazonSageMakerServiceCatalogProductsCodeBuildRole
- **CodePipeline** – AmazonSageMakerServiceCatalogProductsCodePipelineRole
- **Events** – AmazonSageMakerServiceCatalogProductsEventsRole
- **Firehose** – AmazonSageMakerServiceCatalogProductsFirehoseRole
- **Glue** – AmazonSageMakerServiceCatalogProductsGlueRole
- **Lambda** – AmazonSageMakerServiceCatalogProductsLambdaRole
- **SageMaker** – AmazonSageMakerServiceCatalogProductsExecutionRole

If you are using a new SageMaker Domain with JumpStart project templates enabled, these roles are automatically created in your account.

If you are using an existing SageMaker domain, these roles may not exist in your account. If this is the case, you will receive the following error when launching the solution.

<table>
<thead>
<tr>
<th>Solution name</th>
<th>Description</th>
<th>Get started</th>
</tr>
</thead>
<tbody>
<tr>
<td>nitrogen. This solution learns the crop phenology cycle in its entirety using multi-spectral satellite imagery and ground-level observations.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Unable to locate the updated roles required to launch this solution, a general role '/service-role/AmazonSageMakerServiceCatalogProductsUseRole' will be used. Please update your studio domain to generate these roles.

You can still launch a solution without the needed role, but the legacy default role AmazonSageMakerServiceCatalogProductsUseRole is used in place of the needed role. The legacy default role has trust relationships with all of the services that JumpStart solutions need to interact with. For the best security, we recommend that you update your domain to have the newly created default roles for each AWS service.

If you have already onboarded to a SageMaker domain, you can update your domain to generate the default roles using the following procedure.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Control Panel at the top left of the page.
3. From the Domain page, choose the Settings icon (()) to edit the domain settings.
4. On General Settings choose Next.
5. Under SageMaker Projects and JumpStart, select Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for this account and Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for Studio users, choose Next.
6. Select Submit.

You should be able to see the default roles listed in Projects - Amazon SageMaker project templates enabled for this account under the Apps - Studio tab.

Find IAM role

If you select this option, you must select an existing IAM role from the dropdown list for each of the required services. The selected role must have at least the minimum permissions required for the corresponding service. For a description of the permissions required for each service, see AWS Managed Policies for SageMaker projects and JumpStart (p. 3480).

Input IAM role

If you select this option, you must manually enter the ARN for an existing IAM role. The selected role must have at least the minimum permissions required for the corresponding service. For a description of the permissions required for each service, see AWS Managed Policies for SageMaker projects and JumpStart (p. 3480).

JumpStart Foundation Models

Amazon SageMaker JumpStart offers state-of-the-art foundation models for use cases such as content writing, code generation, question answering, copywriting, summarization, classification, information retrieval, and more. Use JumpStart foundation models to build your own generative AI solutions and integrate custom solutions with additional SageMaker features. For more information, see Getting started with Amazon SageMaker JumpStart.

A foundation model is a large pre-trained model that is adaptable to many downstream tasks and often serves as the starting point for developing more specialized models. Examples of foundation models include LLaMa-2-7b, BLOOM 176B, FLAN-T5 XL, or GPT-J 6B, which are pre-trained on massive amounts of text data and can be fine-tuned for specific language tasks.

Amazon SageMaker JumpStart onboards and maintains publicly available foundation models for you to access, customize, and integrate into your machine learning lifecycles. For more information, see
Publicly available foundation models (p. 172). Amazon SageMaker JumpStart also includes proprietary foundation models from third-party providers. For more information, see Proprietary foundation models (p. 172).

To get started exploring and experimenting with available models, see How to use JumpStart foundation models (p. 173). All foundation models are available to use programmatically with the SageMaker Python SDK. For more information, see Use foundation models with the SageMaker Python SDK (p. 175).

For more information on considerations to make when choosing a model, see Choose a foundation model (p. 176).

For specifics about customization and fine-tuning foundation models, see Customize a foundation model (p. 178).

For more general information on foundation models, see the paper On the Opportunities and Risks of Foundation Models.

Explore the latest foundation models

Amazon SageMaker JumpStart offers state-of-the-art, built-in proprietary and publicly available foundation models to customize and integrate into your generative AI workflows.

Proprietary foundation models

Amazon SageMaker JumpStart provides access to proprietary foundation models from third-party providers such as AI21 Labs, Cohere, and LightOn.

To get started with one of these proprietary models, see How to use JumpStart foundation models (p. 173). To use a proprietary foundation model, you must first subscribe to the model in AWS Marketplace. After subscribing to the model, locate the foundation model in SageMaker Studio to run an example notebook.

To explore the latest proprietary foundation models for a variety of use cases, see Getting started with Amazon SageMaker JumpStart.

Publicly available foundation models

Amazon SageMaker JumpStart onboards and maintains open source foundation models from third-party sources. To get started with one of these publicly available models, see How to use JumpStart foundation models (p. 173) or explore one of the available Example notebooks (p. 172). In a given example notebook for a publicly available model, try switching out the model ID to experiment with different models within the same model family.

For more information on model IDs and resources on deploying publicly available JumpStart foundation models with the SageMaker Python SDK, see Use publicly available foundation models with the SageMaker Python SDK (p. 175).

Example notebooks

For step-by-step examples on how to use publicly available JumpStart foundation models with the SageMaker Python SDK, refer to the following notebooks on text generation, image generation, and model customization.

Note

Proprietary and publicly available JumpStart foundation models have different SageMaker Python SDK deployment workflows. Discover proprietary foundation model example notebooks.
through Amazon SageMaker Studio or the SageMaker console. For more information, see How to use JumpStart foundation models (p. 173).

You can find example notebooks associated with foundation models available to run directly in SageMaker Studio. For more information on discovering foundation models in Studio, see Use foundation models in Amazon SageMaker Studio (p. 174).

Alternatively, for instructions on how to create and access Jupyter notebook instances that you can use to run an example notebook in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

### Text generation

Explore text generation example notebooks, including guidance on general text generation workflows, multilingual text classification, real-time batch inference, few-shot learning, chatbot interactions, and more.

- **SageMaker JumpStart Foundation Models - HuggingFace Text2Text Generation with FLAN-T5 XL as an example**
- **SageMaker JumpStart Foundation Models - BloomZ: Multilingual Text Classification, Question and Answering, Code Generation, Paragraph rephrase, and More**
- **SageMaker JumpStart Foundation Models - HuggingFace Text2Text Generation Batch Transform and Real-Time Batch Inference**
- **SageMaker JumpStart Foundation Models - GPT-J, GPT-Neo Few-shot learning**
- **SageMaker JumpStart Foundation Models - Chatbots**

### Image generation

Get started with text-to-image Stable Diffusion models, learn how to deploy an inpainting model, and experiment with a simple workflow to generate images of your dog.

- **Introduction to JumpStart - Text to Image**
- **Introduction to JumpStart Image editing - Stable Diffusion Inpainting**
- **Generate fun images of your dog**

### Model customization

Sometimes your use case requires greater foundation model customization for specific tasks. For more information on model customization approaches, see Customize a foundation model (p. 178) or explore one of the following example notebooks.

- **SageMaker JumpStart Foundation Models - Fine-tuning text generation GPT-J 6B model on domain specific dataset**
- **SageMaker JumpStart Foundation Models - HuggingFace Text2Text Instruction Fine-Tuning**
- **Retrieval-Augmented Generation: Question Answering based on Custom Dataset**
- **Retrieval-Augmented Generation: Question Answering based on Custom Dataset with Open-sourced LangChain Library**

### How to use JumpStart foundation models

Choose, train, or deploy foundation models through Amazon SageMaker Studio, use JumpStart foundation models programmatically with the SageMaker Python SDK, and discover JumpStart foundation models directly through the SageMaker console.
Use foundation models in Amazon SageMaker Studio

You can deploy, train, and fine-tune both proprietary and publicly available JumpStart foundation models directly through the Studio UI. To get started with Studio, see Launch Amazon SageMaker Studio (p. 209).

After opening Amazon SageMaker Studio, choose Models, notebooks, solutions in the SageMaker JumpStart section of the navigation pane. Then, scroll down to find either the Foundation Models: Text Generation or Foundation Models: Image Generation section depending on your use case.

You can choose View model on a suggested foundation model card, or choose Explore All Models to see all available foundation models for either text generation or image generation. If you choose to see all available models, you can further filter available models by task, data type, content type, or framework. You can also search for a model name directly in the Search bar. If you need guidance on selecting a model, see Choose a foundation model (p. 176).

Important
Some foundation models require explicit acceptance of an end-user license agreement (EULA). For more information, see EULA acceptance in Amazon SageMaker Studio (p. 177).

After you choose View model for the foundation model of your choice in Studio, you can deploy the model. For more information, see Deploy a Model (p. 184).

You can also choose Open notebook in the Run in notebook section to run an example notebook for the foundation model directly in Studio.
Note
To deploy a proprietary foundation model in Studio, you must first subscribe to the model in AWS Marketplace. The AWS Marketplace link is provided in the associated example notebook within Studio.

If the model is fine-tunable, you can also fine-tune the model. For more information, see Fine-Tune a Model (p. 192). For a list of which JumpStart foundation models are fine-tunable, see Fine-tune a foundation model (p. 179).

Use foundation models with the SageMaker Python SDK

All JumpStart foundation models are available to deploy programmatically using the SageMaker Python SDK. Proprietary models must be deployed using the model package information after subscribing to the model in AWS Marketplace, while publicly available foundation models can be deployed using the model ID in the Built-in Algorithms with pre-trained Model Table. To get started with JumpStart foundation models using the SageMaker Python SDK, choose a foundation model in Studio, and run and explore any associated example notebooks.

Important
Some foundation models require explicit acceptance of an end-user license agreement (EULA). For more information, see EULA acceptance with the SageMaker Python SDK (p. 177).

Use proprietary foundation models with the SageMaker Python SDK

Proprietary models must be deployed using the model package information after subscribing to the model in AWS Marketplace. For more information about SageMaker and AWS Marketplace, see Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace. To find AWS Marketplace links for the latest proprietary models, see Getting started with Amazon SageMaker JumpStart.

After subscribing to the model of your choice in AWS Marketplace, you can deploy the foundation model using the SageMaker Python SDK and the SDK associated with the model provider. For example, AI21 Labs, Cohere, and LightOn use the "ai21[SM]", cohere-sagemaker, and lightonsage packages, respectively.

For step-by-step examples, find and run the notebook associated with the proprietary foundation model of your choice in SageMaker Studio. See Use foundation models in Amazon SageMaker Studio (p. 174) for more information.

Use publicly available foundation models with the SageMaker Python SDK

For more information on programmatically deploying publicly available JumpStart foundation models, see Deploy a Pre-Trained Model Directly to a SageMaker Endpoint. For information on programmatically fine-tuning a JumpStart foundation model, see Fine-tune a Model and Deploy to a SageMaker Endpoint.

To reference available model IDs for publicly available foundation models, see the Built-in Algorithms with pre-trained Model Table. Search for the name of the foundation model of your choice in the Search bar, change the number of entries shown using the Show entries dropdown menu, or choose the Next text highlighted in blue on the lefthand side of the page to navigate through the available models.

For example notebooks with detailed steps on using publicly available JumpStart foundation models with the SageMaker Python SDK, see Example notebooks (p. 172). You can also explore available example notebooks in the SageMaker JumpStart Studio UI.

Discover foundation models in the SageMaker Console

You can explore JumpStart foundation models directly through the Amazon SageMaker Console.
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Find **JumpStart** on the left-hand navigation panel and choose **Foundation models**.

3. Browse models or search for a specific model. If you need guidance for model selection, see **Choose a foundation model** (p. 176). Choose **View model** to view the model detail page for the foundation model of your choice.

4. If the model is a proprietary model, choose **Subscribe** in the upper right-hand corner of the model detail page to subscribe to the model in AWS Marketplace. You should receive an email confirming your subscription to the model of your choice. For more information about SageMaker and AWS Marketplace, see **Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace**. Publicly available foundation models do not require a subscription.

   **Note**
   Proprietary foundation model discoverability is currently in preview in the SageMaker console. Preview access for proprietary foundation models in the console includes playground availability. In the model detail page, choose **Playground** to test a proprietary model without needing to set up or deploy any model packages.

5. To view an example notebook in GitHub, choose **View code** in the upper right-hand corner of the model detail page.

6. To view and run an example notebook directly in Amazon SageMaker Studio, choose **Open notebook in Studio** in the upper right-hand corner of the model detail page.

### Choose a foundation model

Amazon SageMaker JumpStart provides access to hundreds of publicly available and proprietary foundation models from third-party sources and partners. You can explore the JumpStart foundation model selection directly in the SageMaker console or Studio. When selecting a foundation model, we recommend starting with a specific task in mind and exploring potential models from there.

**Foundation model tasks**

By definition, foundation models are adaptable to many downstream tasks. Foundation models are trained on massive amounts of general domain data and the same model can be implemented or customized for multiple use cases. When choosing your foundation model, start with defining a specific task.

**Choose a text generation model**

Text generation foundation models can be used for a variety of downstream tasks, including text summarization, text classification, question answering, long-form content generation, short-form copywriting, information extraction, and more.

To explore the latest text generation JumpStart foundation models, use the **Text Generation** filter on the **Getting started with Amazon SageMaker JumpStart** product description page. You can also explore foundation models based on tasks directly in the SageMaker Studio UI. See **Use foundation models in Amazon SageMaker Studio** (p. 174) for more information.

**Choose an image generation model**

JumpStart provides a wide variety of Stable Diffusion image generation foundation models including base models from Stability AI as well as pre-trained models for specific text-to-image tasks from Hugging Face. If you need to fine-tune your text-to-image foundation model, you can use Stable Diffusion 2.1 base from Stability AI. If you want to explore models that are already trained on specific art styles, you can explore one of the many third-party models from Hugging Face directly in the SageMaker Studio UI.

To explore the latest image generation JumpStart foundation models, use the **Text to Image** filter on the **Getting started with Amazon SageMaker JumpStart** product description page. To get started
with your chosen text-to-image foundation model, see Use foundation models in Amazon SageMaker Studio (p. 174).

## Licenses and model sources

Amazon SageMaker JumpStart provides access to both publicly available and proprietary foundation models. Foundation models are on-boarded and maintained from third-party open source and proprietary providers. As such, they are released under different licenses as designated by the model source. Be sure to review the license for any foundation model that you use. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using the content. Some examples of common foundation model licenses include:

- Alexa Teacher Model
- Apache 2.0
- BigScience Responsible AI License v1.0
- CreativeML Open RAIL++-M license

Similarly, for any proprietary foundation models, be sure to review and comply with any terms of use and usage guidelines from the model provider. If you have questions about license information for a specific proprietary model, reach out to model provider directly. You can find model provider contact information in the **Support** tab of each model page in AWS Marketplace. To explore the latest proprietary foundation models, see Getting started with Amazon SageMaker JumpStart.

### End-user license agreements

Some JumpStart foundation models require explicit acceptance of an end-user license agreement (EULA) before deployment.

**EULA acceptance in Amazon SageMaker Studio**

You may be prompted to accept an end-user license agreement before deploying a JumpStart foundation model or opening a JumpStart foundation model notebook in Amazon SageMaker Studio. To get started with JumpStart foundation models in Studio, see Use foundation models in Amazon SageMaker Studio (p. 174).

Some JumpStart foundation models require acceptance of an end-user license agreement before deployment. If this applies to the foundation model that you choose to use, Studio prompts you with a window titled **Review the End User License Agreement (EULA) and Acceptable Use Policy (AUP)** below after you choose either Deploy or Open notebook. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using a model.

**EULA acceptance with the SageMaker Python SDK**

After deploying a JumpStart foundation model programatically using the SageMaker Python SDK, you can run inference against your deployed endpoint with the SageMaker *Predictor* class. For models that require the acceptance of an end-user license agreement, you must explicitly declare EULA acceptance in your call to the *Predictor* class.

```python
predictor.predict(payload, custom_attributes="accept_eula=true")
```

The `accept_eula` value is false by default and must be explicitly redefined as true in order to accept the end-user license agreement. The predictor returns a ModelError if you try to run inference while `accept_eula` is set to false. For more information on getting started with JumpStart foundation models.
models using the SageMaker Python SDK, see Use foundation models with the SageMaker Python SDK (p. 175).

**Important**

The `custom_attributes` parameter accepts key-value pairs in the format "key1=value1;key2=value2". If you use the same key multiple times, the inference server uses the last value associated with the key. For example, if you pass "accept_eula=false;accept_eula=true" to the `custom_attributes` parameter, then the inference server associates the value `true` with the `accept_eula` key.

**Customize a foundation model**

Foundation models are extremely powerful models able to solve a wide array of tasks. To solve most tasks effectively, these models require some form of customization.

The recommended way to first customize a foundation model to a specific use case is through prompt engineering. Providing your foundation model with well-engineered, context-rich prompts can help achieve desired results without any fine-tuning or changing of model weights. For more information, see Prompt engineering for foundation models (p. 178).

If prompt engineering alone is not enough to customize your foundation model to a specific task, you can fine-tune a foundation model on additional domain-specific data. For more information, see Fine-tune a foundation model (p. 179). The fine-tuning process involves changing model weights.

If you want to customize your model with information from a knowledge library without any retraining, see Retrieval Augmented Generation (RAG) (p. 180).

**Prompt engineering for foundation models**

Prompt engineering is the process of designing and refining the prompts or input stimuli for a language model to generate specific types of output. Prompt engineering involves selecting appropriate keywords, providing context, and shaping the input in a way that encourages the model to produce the desired response and is a vital technique to actively shape the behavior and output of foundation models.

Effective prompt engineering is crucial for directing model behavior and achieving desired responses. Through prompt engineering, you can control a model's tone, style, and domain expertise without more involved customization measures like fine-tuning. We recommend dedicating time to prompt engineering before you consider fine-tuning a model on additional data. The goal is to provide sufficient context and guidance to the model so that it can generalize and perform well on unseen or limited data scenarios.

**Zero-shot learning**

Zero-shot learning involves training a model to generalize and make predictions on unseen classes or tasks. To perform prompt engineering in zero-shot learning environments, we recommend constructing prompts that explicitly provide information about the target task and the desired output format. For example, if you want to use a foundation model for zero-shot text classification on a set of classes that the model did not see during training, a well-engineered prompt could be: "Classify the following text as either sports, politics, or entertainment: [input text]." By explicitly specifying the target classes and the expected output format, you can guide the model to make accurate predictions even on unseen classes.

**Few-shot learning**

Few-shot learning involves training a model with a limited amount of data for new classes or tasks. Prompt engineering in few-shot learning environments focuses on designing prompts that effectively use the limited available training data. For example, if you use a foundation model for an image classification task and only have a few examples of a new image class, you can engineer a prompt that
includes the available labeled examples with a placeholder for the target class. For example, the prompt could be: "[image 1], [image 2], and [image 3] are examples of [target class]. Classify the following image as [target class]." By incorporating the limited labeled examples and explicitly specifying the target class, you can guide the model to generalize and make accurate predictions even with minimal training data.

If prompt engineering is not sufficient to adapt your foundation model to specific business needs, domain-specific language, target tasks, or other requirements, you can consider fine-tuning your model on additional data or using Retrieval Augmented Generation (RAG) to augment your model architecture with enhanced context from archived knowledge sources. For more information, see Fine-tune a foundation model (p. 179) or Retrieval Augmented Generation (RAG) (p. 180).

**Fine-tune a foundation model**

Foundation models are computationally expensive and trained on a large, unlabeled corpus. Fine-tuning a pre-trained foundation model is an affordable way to take advantage of their broad capabilities while customizing a model on your own small, corpus. Fine-tuning is a customization method that involved further training and does change the weights of your model.

Fine-tuning might be useful to you if you need:

- to customize your model to specific business needs
- your model to successfully work with domain-specific language, such as industry jargon, technical terms, or other specialized vocabulary
- enhanced performance for specific tasks
- accurate, relative, and context-aware responses in applications
- responses that are more factual, less toxic, and better-aligned to specific requirements

There are two main approaches that you can take for fine-tuning depending on your use case and chosen foundation model. If you're interested in fine-tuning your model on domain-specific data, see Domain adaptation fine-tuning (p. 179). If you're interested in instruction-based fine-tuning using prompt and response examples, see Instruction-based fine-tuning (p. 180).

**Domain adaptation fine-tuning**

Domain adaptation fine-tuning allows you to leverage pre-trained foundation models and adapt them to specific tasks using limited domain-specific data. If prompt engineering efforts do not provide enough customization, you can use domain adaption fine-tuning to get your model working with domain-specific language, such as industry jargon, technical terms, or other specialized data. This fine-tuning process modifies the weights of the model.

For more information, see the SageMaker JumpStart Foundation Models - Fine-tuning text generation GPT-J 6B model on domain specific dataset example notebook. You can also follow the domain adaptation dataset format steps in the Fine-tune LLaMA 2 models on SageMaker JumpStart example notebook.

Domain adaptation fine-tuning is available with the following foundation models:

- BloomZ 7b1
- GPT-J 6B
- GPT Neo 2.7B

**Note**

Some JumpStart foundation models, such as LLaMa-2-7B, require acceptance of an end-user license agreement before fine-tuning and performing inference. For more information, see End-user license agreements (p. 177).
Instruction-based fine-tuning

Instruction-based fine-tuning uses labeled examples to improve the performance of a pre-trained foundation model on a specific task. The labeled examples are formatted as prompt, response pairs and phrased as instructions. This fine-tuning process modifies the weights of the model. For more information on instruction-based fine-tuning, see the papers *Introducing FLAN: More generalizable Language Models with Instruction Fine-Tuning* and *Scaling Instruction-Finetuned Language Models*.

Fine-tuned LAnguage Net (FLAN) models use instruction tuning to make models more amenable to solving general downstream NLP tasks. Amazon SageMaker JumpStart provides a number of foundation models in the FLAN model family. For example, FLAN-T5 models are instruction fine-tuned on a wide range of tasks to increase zero-shot performance for a variety of common use cases. With additional data and fine-tuning, instruction-based models can be further adapted to more specific tasks that weren't considered during pre-training.

Instruction-based fine-tuning is available with the following foundation models:

**Note**
Some JumpStart foundation models, such as LLaMa-2-7B, require acceptance of an end-user license agreement before fine-tuning and performing inference. For more information, see *End-user license agreements* (p. 177).

- FLAN-T5 XL
- FLAN-T5 Large
- FLAN-T5 Small
- FLAN-T5 Base
- LLaMa-2-7b
- LLaMa-2-13b

Example notebooks

For more information, see the following example notebooks:

- [Fine-tune LLaMA 2 models on SageMaker JumpStart](#)
- [SageMaker JumpStart Foundation Models - HuggingFace Text2Text Instruction Fine-Tuning](#)

Retrieval Augmented Generation (RAG)

Foundation models are usually trained offline, making the model agnostic to any data that is created after the model was trained. Additionally, foundation models are trained on very general domain corpora, making them less effective for domain-specific tasks. You can use Retrieval Augmented Generation (RAG) to retrieve data from outside a foundation model and augment your prompts by adding the relevant retrieved data in context. For more information about RAG model architectures, see *Retrieval-Augmented Generation for Knowledge-Intensive NLP Tasks*.

With RAG, the external data used to augment your prompts can come from multiple data sources, such as a document repositories, databases, or APIs. The first step is to convert your documents and any user queries into a compatible format to perform relevancy search. To make the formats compatible, a document collection, or knowledge library, and user-submitted queries are converted to numerical representations using embedding language models. *Embedding* is the process by which text is given numerical representation in a vector space. RAG model architectures compare the embeddings of user queries within the vector of the knowledge library. The original user prompt is then appended with
relevant context from similar documents within the knowledge library. This augmented prompt is then sent to the foundation model. You can update knowledge libraries and their relevant embeddings asynchronously.

Example notebooks

For more information, see the following example notebooks:

- Retrieval-Augmented Generation: Question Answering using LangChain and Cohere's Generate and Embedding Models from SageMaker JumpStart
- Retrieval-Augmented Generation: Question Answering using Llama-2, Pinecone and Custom Dataset
- Retrieval-Augmented Generation: Question Answering based on Custom Dataset with Open-sourced LangChain Library
- Retrieval-Augmented Generation: Question Answering based on Custom Dataset

Task-Specific Models

JumpStart supports task-specific models across fifteen of the most popular problem types. Of the supported problem types, Vision and NLP-related types total thirteen. There are eight problem types that support incremental training and fine-tuning. For more information about incremental training and hyper-parameter tuning, see SageMaker Automatic Model Tuning. JumpStart also supports four popular algorithms for tabular data modeling.
You can search and browse models from the JumpStart landing page in Studio. When you select a model, the model detail page provides information about the model, and you can train and deploy your model in a few steps. The description section describes what you can do with the model, the expected types of inputs and outputs, and the data type needed for fine-tuning your model.

You can also programmatically utilize models with the SageMaker Python SDK. For a list of all available models, see the JumpStart Available Model Table.

The list of problem types and links to their example Jupyter notebooks are summarized in the following table.

**Deploy a Model**

When you deploy a model from JumpStart, SageMaker hosts the model and deploys an endpoint that you can use for inference. JumpStart also provides an example notebook that you can use to access the model after it's deployed.

**Model deployment configuration**

After you choose a model, the model's tab opens. In the **Deploy Model** pane, choose **Deployment Configuration** to configure your model deployment.
The default instance type for deploying a model depends on the model. The instance type is the hardware that the training job runs on. In the following example, the `ml.p2.xlarge` instance is the default for this particular BERT model.

You can also change the endpoint name, add `key;value` resource tags, activate or deactivate the `jumpstart-` prefix for any JumpStart resources related to the model, and specify an Amazon S3 bucket for storing model artifacts used by your SageMaker endpoint.
Choose **Security Settings** to specify the AWS Identity and Access Management (IAM) role, Amazon Virtual Private Cloud (Amazon VPC), and encryption keys for the model.

### Security Settings

This model runs in network isolation. **Learn more.**

**Specify the IAM role that Amazon SageMaker should use to deploy your model. Learn more.**

- [ ] Default IAM role
- [ ] Find IAM role
- [ ] Input IAM role

Amazon SageMaker will deploy your model using your Studio execution role.

**Specify whether your model should connect to a virtual private cloud (VPC). Learn more.**

- [ ] No VPC
- [ ] Find VPC
- [ ] Input VPC

No VPC will be used to access your model container.

**Specify the encryption keys to secure your data. Learn more.**

- [ ] Default encryption keys
- [ ] Find encryption keys
- [ ] Input encryption keys

Encrypt your model artifact at rest using your account's default KMS key for S3. **Learn more.**

### Model deployment security

When you deploy a model with JumpStart, you can specify an IAM role, Amazon VPC, and encryption keys for the model. If you don't specify any values for these entries: The default IAM role is your Studio runtime role; default encryption is used; no Amazon VPC is used.

#### IAM role

You can select an IAM role that is passed as part of training jobs and hosting jobs. SageMaker uses this role to access training data and model artifacts. If you don't select an IAM role, SageMaker deploys the model using your Studio runtime role. For more information about IAM roles, see [Identity and Access Management for Amazon SageMaker](p. 3349).

The role that you pass must have access to the resources that the model needs, and must include all of the following.

- For training jobs: [CreateTrainingJob API: Execution Role Permissions](#).
- For hosting jobs: [CreateModel API: Execution Role Permissions](#).
Note
You can scope down the Amazon S3 permissions granted in each of the following roles. Do this by using the ARN of your Amazon Simple Storage Service (Amazon S3) bucket and the JumpStart Amazon S3 bucket.

```
{
   "Effect": "Allow",
   "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:ListMultipartUploadParts",
      "s3:ListBucket"
   ],
   "Resources": [
      "arn:aws:s3:::jumpstart-cache-prod-<region>/*",
      "arn:aws:s3:::jumpstart-cache-prod-<region>",
      "arn:aws:s3:::bucket/*"
   ]
}
```

Find IAM role
If you select this option, you must select an existing IAM role from the dropdown list.

Specify the IAM role that Amazon SageMaker should use to deploy your model

- Default IAM role
- Find IAM role
- Input IAM role

Amazon SageMaker will deploy your model using the IAM role you select below.

Execution role

Input IAM role
If you select this option, you must manually enter the ARN for an existing IAM role. If your Studio runtime role or Amazon VPC block the `iam:list*` call, you must use this option to use an existing IAM role.
Amazon VPC

All JumpStart models run in network isolation mode. After the model container is created, no more calls can be made. You can select an Amazon VPC that is passed as part of training jobs and hosting jobs. SageMaker uses this Amazon VPC to push and pull resources from your Amazon S3 bucket. This Amazon VPC is different from the Amazon VPC that limits access to the public internet from your Studio instance. For more information about the Studio Amazon VPC, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522).

The Amazon VPC that you pass does not need access to the public internet, but it does need access to Amazon S3. The Amazon VPC endpoint for Amazon S3 must allow access to at least the following resources that the model needs.

```
{
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListMultipartUploadParts",
    "s3:ListBucket"
  ],
  "Resources": [
    "arn:aws:s3:::jumpstart-cache-prod-<region>/*",
    "arn:aws:s3:::jumpstart-cache-prod-<region>",
    "arn:aws:s3:::bucket/*"
  ]
}
```

If you do not select an Amazon VPC, no Amazon VPC is used.

Find VPC

If you select this option, you must select an existing Amazon VPC from the dropdown list. After you select an Amazon VPC, you must select a subnet and security group for your Amazon VPC. For more information about subnets and security groups, see Overview of VPCs and subnets.
Specify whether your model should connect to a virtual private cloud (VPC)

○ No VPC  ○ Find VPC  ○ Input VPC

The VPC you select below will control access to and from your model container.

VPC ID

Select...

Input VPC

If you select this option, you must manually select the subnet and security group that compose your Amazon VPC. If your Studio runtime role or Amazon VPC blocks the `ec2:1ist*` call, you must use this option to select the subnet and security group.

Specify whether your model should connect to a virtual private cloud (VPC)

○ No VPC  ○ Find VPC  ○ Input VPC

The subnets and security groups you type below will control access to and from your model container.

Subnet(s)

Type subnet ID  Add

Security group(s)

Type security group ID  Add

Encryption keys

You can select an AWS KMS key that is passed as part of training jobs and hosting jobs. SageMaker uses this key to encrypt the Amazon EBS volume for the container, and the repackaged model in Amazon S3 for hosting jobs and the output for training jobs. For more information about AWS KMS keys, see AWS KMS keys.

The key that you pass must trust the IAM role that you pass. If you do not specify an IAM role, the AWS KMS key must trust your Studio runtime role.

If you do not select an AWS KMS key, SageMaker provides default encryption for the data in the Amazon EBS volume and the Amazon S3 artifacts.
Find encryption keys

If you select this option, you must select existing AWS KMS keys from the dropdown list.

Configure default values for JumpStart models

You can configure default values for parameters such as IAM roles, VPCs, and KMS keys to pre-populate for JumpStart model deployment and training. After configuring default values, the Studio UI automatically provides your specified security settings and tags to SageMaker JumpStart models to simplify deployment and training workflows. Administrators and end-users can initialize default values specified in a configuration file in YAML format.

By default, the SageMaker Python SDK uses two configuration files: one for the administrator and one for the user. Using the administrator configuration file, administrators can define a set of default values. End-users can override values set in the administrator configuration file and set additional default values using the end-user configuration file. For more information, see Default configuration file location.

The following code sample lists the default locations of the configuration files when using the SageMaker Python SDK in Amazon SageMaker Studio.

```
# Location of the admin config file
/etc/xdg/sagemaker/config.yaml

# Location of the user config file
/root/.config/sagemaker/config.yaml
```

Values specified in the user configuration file override values set in the administrator configuration file. The configuration file is unique to each user profile within an Amazon SageMaker Domain. The user profile's Studio application is directly associated with the user profile. For more information, see Domain User Profiles (p. 24).

Administrators can optionally set configuration defaults for JumpStart model training and deployment through JupyterServer lifecycle configurations. For more information, see Create and associate a lifecycle configuration (p. 271).

Default value configuration YAML file

Your configuration file should adhere to the SageMaker Python SDK configuration file structure. Note that specific fields in the TrainingJob, Model, and EndpointConfig configurations apply to JumpStart model training and deployment default values.

```
SchemaVersion: '1.0'
SageMaker:

191
Fine-Tune a Model

Fine-tuning trains a pretrained model on a new dataset without training from scratch. This process, also known as transfer learning, can produce accurate models with smaller datasets and less training time. You can fine-tune a model if its card shows a fine-tunable attribute set to Yes.

Fine-Tuning data source

When you fine-tune a model, you can use the default dataset or choose your own data, which is located in an Amazon S3 bucket.

To browse the buckets available to you, choose Find S3 bucket. These buckets are limited by the permissions used to set up your Studio account. You can also specify an Amazon S3 URI by choosing Enter Amazon S3 bucket location.
Train Model

Create a training job to fit this model to your own data. This model is pretrained, you will fine-tune its parameters instead of starting from scratch. Fine-tuning can produce accurate models with smaller datasets and less training time. Learn more.

▷ Data Source

▷ Deployment Configuration

▷ Hyper-parameters

▷ Security Settings

Tip
To find out how to format the data in your bucket, choose Learn more. The description section for the model has detailed information about inputs and outputs.

For text models:

- The bucket must have a data.csv file.
- The first column must be a unique integer for the class label. For example: 1, 2, 3, 4, n
- The second column must be a string.
- The second column should have the corresponding text that matches the type and language for the model.

For vision models:

- The bucket must have as many subdirectories as the number of classes.
- Each subdirectory should contain images that belong to that class in .jpg format.

Note
The Amazon S3 bucket must be in the same AWS Region where you're running SageMaker Studio because SageMaker doesn't allow cross-Region requests.

Fine-Tuning deployment configuration

The p3 family is recommended as the fastest for deep learning training, and this is recommended for fine-tuning a model. The following chart shows the number of GPUs in each instance type. There are other available options that you can choose from, including p2 and g4 instance types.
Hyperparameters

You can customize the hyperparameters of the training job that are used to fine-tune the model. The hyperparameters available for each fine-tunable model differ depending on the model. For information on each available hyperparameter, reference the hyperparameters documentation for the model of your choosing in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528). For example, see Image Classification - TensorFlow Hyperparameters (p. 1774) for details on the fine-tunable Image Classification - TensorFlow hyperparameters.

If you use the default dataset for text models without changing the hyperparameters, you get a nearly identical model as a result. For vision models, the default dataset is different from the dataset used to train the pretrained models, so your model is different as a result.

The following hyperparameters are common among models:

- **Epochs** – One epoch is one cycle through the entire dataset. Multiple intervals complete a batch, and multiple batches eventually complete an epoch. Multiple epochs are run until the accuracy of the model reaches an acceptable level, or when the error rate drops below an acceptable level.
- **Learning rate** – The amount that values should be changed between epochs. As the model is refined, its internal weights are being nudged and error rates are checked to see if the model improves. A typical learning rate is 0.1 or 0.01, where 0.01 is a much smaller adjustment and could cause the training to take a long time to converge, whereas 0.1 is much larger and can cause the training to overshoot. It is one of the primary hyperparameters that you might adjust for training your model. Note that for text models, a much smaller learning rate (5e-5 for BERT) can result in a more accurate model.
- **Batch size** – The number of records from the dataset that is to be selected for each interval to send to the GPUs for training.

In an image example, you might send out 32 images per GPU, so 32 would be your batch size. If you choose an instance type with more than one GPU, the batch is divided by the number of GPUs. Suggested batch size varies depending on the data and the model that you are using. For example, how you optimize for image data differs from how you handle language data.

In the instance type chart in the deployment configuration section, you can see the number of GPUs per instance type. Start with a standard recommended batch size (for example, 32 for a vision model). Then, multiply this by the number of GPUs in the instance type that you selected. For example, if you’re using a p3.8xlarge, this would be 32(batch size) multiplied by 4 (GPUs), for a total of 128, as your batch size adjusts for the number of GPUs. For a text model like BERT, try starting with a batch size of 64, and then reduce as needed.

Training output

When the fine-tuning process is complete, JumpStart provides information about the model: parent model, training job name, training job ARN, training time, and output path. The output path is where you can find your new model in an Amazon S3 bucket. The folder structure uses the model name that you provided and the model file is in an /output subfolder and it's always named model.tar.gz.
Example: s3://bucket/model-name/output/model.tar.gz

Configure default values for model training

You can configure default values for parameters such as IAM roles, VPCs, and KMS keys to pre-populate for JumpStart model deployment and training. For more information, see, Configure default values for JumpStart models (p. 191).

Share Models

You can share JumpStart models through the Studio UI directly from the Launched JumpStart assets page using the following procedure:

1. Open Amazon SageMaker Studio and choose Launched JumpStart assets in the JumpStart section of the lefthand navigation pane.
2. Select the Training jobs tab to view the list of your model training jobs.
3. Under the Training jobs list, select the training job that you want to share. This opens the training job details page. You cannot share more than one training job at a time.
4. In the header for the training job, choose Share, and select either Share to Canvas or Share with my organization.

For more information about how to share a model with a SageMaker Canvas user, see Bring Your Own Model Into Canvas.

Note
Only tabular models can be shared to SageMaker Canvas. Trying to share a non-tabular model to SageMaker Canvas throws the error Unsupported Data Type.

For more information about sharing models with your organization, see Shared Models and Notebooks (p. 195).

Shared Models and Notebooks

Share your models and notebooks to centralize model artifacts, facilitate discoverability, and increase the reuse of models within your organization. When sharing your models, you can provide training and inference environment information and allow collaborators to use these environments for their own training and inference jobs.

All models that you share and models that are shared with you are searchable in a centralized location directly in Amazon SageMaker Studio. For information on the onboarding steps to sign into Amazon SageMaker Studio, see Onboard to Amazon SageMaker Domain.

Access shared models and notebooks

To access your shared content, choose Shared models in the left navigation pane of the Amazon SageMaker Studio UI.

Add shared content

You can share models or notebooks through the Shared models section of the Studio UI. For details about each step, see Share models and notebooks through the Studio UI (p. 196).

Filter shared content

There are three main options for filtering shared models and notebooks:
1. **Shared by me** – Models and notebooks that you shared to either JumpStart or SageMaker Canvas.

2. **Shared with me** – Models and notebooks shared with you

3. **Shared by my organization** – All models and notebooks that are shared to anyone in your organization

You can also sort your models and notebooks based on the time they were last updated or by ascending or descending alphabetical order. Choose the filter icon to further sort your selections.

**Share tabular models with SageMaker Canvas users**

In addition to sharing models with your organization, you can also share models with collaborators that use SageMaker Canvas. If you share models to SageMaker Canvas, your collaborators can import those models into SageMaker Canvas and use them to generate predictions.

**Important**

Important: You can only share tabular models to SageMaker Canvas.

You can filter for models and notebooks shared to and from SageMaker Canvas by selecting the filter icon in the **Shared by me** or **Shared with me** tabs. For more information about how to share a model to SageMaker Canvas, see [Bring Your Own Model Into Canvas](#).

**Share models and notebooks through the Studio UI**

To share models and notebooks, navigate to the **Shared models** section in Amazon SageMaker Studio, choose **Shared by my organization**, and then
select the Add dropdown list. Choose to either add a model or add a notebook.

Add a model

To add a model, choose Shared by my organization, and then select Add model from the the Add dropdown list. Enter the basic information for your model, and add any training or inference information you want to share with collaborators to train or deploy your model. After you enter all the necessary information, choose Add model in the lower right corner.

Basic information

First, add the basic descriptive information about your model. This information is used to improve the searchability of your model.

1. Add a title for this model. Adding a title automatically populates a unique identifier in the ID field based on the model title.
2. Add a description of the model.
3. Select a data type from the options: text, vision, tabular, or audio.
4. Select a machine learning task from the list of available tasks, such as image classification or text generation.
5. Select a machine learning framework.
6. Add metadata information with keywords or phrases to use when searching for a model. Use commas to separate keywords. Any spaces are automatically replaced with commas.

Enable training

When adding a model to share, you can optionally provide a training environment and allow collaborators in your organization to train the shared model.

Note

If you are adding a tabular model, you also need to specify a column format and target column to enable training. For more information, see Amazon SageMaker Canvas in the Amazon SageMaker Developer Guide.

1. Add a container to use for model training. You can select a container used for an existing training job, bring your own container in Amazon ECR, or use an Amazon SageMaker Deep Learning Container.
2. Add environment variables.
3. Provide a training script location.
4. Provide a script mode entry point.
5. Provide an Amazon S3 URI for model artifacts generated during training.
6. Provide the Amazon S3 URI to the default training dataset.
7. Provide a model output path. The model output path should be the Amazon S3 URI path for any model artifacts generated from training. SageMaker saves the model artifacts as a single compressed TAR file in Amazon S3.
8. Provide a validation dataset to use for evaluating your model during training. Validation datasets must contain the same number of columns and the same feature headers as the training dataset.
9. Turn on network isolation. Network isolation isolates the model container so that no inbound or outbound network calls can be made to or from the model container.
10. Provide training channels through which SageMaker can access your data. For example, you might specify input channels named `train` or `test`. For each channel, specify a channel name and a URI to the location of your data. Choose Browse to search for Amazon S3 locations.
11. Provide hyperparameters. Add any hyperparameters with which collaborators should experiment during training. Provide a range of valid values for these hyperparameters. This range is used for training job hyperparameter validation. You can define ranges based on the datatype of the hyperparameter.
12. Select an instance type. We recommend a GPU instance with more memory for training with large batch sizes. For a comprehensive list of SageMaker training instances across AWS Regions, see the On-Demand Pricing table in Amazon SageMaker Pricing.
13. Provide metrics. Define metrics for a training job by specifying a name and a regular expression for each metric that your training monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. For example, the metric `loss` might have the regular expression "Loss =(.*?);".

Enable deployment

When adding a model to share, you can optionally provide an inference environment in which collaborators in your organization can deploy the shared model for inference.

1. Add a container to use for inference. You can bring your own container in Amazon ECR or use an Amazon SageMaker Deep Learning Container.
2. Provide the Amazon S3 URI to an inference script. Custom inference scripts run inside your chosen container. Your inference script should include a function for model loading, and optionally functions generating predictions, and input and output processing. For more information on creating inference scripts for the framework of your choice, see Frameworks in the SageMaker Python SDK.
documentation. For example, for TensorFlow, see *How to implement the pre- and/or post-processing handler(s)*.

3. Provide an Amazon S3 URI for model artifacts. Model artifacts are the output that results from training a model, and typically consist of trained parameters, a model definition that describes how to compute inferences, and other metadata. If you trained your model in SageMaker, the model artifacts are saved as a single compressed TAR file in Amazon S3. If you trained your model outside SageMaker, you need to create this single compressed TAR file and save it in an Amazon S3 location.

4. Select an instance type. We recommend a GPU instance with more memory for training with large batch sizes. For a comprehensive list of SageMaker training instances across AWS Regions, see the On-Demand Pricing table in *Amazon SageMaker Pricing*.

### Add a notebook

To add a notebook, choose *Shared by my organization*, and then select *Add notebook* from the Add dropdown list. Enter the basic information for your notebook and provide an Amazon S3 URI for the location of that notebook.

**Basic information**

First, add the basic descriptive information about your notebook. This information is used to improve the searchability of your notebook.

1. Add a title for this notebook. Adding a title automatically populates a unique identifier in the ID field based on the notebook title.
2. Add a description of the notebook.
3. Select a data type from the options: *text*, *vision*, *tabular*, or *audio*.
4. Select an ML task from the list of available tasks, such as *image classification* or *text generation*.
5. Select an ML framework.
6. Add metadata information with keywords or phrases to use when searching for a notebook. Use commas to separate keywords. Any spaces are automatically replaced with commas.

### Add notebook

Provide an Amazon S3 URI for the location of that notebook. You can choose *Browse* to search through your Amazon S3 buckets for your notebook file location. After you find your notebook, copy the Amazon S3 URI, choose *Cancel*, and then add the Amazon S3 URI to the *Notebook Location* field.

After you enter all the necessary information, choose *Add notebook* in the lower right corner.

### Amazon SageMaker JumpStart Industry: Financial

Use SageMaker JumpStart Industry: Financial solutions, models, and example notebooks to learn about SageMaker features and capabilities through curated one-step solutions and example notebooks of industry-focused machine learning (ML) problems. The notebooks also walk through how to use the SageMaker JumpStart Industry Python SDK to enhance industry text data and fine-tune pretrained models.

**Topics**

- *Amazon SageMaker JumpStart Industry Python SDK* (p. 200)
- *Amazon SageMaker JumpStart Industry: Financial Solution* (p. 200)
Amazon SageMaker JumpStart Industry Python SDK

SageMaker Runtime JumpStart provides processing tools for curating industry datasets and fine-tuning pretrained models through its client library called SageMaker JumpStart Industry Python SDK. For detailed API documentation of the SDK, and to learn more about processing and enhancing industry text datasets for improving the performance of state-of-the-art models on SageMaker JumpStart, see the SageMaker JumpStart Industry Python SDK open source documentation.

Amazon SageMaker JumpStart Industry: Financial Solution

SageMaker JumpStart Industry: Financial provides the following solution notebooks:

- **Corporate Credit Rating Prediction**
  
  This SageMaker JumpStart Industry: Financial solution provides a template for a text-enhanced corporate credit rating model. It shows how to take a model based on numeric features (in this case, Altman's famous 5 financial ratios) combined with texts from SEC filings to achieve an improvement in the prediction of credit ratings. In addition to the 5 Altman ratios, you can add more variables as needed or set custom variables. This solution notebook shows how SageMaker JumpStart Industry Python SDK helps process Natural Language Processing (NLP) scoring of texts from SEC filings. Furthermore, the solution demonstrates how to train a model using the enhanced dataset to achieve a best-in-class model, deploy the model to a SageMaker endpoint for production, and receive improved predictions in real time.

- **Graph-Based Credit Scoring**
  
  Credit ratings are traditionally generated using models that use financial statement data and market data, which is tabular only (numeric and categorical). This solution constructs a network of firms using SEC filings and shows how to use the network of firm relationships with tabular data to generate accurate rating predictions. This solution demonstrates a methodology to use data on firm linkages to extend the traditionally tabular-based credit scoring models, which have been used by the ratings industry for decades, to the class of machine learning models on networks.

  **Note**
  The solution notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.

  You can find these financial services solutions through the SageMaker JumpStart page in Studio.

  **Note**
  The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio. Log in to the SageMaker console, and launch SageMaker Studio. For more information about how to find the solution card, see the previous topic at SageMaker JumpStart.

Amazon SageMaker JumpStart Industry: Financial Models

SageMaker JumpStart Industry: Financial provides the following pretrained Robustly Optimized BERT approach (RoBERTa) models:

- Financial Text Embedding (RoBERTa-SEC-Base)
- RoBERTa-SEC-WIKI-Base
- RoBERTa-SEC-Large
• **RoBERTa-SEC-WIKI-Large**

The RoBERTa-SEC-Base and RoBERTa-SEC-Large models are the text embedding models based on GluonNLP’s RoBERTa model and pretrained on S&P 500 SEC 10-K/10-Q reports of the decade of the 2010’s (from 2010 to 2019). In addition to these, SageMaker JumpStart Industry: Financial provides two more RoBERTa variations, RoBERTa-SEC-WIKI-Base and RoBERTa-SEC-WIKI-Large, which are pretrained on the SEC filings and common texts of Wikipedia.

You can find these models in SageMaker JumpStart by navigating to the Text Models node, choosing Explore All Text Models, and then filtering for the ML Task Text Embedding. You can access any corresponding notebooks after selecting the model of your choice. The paired notebooks will walk you through how the pretrained models can be fine-tuned for specific classification tasks on multimodal datasets, which are enhanced by the SageMaker JumpStart Industry Python SDK.

**Note**

The model notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.

The following screenshot shows the pretrained model cards provided through the SageMaker JumpStart page on Studio.
Amazon SageMaker JumpStart Industry: Financial Example Notebooks

SageMaker JumpStart Industry: Financial provides the following example notebooks to demonstrate solutions to industry-focused ML problems:

- **Financial TabText Data Construction** – This example introduces how to use the SageMaker JumpStart Industry Python SDK for processing the SEC filings, such as text summarization and scoring texts based on NLP score types and their corresponding word lists. To preview the content of this notebook, see [Simple Construction of a Multimodal Dataset from SEC Filings and NLP Scores](#).

- **Multimodal ML on TabText Data** – This example shows how to merge different types of datasets into a single dataframe called TabText and perform multimodal ML. To preview the content of this notebook, see [Machine Learning on a TabText Dataframe – An Example Based on the Paycheck Protection Program](#).

- **Multi-category ML on SEC filings data** – This example shows how to train an AutoGluon NLP model over the multimodal (TabText) datasets curated from SEC filings for a multiclass classification task. [Classify SEC 10K/Q Filings to Industry Codes Based on the MDNA Text Column](#).

**Note**
The example notebooks are for demonstrative purposes only. They should not be relied on as financial or investment advice.

**Note**
The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio. Log in to the [SageMaker console](#), and launch SageMaker Studio. For more information about how to find the example notebooks, see the previous topic at [SageMaker JumpStart](#).

To preview the content of the example notebooks, see [Tutorials – Finance](#) in the [SageMaker JumpStart Industry Python SDK documentation](#).

Use machine learning environments offered by SageMaker

Amazon SageMaker supports the following machine learning environments.

- **Amazon SageMaker Studio**: Lets you build, train, debug, deploy, and monitor your machine learning models.
- **Amazon SageMaker Notebook Instances**: Lets you prepare and process data, and train and deploy machine learning models from a compute instance running the Jupyter Notebook application.
- **Amazon SageMaker Studio Lab**: Studio Lab is a free service that gives you access to AWS compute resources, in an environment based on open-source JupyterLab, without requiring an AWS account.
- **Amazon SageMaker Canvas**: Gives you the ability to use machine learning to generate predictions without needing to code.
- **Amazon SageMaker geospatial**: Gives you the ability to build, train, and deploy geospatial models.
- **RStudio on Amazon SageMaker**: RStudio is an IDE for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management.

To use these machine learning environments, except Studio Lab and SageMaker Notebook Instances, you or your organization's administrator must create an Amazon SageMaker Domain. Studio Lab has a separate onboarding process.

### Amazon SageMaker Studio

Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models. SageMaker Studio provides all the tools you need to take your models from data preparation to experimentation to production while boosting your productivity. In a single unified visual interface, customers can perform the following tasks:

- Write and execute code in Jupyter notebooks
- Prepare data for machine learning
- Build and train machine learning models
- Deploy the models and monitor the performance of their predictions
- Track and debug the machine learning experiments
For information on the onboarding steps to sign in to SageMaker Studio, see Onboard to Amazon SageMaker Domain (p. 10).

For the AWS Regions supported by SageMaker Studio, see Supported Regions and Quotas (p. 43).

Topics

• Studio Features (p. 205)
• Amazon SageMaker Studio UI Overview (p. 205)
• Launch Amazon SageMaker Studio (p. 209)
• JupyterLab Versioning (p. 211)
• Use the Amazon SageMaker Studio Launcher (p. 218)
• Use Amazon SageMaker Studio Notebooks (p. 221)
• Customize Amazon SageMaker Studio (p. 256)
• Perform Common Tasks in Amazon SageMaker Studio (p. 287)
• Amazon SageMaker Studio Pricing (p. 294)
• Troubleshooting Amazon SageMaker Studio (p. 294)

Studio Features

Studio includes the following features:

• Amazon SageMaker Autopilot
• Amazon SageMaker Clarify
• Amazon SageMaker Data Wrangler
• Amazon SageMaker Debugger
• Amazon SageMaker Experiments
• Amazon SageMaker Feature Store
• Amazon SageMaker JumpStart
• Amazon SageMaker Model Building Pipelines
• Amazon SageMaker Model Registry
• Amazon SageMaker Projects
• Amazon SageMaker Studio Notebooks
• Amazon SageMaker Studio Universal Notebook

Amazon SageMaker Studio UI Overview

Amazon SageMaker Studio extends the capabilities of JupyterLab with custom resources that can speed up your Machine Learning (ML) process by harnessing the power of AWS compute. Previous users of JupyterLab will notice the similarity of the user interface. The most prominent additions are detailed in the following sections. For an overview of the original JupyterLab interface, see The JupyterLab Interface.

The following image shows the default view upon launching Amazon SageMaker Studio. The left navigation panel displays all top-level categories of features, and a Studio Home page (p. 206) is open in the main working area. Come back to this central point of orientation by choosing the Home icon at any time, then selecting the Home node in the navigation menu.
Try the **Getting started notebook** for an in-product hands-on guide on how to set up and get familiar with Amazon SageMaker Studio features. On the **Quick actions** section of the Studio Home page, choose **Open the Getting started notebook**.

**Note**

This chapter is based on Studio's updated user interface (UI) available on version v5.38.x and above on JupyterLab3.

- To retrieve your version of Studio UI, from the **Studio Launcher**, open a System Terminal, then
  1. Run conda activate studio
  2. Run jupyter labextension list
  3. Search for the version displayed after @amzn/sagemaker-ui version in the output.
- For information about updating Amazon SageMaker Studio, see **Shut down and Update SageMaker Studio (p. 292)**.

**Topics**

- **Studio Home page (p. 206)**
- **Studio layout (p. 207)**

**Studio Home page**

The Home page provides access to common tasks and workflows. In particular, it includes a list of **Quick actions** for common tasks such as **Open Launcher** to create notebooks and other resources and **Import & prepare data visually** to create a new flow in Data Wrangler. The **Home** page also offers tooltips on key controls in the UI.

The **Prebuilt and automated solutions** help you get started quickly with SageMaker's low-code solutions such as Amazon SageMaker JumpStart and Autopilot.

In **Workflows and tasks**, you can find a list of relevant tasks for each step of your ML workflow that takes you to the right tool for the job. For example, **Transform, analyse, and export data** takes you
to Amazon SageMaker Data Wrangler and opens the workflow to create a new data flow, or View all experiments takes you to SageMaker Experiments and opens the experiments list view.

Upon Studio launch, the Home page is open in the main working area. You can customize your SageMaker Home page by choosing Customize Layout at the top right of the Home tab.

**Studio layout**

The Amazon SageMaker Studio interface consists of a menu bar at the top, a collapsible left sidebar displaying a variety of icons such as the Home icon and the File Browser, a status bar at the bottom of the screen, and a central area divided horizontally into two panes. The left pane is a collapsible navigation panel. The right pane, or main working area, contains one or more tabs for resources such as launchers, notebooks, terminals, metrics, and graphs, and can be further divided.

Report a bug in Studio or choose the notification icon to view notifications from Studio, such as new Studio versions and new SageMaker features, on the right corner of the menu bar. To update to a new version of Studio, see Shut Down and Update SageMaker Studio and Studio Apps (p. 292).

The following sections describe the Studio main user interface areas.

**Left sidebar**

The left sidebar includes the following icons. When hovering over an icon, a tooltip displays the icon name. A single click on an icon opens up the left navigation panel with the described functionality. A double click minimizes the left navigation panel.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Home Icon" /></td>
<td><strong>Home</strong>&lt;br&gt;Choose the Home icon to open a top-level navigation menu in the left navigation panel. Using the Home navigation menu, you can discover and navigate to the right tools for each step of your ML workflow. The menu also provides shortcuts to quick-start solutions and learning resources such as documentation and guided tutorials. The menu categories group relevant features together. Choosing Data, for example, expands the relevant SageMaker capabilities for your data preparations tasks. From here, you can prepare your data with Data Wrangler, create and store ML features with Amazon SageMaker Feature Store, and manage Amazon EMR clusters for large-scale data processing. The categories are ordered following a typical ML workflow from preparing data, to building, training, and deploying ML models (data, pipelines, models, and deployments). When you choose a specific node (such as Data Wrangler), a corresponding page opens in the main working area. Choose Home in the navigation menu to open the Studio Home page (p. 206).</td>
</tr>
</tbody>
</table>

<p>| <img src="image" alt="File Browser Icon" /> | <strong>File Browser</strong>&lt;br&gt;The File Browser displays lists of your notebooks, experiments, trials, trial components, endpoints, and low-code solutions. |</p>
<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>

</tr>
</tbody>
</table>
| ![Table of Contents](image) | **Table of Contents**  
You can navigate the structure of a document when a notebook or Python files are open.  
A table of contents is auto-generated in the left navigation panel when you have a notebook, Markdown files, or Python files opened. The entries are clickable and scroll the document to the heading in question. |
| ![Extensions](image) | **Extensions**  
You can turn on and manage third-party JupyterLab extensions. You can check the already installed extensions and search for extensions by typing the name in the search bar. When you have found the extension you want to install, choose **Install**. After installing your new extensions, be sure to restart JupyterLab by refreshing your browser.  
For more information, see [JupyterLab Extensions documentation](#). |

**Left navigation panel**

The left navigation panel content varies with the Icon selected in the left sidebar.

For example, choosing the **Home** icon displays the navigation menu. Choosing **File browser** lists all the files and directories available in your workspace (notebooks, experiments, data flows, trials, trial components, endpoints, or low-code solutions).

In the navigation menu, choosing a node brings up the corresponding feature page in the main working area. For example, choosing **Data Wrangler** in the **Data** menu opens up the **Data Wrangler** tab listing all existing flows.

**Main working area**

The main working area consists of multiple tabs that contain your open notebooks, terminals, and detailed information about your experiments and endpoints. In the main working area, you can arrange documents (such as notebooks and text files) and other activities (such as terminals and code consoles) into panels of tabs that you can resize or subdivide. Drag a tab to the center of a tab panel to move the tab to the panel. Subdivide a tab panel by dragging a tab to the left, right, top, or bottom of the panel. The tab for the current activity is marked with a colored top border (blue by default).

**Note**

All feature pages provide in-product contextual help. To access help, choose **Show information**. The help interface provides a brief introduction to the tool and links to additional resources, such as videos, tutorials, or blogs.

**Launch Amazon SageMaker Studio**

After you have onboarded to an Amazon SageMaker Domain, you can launch an Amazon SageMaker Studio application from either the SageMaker console or the AWS CLI. For more information about onboarding to a Domain, see [Onboard to Amazon SageMaker Domain](#).

**Topics**

- [Launch Studio Using the Amazon SageMaker Console](#)  
- [Launch Studio Using the AWS CLI](#)
Launch Studio Using the Amazon SageMaker Console

When launching an Amazon SageMaker Studio application from the SageMaker console, you can use the Studio landing page or the Amazon SageMaker Domain details page. The following sections demonstrate how to launch the Studio application from the SageMaker console.

Topics
- Prerequisite (p. 210)
- Launch Studio from the Domain details page (p. 210)
- Launch Studio from the Studio landing page (p. 210)

Prerequisite

To complete this procedure, you must onboard to a Domain by following the steps in Onboard to Amazon SageMaker Domain.

Launch Studio from the Domain details page

The following sections describe how to launch a Studio application from the Domain details page. The steps to launch the Studio application after you have navigated to the Domain details page differ depending on if you're launching a personal application or a shared space.

Navigate to the Domain details page

The following procedure shows how to navigate to the Domain details page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domain, select the Domain that you want to launch the Studio application in.

Launch a user profile app

The following procedure shows how to launch a Studio application that is scoped to a user profile.

1. On the Domain details page, choose the User profiles tab.
2. Identify the user profile that you want to launch the Studio application for.
3. Choose Launch for your selected user profile, then choose Studio.

Launch a shared space app

The following procedure shows how to launch a Studio application that is scoped to a shared space.

1. On the Domain details page, choose the Space management tab.
2. Identify the shared space that you want to launch the Studio application for.
3. Choose Launch Studio for your selected shared space.

Launch Studio from the Studio landing page

The following procedure describes how to launch a Studio application from the Studio landing page.
Launch Studio

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Studio.
3. Under Get started, select the Domain that you want to launch the Studio application in. If your user profile only belongs to one Domain, you do not see the option for selecting a Domain.
4. Select the user profile that you want to launch the Studio application for. If there is no user profile in the Domain, choose Create user profile. For more information, see Add and Remove User Profiles (p. 24).
5. Choose Launch Studio. If the user profile belongs to a shared space, choose Open Spaces.
6. To launch a Studio application scoped to a user profile, choose Launch personal Studio.
7. To launch a shared Studio application, choose the Launch shared Studio button next to the shared space that you want to launch into.

Launch Studio Using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to launch Amazon SageMaker Studio by creating a presigned Domain URL.

Prerequisites

Before you begin, complete the following prerequisites:

- Onboard to Amazon SageMaker Domain. For more information, see Onboard to Amazon SageMaker Domain.
- Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
- From your local machine, run aws configure and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.

The following code snippet demonstrates how to launch Amazon SageMaker Studio from the AWS CLI using a presigned Domain URL. For more information, see create-presigned-domain-url.

```bash
aws sagemaker create-presigned-domain-url \
  --region region \
  --domain-id domain-id \
  --space-name space-name \
  --user-profile-name user-profile-name \
  --session-expiration-duration-in-seconds 43200
```

JupyterLab Versioning

The Amazon SageMaker Studio interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Studio now supports using both JupyterLab 1 and JupyterLab 3. The default version of JupyterLab in Studio is JupyterLab 3. If you created your Amazon SageMaker Domain and user profile using the AWS Management Console before 08/31/2022 or using the AWS Command Line Interface before 02/22/23, then your Studio instance defaults to JupyterLab 1. After 08/31/2022, JupyterLab version 1 on Amazon SageMaker Studio only receives security fixes. You can choose the version that you want to run. However, you can run only a single instance of JupyterLab at one time per user profile. You can’t run multiple versions of JupyterLab simultaneously.

After 03/31/23, Studio only supports the creation of JupyterLab 3 applications. After that date, Studio stops supporting JupyterLab 1 application creation. On 04/30/2023, Studio removes all existing
applications that run JupyterLab 1. Update your existing JupyterLab 1 applications to JupyterLab 3 before 04/30/2023 following the steps in View and update the JupyterLab version of an application from the console (p. 217).

Topics

• JupyterLab 3 (p. 212)
• Restricting default JupyterLab version using an IAM policy condition key (p. 212)
• Setting a default JupyterLab version (p. 213)
• View and update the JupyterLab version of an application from the console (p. 217)
• Installing JupyterLab and Jupyter Server extensions (p. 217)

JupyterLab 3

JupyterLab 3 includes the following features that are not available in previous versions. For more information about these features, see JupyterLab 3.0 is released!

• Visual debugger when using the Base Python 2.0 and Data Science 2.0 kernels.
• File browser filter
• Table of Contents (TOC)
• Multi-language support
• Simple mode
• Single interface mode

Important changes to JupyterLab 3

Consider the following when using JupyterLab 3:

• When setting the JupyterLab version using the AWS CLI, select the corresponding image for your Region and JupyterLab version from the image list in From the AWS CLI (p. 214).
• In JupyterLab 3, you must activate the studio conda environment before installing extensions. For more information, see Installing JupyterLab and Jupyter Server extensions (p. 217).
• Debugger is only supported when using the following images:
  • Base Python 2.0
  • Data Science 2.0
  • Base Python 3.0
  • Data Science 3.0

Restricting default JupyterLab version using an IAM policy condition key

You can use IAM policy condition keys to restrict the version of JupyterLab that your users can launch.

The following policy shows how to limit the JupyterLab version at the Domain level.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the domain level",
      "Action": "sagemaker:CreateApplication",
      "Condition": {
        "StringEquals": {
          "sagemaker:ApplicationName": "jupyterlab\[3\]"
        }
      }
    }
  ]
}
```
The following policy shows how to limit the JupyterLab version at the user profile level.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the user profile level",
      "Effect": "Deny",
      "Action": [
        "sagemaker:CreateUserProfile",
        "sagemaker:UpdateUserProfile"
      ],
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "sagemaker:ImageArns": "*image/jupyter-server-3"
        }
      }
    }
  ]
}
```

The following policy shows how to limit the JupyterLab version at the application level. The CreateApp request must include the image ARN for this policy to apply.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the application level",
      "Effect": "Deny",
      "Action": "sagemaker:CreateApp",
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "sagemaker:ImageArns": "*image/jupyter-server-3"
        }
      }
    }
  ]
}
```

### Setting a default JupyterLab version

The following sections show how to set a default JupyterLab version for Studio using either the console or the AWS CLI.
From the console

You can select the default JupyterLab version to use on either the Domain or user profile level during resource creation. To set the default JupyterLab version using the console, see Onboard to Amazon SageMaker Domain (p. 10).

From the AWS CLI

You can select the default JupyterLab version to use on either the Domain or user profile level using the AWS CLI.

To set the default JupyterLab version using the AWS CLI, you must include the ARN of the desired default JupyterLab version as part of an AWS CLI command. This ARN differs based on the version and the Region of the SageMaker Domain.

The following table lists the ARNs of the available JupyterLab versions for each Region:

<table>
<thead>
<tr>
<th>Region</th>
<th>JL1</th>
<th>JL3</th>
</tr>
</thead>
</table>
Create or update Domain

The following shows how to create a Domain with JupyterLab 3 as the default, using the AWS CLI:

```bash
aws --region <REGION> \\
  sagemaker create-domain \\
  --domain-name <NEW_DOMAIN_NAME> \\
  --auth-mode <AUTHENTICATION_MODE> \\
  --subnet-ids <SUBNET-IDS> \\
  --vpc-id <VPC-ID> \\
  --default-user-settings '{
```
The following shows how to update a Domain to use JupyterLab 3 as the default, using the AWS CLI:

```
aws --region <REGION> \
  sagemaker update-domain \
  --domain-id <YOUR_DOMAIN_ID> \
  --default-user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```

Create or update user profile

You can set a default JupyterServer version at the user profile level by invoking `CreateUserProfile` or `UpdateUserProfile` and passing the `UserSettings.JupyterServerAppSettings.DefaultResourceSpec.SageMakerImageArn` field.

The following shows how to create a user profile with JupyterLab 3 as the default on an existing Domain, using the AWS CLI:

```
aws --region <REGION> \
  sagemaker create-user-profile \
  --domain-id <YOUR_DOMAIN_ID> \
  --user-profile-name <NEW_USERPROFILE_NAME> \
  --query UserProfileArn --output text \
  --user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```

The following shows how to update a user profile to use JupyterLab 3 as the default, using the AWS CLI:

```
aws --region <REGION> \
  sagemaker update-user-profile \
  --domain-id <YOUR_DOMAIN_ID> \
  --user-profile-name <EXISTING_USERPROFILE_NAME> \
  --user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```
View and update the JupyterLab version of an application from the console

The following shows how to view and update the JupyterLab version of an application.

1. Navigate to the SageMaker Domains page.
2. Select a domain to view its user profiles.
3. Select a user to view their applications.
4. To view the JupyterLab version of an application, select the application's name.
5. To update the JupyterLab version, select Action.
6. From the dropdown menu, select Change JupyterLab version.
7. From the Studio settings page, select the JupyterLab version from the dropdown menu.
8. After the JupyterLab version for the user profile has been successfully updated, restart the JupyterServer application to make the version changes effective. For more information about restarting a JupyterServer application, see Shut down and Update SageMaker Studio (p. 292).

Installing JupyterLab and Jupyter Server extensions

The process for installing JupyterLab and Jupyter Server extensions differs depending on the JupyterLab version of your Studio instance. In JupyterLab 1, you can open the terminal and install extensions without activating any conda environment. In JupyterLab 3, you must activate the studio conda environment before installing extensions. The method for this differs if you're installing the extensions from within Studio or using a lifecycle configuration script.

Installing Extension from within Studio

To install extensions from within Studio, you must activate the studio environment before you install extensions.

```
# Before installing extensions
conda activate studio

# Install your extensions
pip install <JUPYTER_EXTENSION>

# After installing extensions
conda deactivate
```

Installing Extensions using a lifecycle configuration script

If you're installing JupyterLab and Jupyter Server extensions in your lifecycle configuration script, you must modify your script so that it works with JupyterLab 3. The following sections show the code needed for existing and new lifecycle configuration scripts.

Existing lifecycle configuration script

If you're reusing an existing lifecycle configuration script that must work with both versions of JupyterLab, use the following code in your script:
# Before installing extension

```bash
export AWS_SAGEMAKER_JUPYTERSERVER_IMAGE="${AWS_SAGEMAKER_JUPYTERSERVER_IMAGE:-'jupyter-server'}"
if [ "${AWS_SAGEMAKER_JUPYTERSERVER_IMAGE}" = "jupyter-server-3" ]; then
eval "$\{\$(conda shell.bash hook)\}"
  conda activate studio
fi;
```

# Install your extensions

```bash
pip install <JUPYTER_EXTENSION>
```

# After installing extension

```bash
if [ "${AWS_SAGEMAKER_JUPYTERSERVER_IMAGE}" = "jupyter-server-3" ]; then
  conda deactivate
fi;
```

## New lifecycle configuration script

If you're writing a new lifecycle configuration script that only uses JupyterLab 3, you can use the following code in your script:

```bash
# Before installing extension

```

```bash
eval "\$\{\$(conda shell.bash hook)\}"
conda activate studio
```

# Install your extensions

```bash
pip install <JUPYTER_EXTENSION>
```

conda deactivate

## Use the Amazon SageMaker Studio Launcher

You can use the Amazon SageMaker Studio Launcher to create notebooks and text files, and to launch terminals and interactive Python shells.

You can open Studio Launcher in any of the following ways:

- Choose **Amazon SageMaker Studio** at the top left of the Studio interface.
- Use the keyboard shortcut Ctrl + Shift + L.
- From the Studio menu, choose **File** and then choose **New Launcher**.
- If the SageMaker file browser is open, choose the plus (+) sign in the Studio file browser menu.
- In the **Quick actions** section of the **Home** tab, choose **Open Launcher**. The Launcher opens in a new tab. The **Quick actions** section is visible by default but can be toggled off. Choose **Customize Layout** to turn this section back on.
The Launcher consists of the following two sections:

**Topics**
- Notebooks and compute resources (p. 219)
- Utilities and files (p. 220)

**Notebooks and compute resources**

In this section, you can create a notebook, open an image terminal, or open a Python console.

To create or launch one of those items:

1. Choose **Change environment** to select a SageMaker image, a kernel, an instance type, and, optionally, add a lifecycle configuration script that runs on image start-up. For more information on lifecycle configuration scripts, see Use lifecycle configurations with Amazon SageMaker Studio (p. 271). For more information about kernel updates, see Change an Image or a Kernel (p. 236).
2. Select an item.

**Note**
When you choose an item from this section, you might incur additional usage charges. For more information, see Usage Metering (p. 238).

The following items are available:

- **Notebook**

  Launches the notebook in a kernel session on the chosen SageMaker image.

  Creates the notebook in the folder that you have currently selected in the file browser. To view the file browser, in the left sidebar of Studio, choose the **File Browser** icon.

- **Console**
Launches the shell in a kernel session on the chosen SageMaker image.

Opens the shell in the folder that you have currently selected in the file browser.

- **Image terminal**

  Launches the terminal in a terminal session on the chosen SageMaker image.

  Opens the terminal in the root folder for the user (as shown by the **Home** folder in the file browser).

  **Note**

  By default, CPU instances launch on a **ml.t3.medium** instance, while GPU instances launch on a **ml.g4dn.xlarge** instance.

**Utilities and files**

In this section, you can add contextual help in a notebook; create Python, Markdown and text files; and open a system terminal.

  **Note**

  Items in this section run in the context of Amazon SageMaker Studio and don't incur usage charges.

The following items are available:

- **Show Contextual Help**

  Opens a new tab that displays contextual help for functions in a Studio notebook. To display the help, choose a function in an active notebook. To make it easier to see the help in context, drag the help tab so that it's adjacent to the notebook tab. To open the help tab from within a notebook, press Ctrl + I.

  The following screenshot shows the contextual help for the **Experiment.create** method.
Use Amazon SageMaker Studio Notebooks

Amazon SageMaker Studio notebooks are collaborative notebooks that you can launch quickly because you don’t need to set up compute instances and file storage beforehand. A set of instance types, known as Fast launch types are designed to launch in under two minutes. Studio notebooks provide persistent storage, which enables you to view and share notebooks even if the instances that the notebooks run on are shut down.

You can share your notebooks with others, so that they can easily reproduce your results and collaborate while building models and exploring your data. You provide access to a read-only copy of the notebook through a secure URL. Dependencies for your notebook are included in the notebook's metadata. When your colleagues copy the notebook, it opens in the same environment as the original notebook.

A Studio notebook runs in an environment defined by the following:

- **Amazon EC2 instance type** – The hardware configuration the notebook runs on. The configuration includes the number and type of processors (vCPU and GPU), and the amount and type of memory. The instance type determines the pricing rate.
• SageMaker image – A container image that is compatible with SageMaker Studio. The image consists of the kernels, language packages, and other files required to run a notebook in Studio. There can be multiple images in an instance. For more information, see Bring your own SageMaker image (p. 257).
• KernelGateway app – A SageMaker image runs as a KernelGateway app. The app provides access to the kernels in the image. There is a one-to-one correspondence between a SageMaker image and a KernelGateway app.
• Kernel – The process that inspects and runs the code contained in the notebook. A kernel is defined by a kernel spec in the image. There can be multiple kernels in an image.

You can change any of these resources from within the notebook.

The following diagram outlines how a notebook kernel runs in relation to the KernelGateway App, User, and Domain.

Sample SageMaker Studio notebooks are available in the aws_sagemaker_studio folder of the Amazon SageMaker example GitHub repository. Each notebook comes with the necessary SageMaker image that opens the notebook with the appropriate kernel.

We recommend that you familiarize yourself with the SageMaker Studio interface and the Studio notebook toolbar before creating or using a Studio notebook. For more information, see Amazon SageMaker Studio UI Overview (p. 205) and Use the Studio Notebook Toolbar (p. 227).

How Are Amazon SageMaker Studio Notebooks Different from Notebook Instances?

When you're starting a new notebook, we recommend that you create the notebook in Amazon SageMaker Studio instead of launching a notebook instance from the Amazon SageMaker console. There are many benefits to using a Studio notebook, including the following:

- **Faster**: Starting a Studio notebook is faster than launching an instance-based notebook. Typically, it is 5-10 times faster than instance-based notebooks.
- **Easy notebook sharing**: Notebook sharing is an integrated feature in Studio. Users can generate a shareable link that reproduces the notebook code and also the SageMaker image required to execute it, in just a few clicks.
- **Latest Python SDK**: Studio notebooks come pre-installed with the latest Amazon SageMaker Python SDK.
- **Access all Studio features**: Studio notebooks are accessed from within Studio. This enables you to build, train, debug, track, and monitor your models without leaving Studio.
- **Persistent user directories**: Each member of a Studio team gets their own home directory to store their notebooks and other files. The directory is automatically mounted onto all instances and kernels as they're started, so their notebooks and other files are always available. The home directories are stored in Amazon Elastic File System (Amazon EFS) so that you can access them from other services.
- **Direct access**: When using IAM Identity Center, you use your IAM Identity Center credentials through a unique URL to directly access Studio. You don't have to interact with the AWS Management Console to run your notebooks.
- **Optimized images**: Studio notebooks are equipped with a set of predefined SageMaker image settings to get you started faster.

**Note**

Studio notebooks don't support local mode. However, you can use a notebook instance to train a sample of your dataset locally, and then use the same code in a Studio notebook to train on the full dataset.

When you open a notebook in SageMaker Studio, the view is an extension of the JupyterLab interface. The primary features are the same, so you'll find the typical features of a Jupyter notebook and JupyterLab. For more information about the Studio interface, see [Amazon SageMaker Studio UI Overview](p. 205).

**Get Started**

To get started, you or your organization's administrator need to complete the Amazon SageMaker Studio onboarding process. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).

You can access a Studio notebook in any of the following ways:

- You receive an email invitation to access Studio through your organization's IAM Identity Center, which includes a direct link to login to Studio without having to use the Amazon SageMaker console. You can proceed to the the section called “Next Steps” (p. 224).
- You receive a link to a shared Studio notebook, which includes a direct link to log in to Studio without having to use the SageMaker console. You can proceed to the the section called “Next Steps” (p. 224).
- You onboard to Studio and then log in to the SageMaker console. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
Launch Amazon SageMaker

Complete the steps in Launch Amazon SageMaker Studio (p. 209) to launch Studio.

Next Steps

Now that you're in Studio, you can try any of the following options:

- To create a Studio notebook or explore Studio end-to-end tutorial notebooks – See Amazon SageMaker Studio Tour (p. 224) in the next section.
- To familiarize yourself with the Studio interface – See Amazon SageMaker Studio UI Overview (p. 205) or try the Getting started notebook by selecting Open the Getting started notebook in the Quick actions section of the Studio Home page.

Amazon SageMaker Studio Tour

For a walkthrough that takes you on a tour of the main features of Amazon SageMaker Studio, see the xgboost_customer_churn_studio.ipynb sample notebook from the aws/amazon-sagemaker-examples GitHub repository. The code in the notebook trains multiple models and sets up the SageMaker Debugger and SageMaker Model Monitor. The walkthrough shows you how to view the trials, compare the resulting models, show the debugger results, and deploy the best model using the Studio UI. You don't need to understand the code to follow this walkthrough.

Prerequisites

To run the notebook for this tour, you need:

- An IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 10).
- Basic familiarity with the Studio user interface and Jupyter notebooks. For information, see Amazon SageMaker Studio UI Overview (p. 205).
- A copy of the aws/amazon-sagemaker-examples repository in your Studio environment.

To clone the repository

1. Sign in to Studio. For users in IAM Identity Center, sign in using the URL from your invitation email. For IAM users, follow these steps.
   a. Sign in to the SageMaker console.
   b. Choose Studio in the left navigation pane.
   c. Under Get Started, select your domain and user profile.
   d. Choose Open Studio.
2. On the top menu, choose File, then New, then Terminal.
3. At the command prompt, run the following command to clone the aws/amazon-sagemaker-examples GitHub repository.

   $ git clone https://github.com/aws/amazon-sagemaker-examples.git

To navigate to the sample notebook

1. From the File Browser on the left menu, select amazon-sagemaker-examples.
2. Navigate to the example notebook with the following path.
~/amazon-sagemaker-examples/aws_sagemaker_studio/getting_started/
xgboost_customer_churn_studio.ipynb

3. Follow the notebook to learn about Studio’s main features.

Note
If you encounter an error when you run the sample notebook, and some time has passed from
when you cloned the repository, review the notebook on the remote repository for updates.

Create or Open an Amazon SageMaker Studio Notebook

When you Create a Notebook from the File Menu (p. 226) in Amazon SageMaker Studio or Open
a notebook in Studio (p. 225) for the first time, you are prompted to set up your environment by
choosing a SageMaker image, a kernel, an instance type, and, optionally, a lifecycle configuration script
that runs on image start-up. SageMaker launches the notebook on an instance of the chosen type. By
default, the instance type is set to ml.t3.medium (available as part of the AWS Free Tier) for CPU-based
images. For GPU-based images, the default instance type is ml.g4dn.xlarge.

If you create or open additional notebooks that use the same instance type, whether or not the
notebooks use the same kernel, the notebooks run on the same instance of that instance type.

After you launch a notebook, you can change its instance type, SageMaker image, and kernel from within
the notebook. For more information, see Change an Instance Type (p. 235) and Change an Image or a
Kernel (p. 236).

Note
You can have only one instance of each instance type. Each instance can have multiple
SageMaker images running on it. Each SageMaker image can run multiple kernels or terminal
instances.

Billing occurs per instance and starts when the first instance of a given instance type is launched. If
you want to create or open a notebook without the risk of incurring charges, open the notebook from
the File menu and choose No Kernel from the Select Kernel dialog. You can read and edit a notebook
without a running kernel but you can’t run cells.

Billing ends when the SageMaker image for the instance is shut down. For more information, see Usage
Metering (p. 238).

For information about shutting down the notebook, see Shut Down Resources (p. 237).

Topics
• Open a notebook in Studio (p. 225)
• Create a Notebook from the File Menu (p. 226)
• Create a Notebook from the Launcher (p. 226)
• List of the available instance types, images, and kernels (p. 227)

Open a notebook in Studio

Amazon SageMaker Studio can only open notebooks listed in the Studio file browser. For instructions on
uploading a notebook to the file browser, see Upload Files to SageMaker Studio (p. 287) or Clone a Git
Repository in SageMaker Studio (p. 287).

To open a notebook

1. In the left sidebar, choose the File Browser icon ( ) to display the file browser.
2. Browse to a notebook file and double-click it to open the notebook in a new tab.
Create a Notebook from the File Menu

To create a notebook from the File menu

1. From the Studio menu, choose File, choose New, and then choose Notebook.
2. In the Change environment dialog, use the dropdown menus to select your Image, Kernel, Instance type, and Start-up script, then choose Select. Your notebook launches and opens in a new Studio tab.

Create a Notebook from the Launcher

To create a notebook from the Launcher

1. To open the Launcher, choose Amazon SageMaker Studio at the top left of the Studio interface or use the keyboard shortcut Ctrl + Shift + L.

   To learn about all the available ways to open the Launcher, see Use the Amazon SageMaker Studio Launcher (p. 218)

2. In the Launcher, in the Notebooks and compute resources section, choose Change environment.

3. In the Change environment dialog, use the dropdown menus to select your Image, Kernel, Instance type, and Start-up script, then choose Select.

4. In the Launcher, choose Create notebook. Your notebook launches and opens in a new Studio tab.

To view the notebook’s kernel session, in the left sidebar, choose the Running Terminals and Kernels icon ( ). You can stop the notebook’s kernel session from this view.
List of the available instance types, images, and kernels

For a list of all available resources, see:

- [Available Studio Instance Types](#)
- [Available Amazon SageMaker Images](#)

Use the Studio Notebook Toolbar

Amazon SageMaker Studio notebooks extend the JupyterLab interface. For an overview of the original JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows the toolbar and an empty cell from a Studio notebook.

![Toolbar and empty cell](image)

When you pause on a toolbar icon, a tooltip displays the icon function. Additional notebook commands are found in the Studio main menu. The toolbar includes the following icons:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Save and checkpoint](image) | **Save and checkpoint**  
Saves the notebook and updates the checkpoint file. For more information, see [Get the Difference Between the Last Checkpoint](#). |
| ![Insert cell](image) | **Insert cell**  
Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin. |
| ![Cut, copy, and paste cells](image) | **Cut, copy, and paste cells**  
Cuts, copies, and pastes the selected cells. |
| ![Run cells](image) | **Run cells**  
Runs the selected cells and then makes the cell that follows the last selected cell the new selected cell. |
| ![Interrupt kernel](image) | **Interrupt kernel**  
Interrupts the kernel, which cancels the currently running operation. The kernel remains active. |
| ![Restart kernel](image) | **Restart kernel**  
Restarts the kernel. Variables are reset. Unsaved information is not affected. |
| ![Restart kernel and run all cells](image) | **Restart kernel and run all cells**  
Restarts the kernel, then run all the cells of the notebook. |
### Use Studio Notebooks

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Cell type](image) | **Cell type**  
Displays or changes the current cell type. The cell types are:  
- Code – Code that the kernel runs.  
- Markdown – Text rendered as markdown.  
- Raw – Content, including Markdown markup, that's displayed as text. |
| ![Launch terminal](image) | **Launch terminal**  
Launches a terminal in the SageMaker image hosting the notebook. For an example, see [Get App Metadata](#). |
| ![Checkpoint diff](image) | **Checkpoint diff**  
Opens a new tab that displays the difference between the notebook and the checkpoint file. For more information, see [Get the Difference Between the Last Checkpoint](#). |
| ![Git diff](image) | **Git diff**  
Only enabled if the notebook is opened from a Git repository. Opens a new tab that displays the difference between the notebook and the last Git commit. For more information, see [Get the Difference Between the Last Commit](#). |
| ![2 vCPU + 4 GiB](image) | **Instance type**  
Displays or changes the instance type the notebook runs in. The format is as follows:  
num\text{ber of vCPUs} + \text{amount of memory} + \text{number of GPUs}  
Unknown indicates the notebook was opened without specifying a kernel. The notebook runs on the SageMaker Studio instance and doesn't accrue runtime charges. You can't assign the notebook to an instance type. You must specify a kernel and then Studio assigns the notebook to a default type.  
For more information, see [Create or Open an Amazon SageMaker Studio Notebook](#) and [Change an Instance Type](#). |
| ![Cluster](image) | **Cluster**  
Connect your notebook to an Amazon EMR cluster and scale your ETL jobs or run large-scale model training using Apache Spark, Hive, or Presto.  
For more information, see [Prepare data using Amazon EMR](#). |
<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Python 3 (Data Science)</strong></td>
<td>Kernel and SageMaker Image&lt;br&gt;Displays or changes the kernel that processes the cells in the notebook. The format is as follows:&lt;br&gt;&lt;br&gt;Kernel (SageMaker Image)&lt;br&gt;No Kernel indicates the notebook was opened without specifying a kernel. You can edit the notebook but you can't run any cells.&lt;br&gt;&lt;br&gt;For more information, see [Change an Image or a Kernel](p. 236).</td>
</tr>
<tr>
<td><img src="image" alt="Kernel busy status" /></td>
<td>Kernel busy status&lt;br&gt;Displays the busy status of the kernel. When the edge of the circle and its interior are the same color, the kernel is busy. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of SageMaker Studio.</td>
</tr>
<tr>
<td><img src="image" alt="Share notebook" /></td>
<td>Share notebook&lt;br&gt;Shares the notebook. For more information, see [Share and Use an Amazon SageMaker Studio Notebook](p. 231).</td>
</tr>
</tbody>
</table>

To select multiple cells, click in the left margin outside of a cell. Hold down the Shift key and use K or the Up key to select previous cells, or use J or the Down key to select following cells.

**Install External Libraries and Kernels in Amazon SageMaker Studio**

Amazon SageMaker Studio notebooks come with multiple images already installed. These images contain kernels and Python packages including scikit-learn, Pandas, NumPy, TensorFlow, PyTorch, and MXNet. You can also install your own images that contain your choice of packages and kernels. For more information on installing your own image, see [Bring your own SageMaker image](p. 257).

The different Jupyter kernels in Amazon SageMaker Studio notebooks are separate conda environments. For information about conda environments, see [Managing environments]().

**Package installation tools**

The method that you use to install Python packages from the terminal differs depending on the image. Studio supports the following package installation tools:

- **Notebooks** – The following commands are supported. If one of the following does not work on your image, try the other one.<br>%conda install<br>%pip install
- **The Jupyter terminal** – You can install packages using pip and conda directly. You can also use apt-get install to install system packages from the terminal.

**Note**

We do not recommend using `pip install -u` or `pip install --user`, because those commands install packages on the user's Amazon EFS volume and can potentially block...
JupyterServer app restarts. Instead, use a lifecycle configuration to reinstall the required packages on app restarts as shown in Install packages using lifecycle configurations (p. 231).

We recommend using %pip and %conda to install packages from within a notebook because they correctly take into account the active environment or interpreter being used. For more information, see Add %pip and %conda magic functions. You can also use the system command syntax (lines starting with !) to install packages. For example, !pip install and !conda install.

**Conda**

Conda is an open source package management system and environment management system that can install packages and their dependencies. SageMaker supports using conda with either of these two main channels: the default channel or the conda-forge channel. For more information, see Conda channels.

The conda-forge channel is a community channel where contributors can upload packages.

**Note**

Installing packages from conda-forge can take up to 10 minutes. Timing relates to how conda resolves the dependency graph.

All of the SageMaker provided environments are functional. User installed packages may not function correctly.

Conda has two methods for activating environments: conda activate, and source activate. For more information, see Managing environment.

**Supported conda operations**

- conda install of a package in a single environment
- conda install of a package in all environments
- Installing a package from the main conda repository
- Installing a package from conda-forge
- Changing the conda install location to use Amazon EBS
- Supporting both conda activate and source activate

**Pip**

Pip is the tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike conda, pip doesn't have built in environment support. Therefore, pip isn't as thorough as conda when it comes to packages with native or system library dependencies. Pip can be used to install packages in conda environments. You can use alternative package repositories with pip instead of the PyPI.

**Supported pip operations**

- Using pip to install a package without an active conda environment
- Using pip to install a package in a conda environment
- Using pip to install a package in all conda environments
- Changing the pip install location to use Amazon EBS
- Using an alternative repository to install packages with pip

**Unsupported**

SageMaker aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker and you use the following operations on these packages, it might make your environment unstable:
• Uninstalling
• Downgrading
• Upgrading

Due to potential issues with network conditions or configurations, or the availability of conda or PyPi, packages may not install in a fixed or deterministic amount of time.

Note
Attempting to install a package in an environment with incompatible dependencies can result in a failure. If issues occur, you can contact the library maintainer about updating the package dependencies. When you modify the environment, such as removing or updating existing packages, this may result in instability of that environment.

Install packages using lifecycle configurations

Install custom images and kernels on the Studio instance's Amazon EBS volume so that they persist when you stop and restart the notebook, and that any external libraries you install are not updated by SageMaker. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook (on-create) and a script that runs each time you restart the notebook (on-start). For more information about using lifecycle configurations with Studio, see Use lifecycle configurations with Amazon SageMaker Studio (p. 271). For sample lifecycle configuration scripts, see SageMaker Studio Lifecycle Configuration Samples.

Share and Use an Amazon SageMaker Studio Notebook

You can share your Amazon SageMaker Studio notebooks with your colleagues. The shared notebook is a copy. After you share your notebook, any changes you make to your original notebook aren't reflected in the shared notebook and any changes your colleague's make in their shared copies of the notebook aren't reflected in your original notebook. If you want to share your latest version, you must create a new snapshot and then share it.

Topics
• Share a Notebook (p. 231)
• Use a Shared Notebook (p. 232)
• Shared spaces and realtime collaboration (p. 232)

Share a Notebook

The following screenshot shows the menu from a Studio notebook.

To share a notebook
1. In the upper-right corner of the notebook, choose Share.
2. (Optional) In Create shareable snapshot, choose any of the following items:
• **Include Git repo information** – Includes a link to the Git repository that contains the notebook. This enables you and your colleague to collaborate and contribute to the same Git repository.

• **Include output** – Includes all notebook output that has been saved.

**Note**

If you’re an user in IAM Identity Center and you don’t see these options, your IAM Identity Center administrator probably disabled the feature. Contact your administrator.

3. Choose **Create**.
4. After the snapshot is created, choose **Copy link** and then choose **Close**.
5. Share the link with your colleague.

After selecting your sharing options, you are provided with a URL. You can share this link with users that have access to Amazon SageMaker Studio. When the user opens the URL, they’re prompted to log in using IAM Identity Center or IAM authentication. This shared notebook becomes a copy, so changes made by the recipient will not be reproduced in your original notebook.

**Use a Shared Notebook**

You use a shared notebook in the same way you would with a notebook that you created yourself. You must first login to your account, then open the shared link. If you don’t have an active session, you receive an error.

When you choose a link to a shared notebook for the first time, a read-only version of the notebook opens. To edit the shared notebook, choose **Create a Copy**. This copies the shared notebook to your personal storage.

The copied notebook launches on an instance of the instance type and SageMaker image that the notebook was using when the sender shared it. If you aren’t currently running an instance of the instance type, a new instance is started. Customization to the SageMaker image isn’t shared. You can also inspect the notebook snapshot by choosing **Snapshot Details**.

The following are some important considerations about sharing and authentication:

• If you have an active session, you see a read-only view of the notebook until you choose **Create a Copy**.
• If you don’t have an active session, you need to log in.
• If you use IAM to login, after you login, select your user profile then choose **Open Studio**. Then you need to choose the link you were sent.
• If you use IAM Identity Center to login, after you login the shared notebook is opened automatically in Studio.

**Shared spaces and realtime collaboration**

A shared space consists of a shared JupyterServer application and a shared directory. A key benefit of a shared space is that it facilitates collaboration between members of the shared space in real time. Users collaborating in a workspace get access to a shared Studio application where they can access, read, and edit their notebooks in real time. Real time collaboration is only supported for JupyterServer applications within a shared space. Users with access to a shared space can simultaneously open, view, edit, and execute Jupyter notebooks in the shared Studio application in that space. For more information about shared spaced and real time collaboration, see **Collaborate with shared spaces (p. 28)**.

**Get Studio Notebook and App Metadata**

You can access notebook metadata and App metadata using the Amazon SageMaker Studio UI.
Get Studio Notebook Metadata

Jupyter notebooks contain optional metadata that you can access through the Amazon SageMaker Studio UI.

To view the notebook metadata:

1. In the right sidebar, choose the Property Inspector icon (crowd).
2. Open the Advanced Tools section.

The metadata should look similar to the following.

```
{
  "instance_type": "ml.t3.medium",
  "kernelspec": {
    "display_name": "Python 3 (Data Science)",
    "language": "python",
    "name": "python3__SAGEMAKER_INTERNAL__arn:aws:sagemaker:us-west-2:<acct-id>:image/datascience-1.0"
  },
  "language_info": {
    "codemirror_mode": {
      "name": "ipython",
      "version": 3
    },
    "file_extension": ".py",
    "mimetype": "text/x-python",
    "name": "python",
    "nbconvert_exporter": "python",
    "pygments_lexer": "ipython3",
    "version": "3.7.10"
  }
}
```

Get App Metadata

When you create a notebook in Amazon SageMaker Studio, the App metadata is written to a file named resource-metadata.json in the folder /opt/ml/metadata/. You can get the App metadata by opening an Image terminal from within the notebook. The metadata gives you the following information, which includes the SageMaker image and instance type the notebook runs in:

- **AppType** – KernelGateway
- **DomainId** – Same as the StudioID
- **UserProfileName** – The profile name of the current user
- **ResourceArn** – The Amazon Resource Name (ARN) of the App, which includes the instance type
- **ResourceName** – The name of the SageMaker image

Additional metadata might be included for internal use by Studio and is subject to change.
To get the App metadata

1. In the center of the notebook menu, choose the Launch Terminal icon ( ). This opens a terminal in the SageMaker image that the notebook runs in.

2. Run the following commands to display the contents of the resource-metadata.json file.

   ```
   $ cd /opt/ml/metadata/
   cat resource-metadata.json
   ```

   The file should look similar to the following.

   ```
   {
     "AppType": "KernelGateway",
     "DomainId": "d-xxxxxxxxxxxx",
     "UserProfileName": "profile-name",
     "ResourceName": "datascience--1-0-ml",
     "AppImageVersion": ""
   }
   ```

Get Notebook Differences

You can display the difference between the current notebook and the last checkpoint or the last Git commit using the Amazon SageMaker UI.

The following screenshot shows the menu from a Studio notebook.

Topics

- Get the Difference Between the Last Checkpoint (p. 234)
- Get the Difference Between the Last Commit (p. 235)

Get the Difference Between the Last Checkpoint

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file or revert the notebook to match the checkpoint file.

By default, a notebook is auto-saved every 120 seconds and also when you close the notebook. However, the checkpoint file isn't updated to match the notebook. To save the notebook and update the
checkpoint file to match, you must choose the **Save notebook and create checkpoint** icon ( ![icon] ) on the left of the notebook menu or use the **Ctrl + S** keyboard shortcut.

To view the changes between the notebook and the checkpoint file, choose the **Checkpoint diff** icon ( ![icon] ) in the center of the notebook menu.

To revert the notebook to the checkpoint file, from the main Studio menu, choose **File** then **Revert Notebook to Checkpoint**.

**Get the Difference Between the Last Commit**

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit, choose the **Git diff** icon ( ![icon] ) in the center of the notebook menu.

**Manage Resources**

You can change the instance type, and SageMaker image and kernel from within an Amazon SageMaker Studio notebook. To create a custom kernel to use with your notebooks, see **Bring your own SageMaker image** (p. 257).

**Topics**

- **Change an Instance Type** (p. 235)
- **Change an Image or a Kernel** (p. 236)
- **Shut Down Resources** (p. 237)

**Change an Instance Type**

When you open a new Studio notebook for the first time, you are assigned a default Amazon Elastic Compute Cloud (Amazon EC2) instance type to run the notebook. When you open additional notebooks on the same instance type, the notebooks run on the same instance as the first notebook, even if the notebooks use different kernels.

You can change the instance type that your Studio notebook runs on from within the notebook.

The following information only applies to Studio notebooks. For information about how to change the instance type of a Amazon SageMaker notebook instance, see **Update a Notebook Instance** (p. 322).

**Important**

If you change the instance type, unsaved information and existing settings for the notebook are lost, and installed packages must be re-installed. The previous instance type continues to run even if no kernel sessions or apps are active. You must explicitly stop the instance to stop accruing charges. To stop the instance, see **Shut Down Resources** (p. 237).

The following screenshot shows the menu from a Studio notebook. The processor and memory of the instance type powering the notebook are displayed as **2 vCPU + 4 GiB**.
To change the instance type

1. Choose the processor and memory of the instance type powering the notebook. This opens a pop up window.
2. From the Set up notebook environment pop up window, select the Instance type dropdown menu.
3. From the Instance type dropdown, choose one of the instance types that are listed.
4. After choosing a type, choose Select.
5. Wait for the new instance to become enabled, and then the new instance type information is displayed.

For a list of the available instance types, see Available Studio Instance Types (p. 239).

Change an Image or a Kernel

With Amazon SageMaker Studio notebooks, you can change the notebook's image or kernel from within the notebook.

The following screenshot shows the menu from a Studio notebook. The current SageMaker kernel and image are displayed as Python 3 (Data Science), where Python 3 denotes the kernel and Data Science denotes the SageMaker image that contains the kernel. The color of the circle to the right indicates the kernel is idle or busy. The kernel is busy when the center and the edge of the circle are the same color.

To change a notebook's image or kernel

1. Choose the image/kernel name in the notebook menu.
2. From the Set up notebook environment pop up window, select the Image or Kernel dropdown menu.
3. From the dropdown menu, choose one of the images or kernels that are listed.
4. After choosing an image or kernel, choose Select.
5. Wait for the kernel's status to show as idle, which indicates the kernel has started.

For a list of available SageMaker images and kernels, see Available Amazon SageMaker Images (p. 244).
Shut Down Resources

You can shut down individual resources, including notebooks, terminals, kernels, apps, and instances. You can also shut down all resources in one of these categories at the same time.

**Note**
Amazon SageMaker Studio does not support shutting down resources from within a notebook.

**Topics**
- Shut Down an Open Notebook (p. 237)
- Shut Down Resources (p. 237)

**Shut Down an Open Notebook**

You can shut down an open notebook from the Amazon SageMaker Studio File menu or from the Running Terminal and Kernels pane.

**Note**
When you shut down a notebook, any unsaved information in the notebook is lost. The notebook is not deleted.

**To shut down an open notebook from the File menu**

1. Optionally, save the notebook contents by choosing the Disk icon on the left of the notebook menu.
2. Choose File then Close and Shutdown Notebook.
3. Choose OK.

**Shut Down Resources**

You can reach the Running Terminals and Kernels pane on the left side of Amazon SageMaker Studio with the icon. The Running Terminals and Kernels pane consists of four sections. Each section lists all the resources of that type. You can shut down each resource individually or shut down all the resources in a section at the same time.

![Image](image.png)

When you choose to shut down all resources in a section, the following occurs:

- **RUNNING INSTANCES/RUNNING APPS** – All instances, apps, notebooks, kernel sessions, consoles/shells, and image terminals are shut down. System terminals aren't shut down.
Note
When you shutdown the Studio notebook instances, any additional resources, such as SageMaker endpoints, Amazon EMR clusters, and Amazon S3 buckets created from Studio are not deleted. Delete those resources to stop accrual of charges.

- KERNEL SESSIONS – All kernels, notebooks and consoles/shells are shut down.
- TERMINAL SESSIONS – All image terminals and system terminals are shut down.

To shut down resources

1. In the left sidebar, choose the Running Terminals and Kernels icon ( ◦ ).
2. Do either of the following:
   - To shut down a specific resource, choose the Shut Down icon ( ◦ ) on the same row as the resource.

   For running instances, a confirmation dialog lists all the resources that will be shut down. For running apps, a confirmation dialog is displayed. Choose Shut down all to proceed.

   Note
   No confirmation dialog is displayed for kernel sessions or terminal sessions.
   - To shut down all resources in a section, choose the X to the right of the section label. A confirmation dialog is displayed. Choose Shut down all to proceed.

Usage Metering

There is no additional charge for using Amazon SageMaker Studio. The costs incurred for running Amazon SageMaker Studio notebooks, interactive shells, consoles, and terminals are based on Amazon Elastic Compute Cloud (Amazon EC2) instance usage.

When you run the following resources, you must choose a SageMaker image and kernel:

From the Studio Launcher

- Notebook
- Interactive Shell
- Image Terminal

From the File menu

- Notebook
- Console

When launched, the resource is run on an Amazon EC2 instance of the chosen instance type. If an instance of that type was previously launched and is available, the resource is run on that instance.

For CPU based images, the default suggested instance type is ml.t3.medium. For GPU based images, the default suggested instance type is ml.g4dn.xlarge.

The costs incurred are based on the instance type. You are billed separately for each instance.
Metering starts when an instance is created. Metering ends when all the apps on the instance are shut down, or the instance is shut down. For information about how to shut down an instance, see Shut Down Resources (p. 237).

**Important**

You must shut down the instance to stop incurring charges. If you shut down the notebook running on the instance but don’t shut down the instance, you will still incur charges. When you shutdown the Studio notebook instances, any additional resources, such as SageMaker endpoints, Amazon EMR clusters, and Amazon S3 buckets created from Studio are not deleted. Delete those resources to stop accrual of charges.

When you open multiple notebooks on the same instance type, the notebooks run on the same instance even if they are using different kernels. You are billed only for the time that one instance is running.

You can change the instance type from within the notebook after you open it. For more information, see Change an Instance Type (p. 235).

For information about billing along with pricing examples, see Amazon SageMaker Pricing.

### Available Resources

The following sections list the available resources for Amazon SageMaker Studio notebooks.

**Topics**

- Available Studio Instance Types (p. 239)
- Available Amazon SageMaker Images (p. 244)

### Available Studio Instance Types

Amazon SageMaker Studio notebooks run on Amazon Elastic Compute Cloud (Amazon EC2) instances. The following Amazon EC2 instance types are available for use with Studio notebooks. For detailed information on which instance types fit your use case, and their performance capabilities, see Amazon Elastic Compute Cloud Instance types. For information about pricing for these instance types, see Amazon EC2 Pricing.

For information about available Amazon SageMaker Notebook Instance types, see CreateNotebookInstance.

**Note**

For most use cases, you should use a ml.t3.medium. This is the default instance type for CPU-based SageMaker images, and is available as part of the AWS Free Tier.

**Topics**

- CPU instances (p. 239)
- Instances with 1 or more GPUs (p. 242)

### CPU instances

The following table lists the Amazon EC2 CPU instance types with no GPU attached that are available for use with Studio notebooks. It also lists information about the specifications of each instance type. The default instance type for CPU-based images is ml.t3.medium.

For detailed information on which instance types fit your use case, and their performance capabilities, see Amazon Elastic Compute Cloud Instance types. For information about pricing for these instance types, see Amazon EC2 Pricing.

**Note**

Fast launch instances types are optimized to start in under two minutes.

**Available Amazon SageMaker Images**

This page lists the SageMaker images and associated kernels that are available in Amazon SageMaker Studio, as well as the format needed to create the ARN for each image. SageMaker images contain the latest Amazon SageMaker Python SDK and the latest version of the kernel. For more information, see [Deep Learning Containers Images](https://docs.aws.amazon.com/sagemaker/latest/dg/deeplearning-containers-images.html).

**Topics**

- [Image ARN format (p. 245)](https://docs.aws.amazon.com/sagemaker/latest/dg/deeplearning-containers-images.html#arn-format)
- [Supported images (p. 246)](https://docs.aws.amazon.com/sagemaker/latest/dg/deeplearning-containers-images.html#supported-images)
Images slated for deprecation (p. 254)

Image ARN format

The following table lists the image ARN format for each Region. To create the full ARN for an image, replace the `resource-identifier` placeholder with the corresponding resource identifier for the image from the SageMaker images and kernels table.

**Note**

SageMaker Distribution images use a distinct set of image ARNs.

<table>
<thead>
<tr>
<th>Region</th>
<th>Image ARN Format</th>
<th>SageMaker Distribution Image ARN Format</th>
</tr>
</thead>
</table>
### Supported images

The following table gives information about the SageMaker images and associated kernels that are available in Amazon SageMaker Studio, as well as the resource identifier and Python version included in the image.

<table>
<thead>
<tr>
<th>Region</th>
<th>Image ARN 1</th>
<th>Image ARN 2</th>
</tr>

Images slated for deprecation

SageMaker ends support for images the day after any of the packages in the image reach end-of-life by their publisher.

The following SageMaker images are slated for deprecation. These images are based on Python 3.7, which reached end-of-life on June 27, 2023. Starting on October 30, 2023, SageMaker will discontinue support for these images and they will not be selectable from the Studio UI. To avoid non-compliance issues, if you're using any of these images, we recommend that you move to an image with a later version.

### Customize Amazon SageMaker Studio

There are four options for customizing your Amazon SageMaker Studio environment. You bring your own SageMaker image, use a lifecycle configuration script, attach suggested Git repos to Studio, or create kernels using persistent Conda environments in Amazon EFS. Use each option individually, or together.

- **Bring your own SageMaker image:** A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio. Amazon SageMaker provides many built-in images for you to use. If you need different functionality, you can bring your own custom images to Studio.

- **Use lifecycle configurations with Amazon SageMaker Studio:** Lifecycle configurations are shell scripts triggered by Amazon SageMaker Studio lifecycle events, such as starting a new Studio notebook. You can use lifecycle configurations to automate customization for your Studio environment. For example, you can install custom packages, configure notebook extensions, preload datasets, and set up source code repositories.

- **Attach suggested Git repos to Studio:** You can attach suggested Git repository URLs at the Amazon SageMaker Domain or user profile level. Then, you can select the repo URL from the list of suggestions and clone that into your environment using the Git extension in Studio.
• **Persist Conda environments to the Studio Amazon EFS volume:** Studio uses an Amazon EFS volume as a persistent storage layer. You can save your Conda environment on this Amazon EFS volume, then use the saved environment to create kernels. Studio automatically picks up all valid environments saved in Amazon EFS as KernelGateway kernels. These kernels persist through restart of the kernel, app, and Studio. For more information, see the **Persist Conda environments to the Studio EFS volume** section in Four approaches to manage Python packages in Amazon SageMaker Studio notebooks.

The following topics show how to use these three options to customize your Amazon SageMaker Studio environment.

**Topics**
- Bring your own SageMaker image (p. 257)
- Use lifecycle configurations with Amazon SageMaker Studio (p. 271)
- Attach Suggested Git Repos to Studio (p. 283)

**Bring your own SageMaker image**

A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio. These images are used to create an environment that you then run Jupyter notebooks from. Amazon SageMaker provides many built-in images for you to use. For the list of built-in images, see Available Amazon SageMaker Images (p. 244).

If you need different functionality, you can bring your own custom images to Studio. You can create images and image versions, and attach image versions to your domain or shared space, using the SageMaker control panel, the AWS SDK for Python (Boto3), and the AWS Command Line Interface (AWS CLI). You can also create images and image versions using the SageMaker console, even if you haven’t onboarded to a SageMaker domain. SageMaker provides sample Dockerfiles to use as a starting point for your custom SageMaker images in the SageMaker Studio Custom Image Samples repository.

The following topics explain how to bring your own image using the SageMaker console or AWS CLI, then launch the image in Studio. For a similar blog article, see Bringing your own R environment to Amazon SageMaker Studio. For notebooks that show how to bring your own image for use in training and inference, see Amazon SageMaker Studio Container Build CLI.

**Key terminology**

The following section defines key terms for bringing your own image to use with Studio.

- **Dockerfile:** A Dockerfile is a file that identifies the language packages and other dependencies for your Docker image.
- **Docker image:** The Docker image is a built Dockerfile. This image is checked into Amazon ECR and serves as the basis of the SageMaker image.
- **SageMaker image:** A SageMaker image is a holder for a set of SageMaker image versions based on Docker images. Each image version is immutable.
- **Image version:** An image version of a SageMaker image represents a Docker image and is stored in an Amazon ECR repository. Each image version is immutable. These image versions can be attached to a domain or shared space and used with Studio.

**Topics**
- Custom SageMaker image specifications (p. 258)
- Prerequisites (p. 259)
- Add a Docker image compatible with Studio to Amazon ECR (p. 259)
• **Create a custom SageMaker image** (p. 260)
  • **Attach a custom SageMaker image** (p. 263)
  • **Launch a custom SageMaker image in Amazon SageMaker Studio** (p. 268)
  • **Clean up resources** (p. 269)

**Custom SageMaker image specifications**

The following specifications apply to the container image that is represented by a SageMaker image version.

**Running the image**

ENTRYPOINT and CMD instructions are overridden to enable the image to run as a KernelGateway app.

Port 8888 in the image is reserved for running the KernelGateway web server.

**Stopping the image**

The DeleteApp API issues the equivalent of a `docker stop` command. Other processes in the container won’t get the SIGKILL/SIGTERM signals.

**Kernel discovery**

SageMaker recognizes kernels as defined by Jupyter kernel specs.

You can specify a list of kernels to display before running the image. If not specified, python3 is displayed. Use the DescribeAppImageConfig API to view the list of kernels.

Conda environments are recognized as kernel specs by default.

**File system**

The `/opt/.sagemakerinternal` and `/opt/ml` directories are reserved. Any data in these directories might not be visible at runtime.

**User data**

Each user in a domain gets a user directory on a shared Amazon Elastic File System volume in the image. The location of the current user's directory on the Amazon EFS volume is configurable. By default, the location of the directory is `/home/sagemaker-user`.

SageMaker configures POSIX UID/GID mappings between the image and the host. This defaults to mapping the root user's UID/GID (0/0) to the UID/GID on the host.

You can specify these values using the CreateAppImageConfig API.

**GID/UID limits**

Amazon SageMaker Studio only supports the following DefaultUID and DefaultGID combinations:

- DefaultUID: 1000 and DefaultGID: 100, which corresponds to a non-privileged user.
- DefaultUID: 0 and DefaultGID: 0, which corresponds to root access.

**Metadata**

A metadata file is located at `/opt/ml/metadata/resource-metadata.json`. No additional environment variables are added to the variables defined in the image. For more information, see Get App Metadata (p. 233).

**GPU**

On a GPU instance, the image is run with the `--gpus` option. Only the CUDA toolkit should be included in the image not the NVIDIA drivers. For more information, see NVIDIA User Guide.
Metrics and logging

Logs from the KernelGateway process are sent to Amazon CloudWatch in the customer's account. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

Image size

Limited to 25 GB. To view the size of your image, run `docker image ls`.

Sample Dockerfile

The following sample Dockerfile creates an image based Amazon Linux 2, installs third party packages and the python3 kernel, and sets the scope to the non-privileged user.

```bash
FROM public.ecr.aws/amazonlinux/amazonlinux:2
ARG NB_USER="sagemaker-user"
ARG NB_UID="1000"
ARG NB_GID="100"
RUN \
    yum install --assumeyes python3 shadow-utils && \
    useradd --create-home --shell /bin/bash --gid "${NB_GID}" --uid ${NB_UID} ${NB_USER} && \
    yum clean all && \
    python3 -m pip install ipykernel && \
    python3 -m ipykernel install
USER ${NB_UID}
```

Prerequisites

You must satisfy the following prerequisites to bring your own container for use with Amazon SageMaker Studio.

- The Docker application. For information about setting up Docker, see Orientation and setup.
- Install the AWS CLI by following the steps in Getting started with the AWS CLI.
- A local copy of any Dockerfile for creating a Studio compatible image. For sample custom images, see the SageMaker Studio custom image samples repository.
- Permissions to access the Amazon Elastic Container Registry (Amazon ECR) service. For more information, see Amazon ECR Managed Policies.
- An AWS Identity and Access Management execution role that has the AmazonSageMakerFullAccess policy attached. If you have onboarded to Amazon SageMaker domain, you can get the role from the Domain Summary section of the SageMaker control panel.
- Install the Studio image build CLI by following the steps in SageMaker Docker Build. This CLI enables you to build a Dockerfile using AWS CodeBuild.

Add a Docker image compatible with Studio to Amazon ECR

You perform the following steps to add a container image to Amazon ECR:

- Create an Amazon ECR repository.
- Authenticate to Amazon ECR.
- Build a Docker image compatible with Studio.
- Push the image to the Amazon ECR repository.
**Note**
The Amazon ECR repository must be in the same AWS Region as Studio.

**To build and add a container image to Amazon ECR**

1. Create an Amazon ECR repository using the AWS CLI. To create the repository using the Amazon ECR console, see [Creating a repository](#).

```bash
aws ecr create-repository
   --repository-name smstudio-custom
   --image-scanning-configuration scanOnPush=true
```

   The response should look similar to the following.

```json
{
   "repository": {
      "repositoryArn": "arn:aws:ecr:us-east-2:acct-id:repository/smstudio-custom",
      "registryId": "acct-id",
      "repositoryName": "smstudio-custom",
      "repositoryUri": "acct-id.dkr.ecr.us-east-2.amazonaws.com/smstudio-custom",
      ...
   }
}
```

2. Build the Dockerfile using the Studio image build CLI. The period (.) specifies that the Dockerfile should be in the context of the build command. This command builds the image and uploads the built image to the ECR repo. It then outputs the image URI.

```bash
sm-docker build . --repository smstudio-custom:custom
```

   The response should look similar to the following.

```
Image URI: <acct-id>.dkr.ecr.<region>.amazonaws.com/<image_name>
```

**Create a custom SageMaker image**

This topic describes how you can create a custom SageMaker image using the SageMaker console or AWS CLI.

When you create an image from the console, SageMaker also creates an initial image version. The image version represents a container image in Amazon Elastic Container Registry (ECR). The container image must satisfy the requirements to be used in Amazon SageMaker Studio. For more information, see [Custom SageMaker image specifications](p. 258). For information on testing your image locally and resolving common issues, see the [SageMaker Studio Custom Image Samples repo](p. 258).

After you have created your custom SageMaker image, you must attach it to your domain or shared space to use it with Studio. For more information, see [Attach a custom SageMaker image](p. 263).

**Create a SageMaker image from the console**

The following section demonstrates how to create a custom SageMaker image from the SageMaker console.

**To create an image**

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Images**.
4. On the **Custom images** page, choose **Create image**.
5. For **Image source**, enter the registry path to the container image in Amazon ECR. The path is in the following format:

```
acct-id.dkr.ecr.region.amazonaws.com/repo-name[:tag] or [@digest]
```

6. Choose **Next**.
7. Under **Image properties**, enter the following:
   - Image name – The name must be unique to your account in the current AWS Region.
   - (Optional) Display name – The name displayed in the Studio user interface. When not provided, Image name is displayed.
   - (Optional) Description – A description of the image.
   - IAM role – The role must have the `AmazonSageMakerFullAccess` policy attached. Use the dropdown menu to choose one of the following options:
     - Create a new role – Specify any additional Amazon Simple Storage Service (Amazon S3) buckets that you want users of your notebooks to have access to. If you don't want to allow access to additional buckets, choose **None**. SageMaker attaches the `AmazonSageMakerFullAccess` policy to the role. The role allows users of your notebooks access to the S3 buckets listed next to the checkmarks.
     - Enter a custom IAM role ARN – Enter the Amazon Resource Name (ARN) of your IAM role.
     - Use existing role – Choose one of your existing roles from the list.
   - (Optional) Image tags – Choose **Add new tag**. You can add up to 50 tags. Tags are searchable using the Studio user interface, the SageMaker console, or the SageMaker Search API.
8. Choose **Submit**.

The new image is displayed in the **Custom images** list and briefly highlighted. After the image has been successfully created, you can choose the image name to view its properties or choose **Create version** to create another version.

**To create another image version**

1. Choose **Create version** on the same row as the image.
2. For **Image source**, enter the registry path to the Amazon ECR container image. The container image shouldn't be the same image as used in a previous version of the SageMaker image.

**Create a SageMaker image from the AWS CLI**

You perform the following steps to create a SageMaker image from the container image using the AWS CLI.

- Create an Image.
- Create an ImageVersion.
- Create a configuration file.
- Create an AppImageConfig.

**To create the SageMaker image entities**

1. Create a SageMaker image.
aws sagemaker create-image \
   --image-name custom-image \
   --role-arn arn:aws:iam::<acct-id>::role/service-role/<execution-role>

The response should look similar to the following.

```json
{
   "ImageArn": "arn:aws:sagemaker:us-east-2:acct-id:image/custom-image"
}
```

2. Create a SageMaker image version from the container image.

```shell
aws sagemaker create-image-version \
   --image-name custom-image \
   --base-image <acct-id>.dkr.ecr.<region>.amazonaws.com/smstudio-custom:custom-image
```

The response should look similar to the following.

```json
{
   "ImageVersionArn": "arn:aws:sagemaker:us-east-2:acct-id:image-version/custom-image/1"
}
```

3. Check that the image version was successfully created.

```shell
aws sagemaker describe-image-version \
   --image-name custom-image \
   --version-number 1
```

The response should look similar to the following.

```json
{
   "ImageVersionStatus": "CREATED"
}
```

**Note**

If the response is "ImageVersionStatus": "CREATED_FAILED", the response also includes the failure reason. A permissions issue is a common cause of failure. You also can check your Amazon CloudWatch logs if you experience a failure when starting or running the KernelGateway app for a custom image. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

4. Create a configuration file, named app-image-config-input.json. The Name value of KernelSpecs must match the name of the kernelSpec available in the image associated with this AppImageConfig. This value is case sensitive. You can find the available kernelSpecs in an image by running `jupyter-kernelspec list` from a shell inside the container. MountPath is the path within the image to mount your Amazon Elastic File System (Amazon EFS) home directory. It needs to be different from the path you use inside the container because that path will be overridden when your Amazon EFS home directory is mounted.

**Note**

The following DefaultUID and DefaultGID combinations are the only accepted values:

- DefaultUID: 1000 and DefaultGID: 100
Customize Studio

• DefaultUID: 0 and DefaultGID: 0

```
{
  "AppImageConfigName": "custom-image-config",
  "KernelGatewayImageConfig": {
    "KernelSpecs": [
      {
        "Name": "python3",
        "DisplayName": "Python 3 (ipykernel)"
      }
    ],
    "FileSystemConfig": {
      "MountPath": "/home/sagemaker-user",
      "DefaultUid": 1000,
      "DefaultGid": 100
    }
  }
}
```

5. Create the AppImageConfig using the file created in the previous step.

```
aws sagemaker create-app-image-config \
  --cli-input-json file://app-image-config-input.json
```

The response should look similar to the following.

```
{
}
```

### Attach a custom SageMaker image

To use a custom SageMaker image, you must attach a version of the image to your domain or shared space. When you attach an image version, it appears in the SageMaker Studio Launcher and is available in the **Select image** dropdown list, which users use to launch an activity or change the image used by a notebook.

To make a custom SageMaker image available to all users within a domain, you attach the image to the domain. To make an image available to all users within a shared space, you can attach the image to the shared space. To make an image available to a single user, you attach the image to the user's profile. When you attach an image, SageMaker uses the latest image version by default. You can also attach a specific image version. After you attach the version, you can choose the version from the SageMaker Launcher or the image selector when you launch a notebook.

There is a limit to the number of image versions that can be attached at any given time. After you reach the limit, you must detach a version in order to attach another version of the image.

The following sections demonstrate how to attach a custom SageMaker image to your domain using either the SageMaker console or the AWS CLI. You can only attach a custom image to a share space using the AWS CLI.

**Attach the SageMaker image to a Domain**

**Attach the SageMaker image using the Console**

This topic describes how you can attach an existing custom SageMaker image version to your domain using the SageMaker control panel. You can also create a custom SageMaker image and image version,
and then attach that version to your domain. For the procedure to create an image and image version, see Create a custom SageMaker image (p. 260).

To attach an existing image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the Domains page, select the Domain to attach the image to.
5. From the Domain details page, select the Environment tab.
6. On the Environment tab, under Custom SageMaker Studio images attached to domain, choose Attach image.
7. For Image source, choose Existing image.
8. Choose an existing image from the list.
9. Choose a version of the image from the list.
10. Choose Next.
11. Verify the values for Image name, Image display name, and Description.
12. Choose the IAM role. For more information, see Create a custom SageMaker image (p. 260).
13. (Optional) Add tags for the image.
14. Specify the EFS mount path. This is the path within the image to mount the user’s Amazon Elastic File System (EFS) home directory.
15. For Image type, select SageMaker Studio image
16. For Kernel name, enter the name of an existing kernel in the image. For information on how to get the kernel information from the image, see DEVELOPMENT in the SageMaker Studio Custom Image Samples repository. For more information, see the Kernel discovery and User data sections of Custom SageMaker image specifications (p. 258).
17. (Optional) For Kernel display name, enter the display name for the kernel.
18. Choose Add kernel.
19. Choose Submit.

   • Wait for the image version to be attached to the domain. When attached, the version is displayed in the Custom images list and briefly highlighted.

Attach the SageMaker image using the AWS CLI

The following sections demonstrate how to attach a custom SageMaker image when creating a new domain or updating your existing domain using the AWS CLI.

Attach the SageMaker image to a new domain

The following section demonstrates how to create a new domain with the version attached. These steps require that you specify the Amazon Virtual Private Cloud (VPC) information and execution role required to create the domain. You perform the following steps to create the domain and attach the custom SageMaker image:

   • Get your default VPC ID and subnet IDs.
   • Create the configuration file for the domain, which specifies the image.
   • Create the domain with the configuration file.

To add the custom SageMaker image to your domain

1. Get your default VPC ID.
The response should look similar to the following.

vpc-xxxxxxxx

2. Get your default subnet IDs using the VPC ID from the previous step.

```bash/aws ec2 describe-subnets \
--filters Name=vpc-id,Values=<vpc-id> \
--query "Subnets[*].SubnetId" --output json
```

The response should look similar to the following.

```json
[
  "subnet-b55171dd",
  "subnet-8a5f99c6",
  "subnet-e88d1392"
]
```

3. Create a configuration file named `create-domain-input.json`. Insert the VPC ID, subnet IDs, `ImageName`, and `AppImageConfigName` from the previous steps. Because `ImageVersionNumber` isn't specified, the latest version of the image is used, which is the only version in this case.

```json
{
  "DomainName": "domain-with-custom-image",
  "VpcId": "<vpc-id>",
  "SubnetIds": [
    "<subnet-ids>"
  ],
  "DefaultUserSettings": {
    "ExecutionRole": "<execution-role>",
    "KernelGatewayAppSettings": {
      "CustomImages": [
        {
          "ImageName": "custom-image",
          "AppImageConfigName": "custom-image-config"
        }
      ]
    },
    "AuthMode": "IAM"
  }
}
```

4. Create the domain with the attached custom SageMaker image.

```bash
/aws sagemaker create-domain \
--cli-input-json file://create-domain-input.json
```

The response should look similar to the following.

```json
{
  "Url": "https://d-xxxxxxxxxxxx.studio.us-east-2.sagemaker.aws/..."
}
```
Attach the SageMaker image to your current domain

If you have onboarded to a SageMaker domain, you can attach the custom image to your current domain. For more information about onboarding to a SageMaker domain, see Onboard to Amazon SageMaker Domain (p. 10). You don't need to specify the VPC information and execution role when attaching a custom image to your current domain. After you attach the version, you must delete all the apps in your domain and reopen Studio. For information about deleting the apps, see Delete an Amazon SageMaker Domain (p. 21).

You perform the following steps to add the SageMaker image to your current domain.

- Get your DomainID from SageMaker control panel.
- Use the DomainID to get the DefaultUserSettings for the domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultUserSettings.
- Update your domain to include the custom image.

To add the custom SageMaker image to your domain

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the Domains page, select the Domain to attach the image to.
5. From the Domain details page, select the Domain settings tab.
6. From the Domain settings tab, under General settings, find the DomainId. The ID is in the following format: d-xxxxxxxxxxxx.
7. Use the domain ID to get the description of the domain.

```bash
aws sagemaker describe-domain \
   --domain-id <d-xxxxxxxxxxxx>
```

The response should look similar to the following.

```json
{
   "DomainId": "d-xxxxxxxxxxxx",
   "DefaultUserSettings": {
      "KernelGatewayAppSettings": {
         "CustomImages": [
         ],
      },
      ...
   }
}
```

8. Save the default user settings section of the response to a file named default-user-settings.json.
9. Insert the ImageName and AppImageConfigName from the previous steps as a custom image. Because ImageVersionNumber isn't specified, the latest version of the image is used, which is the only version in this case.

```json
{
   "DefaultUserSettings": {
      "KernelGatewayAppSettings": {
         "CustomImages": [
         {
            "ImageName": "string",
```
10. Use the domain ID and default user settings file to update your domain.

```bash
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-user-settings.json
```

The response should look similar to the following.

```json
{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

**Attach the SageMaker image to a shared space**

You can only attach the SageMaker image to a shared space using the AWS CLI. After you attach the version, you must delete all of the applications in your shared space and reopen Studio. For information about deleting the apps, see [Delete an Amazon SageMaker Domain](p. 21).

You perform the following steps to add the SageMaker image to a shared space.

- Get your DomainID from SageMaker control panel.
- Use the DomainID to get the DefaultSpaceSettings for the domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultSpaceSettings.
- Update your domain to include the custom image for the shared space.

**To add the custom SageMaker image to your shared space**

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the Domains page, select the Domain to attach the image to.
5. From the Domain details page, select the Domain settings tab.
6. From the Domain settings tab, under General settings, find the DomainId. The ID is in the following format: d-xxxxxxxxxxxx.
7. Use the domain ID to get the description of the domain.

```bash
aws sagemaker describe-domain \
  --domain-id <d-xxxxxxxxxxxx>
```

The response should look similar to the following.

```json
{
  "DomainId": "d-xxxxxxxxxxxx",
  ...
  "DefaultSpaceSettings": {
    "KernelGatewayAppSettings": {
```

"AppImageConfigName": "string"
]}
...}
}
}
8. Save the default space settings section of the response to a file named default-space-settings.json.

9. Insert the ImageName and AppImageConfigName from the previous steps as a custom image. Because ImageVersionNumber isn't specified, the latest version of the image is used, which is the only version in this case.

```
{
  "DefaultSpaceSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [
        {
          "ImageName": "string",
          "AppImageConfigName": "string"
        },
        ...
      ]
    }
  }
}
```

10. Use the domain ID and default space settings file to update your domain.

```
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-space-settings.json
```

The response should look similar to the following.

```
{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

**View the attached image in SageMaker**

After you create the custom SageMaker image and attach it to your domain, the image appears in the Environment tab of the Domain. You can only view the attached images for shared spaces using the AWS CLI by using the following command.

```
aws sagemaker describe-domain \
  --domain-id <d-xxxxxxxxxxxx>
```

**Launch a custom SageMaker image in Amazon SageMaker Studio**

After you create your custom SageMaker image and attach it to your domain or shared space, the custom image and kernel appear in selectors in the Change environment dialog box of the Studio Launcher.

**To launch and select your custom image and kernel**

1. In Amazon SageMaker Studio, open the Launcher. To open the Launcher, choose Amazon SageMaker Studio at the top left of the Studio interface or use the keyboard shortcut Ctrl + Shift + L.
To learn about all the available ways to open the Launcher, see Use the Amazon SageMaker Studio Launcher (p. 218)

2. In the Launcher, in the Notebooks and compute resources section, choose Change environment.
3. In the Change environment dialog, use the dropdown menus to select your Image from the Custom Image section, and your Kernel, then choose Select.
4. In the Launcher, choose Create notebook or Open image terminal. Your notebook or terminal launches in the selected custom image and kernel.

To change your image or kernel in an open notebook, see Change an Image or a Kernel (p. 236).

Note
If you encounter an error when launching the image, check your Amazon CloudWatch logs. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

Clean up resources

The following sections show how to clean up the resources you created in the previous sections from the SageMaker console or AWS CLI. You perform the following steps to clean up the resources:

- Detach the image and image versions from your domain.
- Delete the image, image version, and app image config.
- Delete the container image and repository from Amazon ECR. For more information, see Deleting a repository.

Clean up resources from the SageMaker console

The following section shows how to clean up resources from the SageMaker console.

When you detach an image from a domain, all versions of the image are detached. When an image is detached, all users of the domain lose access to the image versions. A running notebook that has a kernel session on an image version when the version is detached, continues to run. When the notebook is stopped or the kernel is shut down, the image version becomes unavailable.

To detach an image
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Images**.
4. Under **Custom SageMaker Studio images attached to domain**, choose the image and then choose **Detach**.
5. (Optional) To delete the image and all versions from SageMaker, select **Also delete the selected images**. This does not delete the associated container images from Amazon ECR.
6. Choose **Detach**.

**Clean up resources from the AWS CLI**

The following section shows how to clean up resources from the AWS CLI.

**To clean up resources**

1. Detach the image and image versions from your domain by passing an empty custom image list to the domain. Open the `default-user-settings.json` file you created in **Attach the SageMaker image to your current domain** (p. 266). To detach the image and image version from a shared space, open the `default-space-settings.json` file.
2. Delete the custom images and then save the file.

```
"DefaultUserSettings": {
    "KernelGatewayAppSettings": {
        "CustomImages": [],
        "...
        "...
    }
}
```
3. Use the domain ID and default user settings file to update your domain. To update your shared space, use the default space settings file.

   ```
   aws sagemaker update-domain \
   --domain-id <d-xxxxxxxxxxxx> \
   --cli-input-json file://default-user-settings.json
   ```

   The response should look similar to the following.

   ```
   {
    "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
   }
   ```

4. Delete the app image config.

   ```
   aws sagemaker delete-app-image-config \
   --app-image-config-name custom-image-config
   ```

5. Delete the SageMaker image, which also deletes all image versions. The container images in ECR that are represented by the image versions are not deleted.

   ```
   aws sagemaker delete-image \
   --image-name custom-image
   ```
Use lifecycle configurations with Amazon SageMaker Studio

Lifecycle configurations are shell scripts triggered by Amazon SageMaker Studio lifecycle events, such as starting a new Studio notebook. You can use lifecycle configurations to automate customization for your Studio environment. This customization includes installing custom packages, configuring notebook extensions, preloading datasets, and setting up source code repositories.

Using lifecycle configurations gives you flexibility and control to configure Studio to meet your specific needs. For example, you can create a minimal set of base container images with the most commonly used packages and libraries, then use lifecycle configurations to install additional packages for specific use cases across your data science and machine learning teams.

For example lifecycle configuration scripts, see the Studio Lifecycle Configuration examples GitHub repository. For a blog on implementing lifecycle configuration, see Customize Amazon SageMaker Studio using Lifecycle Configurations.

Note
Each script has a limit of 16384 characters.

Topics
- Create and associate a lifecycle configuration (p. 271)
- Set default lifecycle configurations (p. 276)
- Debug lifecycle configurations (p. 280)
- Update and detach lifecycle configurations (p. 282)

Create and associate a lifecycle configuration

Amazon SageMaker provides interactive applications that enable Studio's visual interface, code authoring, and run experience. This series shows how to create a lifecycle configuration and associate it with a SageMaker domain.

Application types can be either JupyterServer or KernelGateway.

- JupyterServer applications: This application type enables access to the visual interface for Studio. Every user and shared space in Studio gets its own JupyterServer application.
- KernelGateway applications: This application type enables access to the code run environment and kernels for your Studio notebooks and terminals. For more information, see Jupyter Kernel Gateway.

For more information about Studio's architecture and Studio applications, see Use Amazon SageMaker Studio Notebooks.

Topics
- Create a lifecycle configuration from the AWS CLI (p. 271)
- Create a lifecycle configuration from the SageMaker console (p. 274)

Create a lifecycle configuration from the AWS CLI

The following topic shows how to create a lifecycle configuration using the AWS CLI to automate customization for your Studio environment.

Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
Customize Studio

- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.
- Onboard to SageMaker domain by following the steps in Onboard to Amazon SageMaker Domain (p. 10).

Step 1: Create a lifecycle configuration

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

**Note**
Each script can have up to 16,384 characters.

1. From your local machine, create a file named `my-script.sh` with the following content.

   ```bash
   #!/bin/bash
   set -eux
   echo 'Hello World!'
   ``

2. Convert your `my-script.sh` file into base64 format. This requirement prevents errors that occur from spacing and line break encoding.

   ```bash
   LCC_CONTENT=`openssl base64 -A -in my-script.sh`
   ``

3. Create a lifecycle configuration for use with Studio. The following command creates a lifecycle configuration that runs when you launch an associated KernelGateway application.

   ```bash
   aws sagemaker create-studio-lifecycle-config \
   --region region \
   --studio-lifecycle-config-name my-studio-lcc \
   --studio-lifecycle-config-content "$LCC_CONTENT" \
   --studio-lifecycle-config-app-type KernelGateway
   ``

   Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

Step 2: Attach the lifecycle configuration to your domain, user profile, or shared space

To attach the lifecycle configuration, you must update the UserSettings for your domain or user profile, or the SpaceSettings for a shared space. Lifecycle configuration scripts that are associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user, while scripts that are associated at the shared space level are scoped to the shared space.

The following example shows how to create a new user profile with the lifecycle configuration attached. You can also create a new domain or space with a lifecycle configuration attached by using the `create-domain` and `create-space` commands, respectively.

Add the lifecycle configuration ARN from the previous step to the settings for the appropriate app type. For example, place it in the JupyterServerAppSettings of the user. You can add multiple lifecycle configurations at the same time by passing a list of lifecycle configurations. When a user launches a JupyterServer application with the AWS CLI, they can pass a lifecycle configuration to use instead of the default. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in JupyterServerAppSettings.

```bash
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
   --user-profile-name user-profile-name \
```

272
The following example shows how to update an existing shared space to attach the lifecycle configuration. You can also update an existing domain or user profile with a lifecycle configuration attached by using the `update-domain` or `update-user-profile` command. When you update the list of lifecycle configurations attached, you must pass all lifecycle configurations as part of the list. If a lifecycle configuration is not part of this list, it will not be attached to the application.

```
aws sagemaker update-space --domain-id domain-id \  
--space-name space-name \  
--region region \  
--space-settings '\{  
"JupyterServerAppSettings": {  
"LifecycleConfigArns": [lifecycle-configuration-arn-list]  
}  
}
'
```

For information about setting a default lifecycle configuration for a resource, see Set default lifecycle configurations (p. 276).  

Step 3: Launch application with lifecycle configuration

After you attach a lifecycle configuration to a domain, user profile, or space, the user can select it when launching an application with the AWS CLI. This section describes how to launch an application with an attached lifecycle configuration. For information about changing the default lifecycle configuration after launching a JupyterServer application, see Set default lifecycle configurations (p. 276).

Launch the desired application type using the `create-app` command and specify the lifecycle configuration ARN in the `resource-spec` argument.

- The following example shows how to create a JupyterServer application with an associated lifecycle configuration. When creating the JupyterServer, the `app-name` must be `default`. The lifecycle configuration ARN passed as part of the `resource-spec` parameter must be part of the list of lifecycle configuration ARNs specified in `UserSettings` for your domain or user profile, or `SpaceSettings` for a shared space.

```
aws sagemaker create-app --domain-id domain-id \  
--region region \  
--user-profile-name user-profile-name \  
--app-type JupyterServer \  
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn \  
--app-name default
```

- The following example shows how to create a KernelGateway application with an associated lifecycle configuration.

```
aws sagemaker create-app --domain-id domain-id \  
--region region \  
--user-profile-name user-profile-name \  
--app-type KernelGateway \  
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn,SageMakerImageArn=sagemaker-image-arn,InstanceType=instance-type \  
--app-name app-name
```
Create a lifecycle configuration from the SageMaker console

The following topic shows how to create a lifecycle configuration from the Amazon SageMaker console to automate customization for your Studio environment.

Prerequisites

Before you can begin this tutorial, complete the following prerequisite:

- Onboard to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio.

Step 1: Create a new lifecycle configuration

You can create a lifecycle configuration by entering a script from the Amazon SageMaker console.

Note

Each script can have up to 16,384 characters.

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Lifecycle configurations.
4. Choose the Studio tab.
5. Choose Create configuration.
6. Under Select configuration type, select the type of application that the lifecycle configuration should be attached to. For more information about selecting which application to attach the lifecycle configuration to, see Set default lifecycle configurations (p. 276).
7. Choose Next.
8. In the section called Configuration settings, enter a name for your lifecycle configuration.
9. In the Scripts section, enter the following content.

```
#!/bin/bash
set -eux
echo 'Hello World!'
```

10. (Optional) Create a tag for your lifecycle configuration.
11. Choose Submit.

Step 2: Attach the lifecycle configuration to a domain or user profile

Lifecycle configuration scripts associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

You can attach multiple lifecycle configurations to a domain or user profile for both JupyterServer and KernelGateway applications.

Note

To attach a lifecycle configuration to a shared space, you must use the AWS CLI. For more information, see Create a lifecycle configuration from the AWS CLI (p. 271).

The following sections show how to attach a lifecycle configuration to your domain or user profile.

Attach to a domain

The following shows how to attach a lifecycle configuration to your existing domain from the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain to attach the lifecycle configuration to.
5. From the Domain details, choose the Environment tab.
6. Under Lifecycle configurations for personal Studio apps, choose Attach.
7. Under Source, choose Existing configuration.
8. Under Studio lifecycle configurations, select the lifecycle configuration that you created in the previous step.
9. Select Attach to domain.

**Attach to your user profile**

The following shows how to attach a lifecycle configuration to your existing user profile.

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that contains the user profile to attach the lifecycle configuration to.
5. Under User profiles, select the user profile.
6. From the User Details page, choose Edit.
7. On the left navigation, choose Studio settings.
8. Under Lifecycle configurations attached to user, choose Attach.
9. Under Source, choose Existing configuration.
10. Under Studio lifecycle configurations, select the lifecycle configuration that you created in the previous step.
11. Choose Attach to user profile.

**Step 3: Launch an application with the lifecycle configuration**

After you attach a lifecycle configuration to a domain or user profile, you can launch an application with that attached lifecycle configuration. Choosing which lifecycle configuration to launch with depends on the application type.

- **JupyterServer**: When launching a JupyterServer application from the console, SageMaker always uses the default lifecycle configuration. You can't use a different lifecycle configuration when launching from the console. For information about changing the default lifecycle configuration after launching a JupyterServer application, see [Set default lifecycle configurations](p. 276).

To select a different attached lifecycle configuration, you must launch with the AWS CLI. For more information about launching a JupyterServer application with an attached lifecycle configuration from the AWS CLI, see [Create a lifecycle configuration from the AWS CLI](p. 271).

- **KernelGateway**: You can select any of the attached lifecycle configurations when launching a KernelGateway application using the Studio Launcher.

The following procedure describes how to launch a KernelGateway application with an attached lifecycle configuration from the SageMaker console.

2. Launch Studio. For more information, see [Launch Amazon SageMaker Studio](p. 209).
3. In the Studio UI, open the Studio Launcher. For more information, see Use the Amazon SageMaker Studio Launcher (p. 218).

4. In the Studio Launcher, navigate to the Notebooks and compute resources section.

5. Click the Change environment button.

6. On the Change environment dialog, use the dropdown menus to select your Image, Kernel, Instance type, and a Start-up script. If there is no default lifecycle configuration, the Start-up script value defaults to No script. Otherwise, the Start-up script value is your default lifecycle configuration. After you select a lifecycle configuration, you can view the entire script.

7. Click Select.

8. Back to the Launcher, click the Create notebook to launch a new notebook kernel with your selected image and lifecycle configuration.

**Step 4: View logs for a lifecycle configuration**

You can view the logs for your lifecycle configuration after it has been attached to a domain or user profile.

1. First, provide access to CloudWatch for your AWS Identity and Access Management (IAM) role. Add read permissions for the following log group and log stream.

   - Log group: /aws/sagemaker/studio
   - Log stream: domain/user-profile/app-type/app-name/LifecycleConfigOnStart

   For information about adding permissions, see Enabling logging from certain AWS services.

2. From within Studio, navigate to the Running Terminals and Kernels icon to monitor your lifecycle configuration.

3. Select an application from the list of running applications. Applications with attached lifecycle configurations have an attached indicator icon.

4. Select the indicator icon for your application. This opens a new panel that lists the lifecycle configuration.

5. From the new panel, select View logs. This opens a new tab that displays the logs.

**Set default lifecycle configurations**

Although you can attach multiple lifecycle configuration scripts to a single resource, you can only set one default lifecycle configuration for each JupyterServer or KernelGateway application. The behavior of the default lifecycle configuration depends on whether it is set for JupyterServer or KernelGateway apps.

- **JupyterServer apps**: When set as the default lifecycle configuration script for JupyterServer apps, the lifecycle configuration script runs automatically when the user signs in to Studio for the first time or restarts Studio. Use this default lifecycle configuration to automate one-time setup actions for the Studio developer environment, such as installing notebook extensions or setting up a GitHub repo. For an example of this, see Customize Amazon SageMaker Studio using Lifecycle Configurations.

- **KernelGateway apps**: When set as the default lifecycle configuration script for KernelGateway apps, the lifecycle configuration is selected by default in the Studio launcher. Users can launch a notebook or terminal with the default script selected, or they can select a different one from the list of lifecycle configurations.

SageMaker supports setting a default lifecycle configuration for the following resources:
Customize Studio

- Domains
- User profiles
- Shared spaces

While domains and user profiles support setting a default lifecycle configuration from both the Amazon SageMaker console and AWS Command Line Interface, shared spaces only support setting a default lifecycle configuration from the AWS CLI.

You can set a lifecycle configuration as the default when creating a new resource or updating an existing resource. The following topics demonstrate how to set a default lifecycle configuration using the SageMaker console and AWS CLI.

Default lifecycle configuration inheritance

Default lifecycle configurations set at the domain level are inherited by all users and shared spaces. Default lifecycle configurations set at the user and shared space level are scoped to only that user or shared space. User and space defaults override defaults set at the domain level.

A default KernelGateway lifecycle configuration set for a domain applies to all KernelGateway applications launched in the domain. Unless the user selects a different lifecycle configuration from the list presented in the Studio launcher, the default lifecycle configuration is used. The default script also runs if No Script is selected by the user. For more information about selecting a script, see Step 3: Launch an application with the lifecycle configuration (p. 275).

Topics
- Set defaults from the AWS CLI (p. 277)
- Set defaults from the SageMaker console (p. 279)

Set defaults from the AWS CLI

You can set default lifecycle configuration scripts from the AWS CLI for the following resources:

- Domains
- User profiles
- Shared spaces

The following sections outline how to set default lifecycle configuration scripts from the AWS CLI.

Topics
- Prerequisites (p. 277)
- Set a default lifecycle configuration when creating a new resource (p. 278)
- Set a default lifecycle configuration for an existing resource (p. 278)

Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in Installing the current AWS CLI version.
- From your local machine, run aws configure and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.
- Onboard to SageMaker domain by following the steps in Onboard to Amazon SageMaker Domain (p. 10).
• Create a lifecycle configuration following the steps in Create and associate a lifecycle configuration (p. 271).

Set a default lifecycle configuration when creating a new resource

To set a default lifecycle configuration when creating a new domain, user profile, or space, pass the ARN of your previously created lifecycle configuration as part of one of the following AWS CLI commands:

• create-user-profile
• create-domain
• create-space

You must pass the lifecycle configuration ARN for the following values in the KernelGateway or JupyterServer default settings:

• DefaultResourceSpec.LifecycleConfigArn - This specifies the default lifecycle configuration for the application type.

• LifecycleConfigArns - This is the list of all lifecycle configurations attached to the application type. The default lifecycle configuration must also be part of this list.

For example, the following API call creates a new user profile with a default lifecycle configuration.

```
aws sagemaker create-user-profile --domain-id domain-id \
  --user-profile-name user-profile-name \
  --region region \
  --user-settings '{"KernelGatewayAppSettings": {"DefaultResourceSpec": {"InstanceType": "ml.t3.medium", "LifecycleConfigArn": "lifecycle-configuration-arn"}, "LifecycleConfigArns": ["lifecycle-configuration-arn-list"]}}
```
For example, the following API call updates a user profile with a default lifecycle configuration.

```bash
aws sagemaker update-user-profile --domain-id domain-id \   --user-profile-name user-profile-name \   --region region \   --user-settings '{"KernelGatewayAppSettings": {"DefaultResourceSpec": {"InstanceType": "ml.t3.medium", "LifecycleConfigArn": "lifecycle-configuration-arn"}, "LifecycleConfigArns": [lifecycle-configuration-arn-list]}}'
```

The following API call updates a domain to set a new default lifecycle configuration.

```bash
aws sagemaker update-domain --domain-id domain-id \   --region region \   --default-user-settings '{"JupyterServerAppSettings": {"DefaultResourceSpec": {"InstanceType": "ml.t3.medium", "LifecycleConfigArn": "lifecycle-configuration-arn"}, "LifecycleConfigArns": [lifecycle-configuration-arn-list]}}'
```

### Set defaults from the SageMaker console

You can set default lifecycle configuration scripts from the SageMaker console for the following resources.

- Domains
- User profiles

You cannot set default lifecycle configuration scripts for shared spaces from the SageMaker console. For information about setting defaults for shared spaces, see [Set defaults from the AWS CLI (p. 277)](#).

The following sections outline how to set default lifecycle configuration scripts from the SageMaker console.

#### Topics
- [Prerequisites (p. 277)](#)
- Set a default lifecycle configuration for a domain (p. 280)
- Set a default lifecycle configuration for a user profile (p. 280)

#### Prerequisites

Before you begin, complete the following prerequisites:

- Onboard to SageMaker domain by following the steps in [Onboard to Amazon SageMaker Domain (p. 10)].
- Create a lifecycle configuration following the steps in [Create and associate a lifecycle configuration (p. 271)].
Set a default lifecycle configuration for a domain

The following procedure shows how to set a default lifecycle configuration for a domain from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the list of domains, select the name of the domain to set the default lifecycle configuration for.
3. From the Domain details page, choose the Environment tab.
4. Under Lifecycle configurations for personal Studio apps, select the lifecycle configuration that you want to set as the default for the domain. You can set distinct defaults for JupyterServer and KernelGateway applications.
5. Choose Set as default. This opens a pop up window that lists the current defaults for JupyterServer and KernelGateway applications.
6. Choose Set as default to set the lifecycle configuration as the default for its respective application type.

Set a default lifecycle configuration for a user profile

The following procedure shows how to set a default lifecycle configuration for a user profile from the SageMaker console.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the list of domains, select the name of the domain that contains the user profile that you want to set the default lifecycle configuration for.
3. From the Domain details page, choose the User profiles tab.
4. Select the name of the user profile to set the default lifecycle configuration for. This opens a User Details page.
5. From the User Details page, choose Edit. This opens an Edit user profile page.
6. From the Edit user profile page, choose Step 2 Studio settings.
7. Under Lifecycle configurations attached to user, select the lifecycle configuration that you want to set as the default for the user profile. You can set distinct defaults for JupyterServer and KernelGateway applications.
8. Choose Set as default. This opens a pop up window that lists the current defaults for JupyterServer and KernelGateway applications.
9. Choose Set as default to set the lifecycle configuration as the default for its respective application type.

Debug lifecycle configurations

The following topics show how to get information about and debug your lifecycle configurations.

Topics

- Verify lifecycle configuration process from CloudWatch Logs (p. 280)
- JupyterServer app failure (p. 281)
- KernelGateway app failure (p. 281)
- Lifecycle configuration timeout (p. 282)

Verify lifecycle configuration process from CloudWatch Logs

Lifecycle configurations only log STDOUT and STDERR.
STDOUT is the default output for bash scripts. You can write to STDERR by appending `>&2` to the end of a bash command. For example, `echo 'hello'>&2`.

Logs for your lifecycle configurations are published to your AWS account using Amazon CloudWatch. These logs can be found in the `/aws/sagemaker/studio` log stream in the CloudWatch console.

2. Choose **Logs** from the left side. From the dropdown menu, select **Log groups**.
3. On the **Log groups** page, search for `aws/sagemaker/studio`.
4. Select the log group.
5. On the **Log group details** page, choose the **Log streams** tab.
6. To find the logs for a specific app, search the log streams using the following format:

   ```
   domain-id/user-profile-name/app-type/app-name
   ```

   For example, to find the lifecycle configuration logs for domain `d-m851cu8vbqumz`, user profile `i-sonic-js`, application type `JupyterServer` and application name `test-lcc-echo`, use the following search string:

   ```
   d-m851cu8vbqumz/i-sonic-js/JupyterServer/test-lcc-echo
   ```

7. Select the log stream appended with `LifecycleConfigOnStart` to view the script execution logs.

### JupyterServer app failure

If your JupyterServer app crashes because of an issue with the attached lifecycle configuration, Studio displays the following error message on the Studio startup screen.

```
Failed to create SageMaker Studio due to start-up script failure
```

Select the **View script logs** link to view the CloudWatch logs for your JupyterServer app.

In the case where the faulty lifecycle configuration is specified in the `DefaultResourceSpec` of your domain, user profile, or shared space, Studio continues to use the lifecycle configuration even after restarting Studio.

To resolve this error, follow the steps in Set default lifecycle configurations (p. 276) to remove the lifecycle configuration script from the `DefaultResourceSpec` or select another script as the default. Then launch a new JupyterServer app.

### KernelGateway app failure

If your KernelGateway app crashes because of an issue with the attached lifecycle configuration, Studio displays the error message in your Studio Notebook.

Choose **View script logs** to view the CloudWatch logs for your KernelGateway app.

In this case, your lifecycle configuration is specified in the Studio Launcher when launching a new Studio Notebook.

To resolve this error, use the Studio launcher to select a different lifecycle configuration or select No script.

**Note**

A default KernelGateway lifecycle configuration specified in `DefaultResourceSpec` applies to all KernelGateway images in the domain, user profile, or shared space unless the user selects a
different script from the list presented in the Studio launcher. The default script also runs if No Script is selected by the user. For more information on selecting a script, see Step 3: Launch an application with the lifecycle configuration (p. 275).

Lifecycle configuration timeout

There is a lifecycle configuration timeout limitation of 5 minutes. If a lifecycle configuration script takes longer than 5 minutes to run, Studio throws an error.

To resolve this error, ensure that your lifecycle configuration script completes in less than 5 minutes.

To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments to install large packages in.
- Run tasks in parallel processes.
- Use the nohup command in your script to ensure that hangup signals are ignored and do not stop the execution of the script.

Update and detach lifecycle configurations

A lifecycle configuration script can’t be changed after it’s created. To update your script, you must create a new lifecycle configuration script and attach it to the respective domain, user profile, or shared space. For more information about creating and attaching the lifecycle configuration, see Create and associate a lifecycle configuration (p. 271).

The following topic shows how to detach a lifecycle configuration using the AWS CLI and SageMaker console.

Topics

- Prerequisites (p. 282)
- Detach using the AWS CLI (p. 282)
- Detach using the SageMaker console (p. 283)

Prerequisites

Before detaching a lifecycle configuration, you must complete the following prerequisite.

- To successfully detach a lifecycle configuration, no running application can be using the lifecycle configuration. You must first shut down the running applications as shown in Shut Down and Update SageMaker Studio and Studio Apps (p. 292).

Detach using the AWS CLI

To detach a lifecycle configuration using the AWS CLI, remove the desired lifecycle configuration from the list of lifecycle configurations attached to the resource and pass the list as part of the respective command:

- update-user-profile
- update-domain
- update-space

For example, the following command removes all lifecycle configurations for KernelGateways attached to the domain.

282
aws sagemaker update-domain --domain-id domain-id \ 
--region region \ 
--default-user-settings '{
  "KernelGatewayAppSettings": {
  "LifecycleConfigArns": []
  }
}'

**Detach using the SageMaker console**

The procedure to detach a lifecycle configuration from the SageMaker console depends on the type of resource that you are detaching the lifecycle configuration from. You can't detach a lifecycle configuration from a shared space by using the SageMaker console. For that, you must use the AWS CLI.

**Detach from a domain**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Domains.
3. From the list of Domains, select the name of the Domain to detach the lifecycle configuration from.
5. Under Lifecycle configurations for personal Studio apps, select the lifecycle configuration to detach.
6. Choose Detach. This opens a pop-up window.
7. From the pop-up window, choose Detach.

**Detach from a user profile**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Domains.
3. From the list of Domains, select the name of the Domain that contains the user profile to detach the lifecycle configuration from.
4. On the Domain details page, choose the User profiles tab.
5. From the list of user profiles, select the name of the user profile to detach the lifecycle configuration from.
6. From the User Details page, choose Edit.
7. On the left navigation, choose Studio settings.
8. Under Lifecycle configurations attached to user, select the lifecycle configuration to detach.
9. Choose Detach. This opens a pop-up window.
10. From the pop-up window, choose Detach.

**Attach Suggested Git Repos to Studio**

Amazon SageMaker Studio offers a Git extension for you to enter the URL of a Git repository (repo), clone it into your environment, push changes, and view commit history. In addition to this Git extension, you can also attach suggested Git repository URLs at the Amazon SageMaker Domain or user profile level. Then, you can select the repo URL from the list of suggestions and clone that into your environment using the Git extension in Studio.

The following topics show how to attach Git repo URLs to a Domain or user profile from the AWS CLI and SageMaker console. You'll also learn how to detach these repository URLs.

**Topics**
Attach a Git Repository from the AWS CLI

The following topic shows how to attach a Git repository URL using the AWS CLI, so that Amazon SageMaker Studio automatically suggests it for cloning. After you attach the Git repository URL, you can clone it by following the steps in Clone a Git Repository in SageMaker Studio (p. 287).

Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
- From your local machine, run aws configure and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.
- Onboard to Amazon SageMaker Domain. For more information, see Onboard to Amazon SageMaker Domain (p. 10).

Attach the Git repo to a Domain or user profile

Git repo URLs associated at the Domain level are inherited by all users. However, Git repo URLs that are associated at the user profile level are scoped to a specific user. You can attach multiple Git repo URLs to a Domain or user profile by passing a list of repository URLs.

The following sections show how to attach a Git repo URL to your Domain and user profile.

Attach to a Domain

The following command attaches a Git repo URL to an existing Domain.

```bash
aws sagemaker update-domain --region region --domain-id domain-id \ --default-user-settings \ JupyterServerAppSettings={CodeRepositories=[{RepositoryUrl="repository"}])
```

Attach to a user profile

The following shows how to attach a Git repo URL to an existing user profile.

```bash
aws sagemaker update-user-profile --domain-id domain-id --user-profile-name user-name \ --user-settings \ JupyterServerAppSettings={CodeRepositories=[{RepositoryUrl="repository"}])
```

Attach a Git Repository from the SageMaker Console

The following topic shows how to associate a Git repository URL from the Amazon SageMaker console to clone it in your Studio environment. After you associate the Git repository URL, you can clone it by following the steps in Clone a Git Repository in SageMaker Studio (p. 287).

Prerequisites

Before you can begin this tutorial, you must onboard to Amazon SageMaker Domain. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
Attach the Git repo to a Domain or user profile

Git repo URLs associated at the Domain level are inherited by all users. However, Git repo URL that are associated at the user profile level are scoped to a specific user.

The following sections show how to attach a Git repo URL to a Domain and user profile.

Attach to a Domain

To attach a Git repo URL to an existing Domain

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain to attach the Git repo to.
6. On the Suggested code repositories for the domain tab, choose Attach.
7. Under Source, enter the Git repository URL.
8. Select Attach to domain.

Attach to a user profile

The following shows how to attach a Git repository URL to an existing user profile.

To attach a Git repository URL to a user profile

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain that includes the user profile to attach the Git repo to.
5. On the Domain details page, choose the User profiles tab.
6. Select the user profile to attach the Git repo URL to.
7. On the User details page, choose Edit.
8. On the Studio settings page, choose Attach from the Suggested code repositories for the user section.
9. Under Source, enter the Git repository URL.
10. Choose Attach to user.

Detach Git Repos

This guide shows how to detach Git repository URLs from an Amazon SageMaker Domain or user profile using the AWS CLI or Amazon SageMaker console.

Topics
- Detach a Git repo using the AWS CLI (p. 285)
- Detach the Git repo using the SageMaker console (p. 286)

Detach a Git repo using the AWS CLI

To detach all Git repo URLs from a Domain or user profile, you must pass an empty list of code repositories. This list is passed as part of the JupyterServerAppSettings parameter in an update-
domain or update-user-profile command. To detach only one Git repo URL, pass the code repositories list without the desired Git repo URL. This section shows how to detach all Git repo URLs from your Domain or user profile using the AWS Command Line Interface (AWS CLI).

**Detach from a Domain**

The following command detaches all Git repo URLs from a Domain.

```
aws sagemaker update-domain --region region --domain-name domain-name \
--domain-settings JupyterServerAppSettings={CodeRepositories=[]}
```

**Detach from a user profile**

The following command detaches all Git repo URLs from a user profile.

```
aws sagemaker update-user-profile --domain-name domain-name --user-profile-name user-name\n--user-settings JupyterServerAppSettings={CodeRepositories=[]}
```

**Detach the Git repo using the SageMaker console**

The following sections show how to detach a Git repo URL from a Domain or user profile using the SageMaker console.

**Detach from a Domain**

Use the following steps to detach a Git repo URL from an existing Domain.

**To detach a Git repo URL from an existing Domain**

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain with the Git repo URL that you want to detach.
6. On the Suggested code repositories for the domain tab, select the Git repository URL to detach.
7. Choose Detach.
8. From the new window, choose Detach.

**Detach from a user profile**

Use the following steps to detach a Git repo URL from a user profile.

**To detach a Git repo URL from a user profile**

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain that includes the user profile with the Git repo URL that you want to detach.
5. On the Domain details page, choose the User profiles tab.
6. Select the user profile with the Git repo URL that you want to detach.
7. On the User details page, choose Edit.
8. On the **Studio settings** page, select the Git repo URL to detach from the **Suggested code repositories for the user** tab.

9. Choose **Detach**.

10. From the new window, choose **Detach**.

### Perform Common Tasks in Amazon SageMaker Studio

The following sections describe how to perform common tasks in Amazon SageMaker Studio. For an overview of the Studio interface, see [Amazon SageMaker Studio UI Overview](#) (p. 205).

**Topics**

- [Upload Files to SageMaker Studio](#) (p. 287)
- [Clone a Git Repository in SageMaker Studio](#) (p. 287)
- [Stop a Training Job in SageMaker Studio](#) (p. 288)
- [Use TensorBoard in Amazon SageMaker Studio](#) (p. 288)
- [Using CodeWhisperer and CodeGuru extensions with SageMaker](#) (p. 290)
- [Manage Your Amazon EFS Storage Volume in SageMaker Studio](#) (p. 291)
- [Provide Feedback on SageMaker Studio](#) (p. 291)
- [Shut Down and Update SageMaker Studio and Studio Apps](#) (p. 292)

#### Upload Files to SageMaker Studio

When you onboard to Amazon SageMaker Studio, a home directory is created for you in the Amazon Elastic File System (Amazon EFS) volume that was created for your team. Studio can only open files that have been uploaded to your directory. The Studio file browser maps to your home directory.

**Note**

- Studio does not support uploading folders. While you can only upload individual files, you can upload multiple files at the same time.

**To upload files to your home directory**

1. In the left sidebar, choose the **File Browser icon**.
2. In the file browser, choose the **Upload Files icon**.
3. Select the files you want to upload and then choose **Open**.
4. Double-click a file to open the file in a new tab in Studio.

#### Clone a Git Repository in SageMaker Studio

Amazon SageMaker Studio can only connect only to a local Git repository (repo). This means that you must clone the Git repo from within Studio to access the files in the repo. Studio offers a Git extension for you to enter the URL of a Git repo, clone it into your environment, push changes, and view commit history. If the repo is private and requires credentials to access, then you are prompted to enter your user credentials. This includes your username and personal access token. For more information about personal access tokens, see [Managing your personal access tokens](#).
Admins can also attach suggested Git repository URLs at the Amazon SageMaker domain or user profile level. Users can then select the repo URL from the list of suggestions and clone that into Studio. For more information about attaching suggested repos, see [Attach Suggested Git Repos to Studio](p. 283).

The following procedure shows how to clone a GitHub repo from Studio.

**To clone the repo**

1. In the left sidebar, choose the Git icon ( ).
2. Choose Clone a Repository. This opens a new window.
3. In the Clone Git Repository window, enter the URL in the following format for the Git repo that you want to clone or select a repository from the list of Suggested repositories.

   ```
   https://github.com/path-to-git-repo/repo.git
   ```

4. If you entered the URL of the Git repo manually, select Clone "git-url" from the dropdown menu.
5. Under Project directory to clone into, enter the path to the local directory that you want to clone the Git repo into. If this value is left empty, Studio clones the repo into JupyterLab's root directory.
6. Choose Clone. This opens a new terminal window.
7. If the repo requires credentials, you are prompted to enter your username and personal access token. This prompt does not accept passwords, you must use a personal access token. For more information about personal access tokens, see [Managing your personal access tokens](p. 288).
8. Wait for the download to finish. After the repo has been cloned, the File Browser opens to display the cloned repo.
9. Double click the repo to open it.
10. Choose the Git icon to view the Git user interface which now tracks the repo.
11. To track a different repo, open the repo in the file browser and then choose the Git icon.

**Stop a Training Job in SageMaker Studio**

You can stop a training job with the Amazon SageMaker Studio UI. When you stop a training job, its status changes to Stopping at which time billing ceases. An algorithm can delay termination in order to save model artifacts after which the job status changes to Stopped. For more information, see the `stop_training_job` method in the AWS SDK for Python (Boto3).

**To stop a training job**

1. Follow the [View, search, and compare experiment runs](p. 1843) procedure on this page until you open the Describe Trial Component tab.
2. At the upper-right side of the tab, choose Stop training job. The Status at the top left of the tab changes to Stopped.
3. To view the training time and billing time, choose AWS Settings.

**Use TensorBoard in Amazon SageMaker Studio**

The following doc outlines how to install and run TensorBoard in Amazon SageMaker Studio.

**Note**

This guide shows how to open the TensorBoard application through a SageMaker Studio notebook server of an individual SageMaker Domain user profile. For a more comprehensive TensorBoard experience integrated with SageMaker Training and the access control functionalities of SageMaker Domain, see [Use TensorBoard to debug and analyze training jobs in Amazon SageMaker](p. 1904).
Prerequisites

This tutorial requires an Amazon SageMaker Studio Domain. For more information, see Onboard to Amazon SageMaker Domain (p. 10)

Set Up TensorBoardCallback

1. Launch Studio, and open the Launcher. For more information, see Use the Amazon SageMaker Studio Launcher (p. 218)
2. In the Amazon SageMaker Studio Launcher, under Notebooks and compute resources, choose the Change environment button.
3. On the Change environment dialog, use the dropdown menus to select the TensorFlow 2.3 Python 3.7 (optimized for CPU) Studio Image.
4. Back to the Launcher, click the Create notebook tile. Your notebook launches and opens in a new Studio tab.
5. Run this code from within your notebook cells.
6. Import the required packages.

```python
import os
import datetime
import tensorflow as tf
```

7. Create a Keras model.

```python
mnist = tf.keras.datasets.mnist
(x_train, y_train),(x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

def create_model():
    return tf.keras.models.Sequential([
        tf.keras.layers.Flatten(input_shape=(28, 28)),
        tf.keras.layers.Dense(512, activation='relu'),
        tf.keras.layers.Dropout(0.2),
        tf.keras.layers.Dense(10, activation='softmax')
    ])
```

8. Create a directory for your TensorBoard logs

```python
LOG_DIR = os.path.join(os.getcwd(), "logs/fit/" + datetime.datetime.now().strftime("%Y %m%d-%H%M%S"))
```

9. Run training with TensorBoard.

```python
model = create_model()
model.compile(optimizer='adam',
              loss='sparse_categorical_crossentropy',
              metrics=['accuracy'])

tensorboard_callback = tf.keras.callbacks.TensorBoard(log_dir=LOG_DIR,
                                                        histogram_freq=1)

model.fit(x=x_train,
          y=y_train,
          epochs=5,
          validation_data=(x_test, y_test),
          callbacks=[tensorboard_callback])
```
10. Generate the EFS path for the TensorBoard logs. You use this path to set up your logs from the terminal.

```python
EFS_PATH_LOG_DIR = "".join(LOG_DIR.strip("/").split('/')[1:-1])
print(EFS_PATH_LOG_DIR)
```

Retrieve the `EFS_PATH_LOG_DIR`. You will need it in the TensorBoard installation section.

## Install TensorBoard

1. Click on the Amazon SageMaker Studio button on the top left corner of Studio to open the Amazon SageMaker Studio Launcher. This launcher must be opened from your root directory. For more information, see [Use the Amazon SageMaker Studio Launcher](p. 218)
2. In the Launcher, under Utilities and files, click System terminal.
3. From the terminal, run the following commands. Copy `EFS_PATH_LOG_DIR` from the Jupyter notebook. You must run this from the `/home/sagemaker-user` root directory.

   ```bash
   pip install tensorboard
tensorboard --logdir <EFS_PATH_LOG_DIR>
   ```

## Launch TensorBoard

1. To launch TensorBoard, copy your Studio URL and replace `lab?` with `proxy/6006/` as follows. You must include the trailing `/` character.

   ```text
   https://<YOUR_URL>.studio.region.sagemaker.aws/jupyter/default/proxy/6006/
   ```
2. Navigate to the URL to examine your results.

## Using CodeWhisperer and CodeGuru extensions with SageMaker

Amazon SageMaker Studio is an integrated machine learning environment where you can build, train, deploy, and analyze your models all in the same application. This topic shows how to generate code recommendations and suggest improvements related to code issues by using Amazon CodeWhisperer and Amazon CodeGuru with Amazon SageMaker.

The following extensions support writing code by generating code recommendations and suggesting improvements related to code issues:

- Amazon CodeWhisperer
- Amazon CodeGuru

### What is Amazon CodeWhisperer?

Amazon CodeWhisperer is a service powered by machine learning that helps improve developer productivity. CodeWhisperer achieves this by generating code recommendations based on developers' comments in natural language and their code in the IDE. During preview, Amazon CodeWhisperer is available for the Java, JavaScript, Python, C# and TypeScript programming languages. The service integrates with JupyterLab, Amazon SageMaker Studio, Amazon SageMaker notebook instances, and other integrated development environments (IDEs).

For more information, see the [Setting up CodeWhisperer with Amazon SageMaker Studio](https://aws.amazon.com/sagemaker/codewhisperer/).
What is Amazon CodeGuru?

CodeGuru Security improves the security of your code in the following ways:

- Proactively detects security policy violations and vulnerabilities.
- Provides recommendations for addressing security risks.
- Suggests improvements to inefficient methods.

From SageMaker, you can call CodeGuru Security by using the open-source Jupyter plugin. You can use CodeGuru Security to scan notebooks for a variety of issues that can affect the security, correctness, reproducibility, maintainability, and performance of your code. For more information, see Tutorial: Run scans with SageMaker Studio and JupyterLab.

Manage Your Amazon EFS Storage Volume in SageMaker Studio

The first time a user on your team onboards to Amazon SageMaker Studio, Amazon SageMaker creates an Amazon Elastic File System (Amazon EFS) volume for the team. A home directory is created in the volume for each user who onboards to Studio as part of your team. Notebook files and data files are stored in these directories. Users don't have access to other team member's home directories. Amazon SageMaker Domain does not support mounting custom or additional Amazon EFS volumes.

**Important**

Don't delete the Amazon EFS volume. If you delete it, the domain will no longer function and all of your users will lose their work.

To find your Amazon EFS volume

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the Domains page, select the domain to find the ID for.
5. From the Domain details page, select the Domain settings tab.
6. Under General settings, find the Domain ID. The ID will be in the following format: d-xxxxxxxxxxxx.
7. Pass the Domain ID, as DomainId, to the describe_domain method.
8. In the response from describe_domain, note the value for the HomeEfsFileSystemId key. This is the Amazon EFS file system ID.
9. Open the Amazon EFS console. Make sure the AWS Region is the same Region that's used by Studio.
10. Under File systems, choose the file system ID from the previous step.
11. To verify that you've chosen the correct file system, select the Tags heading. The value corresponding to the ManagedByAmazonSageMakerResource key should match the Studio ID.

For information on how to access the Amazon EFS volume, see Using file systems in Amazon EFS.

To delete the Amazon EFS volume, see Deleting an Amazon EFS file system.

Provide Feedback on SageMaker Studio

Amazon SageMaker takes your feedback seriously. We encourage you to provide feedback.
To provide feedback

1. At the right of SageMaker Studio, find the Feedback icon.
2. Choose a smiley emoji to let us know how satisfied you are with SageMaker Studio and add any feedback you'd care to share with us.
3. Decide whether to share your identity with us, then choose Submit.

Shut Down and Update SageMaker Studio and Studio Apps

The following topics show how to shut down and update SageMaker Studio and Studio Apps.

Studio provides a notification icon in the upper-right corner of the Studio UI. This notification icon displays the number of unread notices. To read the notices, select the icon.

Studio provides two types of notifications:

- Upgrade – Displayed when Studio or one of the Studio apps have released a new version. To update Studio, see Shut down and Update SageMaker Studio (p. 292). To update Studio apps, see Shut down and Update Studio Apps (p. 293).
- Information – Displayed for new features and other information.

To reset the notification icon, you must select the link in each notice. Read notifications may still display in the icon. This does not indicate that updates are still needed after you have updated Studio and Studio Apps.

To learn how to update Amazon SageMaker Data Wrangler, see Shut down and Update Studio Apps (p. 293).

To ensure that you have the most recent software updates, update Amazon SageMaker Studio and your Studio apps using the methods outlined in the following topics.

Topics

- Shut down and Update SageMaker Studio (p. 292)
- Shut down and Update Studio Apps (p. 293)

Shut down and Update SageMaker Studio

To update Amazon SageMaker Studio to the latest release, you must shut down the JupyterServer app. You can shut down the JupyterServer app from the SageMaker console or from within Studio. After the JupyterServer app is shut down, you must reopen Studio through the SageMaker console which creates a new version of the JupyterServer app.

You cannot delete the JupyterServer application while the Studio UI is still open in the browser. If you delete the JupyterServer application while the Studio UI is still open in the browser, SageMaker automatically re-creates the JupyterServer application.

Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

Some of the services within Studio, like Data Wrangler, run on their own app. To update these services you must delete the app for that service. To learn more, see Shut down and Update Studio Apps (p. 293).
Note
A JupyterServer app is associated with a single Studio user. When you update the app for one user it doesn't affect other users.

The following topic shows how to update the JupyterServer App from the SageMaker console or from inside Studio.

To update the JupyterServer app from the SageMaker console
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the Domain that includes the Studio application that you want to update.
5. Under User profiles, select your user name.
6. Under Apps, in the row displaying JupyterServer, choose Action, then choose Delete.
7. Choose Yes, delete app.
8. Type delete in the confirmation box.
9. Choose Delete.
10. After the app has been deleted, launch a new Studio app to get the latest version.

To update the JupyterServer app from inside Studio
1. Launch Studio.
2. On the top menu, choose File then Shut Down.
3. Choose one of the following options:
   • Shutdown Server – Shuts down the JupyterServer app. Terminal sessions, kernel sessions, SageMaker images, and instances aren't shut down. These resources continue to accrue charges.
   • Shutdown All – Shuts down all apps, terminal sessions, kernel sessions, SageMaker images, and instances. These resources no longer accrue charges.
4. Close the window.
5. After the app has been deleted, launch a new Studio app to use the latest version.

Shut down and Update Studio Apps
To update an Amazon SageMaker Studio app to the latest release, you must first shut down the corresponding KernelGateway app from the SageMaker console. After the KernelGateway app is shut down, you must reopen it through SageMaker Studio by running a new kernel. The kernel automatically updates. Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

After an application has been shut down for 24 hours, SageMaker deletes all metadata for the application. To be considered an update and retain application metadata, applications must be restarted within 24 hours after the previous application has been shut down. After this time window, creation of an application is considered a new application rather than an update of the previous application.

Note
A KernelGateway app is associated with a single Studio user. When you update the app for one user it doesn't effect other users.

To update the KernelGateway app
2. On the left navigation pane, choose Admin configurations.
3. Under **Admin configurations**, choose **Domains**.

4. Select the Domain that includes the application that you want to update.

5. Under **User profiles**, select your user name.

6. Under **Apps**, in the row displaying the **App name**, choose **Action**, then choose Delete

   To update Data Wrangler, delete the app that starts with *sagemaker-data-wrang*.

7. Choose **Yes**, delete app.

8. Type `delete` in the confirmation box.

9. Choose **Delete**.

10. After the app has been deleted, launch a new kernel from within Studio to use the latest version.

---

**Amazon SageMaker Studio Pricing**

When the first member of your team onboards to Amazon SageMaker Studio, Amazon SageMaker creates an Amazon Elastic File System (Amazon EFS) volume for the team. In the SageMaker Control Panel, when the Studio **Status** displays as Ready, the Amazon EFS volume has been created.

When this member, or any member of the team, opens Studio, a home directory is created in the volume for the member. A storage charge is incurred for this directory. Subsequently, additional storage charges are incurred for the notebooks and data files stored in the member's home directory. For pricing information on Amazon EFS, see [Amazon EFS Pricing](#).

Additional costs are incurred when other operations are run inside Studio, for example, running a notebook, running training jobs, and hosting a model.

For information on the costs associated with using Studio notebooks, see [Usage Metering (p. 238)](#).

For information about billing along with pricing examples, see [Amazon SageMaker Pricing](#).

---

**Troubleshooting Amazon SageMaker Studio**

This topic describes how to troubleshoot common Amazon SageMaker Studio issues during setup and use. The following are common errors that might occur while using Amazon SageMaker Studio. Each error is followed by its solution.

### Studio application issues

The following issues occur when launching and using the Studio application.

- **Screen not loading: Clearing workspace and waiting doesn't help**

  When launching the Studio application, a pop-up displays the following message. No matter which option is selected, Studio does not load.

  ![Loading Message](#)

  The Studio application can have a launch delay if multiple tabs are open in the Studio workspace or several files are on Amazon EFS. This pop-up should disappear in a few seconds after the Studio workspace is ready.

  If you continue to see a loading screen with a spinner after selecting either of the options, there could be connectivity issues with the Amazon Virtual Private Cloud used by Studio.
To resolve connectivity issues with the Amazon Virtual Private Cloud (Amazon VPC) used by Studio, verify the following networking configurations:

- If your domain is set up in VpcOnlOnly mode: Verify that there is an Amazon VPC endpoint for AWS STS, or a NAT Gateway for outbound traffic, including traffic over the internet. To do this, follow the steps in Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522).

- If your Amazon VPC is set up with a custom DNS instead of the DNS provided by Amazon: Verify that the routes are configured using Dynamic Host Configuration Protocol (DHCP) for each Amazon VPC endpoint added to the Amazon VPC used by Studio. For more information about setting default and custom DHCP option sets, see DHCP option sets in Amazon VPC.

- **Internal Failure when launching Studio**

When launching Studio, you are unable to view the Studio UI. You also see an error similar to the following, with Internal Failure as the error detail.

```
Amazon SageMaker Studio
The JupyterServer app default encountered a problem and was stopped.
```

This error can be caused by multiple factors. If completion of these steps does not resolve your issue, create an issue with https://aws.amazon.com/premiumsupport/.

- **Missing Amazon EFS mount target**: Studio uses Amazon EFS for storage. The Amazon EFS volume needs a mount target for each subnet that the Amazon SageMaker domain is created in. If this Amazon EFS mount target is deleted accidentally, the Studio application cannot load because it cannot mount the user's file directory. To resolve this issue, complete the following steps.

  **To verify or create mount targets.**

  1. Find the Amazon EFS volume that is associated with the domain by using the DescribeDomain API call.
  2. Sign in to the AWS Management Console and open the Amazon EFS console at https://console.aws.amazon.com/efs/.
  3. From the list of Amazon EFS volumes, select the Amazon EFS volume that is associated with the domain.
  4. On the Amazon EFS details page, select the Network tab. Verify that there are mount targets for all of the subnets that the domain is set up in.
  5. If mount targets are missing, add the missing Amazon EFS mount targets. For instructions, see Creating and managing mount targets and security groups.
  6. After the missing mount targets are created, launch the Studio application.

- **Conflicting files in the user's .local folder**: If you're using JupyterLab version 1 on Studio, conflicting libraries in your .local folder can cause issues when launching the Studio application. To resolve this, update your user profile's default JupyterLab version to JupyterLab 3.0. For more information about viewing and updating the JupyterLab version, see JupyterLab Versioning (p. 211).

- **ConfigurationException: LifecycleConfig when launching Studio**

You can't view the Studio UI when launching Studio. This is caused by issues with the default lifecycle configuration script attached to the domain.

**To resolve lifecycle configuration issues**

1. View the Amazon CloudWatch Logs for the lifecycle configuration to trace the command that caused the failure. To view the log, follow the steps in Verify lifecycle configuration process from CloudWatch Logs (p. 280).
2. Detach the default script from the user profile or domain. For more information, see Update and detach lifecycle configurations (p. 282).

3. Launch the Studio application.

4. Debug your lifecycle configuration script. You can run the lifecycle configuration script from the system terminal to troubleshoot. When the script runs successfully from the terminal, you can attach the script to the user profile or the domain.

• **SageMaker Studio core functionalities are not available.**

If you get this error message when opening Studio, it may be due to Python package version conflicts. This occurs if you used the following commands in a notebook or terminal to install Python packages that have version conflicts with SageMaker package dependencies.

```shell
!pip install
```

```shell
pip install --user
```

To resolve this issue, complete the following steps:

1. Uninstall recently installed Python packages. If you’re not sure which package to uninstall, create an issue with https://aws.amazon.com/premiumsupport/.

2. Restart Studio:
   a. Shut down Studio from the File menu.
   b. Wait for one minute.
   c. Reopen Studio by refreshing the page or opening it from the AWS Management Console.

The problem should be resolved if you have uninstalled the package which caused the conflict. To install packages without causing this issue again, use `%pip install` without the `--user` flag.

If the issue persists, create a new user profile and set up your environment with that user profile.

If these solutions don’t fix the issue, create an issue with https://aws.amazon.com/premiumsupport/.

• **Unable to open Studio from the AWS Management Console.**

If you are unable to open Studio and cannot make a new running instance with all default settings, create an issue with https://aws.amazon.com/premiumsupport/.

### KernelGateway application issues

The following issues are specific to KernelGateway applications that are launched in Studio.

• **Cannot access the Kernel session**

When the user launches a new notebook, they are unable to connect to the notebook session. If the KernelGateway application's status is In Service, you can verify the following to resolve the issue.

• **Check Security Group configurations**

If the domain is set up in VPC0nly mode, the security group associated with the domain must allow traffic between the ports in the range 8192-65535 for connectivity between the JupyterServer and KernelGateway apps.

**To verify the security group rules**

1. Get the security groups associated with the domain using the [DescribeDomain](https://aws.amazon.com/premiumsupport/) API call.
2. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
3. From the left navigation, under Security, choose Security Groups.
4. Filter by the IDs of the security groups that are associated with the domain.
5. For each security group:
   a. Select the security group.
   b. From the security group details page, view the Inbound rules. Verify that traffic is allowed between ports in the range 8192–65535.

For more information about security group rules, see Control traffic to resources using security groups. For more information about requirements to use Studio in VPCOnly mode, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522).

• Verify firewall and WebSocket connections

If the KernelGateway apps have an InService status and the user is unable to connect to the Studio notebook session, verify the firewall and WebSocket settings.

1. Launch the Studio application. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Open your web browser's developer tools.
3. Choose the Network tab.
4. Search for an entry that matches the following format.

   wss://<domain-id>.studio.<region>.sagemaker.aws/jupyter/default/api/kernels/<unique-code>/channels?session_id=<unique-code>

   If the status or response code for the entry is anything other than 101, then your network settings are preventing the connection between the Studio application and the KernelGateway apps.

   To resolve this issue, contact the team that manages your networking settings to allow list the Studio URL and enable WebSocket connections.

• Unable to launch an app caused by exceeded resource quotas

When a user tries to launch a new notebook, the notebook creation fails with either of the following errors. This is caused by exceeding resource quotas.

* Unable to start more Apps of AppType [KernelGateway] and ResourceSpec(instanceType=[]). Please delete an App with a matching AppType and ResourceSpec, then try again

Studio supports up to four running KernelGateway apps on the same instance. To resolve this issue, you can do either of the following:

• Delete an existing KernelGateway application running on the instance, then restart the new notebook.
• Start the new notebook on a different instance type

For more information, see Change an Instance Type (p. 235).

* An error occurred (ResourceLimitExceeded) when calling the CreateApp operation

In this case, the account does not have sufficient limits to create a Studio application on the specified instance type. To resolve this, navigate to the Service Quotas console at https://
Amazon SageMaker Notebook Instances

An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook App. SageMaker manages creating the instance and related resources. Use Jupyter notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models.

SageMaker also provides sample notebooks that contain complete code walkthroughs. These walkthroughs show how to use SageMaker to perform common machine learning tasks. For more information, see Example Notebooks (p. 330).

For information about pricing with Amazon SageMaker notebook instance, see Amazon SageMaker Pricing.

Maintenance

SageMaker updates the underlying software for Amazon SageMaker Notebook Instances at least once every 90 days. Some maintenance updates, such as operating system upgrades, may require your application to be taken offline for a short period of time. It is not possible to perform any operations during this period while the underlying software is being updated. We recommend that you restart your notebooks at least once every 30 days to automatically consume patches.

For more information, contact https://aws.amazon.com/premiumsupport/.

Use Notebook Instances to build models

One of the best ways for machine learning (ML) practitioners to use Amazon SageMaker is to train and deploy ML models using SageMaker notebook instances. The SageMaker notebook instances help create the environment by initiating Jupyter servers on Amazon Elastic Compute Cloud (Amazon EC2) and providing preconfigured kernels with the following packages: the Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), AWS Command Line Interface (AWS CLI), Conda, Pandas, deep learning framework libraries, and other libraries for data science and machine learning.
Machine Learning with the SageMaker Python SDK

To train, validate, deploy, and evaluate an ML model in a SageMaker notebook instance, use the SageMaker Python SDK. The SageMaker Python SDK abstracts AWS SDK for Python (Boto3) and SageMaker API operations. It enables you to integrate with and orchestrate other AWS services, such as Amazon Simple Storage Service (Amazon S3) for saving data and model artifacts, Amazon Elastic Container Registry (ECR) for importing and servicing the ML models, Amazon Elastic Compute Cloud (Amazon EC2) for training and inference.

You can also take advantage of SageMaker features that help you deal with every stage of a complete ML cycle: data labeling, data preprocessing, model training, model deployment, evaluation on prediction performance, and monitoring the quality of model in production.

If you're a first-time SageMaker user, we recommend you to use the SageMaker Python SDK, following the end-to-end ML tutorial. To find the open source documentation, see the Amazon SageMaker Python SDK.

Tutorial Overview

This Get Started tutorial walks you through how to create a SageMaker notebook instance, open a Jupyter notebook with a preconfigured kernel with the Conda environment for machine learning, and start a SageMaker session to run an end-to-end ML cycle. You'll learn how to save a dataset to a default Amazon S3 bucket automatically paired with the SageMaker session, submit a training job of an ML model to Amazon EC2, and deploy the trained model for prediction by hosting or batch inferencing through Amazon EC2.

This tutorial explicitly shows a complete ML flow of training the XGBoost model from the SageMaker built-in model pool. You use the US Adult Census dataset, and you evaluate the performance of the trained SageMaker XGBoost model on predicting individuals' income.

- **SageMaker XGBoost** – The XGBoost model is adapted to the SageMaker environment and preconfigured as Docker containers. SageMaker provides a suite of built-in algorithms that are prepared for using SageMaker features. To learn more about what ML algorithms are adapted to SageMaker, see Choose an Algorithm and Use Amazon SageMaker Built-in Algorithms. For the SageMaker built-in algorithm API operations, see First-Party Algorithms in the Amazon SageMaker Python SDK.
- **Adult Census dataset** – The dataset from the 1994 Census bureau database by Ronny Kohavi and Barry Becker (Data Mining and Visualization, Silicon Graphics). The SageMaker XGBoost model is trained using this dataset to predict if an individual makes over $50,000 a year or less.

Topics

- Step 1: Create an Amazon SageMaker Notebook Instance (p. 299)
- Step 2: Create a Jupyter Notebook (p. 301)
- Step 3: Download, Explore, and Transform a Dataset (p. 302)
- Step 4: Train a Model (p. 305)
- Step 5: Deploy the Model to Amazon EC2 (p. 310)
- Step 6: Evaluate the Model (p. 312)
- Step 7: Clean Up (p. 315)

Step 1: Create an Amazon SageMaker Notebook Instance

An Amazon SageMaker notebook instance is a fully managed machine learning (ML) Amazon Elastic Compute Cloud (Amazon EC2) compute instance that runs the Jupyter Notebook App. You use the
To create a SageMaker notebook instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Notebook instances, and then choose Create notebook instance.
3. On the Create notebook instance page, provide the following information (if a field is not mentioned, leave the default values):
   a. For Notebook instance name, type a name for your notebook instance.
   b. For Notebook Instance type, choose ml.t2.medium. This is the least expensive instance type that notebook instances support, and it suffices for this exercise. If a ml.t2.medium instance type isn’t available in your current AWS Region, choose ml.t3.medium.
   c. For Platform Identifier, choose a platform type to create the notebook instance on. This platform type dictates the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see Amazon Linux 2 notebook instances (p. 315). For information about JupyterLab versions, see JupyterLab versioning (p. 317).
   d. For IAM role, choose Create a new role, and then choose Create role. This IAM role automatically gets permissions to access any S3 bucket that has sagemaker in the name. It gets these permissions through the AmazonSageMakerFullAccess policy, which SageMaker attaches to the role.
      
      Note
      If you want to grant the IAM role permission to access S3 buckets without sagemaker in the name, you need to attach the S3FullAccess policy or limit the permissions to specific S3 buckets to the IAM role. For more information and examples of adding bucket policies to the IAM role, see Bucket Policy Examples.
   e. Choose Create notebook instance.

In a few minutes, SageMaker launches an ML compute instance—in this case, a notebook instance—and attaches a 5 GB of Amazon EBS storage volume to it. The notebook instance has a preconfigured Jupyter notebook server, SageMaker and AWS SDK libraries, and a set of Anaconda libraries.

For more information about creating a SageMaker notebook instance, see Create a Notebook Instance.

(Optional) Change SageMaker Notebook Instance Settings

If you want to change the ML compute instance type or the size of the Amazon EBS storage of a SageMaker notebook instance that's already created, you can edit the notebook instance settings.

To change and update the SageMaker Notebook instance type and the EBS volume

1. On the Notebook instances page in the SageMaker console, choose your notebook instance.
2. Choose Actions, choose Stop, and then wait until the notebook instance fully stops.
3. After the notebook instance status changes to Stopped, choose Actions, and then choose Update settings.
   a. For Notebook instance type, choose a different ML instance type.
   b. For Volume size in GB, type a different integer to specify a new EBS volume size.
Note
EBS storage volumes are encrypted, so SageMaker can't determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can't decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

4. At the bottom of the page, choose **Update notebook instance**.
5. When the update is complete, **Start** the notebook instance with the new settings.

For more information about updating SageMaker notebook instance settings, see **Update a Notebook Instance**.

(Optional) Advanced Settings for SageMaker Notebook Instances

The following tutorial video shows how to set up and use SageMaker notebook instances through the SageMaker console with advanced options, such as SageMaker lifecycle configuration and importing GitHub repositories. (Length: 26:04)

For complete documentation about SageMaker notebook instance, see **Use Amazon SageMaker notebook instances**.

Step 2: Create a Jupyter Notebook

To start scripting for training and deploying your model, create a Jupyter notebook in the SageMaker notebook instance. Using the Jupyter notebook, you can conduct machine learning (ML) experiments for training and inference while accessing the SageMaker features and the AWS infrastructure.

To create a Jupyter notebook

1. Open the notebook instance as follows:
   b. On the **Notebook instances** page, open your notebook instance by choosing either **Open JupyterLab** for the JupyterLab interface or **Open Jupyter** for the classic Jupyter view.

   **Note**
   If the notebook instance status shows **Pending** in the **Status** column, your notebook instance is still being created. The status will change to **InService** when the notebook instance is ready for use.

2. Create a notebook as follows:
   - If you opened the notebook in the JupyterLab view, on the **File** menu, choose **New**, and then choose **Notebook**. For **Select Kernel**, choose **conda_python3**. This preinstalled environment includes the default Anaconda installation and Python 3.
   - If you opened the notebook in the classic Jupyter view, on the **Files** tab, choose **New**, and then choose **conda_python3**. This preinstalled environment includes the default Anaconda installation and Python 3.

3. Save the notebooks as follows:
   - In the JupyterLab view, choose **File**, choose **Save Notebook As...**, and then rename the notebook.
   - In the Jupyter classic view, choose **File**, choose **Save as...**, and then rename the notebook.
Step 3: Download, Explore, and Transform a Dataset

In this step, you load the Adult Census dataset to your notebook instance using the SHAP (SHapley Additive exPlanations) Library, review the dataset, transform it, and upload it to Amazon S3. SHAP is a game theoretic approach to explain the output of any machine learning model. For more information about SHAP, see Welcome to the SHAP documentation.

To run the following example, paste the sample code into a cell in your notebook instance.

Load Adult Census Dataset Using SHAP

Using the SHAP library, import the Adult Census dataset as shown following:

```python
import shap
X, y = shap.datasets.adult()
X_display, y_display = shap.datasets.adult(display=True)
feature_names = list(X.columns)
feature_names
```

**Note**

If the current Jupyter kernel does not have the SHAP library, install it by running the following conda command:

```
%conda install -c conda-forge shap
```

If you're using JupyterLab, you must manually refresh the kernel after the installation and updates have completed. Run the following IPython script to shut down the kernel (the kernel will restart automatically):

```python
import IPython
IPython.Application.instance().kernel.do_shutdown(True)
```

The `feature_names` list object should return the following list of features:

```
['Age',
 'Workclass',
 'Education-Num',
 'Marital Status',
 'Occupation',
 'Relationship',
 'Race',
 'Sex',
 'Capital Gain',
 'Capital Loss',
 'Hours per week',
 'Country']
```

**Tip**

If you're starting with unlabeled data, you can use Amazon SageMaker Ground Truth to create a data labeling workflow in minutes. To learn more, see Label Data.

Overview the Dataset

Run the following script to display the statistical overview of the dataset and histograms of the numeric features.
Tip

If you want to use a dataset that needs to be cleaned and transformed, you can simplify and streamline data preprocessing and feature engineering using Amazon SageMaker Data Wrangler. To learn more, see [Prepare ML Data with Amazon SageMaker Data Wrangler](#).

### Split the Dataset into Train, Validation, and Test Datasets

Using Scikit-learn, split the dataset into a training set and a test set. The training set is used to train the model, while the test set is used to evaluate the performance of the final trained model. The dataset is randomly sorted with the fixed random seed: 80 percent of the dataset for training set and 20 percent of it for a test set.

```python
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=1)
X_train_display = X_display.loc[X_train.index]
```

Split the training set to separate out a validation set. The validation set is used to evaluate the performance of the trained model while tuning the model's hyperparameters. 75 percent of the training set becomes the final training set, and the rest is the validation set.

```python
X_train, X_val, y_train, y_val = train_test_split(X_train, y_train, test_size=0.25, random_state=1)
X_train_display = X_display.loc[X_train.index]
X_val_display = X_display.loc[X_val.index]
```
Using the pandas package, explicitly align each dataset by concatenating the numeric features with the true labels.

```python
import pandas as pd
train = pd.concat([pd.Series(y_train, index=X_train.index, name='Income>50K', dtype=int), X_train], axis=1)
validation = pd.concat([pd.Series(y_val, index=X_val.index, name='Income>50K', dtype=int), X_val], axis=1)
test = pd.concat([pd.Series(y_test, index=X_test.index, name='Income>50K', dtype=int), X_test], axis=1)
```

Check if the dataset is split and structured as expected:

**test**
Convert the Train and Validation Datasets to CSV Files

Convert the train and validation dataframe objects to CSV files to match the input file format for the XGBoost algorithm.

```python
# Use 'csv' format to store the data
# The first column is expected to be the output column
train.to_csv('train.csv', index=False, header=False)
validation.to_csv('validation.csv', index=False, header=False)
```

Upload the Datasets to Amazon S3

Using the SageMaker and Boto3, upload the training and validation datasets to the default Amazon S3 bucket. The datasets in the S3 bucket will be used by a compute-optimized SageMaker instance on Amazon EC2 for training.

The following code sets up the default S3 bucket URI for your current SageMaker session, creates a new demo-sagemaker-xgboost-adult-income-prediction folder, and uploads the training and validation datasets to the data subfolder.

```python
import sagemaker, boto3, os
bucket = sagemaker.Session().default_bucket()
prefix = "demo-sagemaker-xgboost-adult-income-prediction"
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'data/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'data/validation.csv')).upload_file('validation.csv')
```

Run the following AWS CLI to check if the CSV files are successfully uploaded to the S3 bucket.

```bash
! aws s3 ls {bucket}/{prefix}/data --recursive
```

This should return the following output:

```
2021-01-14 17:52:09 786285 demo-sagemaker-xgboost-adult-income-prediction/data/train.csv
2021-01-14 17:52:10 262122 demo-sagemaker-xgboost-adult-income-prediction/data/validation.csv
```
for training and the AWS infrastructures, such as Amazon Elastic Container Registry (Amazon ECR), Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3). For more information about SageMaker built-in framework estimators, see Frameworks in the Amazon SageMaker Python SDK documentation. For more information about built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528).

Topics
- Choose the Training Algorithm (p. 306)
- Create and Run a Training Job (p. 306)

Choose the Training Algorithm

To choose the right algorithm for your dataset, you typically need to evaluate different models to find the most suitable models to your data. For simplicity, the SageMaker XGBoost Algorithm (p. 1617) built-in algorithm is used throughout this tutorial without the pre-evaluation of models.

Tip
If you want SageMaker to find an appropriate model for your tabular dataset, use Amazon SageMaker Autopilot that automates a machine learning solution. For more information, see SageMaker Autopilot (p. 44).

Create and Run a Training Job

After you figured out which model to use, start constructing a SageMaker estimator for training. This tutorial uses the XGBoost built-in algorithm for the SageMaker generic estimator.

To run a model training job

1. Import the Amazon SageMaker Python SDK and start by retrieving the basic information from your current SageMaker session.

   ```python
   import sagemaker
   region = sagemaker.Session().boto_region_name
   print("AWS Region: {}".format(region))
   role = sagemaker.get_execution_role()
   print("RoleArn: {}".format(role))
   ```

   This returns the following information:
   - region – The current AWS Region where the SageMaker notebook instance is running.
   - role – The IAM role used by the notebook instance.

   Note
   Check the SageMaker Python SDK version by running sagemaker.__version__. This tutorial is based on sagemaker>=2.20. If the SDK is outdated, install the latest version by running the following command:

   ```bash
   ! pip install -qU sagemaker
   ```

   If you run this installation in your exiting SageMaker Studio or notebook instances, you need to manually refresh the kernel to finish applying the version update.

2. Create an XGBoost estimator using the sagemaker.estimator.Estimator class. In the following example code, the XGBoost estimator is named xgb_model.
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
from sagemaker.session import TrainingInput

s3_output_location='s3://{}/{}{}'.format(bucket, prefix, 'xgboost_model')

container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")
print(container)

xgb_model=sagemaker.estimator.Estimator(
    image_uri=container,
    role=role,
    instance_count=1,
    instance_type='ml.m4.xlarge',
    volume_size=5,
    output_path=s3_output_location,
    sagemaker_session=sagemaker.Session(),
    rules=[
        Rule.sagemaker(rule_configs.create_xgboost_report()),
        ProfilerRule.sagemaker(rule_configsProfilerReport())
    ]
)

To construct the SageMaker estimator, specify the following parameters:

- **image_uri** – Specify the training container image URI. In this example, the SageMaker XGBoost training container image URI is specified using `sagemaker.image_uris.retrieve`.

- **role** – The AWS Identity and Access Management (IAM) role that SageMaker uses to perform tasks on your behalf (for example, reading training results, call model artifacts from Amazon S3, and writing training results to Amazon S3).

- **instance_count** and **instance_type** – The type and number of Amazon EC2 ML compute instances to use for model training. For this training exercise, you use a single `ml.m4.xlarge` instance, which has 4 CPUs, 16 GB of memory, an Amazon Elastic Block Store (Amazon EBS) storage, and a high network performance. For more information about EC2 compute instance types, see [Amazon EC2 Instance Types](https://aws.amazon.com/ec2/instance-types/). For more information about billing, see [Amazon SageMaker pricing](https://aws.amazon.com/sagemaker/pricing).

- **volume_size** – The size, in GB, of the EBS storage volume to attach to the training instance. This must be large enough to store training data if you use File mode (File mode is on by default). If you don’t specify this parameter, its value defaults to 30.

- **output_path** – The path to the S3 bucket where SageMaker stores the model artifact and training results.

- **sagemaker_session** – The session object that manages interactions with SageMaker API operations and other AWS service that the training job uses.

- **rules** – Specify a list of SageMaker Debugger built-in rules. In this example, the `create_xgboost_report()` rule creates an XGBoost report that provides insights into the training progress and results, and the `ProfilerReport()` rule creates a report regarding the EC2 compute resource utilization. For more information, see [SageMaker Debugger XGBoost Training Report](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-debugger-xgboost-report.html).

**Tip**

If you want to run distributed training of large sized deep learning models, such as convolutional neural networks (CNN) and natural language processing (NLP) models, use SageMaker Distributed for data parallelism or model parallelism. For more information, see [Distributed training in Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/distributed-training.html).
3. Set the hyperparameters for the XGBoost algorithm by calling the `set_hyperparameters` method of the estimator. For a complete list of XGBoost hyperparameters, see XGBoost Hyperparameters (p. 1625).

```python
xgb_model.set_hyperparameters(
    max_depth = 5,
    eta = 0.2,
    gamma = 4,
    min_child_weight = 6,
    subsample = 0.7,
    objective = "binary:logistic",
    num_round = 1000
)
```

**Tip**
You can also tune the hyperparameters using the SageMaker hyperparameter optimization feature. For more information, see Perform Automatic Model Tuning with SageMaker (p. 1863).

4. Use the `TrainingInput` class to configure a data input flow for training. The following example code shows how to configure `TrainingInput` objects to use the training and validation datasets you uploaded to Amazon S3 in the Split the Dataset into Train, Validation, and Test Datasets (p. 303) section.

```python
from sagemaker.session import TrainingInput

train_input = TrainingInput(
    "s3://{}/{}/{}".format(bucket, prefix, "data/train.csv"), content_type="csv"
)

validation_input = TrainingInput(
    "s3://{}/{}/{}".format(bucket, prefix, "data/validation.csv"), content_type="csv"
)
```

5. To start model training, call the estimator's `fit` method with the training and validation datasets. By setting `wait=True`, the `fit` method displays progress logs and waits until training is complete.

```python
xgb_model.fit({'train': train_input, 'validation': validation_input}, wait=True)
```

For more information about model training, see Train a Model with Amazon SageMaker (p. 1521).
This tutorial training job might take up to 10 minutes.

After the training job has done, you can download an XGBoost training report and a profiling report generated by SageMaker Debugger. The XGBoost training report offers you insights into the training progress and results, such as the loss function with respect to iteration, feature importance, confusion matrix, accuracy curves, and other statistical results of training. For example, you can find the following loss curve from the XGBoost training report which clearly indicates that there is an overfitting problem.
Run the following code to specify the S3 bucket URI where the Debugger training reports are generated and check if the reports exist.

```python
rule_output_path = xgb_model.output_path + "/" + xgb_model.latest_training_job.job_name + "/rule-output"
! aws s3 ls {rule_output_path} --recursive
```

Download the Debugger XGBoost training and profiling reports to the current workspace:

```bash
! aws s3 cp {rule_output_path} ./ --recursive
```

Run the following IPython script to get the file link of the XGBoost training report:

```python
from IPython.display import FileLink, FileLinks
display("Click link below to view the XGBoost Training report", FileLink("CreateXgboostReport/xgboost_report.html"))
```

The following IPython script returns the file link of the Debugger profiling report that shows summaries and details of the EC2 instance resource utilization, system bottleneck detection results, and python operation profiling results:

```python
profiler_report_name = [rule["RuleConfigurationName"]
    for rule in xgb_model.latest_training_job.rule_job_summary()
    if "Profiler" in rule["RuleConfigurationName"]][0]

profiler_report_name
display("Click link below to view the profiler report", FileLink(profiler_report_name +"/profiler-output/profiler-report.html"))
```
Tip
If the HTML reports do not render plots in the JupyterLab view, you must choose Trust HTML at the top of the reports.
To identify training issues, such as overfitting, vanishing gradients, and other problems that prevents your model from converging, use SageMaker Debugger and take automated actions while prototyping and training your ML models. For more information, see Use Amazon SageMaker Debugger to debug and improve model performance (p. 1916). To find a complete analysis of model parameters, see the Explainability with Amazon SageMaker Debugger example notebook.

You now have a trained XGBoost model. SageMaker stores the model artifact in your S3 bucket. To find the location of the model artifact, run the following code to print the model_data attribute of the xgb_model estimator:

```python
xgb_model.model_data
```

Tip
To measure biases that can occur during each stage of the ML lifecycle (data collection, model training and tuning, and monitoring of ML models deployed for prediction), use SageMaker Clarify. For more information, see Amazon SageMaker Clarify Model Explainability (p. 3241). For an end-to-end example, see the Fairness and Explainability with SageMaker Clarify example notebook.

### Step 5: Deploy the Model to Amazon EC2

To get predictions, deploy your model to Amazon EC2 using Amazon SageMaker.

**Topics**
- Deploy the Model to SageMaker Hosting Services (p. 310)
- (Optional) Use SageMaker Predictor to Reuse the Hosted Endpoint (p. 311)
- (Optional) Make Prediction with Batch Transform (p. 311)

**Deploy the Model to SageMaker Hosting Services**

To host a model through Amazon EC2 using Amazon SageMaker, deploy the model that you trained in Create and Run a Training Job (p. 306) by calling the deploy method of the xgb_model estimator. When you call the deploy method, you must specify the number and type of EC2 ML instances that you want to use for hosting an endpoint.

```python
import sagemaker
from sagemaker.serializers import CSVSerializer
xgb_predictor=xgb_model.deploy(
    initial_instance_count=1,
    instance_type='ml.t2.medium',
    serializer=CSVSerializer()
)
```

- `initial_instance_count` (int) – The number of instances to deploy the model.
- `instance_type` (str) – The type of instances that you want to operate your deployed model.
- `serializer` (int) – Serialize input data of various formats (a NumPy array, list, file, or buffer) to a CSV-formatted string. We use this because the XGBoost algorithm accepts input files in CSV format.
The deploy method creates a deployable model, configures the SageMaker hosting services endpoint, and launches the endpoint to host the model. For more information, see the SageMaker generic Estimator's deploy class method in the Amazon SageMaker Python SDK. To retrieve the name of the endpoint that's generated by the deploy method, run the following code:

```
xgb_predictor.endpoint_name
```

This should return the endpoint name of the `xgb_predictor`. The format of the endpoint name is "sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS". This endpoint stays active in the ML instance, and you can make instantaneous predictions at any time unless you shut it down later. Copy this endpoint name and save it to reuse and make real-time predictions elsewhere in SageMaker Studio or SageMaker notebook instances.

**Tip**

To learn more about compiling and optimizing your model for deployment to Amazon EC2 instances or edge devices, see Compile and Deploy Models with Neo.

(Optional) Use SageMaker Predictor to Reuse the Hosted Endpoint

After you deploy the model to an endpoint, you can set up a new SageMaker predictor by pairing the endpoint and continuously make real-time predictions in any other notebooks. The following example code shows how to use the SageMaker Predictor class to set up a new predictor object using the same endpoint. Re-use the endpoint name that you used for the `xgb_predictor`.

```python
import sagemaker
xgb_predictor_reuse = sagemaker.predictor.Predictor(
    endpoint_name="sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS",
    sagemaker_session=sagemaker.Session(),
    serializer=sagemaker.serializers.CSVSerializer()
)
```

The `xgb_predictor_reuse` Predictor behaves exactly the same as the original `xgb_predictor`. For more information, see the SageMaker Predictor class in the Amazon SageMaker Python SDK.

(Optional) Make Prediction with Batch Transform

Instead of hosting an endpoint in production, you can run a one-time batch inference job to make predictions on a test dataset using the SageMaker batch transform. After your model training has completed, you can extend the estimator to a transformer object, which is based on the SageMaker Transformer class. The batch transformer reads in input data from a specified S3 bucket and makes predictions.

**To run a batch transform job**

1. Run the following code to convert the feature columns of the test dataset to a CSV file and uploads to the S3 bucket:

   ```python
   X_test.to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'test/test.csv')).upload_file('test.csv')
   ```

2. Specify S3 bucket URIs of input and output for the batch transform job as shown following:

   ```python
   # The location of the test dataset
   batch_input = 's3:///{}/test'.format(bucket, prefix)
   ```
3. Create a transformer object specifying the minimal number of parameters: the `instance_count` and `instance_type` parameters to run the batch transform job, and the `output_path` to save prediction data as shown following:

```python
transformer = xgb_model.transformer(
    instance_count=1,
    instance_type='ml.m4.xlarge',
    output_path=batch_output
)
```

4. Initiate the batch transform job by executing the `transform()` method of the `transformer` object as shown following:

```python
transformer.transform(
    data=batch_input,
    data_type='S3Prefix',
    content_type='text/csv',
    split_type='Line'
)
transformer.wait()
```

5. When the batch transform job is complete, SageMaker creates the `test.csv.out` prediction data saved in the `batch_output` path, which should be in the following format: `s3://sagemaker-<region>-111122223333/demo-sagemaker-xgboost-adult-income-prediction/batch-prediction`. Run the following AWS CLI to download the output data of the batch transform job:

```bash
! aws s3 cp {batch_output} ./ --recursive
```

This should create the `test.csv.out` file under the current working directory. You'll be able to see the float values that are predicted based on the logistic regression of the XGBoost training job.

---

**Step 6: Evaluate the Model**

Now that you have trained and deployed a model using Amazon SageMaker, evaluate the model to ensure that it generates accurate predictions on new data. For model evaluation, use the test dataset that you created in *Step 3: Download, Explore, and Transform a Dataset (p. 302)*.

**Evaluate the Model Deployed to SageMaker Hosting Services**

To evaluate the model and use it in production, invoke the endpoint with the test dataset and check whether the inferences you get returns a target accuracy you want to achieve.

**To evaluate the model**

1. Set up the following function to predict each line of the test set. In the following example code, the `rows` argument is to specify the number of lines to predict at a time. You can change the value of it to perform a batch inference that fully utilizes the instance’s hardware resource.

```python
import numpy as np

def predict(data, rows=1000):
    split_array = np.array_split(data, int(data.shape[0] / float(rows) + 1))
    predictions = ''
    for array in split_array:
        predictions = ','.join([predictions,
                                xgb_predictor.predict(array).decode('utf-8')])
```

---

312
2. Run the following code to make predictions of the test dataset and plot a histogram. You need to take only the feature columns of the test dataset, excluding the 0th column for the actual values.

```python
import matplotlib.pyplot as plt
predictions=predict(test.to_numpy()[:,1:])
plt.hist(predictions)
plt.show()
```

3. The predicted values are float type. To determine True or False based on the float values, you need to set a cutoff value. As shown in the following example code, use the Scikit-learn library to return the output confusion metrics and classification report with a cutoff of 0.5.

```python
import sklearn
cutoff=0.5
print(sklearn.metrics.confusion_matrix(test.iloc[:, 0], np.where(predictions > cutoff, 1, 0)))
print(sklearn.metrics.classification_report(test.iloc[:, 0], np.where(predictions > cutoff, 1, 0)))
```

This should return the following confusion matrix:

```
[[4670  356]
 [ 480 1007]]
```

<table>
<thead>
<tr>
<th>precision</th>
<th>recall</th>
<th>f1-score</th>
<th>support</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.91</td>
<td>0.93</td>
<td>5026</td>
</tr>
<tr>
<td>1</td>
<td>0.74</td>
<td>0.68</td>
<td>1487</td>
</tr>
</tbody>
</table>

| accuracy | 0.87 | 6513    |
| macro avg| 0.82 | 0.80    | 6513    |
| weighted avg| 0.87 | 0.87    | 6513    |

4. To find the best cutoff with the given test set, compute the log loss function of the logistic regression. The log loss function is defined as the negative log-likelihood of a logistic model that returns prediction probabilities for its ground truth labels. The following example code numerically and iteratively calculates the log loss values \(-y \cdot \log(p) + (1-y) \cdot \log(1-p)\), where \(y\) is the true label and \(p\) is a probability estimate of the corresponding test sample. It returns a log loss versus cutoff graph.

```python
import matplotlib.pyplot as plt
```
cutoffs = np.arange(0.01, 1, 0.01)
log_loss = []
for c in cutoffs:
    log_loss.append(
        sklearn.metrics.log_loss(test.iloc[:, 0], np.where(predictions > c, 1, 0))
    )
plt.figure(figsize=(15,10))
plt.plot(cutoffs, log_loss)
plt.xlabel("Cutoff")
plt.ylabel("Log loss")
plt.show()

This should return the following log loss curve.

5. Find the minimum points of the error curve using the NumPy `argmin` and `min` functions:

```python
print(  
    'Log loss is minimized at a cutoff of ', cutoffs[np.argmin(log_loss)],  
    ',', and the log loss value at the minimum is ', np.min(log_loss)  
)
```

This should return: Log loss is minimized at a cutoff of 0.53, and the log loss value at the minimum is 4.348539186773897.

Instead of computing and minimizing the log loss function, you can estimate a cost function as an alternative. For example, if you want to train a model to perform a binary classification for a business problem such as a customer churn prediction problem, you can set weights to the elements of confusion matrix and calculate the cost function accordingly.

You have now trained, deployed, and evaluated your first model in SageMaker.

**Tip**
To monitor model quality, data quality, and bias drift, use Amazon SageMaker Model Monitor and SageMaker Clarify. To learn more, see Amazon SageMaker Model Monitor, Monitor Data Quality, Monitor Model Quality, Monitor Bias Drift, and Monitor Feature Attribution Drift.
**Tip**
To get human review of low confidence ML predictions or a random sample of predictions, use Amazon Augmented AI human review workflows. For more information, see [Using Amazon Augmented AI for Human Review](#).

## Step 7: Clean Up

To avoid incurring unnecessary charges, use the AWS Management Console to delete the endpoints and resources that you created while running the exercises.

**Note**
Training jobs and logs cannot be deleted and are retained indefinitely.

**Note**
If you plan to explore other exercises in this guide, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the Amazon SageMaker console at [https://console.aws.amazon.com/sagemaker/](https://console.aws.amazon.com/sagemaker/) and delete the following resources:
   - The endpoint. Deleting the endpoint also deletes the ML compute instance or instances that support it.
     1. Under **Inference**, choose **Endpoints**.
     2. Choose the endpoint that you created in the example, choose **Actions**, and then choose **Delete**.
   - The endpoint configuration.
     1. Under **Inference**, choose **Endpoint configurations**.
     2. Choose the endpoint configuration that you created in the example, choose **Actions**, and then choose **Delete**.
   - The model.
     1. Under **Inference**, choose **Models**.
     2. Choose the model that you created in the example, choose **Actions**, and then choose **Delete**.
   - The notebook instance. Before deleting the notebook instance, stop it.
     1. Under **Notebook**, choose **Notebook instances**.
     2. Choose the notebook instance that you created in the example, choose **Actions**, and then choose **Stop**. The notebook instance takes several minutes to stop. When the **Status** changes to **Stopped**, move on to the next step.
     3. Choose **Actions**, and then choose **Delete**.

2. Open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/), and then delete the bucket that you created for storing model artifacts and the training dataset.

3. Open the Amazon CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/), and then delete all of the log groups that have names starting with `/aws/sagemaker/`.

## Amazon Linux 2 notebook instances

Amazon SageMaker notebook instances currently support Amazon Linux 2 (AL2) operating systems. You can select the operating system that your notebook instance is based on when you create the notebook instance.

SageMaker supports notebook instances based on the following Amazon Linux 2 operating systems.

- **notebook-al2-v1**: These notebook instances support JupyterLab version 1. For information about JupyterLab versions, see [JupyterLab versioning](#).
- **notebook-al2-v2**: These notebook instances support JupyterLab version 3. For information about JupyterLab versions, see [JupyterLab versioning](p. 317).

Notebook instances created before 08/18/2021 automatically run on Amazon Linux (AL1). Notebook instances based on AL1 entered a maintenance phase as of 12/01/2022 and are no longer available for new notebook instance creation as of 02/01/2023. To replace AL1, you now have the option to create Amazon SageMaker notebook instances with AL2. For more information, see [AL1 Maintenance Phase Plan](p. 317).

**Topics**
- [Supported instance types](p. 316)
- [Available Kernels](p. 316)
- [AL1 Maintenance Phase Plan](p. 317)

**Supported instance types**

Amazon Linux 2 supports instance types listed under **Notebook Instances** in [Amazon SageMaker Pricing](p. 316) with the exception that Amazon Linux 2 does not support ml.p2 instances.

**Available Kernels**

The following table gives information about the available kernels for SageMaker notebook instances. All of these images are supported on notebook instances based on both the `notebook-al2-v1` and `notebook-al2-v2` operating systems.

### SageMaker notebook instance kernels

<table>
<thead>
<tr>
<th>Kernel name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>A kernel used to perform data analysis and visualization using R code from a Jupyter notebook.</td>
</tr>
<tr>
<td>Sparkmagic (PySpark)</td>
<td>A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the Python programming language. This kernel comes with Python 3.10.</td>
</tr>
<tr>
<td>Sparkmagic (Spark)</td>
<td>A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the Scala programming language. This kernel comes with Python 3.10.</td>
</tr>
<tr>
<td>Sparkmagic (SparkR)</td>
<td>A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the R programming language. This kernel comes with Python 3.10.</td>
</tr>
<tr>
<td>conda_python3</td>
<td>A conda environment that comes pre-installed with popular packages for data science and machine learning. This kernel comes with Python 3.10.</td>
</tr>
<tr>
<td>conda_pytorch_p310</td>
<td>A conda environment that comes pre-installed with PyTorch version 2.0.1, as well as popular</td>
</tr>
</tbody>
</table>
### Kernel name

<table>
<thead>
<tr>
<th>Kernel name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>data science and machine learning packages. This kernel comes with Python 3.10.</td>
</tr>
<tr>
<td>conda_tensorflow2_p310</td>
<td>A conda environment that comes pre-installed with TensorFlow version 2.13, as well as popular data science and machine learning packages. This kernel comes with Python 3.10.</td>
</tr>
</tbody>
</table>

### AL1 Maintenance Phase Plan

The following table is a timeline for when AL1 entered its extended maintenance phase. The AL1 maintenance phase also coincides with the deprecation of Python 2 and Chainer. Notebooks based on AL2 do not have managed Python 2 and Chainer kernels.

<table>
<thead>
<tr>
<th>Date</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>08/18/2021</td>
<td>Notebook instances based on AL2 are launched. Newly launched notebook instances still default to AL1. AL1 is supported with security patches and updates, but no new features. You can choose between the two operating systems when launching a new notebook instance.</td>
</tr>
<tr>
<td>10/31/2022</td>
<td>The default platform identifier for SageMaker notebook instances changes from Amazon Linux (al1-v1) to Amazon Linux 2 (al2-v2). You can choose between the two operating systems when launching a new notebook instance.</td>
</tr>
<tr>
<td>12/01/2022</td>
<td>AL1 is no longer supported with non-critical security patches and updates. AL1 still receives fixes for critical security-related issues. You can still launch instances on AL1, but assume the risks associated with using an unsupported operating system.</td>
</tr>
<tr>
<td>02/01/2023</td>
<td>AL1 is no longer an available option for new notebook instance creation. After this date, customers can create notebook instances with the AL2 platform identifiers. Existing al1-v1 notebook instances are not affected.</td>
</tr>
</tbody>
</table>

### Migrating to Amazon Linux 2

Your existing AL1 notebook instance is not automatically migrated to Amazon Linux 2. To upgrade your AL1 notebook instance to Amazon Linux 2, you must create a new notebook instance, replicate your code and environment, and delete your old notebook instance. For more information, see the Amazon Linux 2 migration blog.

### JupyterLab versioning

The Amazon SageMaker notebook instance interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Notebooks now support using...
either JupyterLab 1 or JupyterLab 3. A single notebook instance can run a single instance of JupyterLab (at most). You can have multiple notebook instances with different JupyterLab versions.

You can configure your notebook to run your preferred JupyterLab version by selecting the appropriate platform identifier. Use either the AWS CLI or the SageMaker console when creating your notebook instance. For more information about platform identifiers, see Amazon Linux 2 vs Amazon Linux notebook instances. If you don’t explicitly configure a platform identifier, your notebook instance defaults to running JupyterLab 1.

Topics
• JupyterLab 3 (p. 318)
• Creating a notebook with your JupyterLab version (p. 319)
• View the JupyterLab version of a notebook from the console (p. 319)

JupyterLab 3

JupyterLab 3 support is available only on the Amazon Linux 2 operating system platform. JupyterLab 3 includes the following features that are not available in JupyterLab 1. For more information about these features, see JupyterLab 3.0 is released!

• Visual debugger when using the following kernels:
  • conda_pytorch_p38
  • conda_tensorflow2_p38
  • conda_amazonei_pytorch_latest_p37
• File browser filter
• Table of Contents (TOC)
• Multi-language support
• Simple mode
• Single interface mode
• Live editing SVG files with updated rendering
• User interface for notebook cell tags

Important changes to JupyterLab 3

For information about important changes when using JupyterLab 3, see the following JupyterLab change logs:
• v2.0.0
• v3.0.0

Package version changes

JupyterLab 3 has the following package version changes from JupyterLab 1:
• JupyterLab has been upgraded from 1.x to 3.x.
• Jupyter notebook has been upgraded from 5.x to 6.x.
• jupyterlab-git has been updated to version 0.37.1.
• nbserverproxy 0.x (0.3.2) has been replaced with jupyter-server-proxy 3.x (3.2.1).
Creating a notebook with your JupyterLab version

You can select the JupyterLab version when creating your notebook instance from the console following the steps in Create a Notebook Instance (p. 319).

You can also select the JupyterLab version by passing the `platform-identifier` parameter when creating your notebook instance using the AWS CLI as follows:

```
create-notebook-instance --notebook-instance-name <NEW_NOTEBOOK_NAME> \
--instance-type <INSTANCE_TYPE> \
--role-arn <YOUR_ROLE_ARN> \
--platform-identifier <PLATFORM_TO_USE>
```

View the JupyterLab version of a notebook from the console

You can view the JupyterLab version of a notebook using the following procedure:

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the left navigation, select Notebook.
3. From the dropdown menu, select Notebook instances to navigate to the Notebook instances page.
4. From the list of notebook instances, select your notebook instance name.
5. On the Notebook instance settings page, view the Platform Identifier to see the JupyterLab version of the notebook.

Create a Notebook Instance

An Amazon SageMaker notebook instance is a ML compute instance running the Jupyter Notebook App. SageMaker manages creating the instance and related resources. Use Jupyter notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models.

To create a notebook instance, use either the SageMaker console or the CreateNotebookInstance API.

The notebook instance type you choose depends on how you use your notebook instance. You want to ensure that your notebook instance is not bound by memory, CPU, or I/O. If you plan to load a dataset into memory on the notebook instance for exploration or preprocessing, we recommend that you choose an instance type with enough RAM memory for your dataset. This would require an instance with at least 16 GB of memory (xlarge or larger). If you plan to use the notebook for compute intensive preprocessing, we recommend you choose a compute-optimized instance such as a c4 or c5.

A best practice when using a SageMaker notebook is to use the notebook instance to orchestrate other AWS services. For example, you can use the notebook instance to manage large dataset processing by making calls to AWS Glue for ETL (extract, transform, and load) services or Amazon EMR for mapping and data reduction using Hadoop. You can use AWS services as temporary forms of computation or storage for your data.

You can store and retrieve your training and test data using an Amazon S3 bucket. You can then use SageMaker to train and build your model, so the instance type of your notebook would have no bearing on the speed of your model training and testing.

After receiving the request, SageMaker does the following:

- Creates a network interface—If you choose the optional VPC configuration, SageMaker creates the network interface in your VPC. It uses the subnet ID that you provide in the request to determine which Availability Zone to create the subnet in. SageMaker associates the security group that you
Create a Notebook Instance

provide in the request with the subnet. For more information, see Connect a Notebook Instance in a VPC to External Resources (p. 3524).

- **Launches an ML compute instance**—SageMaker launches an ML compute instance in a SageMaker VPC. SageMaker performs the configuration tasks that allow it to manage your notebook instance, and if you specified your VPC, it enables traffic between your VPC and the notebook instance.

- **Installs Anaconda packages and libraries for common deep learning platforms**—SageMaker installs all of the Anaconda packages that are included in the installer. For more information, see Anaconda package list. In addition, SageMaker installs the Tensorflow and Apache MXNet deep learning libraries.

- **Attaches an ML storage volume**—SageMaker attaches an ML storage volume to the ML compute instance. You can use the volume as a working area to clean up the training dataset or to temporarily store validation, test, or other data. Choose any size between 5 GB and 16384 GB, in 1 GB increments, for the volume. The default is 5 GB. ML storage volumes are encrypted, so SageMaker can't determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can't decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

Only files and data saved within the /home/ec2-user/SageMaker folder persist between notebook instance sessions. Files and data that are saved outside this directory are overwritten when the notebook instance stops and restarts. Each notebook instance's /tmp directory provides a minimum of 10 GB of storage in an instance store. An instance store is temporary, block-level storage that isn't persistent. When the instance is stopped or restarted, SageMaker deletes the directory's contents. This temporary storage is part of the root volume of the notebook instance.

- **Copies example Jupyter notebooks**—These Python code examples illustrate model training and hosting exercises using various algorithms and training datasets.

**To create a SageMaker notebook instance:**

2. Choose Notebook instances, then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   
   a. For Notebook instance name, type a name for your notebook instance.

   b. For Notebook instance type, choose an instance size suitable for your use case. For a list of supported instance types and quotas, see Amazon SageMaker Service Quotas.

   c. For Elastic Inference, choose an inference accelerator type to associate with the notebook instance if you plan to conduct inferences from the notebook instance, or choose none. For information about elastic inference, see Use Amazon SageMaker Elastic Inference (EI) (p. 2760).

   d. For Platform Identifier, choose a platform type to create the notebook instance on. This platform type dictates the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see Amazon Linux 2 notebook instances (p. 315). For information about JupyterLab versions, see JupyterLab versioning (p. 317).

   e. (Optional) Additional configuration lets advanced users create a shell script that can run when you create or start the instance. This script, called a lifecycle configuration script, can be used to set the environment for the notebook or to perform other functions. For information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 323).

   f. (Optional) Additional configuration also lets you specify the size, in GB, of the ML storage volume that is attached to the notebook instance. You can choose a size between 5 GB and 16,384 GB, in 1 GB increments. You can use the volume to clean up the training dataset or to temporarily store validation or other data.

   g. (Optional) For Minimum IMDS Version, select a version from the dropdown list. If this value is set to v1, both versions can be used with the notebook instance. If v2 is selected, then only IMDSv2 can be used with the notebook instance. For information about IMDSv2, see Use IMDSv2.
Note
Starting October 31, 2022, the default minimum IMDS Version for SageMaker
notebook instances changes from IMDSv1 to IMDSv2.
Starting February 1, 2023, IMDSv1 is no longer be available for new notebook instance
creation. After this date, you can create notebook instances with a minimum IMDS
version of 2.

h. For IAM role, choose either an existing IAM role in your account that has the
necessary permissions to access SageMaker resources or choose Create a new
role. If you choose Create a new role, SageMaker creates an IAM role named
AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmsS. The AWS managed policy
AmazonSageMakerFullAccess is attached to the role. The role provides permissions
that allow the notebook instance to call SageMaker and Amazon S3.

i. For Root access, to enable root access for all notebook instance users, choose Enable. To disable
root access for users, choose Disable. If you enable root access, all notebook instance users have
administrator privileges and can access and edit all files on it.

j. (Optional) Encryption key lets you encrypt data on the ML storage volume attached to the
notebook instance using an AWS Key Management Service (AWS KMS) key. If you plan to store
sensitive information on the ML storage volume, consider encrypting the information.

k. (Optional) Network lets you put your notebook instance inside a Virtual Private Cloud (VPC).
A VPC provides additional security and restricts access to resources in the VPC from sources
outside the VPC. For more information on VPCs, see Amazon VPC User Guide.

To add your notebook instance to a VPC:

i. Choose the VPC and a SubnetId.

ii. For Security Group, choose your VPC’s default security group.

iii. If you need your notebook instance to have internet access, enable direct internet access.
For Direct internet access, choose Enable. Internet access can make your notebook
instance less secure. For more information, see Connect a Notebook Instance in a VPC to
External Resources (p. 3524).

l. (Optional) To associate Git repositories with the notebook instance, choose a default repository
and up to three additional repositories. For more information, see Associate Git Repositories
with SageMaker Notebook Instances (p. 332).

m. Choose Create notebook instance.

In a few minutes, Amazon SageMaker launches an ML compute instance—in this case, a
notebook instance—and attaches an ML storage volume to it. The notebook instance has a
preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information,
see the CreateNotebookInstance API.

4. When the status of the notebook instance is InService, in the console, the notebook instance
is ready to use. Choose Open Jupyter next to the notebook name to open the classic Jupyter
dashboard.

You can choose Open JupyterLab to open the JupyterLab dashboard. The dashboard provides
access to your notebook instance and sample SageMaker notebooks that contain complete code
walkthroughs. These walkthroughs show how to use SageMaker to perform common machine
learning tasks. For more information, see Example Notebooks (p. 330). For more information, see
Control root access to a SageMaker notebook instance (p. 3343).

For more information about Jupyter notebooks, see The Jupyter notebook.
Access Notebook Instances

To access your Amazon SageMaker notebook instances, choose one of the following options:

- **Use the console.**

  Choose Notebook instances. The console displays a list of notebook instances in your account. To open a notebook instance with a standard Jupyter interface, choose Open Jupyter for that instance. To open a notebook instance with a JupyterLab interface, choose Open JupyterLab for that instance.

  The console uses your sign-in credentials to send a CreatePresignedNotebookInstanceUrl API request to SageMaker. SageMaker returns the URL for your notebook instance, and the console opens the URL in another browser tab and displays the Jupyter notebook dashboard.

    **Note**
    The URL that you get from a call to CreatePresignedNotebookInstanceUrl is valid only for 5 minutes. If you try to use the URL after the 5-minute limit expires, you are directed to the AWS Management Console sign-in page.

- **Use the API.**

  To get the URL for the notebook instance, call the CreatePresignedNotebookInstanceUrl API and use the URL that the API returns to open the notebook instance.

Use the Jupyter notebook dashboard to create and manage notebooks and to write code. For more information about Jupyter notebooks, see [http://jupyter.org/documentation.html](http://jupyter.org/documentation.html).

Update a Notebook Instance

After you create a notebook instance, you can update it using the SageMaker console and UpdateNotebookInstance API operation.

You can update the tags of a notebook instance that is InService. To update any other attribute of a notebook instance, its status must be Stopped.

**To update a notebook instance in the SageMaker console:**

2. Choose Notebook instances.
3. Choose the notebook instance that you want to update by selecting the notebook instance Name from the list.
4. If your notebook Status is not Stopped, select the Stop button to stop the notebook instance.

    When you do this, the notebook instance status changes to Stopping. Wait until the status changes to Stopped to complete the following steps.
5. Select the Edit button to open the Edit notebook instance page. For information about the notebook properties you can update, see Create a Notebook Instance (p. 319).

6. Update your notebook instance and select the Update notebook instance button at the bottom of the page when you are done to return to the notebook instances page. Your notebook instance status changes to Updating.

When the notebook instance update is complete, the status changes to Stopped.

Customize a Notebook Instance Using a Lifecycle Configuration Script

To install packages or sample notebooks on your notebook instance, configure networking and security for it, or otherwise use a shell script to customize it, use a lifecycle configuration. A lifecycle configuration provides shell scripts that run only when you create the notebook instance or whenever you start one. When you create a notebook instance, you can create a new lifecycle configuration and the scripts it uses or apply one that you already have.

You can also use a lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook to control other AWS resources, such as an Amazon EMR instance.

We maintain a public repository of notebook lifecycle configuration scripts that address common use cases for customizing notebook instances at https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-configuration-samples.

Note

Each script has a limit of 16384 characters.

The value of the $PATH environment variable that is available to both scripts is /usr/local/sbin:/usr/local/bin:/usr/bin:/usr/sbin:/sbin:/bin. The working directory, which is the value of the $PWD environment variable, is /.

View CloudWatch Logs for notebook instance lifecycle configurations in log group /aws/sagemaker/NotebookInstances in log stream [notebook-instance-name]/[LifecycleConfigHook].

Scripts cannot run for longer than 5 minutes. If a script runs for longer than 5 minutes, it fails and the notebook instance is not created or started. To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments in which to install large packages.
- Run tasks in parallel processes.
- Use the nohup command in your script.

You can see a list of notebook instance lifecycle configurations you previously created by choosing Lifecycle configuration in the SageMaker console. You can attach a notebook instance lifecycle configuration when you create a new notebook instance. For more information about creating a notebook instance, see Create a Notebook Instance (p. 319).

To create a lifecycle configuration

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Lifecycle configurations.
4. From the Lifecycle configurations page, choose the Notebook Instance tab.
5. Choose Create configuration.
6. For Name, type a name using alphanumeric characters and "-", but no spaces. The name can have a maximum of 63 characters.

7. (Optional) To create a script that runs when you create the notebook and every time you start it, choose Start notebook.

8. In the Start notebook editor, type the script.

9. (Optional) To create a script that runs only once, when you create the notebook, choose Create notebook.

10. In the Create notebook editor, type the script configure networking.

11. Choose Create configuration.

Lifecycle Configuration Best Practices

The following are best practices for using lifecycle configurations:

Important
We do not recommend storing sensitive information in your lifecycle configuration script.

- Lifecycle configurations run as the root user. If your script makes any changes within the /home/ec2-user/SageMaker directory, (for example, installing a package with pip), use the command sudo -u ec2-user to run as the ec2-user user. This is the same user that Amazon SageMaker runs as.
- SageMaker notebook instances use conda environments to implement different kernels for Jupyter notebooks. If you want to install packages that are available to one or more notebook kernels, enclose the commands to install the packages with conda environment commands that activate the conda environment that contains the kernel where you want to install the packages.

For example, if you want to install a package only for the python3 environment, use the following code:

```bash
#!/bin/bash
sudo -u ec2-user -i <<EOF
# This will affect only the Jupyter kernel called "conda_python3".
sudo -u ec2-user bash -c "source activate python3"
# Replace myPackage with the name of the package you want to install.
pip install myPackage
# You can also perform "conda install" here as well.
source deactivate
EOF
```

If you want to install a package in all conda environments in the notebook instance, use the following code:

```bash
#!/bin/bash
sudo -u ec2-user -i <<EOF
# Note that "base" is special environment name, include it there as well.
for env in base /home/ec2-user/anaconda3/envs/*; do
    source /home/ec2-user/anaconda3/bin/activate $env
    # Installing packages in the Jupyter system environment can affect stability of your SageMaker
    # Notebook Instance. You can remove this check if you'd like to install Jupyter extensions, etc.
    if [ $env = 'JupyterSystemEnv' ]; then
        continue
    fi
    # Perform installation here.
EOF
```
# Replace `myPackage` with the name of the package you want to install.

```bash
    pip install --upgrade --quiet myPackage

    # You can also perform "conda install" here as well.
```

```bash
    source /home/ec2-user/anaconda3/bin/deactivate
done
EOF
```

- You must store all conda environments in the default environments folder (`/home/user/anaconda3/envs`).

**Important**

When you create or change a script, we recommend that you use a text editor that provides Unix-style line breaks, such as the text editor available in the console when you create a notebook. Copying text from a non-Linux operating system might introduce incompatible line breaks and result in an unexpected error.

Install External Libraries and Kernels in Notebook Instances

Amazon SageMaker notebook instances come with multiple environments already installed. These environments contain Jupyter kernels and Python packages including: scikit, Pandas, NumPy, TensorFlow, and MXNet. These environments, along with all files in the sample-notebooks folder, are refreshed when you stop and start a notebook instance. You can also install your own environments that contain your choice of packages and kernels.

The different Jupyter kernels in Amazon SageMaker notebook instances are separate conda environments. For information about conda environments, see Managing environments in the Conda documentation.

Install custom environments and kernels on the notebook instance's Amazon EBS volume. This ensures that they persist when you stop and restart the notebook instance, and that any external libraries you install are not updated by SageMaker. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook instance (on-create) and a script that runs each time you restart the notebook instance (on-start). For more information about using notebook instance lifecycle configurations, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 323).

There is a GitHub repository that contains sample lifecycle configuration scripts at SageMaker Notebook Instance Lifecycle Config Samples.

The examples at [https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-create.sh](https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-create.sh) and [https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-start.sh](https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-start.sh) show the best practice for installing environments and kernels on a notebook instance. The on-create script installs the ipykernel library to create custom environments as Jupyter kernels, then uses pip install and conda install to install libraries. You can adapt the script to create custom environments and install libraries that you want. SageMaker does not update these libraries when you stop and restart the notebook instance, so you can ensure that your custom environment has specific versions of libraries that you want. The on-start script installs any custom environments that you create as Jupyter kernels, so that they appear in the dropdown list in the Jupyter New menu.

**Package installation tools**

SageMaker notebooks support the following package installation tools:

- conda install
- pip install
You can install packages using the following methods:

- Lifecycle configuration scripts.
  
  For example scripts, see SageMaker Notebook Instance Lifecycle Config Samples. For more information on lifecycle configuration, see Customize a Notebook Instance Using a Lifecycle Configuration Script.
- Notebooks – The following commands are supported.
  
  - `%conda install`
  - `%pip install`
  
  - The Jupyter terminal – You can install packages using pip and conda directly.

From within a notebook you can use the system command syntax (lines starting with !) to install packages, for example, `!pip install` and `!conda install`. More recently, new commands have been added to IPython: `%pip` and `%conda`. These commands are the recommended way to install packages from a notebook as they correctly take into account the active environment or interpreter being used. For more information, see Add %pip and %conda magic functions.

Conda

Conda is an open source package management system and environment management system, which can install packages and their dependencies. SageMaker supports using Conda with either of the two main channels, the default channel, and the conda-forge channel. For more information, see Conda channels. The conda-forge channel is a community channel where contributors can upload packages.

Note

Due to how Conda resolves the dependency graph, installing packages from conda-forge can take significantly longer (in the worst cases, upwards of 10 minutes).

The Deep Learning AMI comes with many conda environments and many packages preinstalled. Due to the number of packages preinstalled, finding a set of packages that are guaranteed to be compatible is difficult. You may see a warning "The environment is inconsistent, please check the package plan carefully". Despite this warning, SageMaker ensures that all the SageMaker provided environments are correct. SageMaker cannot guarantee that any user installed packages will function correctly.

Note

Users of SageMaker, AWS Deep Learning AMI and Amazon EMR can access the commercial Anaconda repository without taking a commercial license through February 1, 2024 when using Anaconda in those services. For any usage outside of these three services, customers are responsible for determining their own Anaconda license requirements.

Conda has two methods for activating environments: conda activate/deactivate, and source activate/deactivate. For more information, see Should I use 'conda activate' or 'source activate' in Linux.

SageMaker supports moving Conda environments onto the Amazon EBS volume, which is persisted when the instance is stopped. The environments aren’t persisted when the environments are installed to the root volume, which is the default behavior. For an example lifecycle script, see persistent-conda-ebs.

Supported conda operations (see note at the bottom of this topic)

- conda install of a package in a single environment
- conda install of a package in all environments
- conda install of a R package in the R environment
- Installing a package from the main conda repository
- Installing a package from conda-forge
- Changing the Conda install location to use EBS
- Supporting both conda activate and source activate
Pip

Pip is the de facto tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike Conda, pip doesn't have built in environment support, and is not as thorough as Conda when it comes to packages with native/system library dependencies. Pip can be used to install packages in Conda environments.

You can use alternative package repositories with pip instead of the PyPI. For an example lifecycle script, see on-start.sh.

Supported pip operations (see note at the bottom of this topic)

- Using pip to install a package without an active conda environment (install packages system wide)
- Using pip to install a package in a conda environment
- Using pip to install a package in all conda environments
- Changing the pip install location to use EBS
- Using an alternative repository to install packages with pip

Unsupported

SageMaker aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker or DLAMI, and you use the following operations on these packages, it might make your notebook instance unstable:

- Uninstalling
- Downgrading
- Upgrading

We do not provide support for installing packages via yum install or installing R packages from CRAN.

Due to potential issues with network conditions or configurations, or the availability of Conda or PyPi, we cannot guarantee that packages will install in a fixed or deterministic amount of time.

Note

We cannot guarantee that a package installation will be successful. Attempting to install a package in an environment with incompatible dependencies can result in a failure. In such a case you should contact the library maintainer to see if it is possible to update the package dependencies. Alternatively you can attempt to modify the environment in such a way as to allow the installation. This modification however will likely mean removing or updating existing packages, which means we can no longer guarantee stability of this environment.

Notebook Instance Software Updates

Amazon SageMaker periodically tests and releases software that is installed on notebook instances. This includes:

- Kernel updates
- Security patches
- AWS SDK updates
- Amazon SageMaker Python SDK updates
- Open source software updates

To ensure that you have the most recent software updates, stop and restart your notebook instance, either in the SageMaker console or by calling StopNotebookInstance.
You can also manually update software installed on your notebook instance while it is running by using update commands in a terminal or in a notebook.

**Note**
Updating kernels and some packages might depend on whether root access is enabled for the notebook instance. For more information, see [Control root access to a SageMaker notebook instance](p. 3343).

You can check the [Personal Health Dashboard](#) or the security bulletin at [Security Bulletins](#) for updates.

### Control an Amazon EMR Spark Instance Using a Notebook

You can use a notebook instance created with a custom lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook with Sparkmagic to control other AWS resources, such as an Amazon EMR instance. You can then use the Amazon EMR instance to process your data instead of running the data analysis on your notebook. This allows you to create a smaller notebook instance because you won't use the instance to process data. This is helpful when you have large datasets that would require a large notebook instance to process the data.

The process requires three procedures using the Amazon SageMaker console:

- Create the Amazon EMR Spark instance
- Create the Jupyter Notebook
- Test the notebook-to-Amazon EMR connection

**To create an Amazon EMR Spark instance that can be controlled from a notebook using Sparkmagic**

1. Open the Amazon EMR console at [https://console.aws.amazon.com/elasticmapreduce/](https://console.aws.amazon.com/elasticmapreduce/).
2. In the navigation pane, choose Create cluster.
3. On the Create Cluster - Quick Options page, under Software configuration, choose Spark: Spark 2.4.4 on Hadoop 2.8.5 YARN with Ganglia 3.7.2 and Zeppelin 0.8.2.
4. Set additional parameters on the page and then choose Create cluster.
5. On the Cluster page, choose the cluster name that you created. Note the [Master Public DNS](#), the EMR master's security group, and the VPC name and subnet ID where the EMR cluster was created. You will use these values when you create a notebook.

**To create a notebook that uses Sparkmagic to control an Amazon EMR Spark instance**

2. In the navigation pane, under Notebook instances, choose Create notebook.
3. Enter the notebook instance name and choose the instance type.
4. Choose Additional configuration, then, under Lifecycle configuration, choose Create a new lifecycle configuration.
5. Add the following code to the lifecycle configuration script:

```bash
# OVERVIEW
# This script connects an Amazon EMR cluster to an Amazon SageMaker notebook instance
# that uses Sparkmagic.
#
# Note that this script will fail if the Amazon EMR cluster's master node IP address is
# not reachable.
```
# 1. Ensure that the EMR master node IP is resolvable from the notebook instance. 
# One way to accomplish this is to have the notebook instance and the Amazon EMR 
# cluster in the same subnet. 
# 2. Ensure the EMR master node security group provides inbound access from the 
# notebook instance security group. 
# Type - Protocol - Port - Source 
# Custom TCP - TCP - 8998 - $NOTEBOOK_SECURITY_GROUP 
# 3. Ensure the notebook instance has internet connectivity to fetch the SparkMagic 
# example config. 
# https://aws.amazon.com/blogs/machine-learning/build-amazon-sagemaker-notebooks- 
# backed-by-spark-in-amazon-emr/ 

PARAMETERS 
EMR_MASTER_IP=your.emr.master.ip 

cd /home/ec2-user/.sparkmagic 

```
  echo "Fetching Sparkmagic example config from GitHub..."
  wget https://raw.githubusercontent.com/jupyter-incubator/sparkmagic/master/sparkmagic/
  example_config.json

  echo "Replacing EMR master node IP in Sparkmagic config..."
  sed -i -- "s/localhost/$EMR_MASTER_IP/g" example_config.json
  mv example_config.json config.json

  echo "Sending a sample request to Livy.."
  curl "$EMR_MASTER_IP:8998/sessions"
```

6. In the PARAMETERS section of the script, replace your.emr.master.ip with the Master Public DNS 
name for the Amazon EMR instance.

7. Choose **Create configuration**.

8. On the **Create notebook** page, choose **Network - optional**.

9. Choose the VPC and subnet where the Amazon EMR instance is located.

10. Choose the security group used by the Amazon EMR master node.

11. Choose **Create notebook instance**.

While the notebook instance is being created, the status is **Pending**. After the instance has been created 
and the lifecycle configuration script has successfully run, the status is **InService**.

**Note**
If the notebook instance can't connect to the Amazon EMR instance, SageMaker can't create 
the notebook instance. The connection can fail if the Amazon EMR instance and notebook are 
not in the same VPC and subnet, if the Amazon EMR master security group is not used by the 
notebook, or if the Master Public DNS name in the script is incorrect.

**To test the connection between the Amazon EMR instance and the notebook**

1. When the status of the notebook is **InService**, choose **Open Jupyter** to open the notebook.
2. Choose **New**, then choose **Sparkmagic (PySpark)**.
3. In the code cell, enter `%%info` and then run the cell.

The output should be similar to the following:

```
Current session configs: {'driverMemory': '1000M', 'executorCores': 2, 'kind': 'pyspark'}
            No active sessions.
```
Example Notebooks

Your notebook instance contains example notebooks provided by Amazon SageMaker. The example notebooks contain code that shows how to apply machine learning solutions by using SageMaker. Notebook instances use the nbexamples Jupyter extension, which enables you to view a read-only version of an example notebook or create a copy of it that you can modify and run. For more information about the nbexamples extension, see [https://github.com/danielballan/nbexamples](https://github.com/danielballan/nbexamples). For information about example notebooks for SageMaker Studio, see [Use Amazon SageMaker Studio Notebooks](p. 221).

**Note**

Example notebooks typically download datasets from the internet. If you disable SageMaker-provided internet access when you create your notebook instance, example notebooks might not work. For more information, see [Connect a Notebook Instance in a VPC to External Resources](p. 3524).

Use or View Example Notebooks in Jupyter Classic

To view or use the example notebooks in the classic Jupyter view, choose the SageMaker Examples tab.

To view a read-only version of an example notebook in the Jupyter classic view, on the SageMaker Examples tab, choose Preview for that notebook. To create a copy of an example notebook in the home directory of your notebook instance, choose Use. In the dialog box, you can change the notebook's name before saving it.

Use or View Example Notebooks in Jupyterlab

To view or use the example notebooks in the Jupyterlab view, choose the examples icon in the left navigation panel.
To view a read-only version of an example notebook, choose the name of the notebook. This opens the notebook as a tab in the main area. To create a copy of an example notebook in the home directory of your notebook instance, choose Create a Copy in the top banner. In the dialog box, type a name for the notebook and then choose CREATE COPY.

For more information about the example notebooks, see the SageMaker examples GitHub repository.

**Set the Notebook Kernel**

Amazon SageMaker provides several kernels for Jupyter that provide support for Python 2 and 3, Apache MXNet, TensorFlow, and PySpark. To set a kernel for a new notebook in the Jupyter notebook dashboard, choose New, and then choose the kernel from the list. For more information about the available kernels, see Available Kernels (p. 316).
You can also create a custom kernel that you can use in your notebook instance. For information, see Install External Libraries and Kernels in Notebook Instances (p. 325).

## Associate Git Repositories with SageMaker Notebook Instances

Associate Git repositories with your notebook instance to save your notebooks in a source control environment that persists even if you stop or delete your notebook instance. You can associate one default repository and up to three additional repositories with a notebook instance. The repositories can be hosted in AWS CodeCommit, GitHub, or on any other Git server. Associating Git repositories with your notebook instance can be useful for:

- **Persistence** - Notebooks in a notebook instance are stored on durable Amazon EBS volumes, but they do not persist beyond the life of your notebook instance. Storing notebooks in a Git repository enables you to store and use notebooks even if you stop or delete your notebook instance.
- **Collaboration** - Peers on a team often work on machine learning projects together. Storing your notebooks in Git repositories allows peers working in different notebook instances to share notebooks and collaborate on them in a source-control environment.
- **Learning** - Many Jupyter notebooks that demonstrate machine learning techniques are available in publicly hosted Git repositories, such as on GitHub. You can associate your notebook instance with a repository to easily load Jupyter notebooks contained in that repository.

There are two ways to associate a Git repository with a notebook instance:

- **Add a Git repository as a resource in your Amazon SageMaker account.** Then, to access the repository, you can specify an AWS Secrets Manager secret that contains credentials. That way, you can access repositories that require authentication.
- **Associate a public Git repository that is not a resource in your account.** If you do this, you cannot specify credentials to access the repository.

### Topics
- Add a Git Repository to Your Amazon SageMaker Account (p. 332)
- Create a Notebook Instance with an Associated Git Repository (p. 335)
- Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance (p. 336)
- Use Git Repositories in a Notebook Instance (p. 337)

### Add a Git Repository to Your Amazon SageMaker Account

To manage your GitHub repositories, easily associate them with your notebook instances, and associate credentials for repositories that require authentication, add the repositories as resources in your Amazon SageMaker account. You can view a list of repositories that are stored in your account and details about each repository in the SageMaker console and by using the API.
You can add Git repositories to your SageMaker account in the SageMaker console or by using the AWS CLI.

**Note**
You can use the SageMaker API `CreateCodeRepository` to add Git repositories to your SageMaker account, but step-by-step instructions are not provided here.

### Add a Git Repository to Your SageMaker Account (Console)

**To add a Git repository as a resource in your SageMaker account**

2. Under **Notebook**, choose **Git repositories**, then choose **Add repository**.
3. To add a CodeCommit repository, choose **AWS CodeCommit**. To add a GitHub or other Git-based repository, choose **GitHub/Other Git-based repo**.

**To add an existing CodeCommit repository**

1. Choose **Use existing repository**.
2. For **Repository**, choose a repository from the list.
3. Enter a name to use for the repository in SageMaker. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
4. Choose **Add repository**.

**To create a new CodeCommit repository**

1. Choose **Create new repository**.
2. Enter a name for the repository that you can use in both CodeCommit and SageMaker. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
3. Choose **Create repository**.

**To add a Git repository hosted somewhere other than CodeCommit**

1. Choose **GitHub/Other Git-based repo**.
2. Enter a name of up to 63 characters. Valid characters include alpha-numeric characters, a hyphen (-), and 0-9.
3. Enter the URL for the repository. Do not provide a username in the URL. Add the sign-in credentials in AWS Secrets Manager as described in the next step.
4. For **Git credentials**, choose the credentials to use to authenticate to the repository. This is necessary only if the Git repository is private.

   **Note**
   If you have two-factor authentication enabled for your Git repository, enter a personal access token generated by your Git service provider in the **password** field.

   a. To use an existing AWS Secrets Manager secret, choose **Use existing secret**, and then choose a secret from the list. For information about creating and storing a secret, see [Creating a Basic Secret](https://docs.aws.amazon.com/secretsmanager/latest/userguide/create-basic-secret.html) in the **AWS Secrets Manager User Guide**. The name of the secret you use must contain the string *sagemaker*.

   **Note**
   The secret must have a staging label of *AWSCURRENT* and must be in the following format:
For GitHub repositories, we recommend using a personal access token in the password field. For information, see https://help.github.com/articles/creating-a-personal-access-token-for-the-command-line/.

b. To create a new AWS Secrets Manager secret, choose Create secret, enter a name for the secret, and then enter the sign-in credentials to use to authenticate to the repository. The name for the secret must contain the string sagemaker.

Note
The IAM role you use to create the secret must have the secretsmanager:GetSecretValue permission in its IAM policy.
The secret must have a staging label of AWSCURRENT and must be in the following format:
{"username": UserName, "password": Password}
For GitHub repositories, we recommend using a personal access token.

c. To not use any credentials, choose No secret.

5. Choose Create secret.

Add a Git Repository to Your Amazon SageMaker Account (CLI)

Use the create-code-repository AWS CLI command. Specify a name for the repository as the value of the code-repository-name argument. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and -(hyphen). Also specify the following:

- The default branch
- The URL of the Git repository

Note
Do not provide a username in the URL. Add the sign-in credentials in AWS Secrets Manager as described in the next step.

- The Amazon Resource Name (ARN) of an AWS Secrets Manager secret that contains the credentials to use to authenticate the repository as the value of the git-config argument

For information about creating and storing a secret, see Creating a Basic Secret in the AWS Secrets Manager User Guide. The following command creates a new repository named MyRepository in your Amazon SageMaker account that points to a Git repository hosted at https://github.com/myprofile/my-repo".

For Linux, OS X, or Unix:

```bash
```

For Windows:

```bash
```

Note
The secret must have a staging label of AWSCURRENT and must be in the following format:
Create a Notebook Instance with an Associated Git Repository

You can associate Git repositories with a notebook instance when you create the notebook instance by using the AWS Management Console, or the AWS CLI. If you want to use a CodeCommit repository that is in a different AWS account than the notebook instance, set up cross-account access for the repository. For information, see Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance (p. 336).

Topics
• Create a Notebook Instance with an Associated Git Repository (Console) (p. 335)
• Create a Notebook Instance with an Associated Git Repository (CLI) (p. 335)

Create a Notebook Instance with an Associated Git Repository (Console)

To create a notebook instance and associate Git repositories in the Amazon SageMaker console

1. Follow the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 299).
2. For Git repositories, choose Git repositories to associate with the notebook instance.

   a. For Default repository, choose a repository that you want to use as your default repository. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker. When you open your notebook instance, it opens in this repository. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as a resource in your account, choose Add a repository to SageMaker (opens the Add repository flow in a new window) and then follow the instructions at Create a Notebook Instance with an Associated Git Repository (Console) (p. 335). To clone a public repository that is not stored in your account, choose Clone a public Git repository to this notebook instance only, and then specify the URL for that repository.

   b. For Additional repository 1, choose a repository that you want to add as an additional directory. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as a resource in your account, choose Add a repository to SageMaker (opens the Add repository flow in a new window) and then follow the instructions at Create a Notebook Instance with an Associated Git Repository (Console) (p. 335). To clone a repository that is not stored in your account, choose Clone a public Git repository to this notebook instance only, and then specify the URL for that repository.

Repeat this step up to three times to add up to three additional repositories to your notebook instance.

Create a Notebook Instance with an Associated Git Repository (CLI)

To create a notebook instance and associate Git repositories by using the AWS CLI, use the create-notebook-instance command as follows:

• Specify the repository that you want to use as your default repository as the value of the default-code-repository argument. Amazon SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker. When you open your notebook instance, it opens in this repository. To use a repository that is stored as a resource in your SageMaker account, specify the name of the repository as the value of the default-code-repository argument. To use
a repository that is not stored in your account, specify the URL of the repository as the value of the default-code-repository argument.

- Specify up to three additional repositories as the value of the additional-code-repositories argument. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker, and the repository is excluded from the default repository by adding it to the .git/info/exclude directory of the default repository. To use repositories that are stored as resources in your SageMaker account, specify the names of the repositories as the value of the additional-code-repositories argument. To use repositories that are not stored in your account, specify the URLs of the repositories as the value of the additional-code-repositories argument.

For example, the following command creates a notebook instance that has a repository named MyGitRepo, that is stored as a resource in your SageMaker account, as a default repository, and an additional repository that is hosted on GitHub:

```bash
aws sagemaker create-notebook-instance \
  --notebook-instance-name "MyNotebookInstance" \
  --instance-type "ml.t2.medium" \
  --role-arn "arn:aws:iam::012345678901:role/service-role/AmazonSageMaker-ExecutionRole-20181129T121390" \
  --default-code-repository "MyGitRepo" \
  --additional-code-repositories "https://github.com/myprofile/my-other-repo"
```

**Note**

If you use an AWS CodeCommit repository that does not contain "SageMaker" in its name, add the codecommit:GitPull and codecommit:GitPush permissions to the role that you pass as the role-arn argument to the create-notebook-instance command. For information about how to add permissions to a role, see Adding and Removing IAM Policies in the AWS Identity and Access Management User Guide.

### Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance

To associate a CodeCommit repository in a different AWS account with your notebook instance, set up cross-account access for the CodeCommit repository.

**To set up cross-account access for a CodeCommit repository and associate it with a notebook instance:**

1. In the AWS account that contains the CodeCommit repository, create an IAM policy that allows access to the repository from users in the account that contains your notebook instance. For information, see Step 1: Create a Policy for Repository Access in AccountA in the CodeCommit User Guide.

2. In the AWS account that contains the CodeCommit repository, create an IAM role, and attach the policy that you created in the previous step to that role. For information, see Step 2: Create a Role for Repository Access in AccountA in the CodeCommit User Guide.

3. Create a profile in the notebook instance that uses the role that you created in the previous step:
   a. Open the notebook instance.
   b. Open a terminal in the notebook instance.
   c. Edit a new profile by typing the following in the terminal:

```bash
vi /home/ec2-user/.aws/config
```
d. Edit the file with the following profile information:

```
[profile CrossAccountAccessProfile]
region = us-west-2
role_arn = arn:aws:iam::CodeCommitAccount:role/CrossAccountRepositoryContributorRole
credential_source=Ec2InstanceMetadata
output = json
```

Where CodeCommitAccount is the account that contains the CodeCommit repository, CrossAccountAccessProfile is the name of the new profile, and CrossAccountRepositoryContributorRole is the name of the role you created in the previous step.

4. On the notebook instance, configure git to use the profile you created in the previous step:
   a. Open the notebook instance.
   b. Open a terminal in the notebook instance.
   c. Edit the Git configuration file typing the following in the terminal:

   ```
   vi /home/ec2-user/.gitconfig
   ```

   d. Edit the file with the following profile information:

   ```
   [credential]
   helper = !aws codecommit credential-helper --
   profile CrossAccountAccessProfile $@
   UseHttpPath = true
   ```

   Where CrossAccountAccessProfile is the name of the profile that you created in the previous step.

**Use Git Repositories in a Notebook Instance**

When you open a notebook instance that has Git repositories associated with it, it opens in the default repository, which is installed in your notebook instance directly under /home/ec2-user/SageMaker. You can open and create notebooks, and you can manually run Git commands in a notebook cell. For example:

```
!git pull origin master
```

To open any of the additional repositories, navigate up one folder. The additional repositories are also installed as directories under /home/ec2-user/SageMaker.

If you open the notebook instance with a JupyterLab interface, the jupyter-git extension is installed and available to use. For information about the jupyter-git extension for JupyterLab, see [https://github.com/jupyterlab/jupyterlab-git](https://github.com/jupyterlab/jupyterlab-git).

When you open a notebook instance in JupyterLab, you see the git repositories associated with it on the left menu:
You can use the jupyter-git extension to manage git visually, instead of using the command line:
Notebook Instance Metadata

When you create a notebook instance, Amazon SageMaker creates a JSON file on the instance at the location `/opt/ml/metadata/resource-metadata.json` that contains the `ResourceName` and `ResourceArn` of the notebook instance. You can access this metadata from anywhere within the notebook instance, including in lifecycle configurations. For information about notebook instance lifecycle configurations, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 323).

**Note**
The `resource-metadata.json` file can be modified with root access.

The `resource-metadata.json` file has the following structure:

```
{
  "ResourceArn": "NotebookInstanceArn",
  "ResourceName": "NotebookInstanceName"
}
```

You can use this metadata from within the notebook instance to get other information about the notebook instance. For example, the following commands get the tags associated with the notebook instance:

```
NOTEBOOK_ARN=$(jq '.ResourceArn' /opt/ml/metadata/resource-metadata.json --raw-output)
aws sagemaker list-tags --resource-arn $NOTEBOOK_ARN
```

The output looks like the following:

```
{
  "Tags": [
    {
      "Key": "test",
      "Value": "true"
    }
  ]
}
```

Monitor Jupyter Logs in Amazon CloudWatch Logs

Jupyter logs include important information such as events, metrics, and health information that provide actionable insights when running Amazon SageMaker notebooks. By importing Jupyter logs into CloudWatch Logs, customers can use CloudWatch Logs to detect anomalous behaviors, set alarms, and discover insights to keep the SageMaker notebooks running more smoothly. You can access the logs even when the Amazon EC2 instance that hosts the notebook is unresponsive, and use the logs to troubleshoot the unresponsive notebook. Sensitive information such as AWS account IDs, secret keys, and authentication tokens in presigned URLs are removed so that customers can share logs without leaking private information.

**To view Jupyter logs for a notebook instance:**

2. Choose Notebook instances.
3. In the list of notebook instances, choose the notebook instance for which you want to view Jupyter logs by selecting the Notebook instance Name.
This will bring you to the details page for that notebook instance.

4. Under Monitor on the notebook instance details page, choose View logs.
5. In the CloudWatch console, choose the log stream for your notebook instance. Its name is in the form NotebookInstanceName/jupyter.log.

For more information about monitoring CloudWatch logs for SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

Amazon SageMaker Studio Lab

Amazon SageMaker Studio Lab is a free service that gives customers access to AWS compute resources, in an environment based on open-source JupyterLab. It is based on the same architecture and user interface as Amazon SageMaker Studio, but with a subset of Studio capabilities.

With Studio Lab, you can use AWS compute resources to create and run your Jupyter notebooks without signing up for an AWS account. Because Studio Lab is based on open-source JupyterLab, you can take advantage of open-source Jupyter extensions to run your Jupyter notebooks.

Studio Lab compared to Amazon SageMaker Studio

While Studio Lab provides free access to AWS compute resources, Amazon SageMaker Studio provides the following advanced machine learning capabilities that Studio Lab does not support.

• Continuous integration and continuous delivery (SageMaker Pipelines)
• Real-time predictions
• Large-scale distributed training
• Data preparation (Amazon SageMaker Data Wrangler)
• Data labeling (Amazon SageMaker Ground Truth)
• Feature Store
• Bias analysis (Clarify)
• Model deployment
• Model monitoring

Studio also supports fine-grained access control and security by using AWS Identity and Access Management (IAM), Amazon Virtual Private Cloud (Amazon VPC), and AWS Key Management Service (AWS KMS). Studio Lab does not support these Studio features, nor does it support the use of estimators and built-in SageMaker algorithms.

To export your Studio Lab projects for use with Studio, see Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 362).

The following topics give information about Studio Lab and how to use it

Topics

• Amazon SageMaker Studio Lab components overview (p. 341)
• Onboard to Amazon SageMaker Studio Lab (p. 344)
• Manage your account (p. 345)
• Launch your Amazon SageMaker Studio Lab project runtime (p. 346)
• Use Amazon SageMaker Studio Lab starter assets (p. 348)
Amazon SageMaker Studio Lab consists of the following components. The following topics give more details about these components.

**Topics**
- Landing page (p. 341)
- Studio Lab account (p. 341)
- Project overview page (p. 342)
- Preview page (p. 342)
- Project (p. 342)
- Compute instance type (p. 343)
- Project runtime (p. 344)
- Session (p. 344)

**Landing page**
You can request an account and sign in to an existing account on your landing page. To navigate to the landing page, see the Amazon SageMaker Studio Lab website. For more information about creating a Studio Lab account, see Onboard to Amazon SageMaker Studio Lab (p. 344).

The following screenshot shows the Studio Lab landing page interface for requesting a user account and signing in.

![Landing page screenshot](image)

**Studio Lab account**
Your Studio Lab account gives you access to Studio Lab. For more information about creating a user account, see Onboard to Amazon SageMaker Studio Lab (p. 344).
Project overview page

You can launch a compute instance and view information about your project on this page. To navigate to this page, you must sign in from the Amazon SageMaker Studio Lab website. The URL takes the following format.

https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

The following screenshot shows a project overview in the Studio Lab user interface.

![Project overview screenshot]

Preview page

On this page, you can access a read-only preview of a Jupyter notebook. You cannot execute the notebook from preview, but you can copy that notebook into your project. For many customers, this may be the first Studio Lab page that customers see, as they may be opening a notebook from GitHub notebook. For more information on how to use GitHub resources, see Use GitHub resources (p. 359).

To copy the notebook preview to your Studio Lab project:

1. Sign in to your Studio Lab account. For more information about creating a Studio Lab account, see Onboard to Amazon SageMaker Studio Lab (p. 344).
2. Under Notebook compute instance, choose a compute instance type. For more information about compute instance types, see Compute instance type (p. 343).
3. Choose Start runtime. You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see What is a CAPTCHA puzzle?
4. One time setup, for first time starting runtime using your Studio Lab account:
   a. Enter a mobile phone number to associate with your Amazon SageMaker Studio Lab account and choose Continue.
      For information on supported countries and regions, see Supported countries and regions (SMS channel).
   b. Enter the 6-digit code sent to the associated mobile phone number and choose Verify.
5. Choose Copy to project.

Project

Your project contains all of your files and folders, including your Jupyter notebooks. You have full control over the files in your project. Your project also includes the JupyterLab-based user interface. From this
interface, you can interact with your Jupyter notebooks, edit your source code files, integrate with GitHub, and connect to Amazon S3. For more information, see Use the Amazon SageMaker Studio Lab project runtime (p. 350).

The following screenshot shows a Studio Lab project with the file browser open and the Studio Lab Launcher displayed.

Compute instance type

Your Amazon SageMaker Studio Lab project runtime is based on an EC2 instance. You are allotted 15 GB of storage and 16 GB of RAM. Availability of compute instances is not guaranteed and is subject to demand. If you require additional storage or compute resources, consider switching to Amazon SageMaker Studio.

Amazon SageMaker Studio Lab offers the choice of a CPU (Central Processing Unit) and a GPU (Graphical Processing Unit). The following sections give information about these two options, including selection guidance.

CPU

A central processing unit (CPU) is designed to handle a wide range of tasks efficiently, but is limited in how many tasks it can run concurrently. For machine learning, a CPU is recommended for compute intensive algorithms, such as time series, forecasting, and tabular data.

The CPU compute type has up to 4 hours at a time with a limit of 8 hours in a 24-hour period.

GPU

A graphics processing unit (GPU) is designed to render high-resolution images and video concurrently. A GPU is recommended for deep learning tasks, especially for transformers and computer vision.

The GPU compute type has up to 4 hours at a time with a limit of 4 hours in a 24-hour period.

Compute time

When compute time for Studio Lab reaches its time limit, the instance stops all running computations. Studio Lab does not support time limit increases.
Studio Lab automatically saves your environment when you update your environment and every time you create a new file. Custom-installed extensions and packages persist even after your runtime has ended.

File edits are periodically saved, but are not saved when your runtime ends. To ensure that you do not lose your progress, save your work manually. If you have content in your Studio Lab project that you don’t want to lose, we recommend that you back up your content elsewhere. For more information about exporting your environment and files, see Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 362).

During long computation, you do not need to keep your project open. For example, you can start training a model, then close your browser. The instance keeps running for up to the compute type limit in a 24-hour period. You can then sign in later to continue your work.

We recommend that you use checkpointing in your deep learning jobs. You can use saved checkpoints to restart a job from the previously saved checkpoint. For more information, see File I/O.

## Project runtime

The project runtime is the period of time when your compute instance is running.

## Session

A user session begins every time you launch your project.

## Onboard to Amazon SageMaker Studio Lab

To onboard to Amazon SageMaker Studio Lab, follow the steps in this guide. In the following sections, you learn how to request a Studio Lab account, create your account, and sign in.

### Topics

- Request a Studio Lab account (p. 344)
- Create a Studio Lab account (p. 345)
- Sign in to Studio Lab (p. 345)

### Request a Studio Lab account

To use Studio Lab, you must first request approval to create a Studio Lab account. An AWS account cannot be used for onboarding to Studio Lab.

The following steps show how to request a Studio Lab account.

1. Navigate to the Studio Lab landing page.
2. Select Request account.
3. Enter the required information into the form.
4. Select Submit request.
5. If you receive an email to verify your email address, follow the instructions in the email to complete this step.

Your account request must be approved before you can register for a Studio Lab account. Your request will be reviewed within five business days. When your account request is approved, you receive an email with a link to the Studio Lab account registration page. This link expires seven days after your request is approved. If the link expires, you must submit a new account request.
Note: Your account request is denied if your email has been associated with activity that violates our Terms of Service or other agreements.

Referral codes

Studio Lab referral codes enable new account requests to be automatically approved to support machine learning events like workshops, hackathons, and classes. With a referral code, a trusted host can get their participants immediate access to Studio Lab. After an account has been created using a referral code, the account continues to exist after the expiration of the code.

To get a referral code, contact Sales Support. To use a referral code, enter the code as part of the account request form.

Create a Studio Lab account

After your request is approved, complete the following steps to create your Studio Lab account.

1. Select Create account in the account request approval email to open a new page.
2. From the new page, enter your Email, a Password, and a Username.
3. Select Create account.

You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see What is a CAPTCHA puzzle?

Sign in to Studio Lab

After you register for your account, you can sign in to Studio Lab.

1. Navigate to the Studio Lab landing page.
2. Select Sign in to open a new page.
3. Enter your Email or Username and Password.
4. Select Sign in to open a new page to your project.

You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see What is a CAPTCHA puzzle?

Manage your account

The following topic gives information about managing your account, including changing your password, deleting your account, and getting information that we have collected. These topics require that you sign in to your Amazon SageMaker Studio Lab account. For more information, see Sign in to Studio Lab (p. 345).

Change your password

Follow these steps to change your Amazon SageMaker Studio Lab password.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select Change password to open a new page.
4. Enter your current password into the **Enter your current password** field.
5. Enter your new password into the **Create a new password** and **Confirm your new password** fields.
6. Select **Submit**.

### Delete your account

Follow these steps to delete your Studio Lab account.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   ```
   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
   ```

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select **Delete account** to open a new page.
4. Enter your password to confirm the deletion of your Studio Lab account.
5. Select **Delete**.

### Customer information

Studio Lab collects your email address, user name, encrypted password, project files, and metadata. When requesting an account, you can optionally choose to provide your first and last name, country, organization name, occupation, and the reason for your interest in this product. We protect all customer personal data with encryption. For more information about how your personal information is handled, see the [Privacy Notice](#).

When you delete your account, all of your information is deleted immediately. If you have an inquiry about this, submit the [Amazon SageMaker Studio Lab Form](#). For information and support related to AWS compliance, see [Compliance support](#).

### Launch your Amazon SageMaker Studio Lab project runtime

The Amazon SageMaker Studio Lab project runtime lets you write and run code directly from your browser. It is based on JupyterLab and has an integrated terminal and console. For more information about JupyterLab, see the [JupyterLab Documentation](#).

The following topic gives information about how to manage your project runtime. These topics require that you sign in to your Amazon SageMaker Studio Lab account. For more information about signing in, see [Sign in to Studio Lab](p. 345). For more information about your project, see [Amazon SageMaker Studio Lab components overview](p. 341).

#### Topics

- [Start your project runtime](p. 346)
- [Stop your project runtime](p. 347)
- [View remaining compute time](p. 347)
- [Change your compute type](p. 347)

### Start your project runtime

To use Studio Lab, you must start your project runtime. This runtime gives you access to the JupyterLab environment.
1. Navigate to the Studio Lab project overview page. The URL takes the following format.

https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. Under My Project, select a compute type. For more information about compute types, see Compute instance type (p. 343).

3. Select Start runtime.

   You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see What is a CAPTCHA puzzle?

4. One time setup, for first time starting runtime using your Studio Lab account:

   a. Enter a mobile phone number to associate with your Amazon SageMaker Studio Lab account and choose Continue.

      For information on supported countries and regions, see Supported countries and regions (SMS channel).

   b. Enter the 6-digit code sent to the associated mobile phone number and choose Verify.

5. After the runtime is running, select Open project to open the project runtime environment in a new browser tab.

### Stop your project runtime

When you stop your project runtime, your files are not automatically saved. To ensure that you don't lose your work, save all of your changes before stopping your project runtime.

- Under My Project, select Stop runtime.

### View remaining compute time

Your project runtime has limited compute time based on the compute type that you select. For more information about compute time in Studio Lab, see Compute instance type (p. 343).

- Under My Project, view Time remaining.

### Change your compute type

You can switch your compute type based on your workflow. For more information about compute types, see Compute instance type (p. 343).

1. Save any project files before changing the compute type.

2. Navigate to the Studio Lab project overview page. The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

3. Under My Project, select the desired compute type (CPU or GPU).

4. Confirm your choice by selecting Restart in the Restart project runtime? dialog box. Studio Lab stops your current project runtime, then starts a new project runtime with your updated compute type.

5. After your project runtime has started, select Open project. This opens your project runtime environment in a new browser tab. For information about using your project runtime environment, see Use the Amazon SageMaker Studio Lab project runtime (p. 350).
Use Amazon SageMaker Studio Lab starter assets

Amazon SageMaker Studio Lab supports the following assets to help machine learning (ML) practitioners get started. This guide shows you how to clone notebooks for your project.

Getting started notebook

Studio Lab comes with a starter notebook that gives general information and guides you through key workflows. When you launch your project runtime for the first time, this notebook automatically opens.

Dive into Deep Learning

Dive into Deep Learning (D2L) is an interactive, open-source book that teaches the ideas, mathematical theory, and code that power machine learning. With over 150 Jupyter notebooks, D2L provides a comprehensive overview of deep learning principles. For more information about D2L, see the D2L website.

The following procedure shows how to clone the D2L Jupyter notebooks to your instance.

1. Start and open the Studio Lab project runtime environment by following Start your project runtime (p. 346).
2. Once Studio Lab is open, choose the Git tab on the left sidebar.
3. Choose Clone a Repository. Under Git repository URL (.git) paste the MLU git repository D2L by following the steps below. If you do not see the Clone a Repository option because you are currently in a Git repository, return to the user directory to clone a new repository. You return to the user directory by choosing the Folder tab on the left sidebar. In the Folder tab beneath the file search bar choose the folder icon to the left of the currently open repository. Once you are in the user directory, choose the Git tab on the left sidebar and choose Clone a Repository.
4. Navigate to the Studio Lab project overview page. The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

6. From the new Dive into Deep Learning browser tab, choose GitHub to open a new page with the example notebooks.
7. Choose Code and copy the GitHub repository’s URL in the HTTPS tab.
8. Return to the Studio Lab open project browser tab, paste the D2L repository URL, and clone the repository.

AWS Machine Learning University

The AWS Machine Learning University (MLU) provides access to the machine learning courses used to train Amazon's own developers. With AWS MLU, any developer can learn how to use machine learning with the learn-at-your-own-pace MLU Accelerator learning series. The MLU Accelerator series is designed to help developers begin their ML journey. It offers three-day foundational courses on these three subjects: Natural Language Processing, Tabular Data, and Computer Vision. For more information, see Machine Learning University.

The following procedure shows how to clone the AWS MLU Jupyter notebooks to your instance.

1. Start and open the Studio Lab project runtime environment by following Start your project runtime (p. 346).
2. Once Studio Lab is open, choose the Git tab ( ) on the left sidebar.

3. Choose **Clone a Repository**. Under **Git repository URL (.git)** paste the MLU git repository URL by following the steps below. If you do not see the **Clone a Repository** option because you are currently in a Git repository, return to the user directory to clone a new repository. You return to the user directory by choosing the Folder tab ( ) on the left sidebar. In the Folder tab beneath the file search bar choose the folder icon to the left of the currently open repository. Once you are in the user directory, choose the Git tab on the left sidebar and choose **Clone a Repository**.

4. Navigate to the Studio Lab project overview page. The URL takes the following format.

   

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

5. Under **New to machine learning?**, choose **AWS Machine Learning University**.

6. From the new **AWS Machine Learning University** browser tab, find a course that interests you by reading the **Course Summary** for each course.

7. Choose the corresponding GitHub repository of interest under **Course Content**, to open a new page with the example notebooks.

8. Choose **Code** and copy the GitHub repository's URL in the **HTTPS** tab.

9. Return to the Studio Lab open project browser tab, paste the D2L repository URL, and choose **Clone** to clone the repository.

---

**Roboflow**

Roboflow gives you the tools to train, fine-tune, and label objects for computer vision applications. For more information, see [https://roboflow.com/](https://roboflow.com/).

The following procedure shows how to clone the Roboflow Jupyter notebooks to your instance.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. Under **Resources and community**, find **Try Computer Vision**.

3. Under **Try Computer Vision** choose a Roboflow model. For more information, see [https://roboflow.com/](https://roboflow.com/).

4. Follow the tutorial under the Notebook preview.

---

**Studio Lab pre-installed environments**

Amazon SageMaker Studio Lab uses conda environments to contain your packages (or libraries). An environment is a folder that contains the packages you have installed. You can interact with an environment by using the terminal or your JupyterLab notebook. To use an environment and the packages installed within, you must choose the corresponding kernel that contains the same name as the environment when opening your JupyterLab notebook. For a walkthrough on how to manage your environments, see *Manage your environment (p. 355)*. For more information on installing packages within your environment, see *Customize your environment (p. 357)*.

Studio Lab has various environments pre-installed for you. Any changes made to persistent memory environments will remain for your next session. Any changes to non-persistent memory environments will not remain for your next sessions, but the packages within will be updated and tested for compatibility by Amazon SageMaker. You will typically want to use the sagemaker-distribution
non-persistent memory environment if you want to use a fully managed environment that already contains many popular packages used by machine learning (ML) engineers and data scientists. Otherwise you can use the default environment if you want to significantly customize your environment.

In the following we list the pre-installed environments and their use cases. To view the packages installed in an environment, see Customize your environment (p. 357).

- **sagemaker-distribution**: Non-persistent memory environment that is regularly updated and tested for compatibility, fully managed by Amazon SageMaker. This environment contains popular packages used in ML, data science, and visualization. The sagemaker-distribution environment is closely related to the environment used in Amazon SageMaker Studio, so after graduating from Studio Lab to Studio the notebooks should run similarly. For information on exporting your environment from Studio Lab to Studio, see Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 362).
- **default**: Persistent memory environment with very few packages pre-installed. Any installed packages or changes to this environment will continue on your next session.
- **studiolab**: Persistent memory environment where JupyterLab and other related packages are installed. This environment should only be used for JupyterLab and Jupyter server extensions, for configuring the JupyterLab user interface.
- **studiolab-safemode**: Non-persistent memory environment. This environment is automatically activated when there is an issue while starting your project runtime. Used for troubleshooting. For information on troubleshooting, see Troubleshooting (p. 366).
- **base**: Non-persistent memory environment. This environment is only used for system tooling and should not be used by customers.

For information on SageMaker images and their versions, see Available Amazon SageMaker Images (p. 244).

**Use the Amazon SageMaker Studio Lab project runtime**

The following topics give information about using the Amazon SageMaker Studio Lab project runtime. Before you can use the Studio Lab project runtime, you must onboard to Studio Lab by following the steps in Onboard to Amazon SageMaker Studio Lab (p. 344).

**Topics**
- Amazon SageMaker Studio Lab UI overview (p. 350)
- Create or open an Amazon SageMaker Studio Lab notebook (p. 352)
- Use the Amazon SageMaker Studio Lab notebook toolbar (p. 353)
- Manage your environment (p. 355)
- Use external resources in Amazon SageMaker Studio Lab (p. 358)
- Get notebook differences (p. 361)
- Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 362)
- Shut down resources (p. 365)

**Amazon SageMaker Studio Lab UI overview**

Amazon SageMaker Studio Lab extends the JupyterLab interface. Previous users of JupyterLab will notice similarities between the JupyterLab and Studio Lab UI, including the workspace. For an overview of the basic JupyterLab interface, see The JupyterLab Interface.
The following image shows Studio Lab with the file browser open and the Studio Lab Launcher displayed.

You will find the menu bar at the top of the screen. The left sidebar contains icons to open file browsers, resource browsers, and tools. The status bar is located at the bottom-left corner of Studio Lab.

The main work area is divided horizontally into two panes. The left pane is the file and resource browser. The right pane contains one or more tabs for resources, such as notebooks and terminals.

**Topics**
- [Left sidebar](p. 351)
- [File and resource browser](p. 352)
- [Main work area](p. 352)

### Left sidebar

The left sidebar includes the following icons. When you hover over an icon, a tooltip displays the icon name. When you choose an icon, the file and resource browser displays the described functionality. For hierarchical entries, a selectable breadcrumb at the top of the browser shows your location in the hierarchy.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Folder Icon" /></td>
<td><strong>File Browser</strong></td>
</tr>
</tbody>
</table>

Choose the **Upload Files** icon (↑) to add files to Studio Lab.

Double-click a file to open the file in a new tab.

To have adjacent files open, choose a tab that contains a notebook, Python, or text file, and then choose **New View for File**.

Choose the plus (+) sign on the menu at the top of the file browser to open the Studio Lab Launcher.
### Running Terminals and Kernels

You can see a list of all of the running terminals and kernels in your project. For more information, see [Shut down resources](p. 365).

### Git

You can connect to a Git repository and then access a full range of Git tools and operations. For more information, see [Use external resources in Amazon SageMaker Studio Lab](p. 358).

### Table of Contents

You can access the Table of Contents for your current Jupyter notebook.

### Extension Manager

You can enable and manage third-party JupyterLab extensions.

---

**File and resource browser**

The file and resource browser shows lists of your notebooks and files. On the menu at the top of the file browser, choose the plus (+) sign to open the Studio Lab Launcher. The Launcher allows you to create a notebook or open a terminal.

**Main work area**

The main work area has multiple tabs that contain your open notebooks and terminals.

### Create or open an Amazon SageMaker Studio Lab notebook

When you create a notebook in Amazon SageMaker Studio Lab or open a notebook in Studio Lab, you must select a kernel for the notebook. The following topics describe how to create and open notebooks in Studio Lab.

For information about shutting down the notebook, see [Shut down resources](p. 365).

**Topics**

- [Open a Studio Lab notebook](p. 352)
- [Create a notebook from the file menu](p. 353)
- [Create a notebook from the Launcher](p. 353)

**Open a Studio Lab notebook**

Studio Lab can only open notebooks listed in the Studio Lab file browser. To clone a notebook into your file browser from an external repository, see [Use external resources in Amazon SageMaker Studio Lab](p. 358).

**To open a notebook**

1. In the left sidebar, choose the **File Browser** icon (📄) to display the file browser.
2. Browse to a notebook file and double-click it to open the notebook in a new tab.
Create a notebook from the file menu

To create a notebook from the File menu

1. From the Studio Lab menu, choose **File**, choose **New**, and then choose **Notebook**.
2. To use the default kernel, in the **Select Kernel** dialog box, choose **Select**. Otherwise, to select a different kernel, use the dropdown menu.

Create a notebook from the Launcher

To create a notebook from the Launcher

1. Open the Launcher by using the keyboard shortcut **Ctrl + Shift + L**. Alternatively, you can open Launcher from the left sidebar: Choose the **File Browser** icon, and then choose the plus (+) icon.
2. To use the default kernel from the Launcher, under **Notebook**, choose **default:Python**. Otherwise, select a different kernel.

After you choose the kernel, your notebook launches and opens in a new Studio Lab tab.

To view the notebook's kernel session, in the left sidebar, choose the **Running Terminals and Kernels** icon ( ). You can stop the notebook's kernel session from this view.

Use the Amazon SageMaker Studio Lab notebook toolbar

Amazon SageMaker Studio Lab notebooks extend the JupyterLab interface. For an overview of the basic JupyterLab interface, see **The JupyterLab Interface**.

The following image shows the toolbar and an empty cell from a Studio Lab notebook.

When you hover over a toolbar icon, a tooltip displays the icon function. You can find additional notebook commands in the Studio Lab main menu. The toolbar includes the following icons:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Save and checkpoint" /></td>
<td><strong>Save and checkpoint</strong>&lt;br&gt;Saves the notebook and updates the checkpoint file.</td>
</tr>
<tr>
<td><img src="image" alt="Insert cell" /></td>
<td><strong>Insert cell</strong>&lt;br&gt;Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin.</td>
</tr>
<tr>
<td><img src="image" alt="Cut, copy, and paste cells" /></td>
<td><strong>Cut, copy, and paste cells</strong>&lt;br&gt;Cuts, copies, and pastes the selected cells.</td>
</tr>
</tbody>
</table>
### Use the Studio Lab project runtime

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Run cells](image) | **Run cells**  
Runs the selected cells. The cell that follows the last-selected cell becomes the new-selected cell. |
| ![Interrupt kernel](image) | **Interrupt kernel**  
Interrupts the kernel, which cancels the currently-running operation. The kernel remains active. |
| ![Restart kernel](image) | **Restart kernel**  
Restarts the kernel. Variables are reset. Unsaved information is not affected. |
| ![Restart kernel and re-run notebook](image) | **Restart kernel and re-run notebook**  
Restarts the kernel. Variables are reset. Unsaved information is not affected. Then re-runs the entire notebook. |
| ![Cell type](image) | **Cell type**  
Displays or changes the current cell type. The cell types are:  
- Code – Code that the kernel runs.  
- Markdown – Text rendered as markdown.  
- Raw – Content, including Markdown markup, that's displayed as text. |
| ![Checkpoint diff](image) | **Checkpoint diff**  
Opens a new tab that displays the difference between the notebook and the checkpoint file. For more information, see [Get notebook differences](p. 361). |
| ![Git diff](image) | **Git diff**  
Only enabled if the notebook is opened from a Git repository. Opens a new tab that displays the difference between the notebook and the last Git commit. For more information, see [Get notebook differences](p. 361). |
| ![default Kernel](image) | **Kernel**  
Displays or changes the kernel that processes the cells in the notebook.  
No Kernel indicates that the notebook was opened without specifying a kernel. You can edit the notebook, but you can't run any cells. |
| ![Kernel busy status](image) | **Kernel busy status**  
Displays a kernel's busy status by showing the circle's edge and its interior as the same color. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of Studio Lab. |
Manage your environment

Amazon SageMaker Studio Lab provides pre-installed environments for your Studio Lab notebook instances. Environments allow you to start up a Studio Lab notebook instance with the packages you want to use. This is done by installing packages in the environment and then selecting the environment as a Kernel.

Studio Lab has various environments pre-installed for you. You will typically want to use the sagemaker-distribution environment if you want to use a fully managed environment that already contains many popular packages used for machine learning (ML) engineers and data scientists. Otherwise you can use the default environment if you want persistent customization for your environment. For more information on the available pre-installed Studio Lab environments, see Studio Lab pre-installed environments (p. 349).

You can customize your environment by adding new packages (or libraries) to it. You can also create new environments from Studio Lab, import compatible environments, reset your environment to create space, and more.

The following commands are for running in a Studio Lab terminal. However, while installing packages it is highly recommended to install them within your Studio Lab Jupyter notebook to ensure that the packages are installed in the intended environment. To run the commands in a Jupyter notebook, prefix the command with a % before running the cell. For example, the code snippet pip list in a terminal is the same as %pip list in a Jupyter notebook.

The following sections give information about your default conda environment, how to customize it, and how to add and remove conda environments. For a list of sample environments that you can install into Studio Lab, see Creating Custom conda Environments. To use these sample environment YAML files with Studio Lab, see Step 4: Install your Studio Lab conda environments in Studio (p. 365).

Topics

- Your default environment (p. 355)
- View environments (p. 355)
- Create, activate, and use new conda environments (p. 356)
- Using sample Studio Lab environments (p. 357)
- Customize your environment (p. 357)
- Refresh Studio Lab (p. 358)

Your default environment

Studio Lab uses conda environments to encapsulate the software packages that are needed to run notebooks. Your project contains a default conda environment, named default, with the IPython kernel. This environment serves as the default kernel for your Jupyter notebooks.

View environments

To view the environments in Studio Lab you can use a terminal or Jupyter notebook. The following command will be for a Studio Lab terminal. If you wish to run the corresponding commands in a Jupyter notebook, see Manage your environment (p. 355).

Open the Studio Lab terminal by opening the File Browser panel, choose the plus (+) sign on the menu at the top of the file browser to open the Launcher, then choose Terminal. From the Studio Lab terminal, list the conda environments by running the following.

```
conda env list
```
This command outputs a list of the conda environments and their locations in the file system. When you onboard to Studio Lab, you automatically activate the studiolab conda environment. The following is an example of listed environments after you onboard.

```
# conda environments:
#
default                  /home/studio-lab-user/.conda/envs/default
studiolab             *  /home/studio-lab-user/.conda/envs/studiolab
studiolab-safemode       /opt/amazon/sagemaker/safemode-home/.conda/envs/studiolab-safemode
base                     /opt/conda
sagemaker-distribution     /opt/conda/envs/sagemaker-distribution
```

The * marks the activated environment.

**Create, activate, and use new conda environments**

If you would like to maintain multiple environments for different use cases, you can create new conda environments in your project. The following sections show how to create and activate new conda environments. For a Jupyter notebook that shows how to create a custom environment, see [Setting up a Custom Environment in SageMaker Studio Lab](#).

**Note**

Maintaining multiple environments counts against your available Studio Lab memory.

**Create conda environment**

To create a conda environment, run the following conda command from your terminal. This example creates a new environment with Python 3.9.

```
conda create --name <ENVIRONMENT_NAME> python=3.9
```

Once the conda environment is created, you can view the environment in your environment list. For more information on how to view your environment list, see [View environments](#).

**Activate a conda environment**

To activate any conda environment, run the following command in the terminal.

```
conda activate <ENVIRONMENT_NAME>
```

When you run this command, any packages installed using conda or pip are installed in the environment. For more information on installing packages, see [Customize your environment](#).

**Use a conda environment**

To use your new conda environments with notebooks, make sure the ipykernel package is installed in the environment.

```
conda install ipykernel
```

Once the ipykernel package is installed in the environment, you can select the environment as the kernel for your notebook.

You may need to restart JupyterLab to see the environment available as a kernel. This can be done by choosing [Amazon SageMaker Studio Lab](#) in the top menu of Studio Lab and choosing [Restart JupyterLab](#)....
When you create a new notebook from the Studio Lab Launcher, you will have the option to choose the kernel under **Notebook**. For an overview of the Studio Lab UI, see [Amazon SageMaker Studio Lab UI overview](p. 350).

When a Jupyter notebook is open, you can choose the kernel by choosing **Kernel** from the top menu and choose **Change Kernel**....

**Using sample Studio Lab environments**

Studio Lab provides sample custom environments through the [SageMaker Studio Lab Examples](repository). The following shows how to clone and build these environments.

1. Clone the SageMaker Studio Lab Examples GitHub repository by following the instructions in [Use GitHub resources](p. 359).
2. In Studio Lab choose the **File Browser** icon (folder) on the left menu, so that the **File Browser** panel shows on the left.
3. Navigate to the `studio-lab-examples/custom-environments` directory in the File Browser.
4. Open the directory for the environment that you want to build.
5. Right click the `.yml` file in the folder, then select **Build conda Environment**.
6. You can now use the environment as a kernel after your conda environment has finished building. For instructions on how to use an existing environment as a kernel, see [Create, activate, and use new conda environments](p. 356).

**Customize your environment**

You can customize your environment by installing and removing extensions and packages as needed. Studio Lab comes with environments with packages pre-installed and using an existing environment may save you time and memory, as pre-installed packages do not count against your available Studio Lab memory. For more information on the available pre-installed Studio Lab environments, see [Studio Lab pre-installed environments](p. 349).

Any installed extensions and packages installed on your default environment will persist in your project, so you do not need to install your packages for every project runtime session. However, extensions and packages installed on your sagemaker-distribution environment will not persist, so you will need to install new packages during your next session. Thus, it is highly recommended to install packages within your notebook to ensure that the packages are installed in the intended environment.

To view your environments, run the command `conda env list`.

To activate your environment, run the command `conda activate <ENVIRONMENT_NAME>`.

To view the packages in an environment, run the command `conda list`.

**Install packages**

It is highly recommended to install your packages within your Jupyter notebook to ensure that your packages are installed in the intended environment. To install additional packages to your environment from a Jupyter notebook, run one of the following commands in a cell within your Jupyter notebook. These commands install packages in the currently activated environment.

- `%conda install <PACKAGE>`
- `%pip install <PACKAGE>`

We don't recommend using the `%pip` or `%conda` commands because they can behave in unexpected ways when you have multiple environments.
After you install new packages to your environment, you may need to restart the kernel to ensure that the packages work in your notebook. This can be done by choosing Amazon SageMaker Studio Lab in the top menu of Studio Lab and choosing Restart JupyterLab...

**Remove packages**

To remove a package, run the command

```bash
%conda remove <PACKAGE_NAME>
```

This command will also remove any package that depends on `<PACKAGE_NAME>`, unless a replacement can be found without that dependency.

To remove all of the packages in an environment, run the command

```bash
conda deactivate
&& conda env remove --name <ENVIRONMENT_NAME>
```

**Refresh Studio Lab**

To refresh Studio Lab, remove all of your environments and files.

1. List all conda environments.
   ```bash
   conda env list
   ```

2. Activate the base environment.
   ```bash
   conda activate base
   ```

3. Remove each environment in the list of conda environments, besides base.
   ```bash
   conda remove --name <ENVIRONMENT_NAME> --all
   ```

4. Delete all of the files on your Studio Lab.
   ```bash
   rm -rf *.*
   ```

**Use external resources in Amazon SageMaker Studio Lab**

With Amazon SageMaker Studio Lab, you can integrate external resources, such as Jupyter notebooks and data, from Git repositories and Amazon S3. You can also add an Open in Studio Lab button to your GitHub repo and notebooks. This button lets you clone your notebooks directly from Studio Lab.

The following topics show how to integrate external resources.

**Topics**

- [Use GitHub resources](p. 359)
- [Add an Open in Studio Lab button to your notebook](p. 360)
- [Import files from your computer](p. 360)
- [Connect to Amazon S3](p. 361)
Use GitHub resources

Studio Lab offers integration with GitHub. With this integration, you can clone notebooks and repositories directly to your Studio Lab project.

The following topics give information about how to use GitHub resources with Studio Lab.

Studio Lab sample notebooks

To get started with a repository of sample notebooks tailored for Studio Lab, see Studio Lab Sample Notebooks.

This repository provides notebooks for the following use cases and others.

- Computer vision
- Connecting to AWS
- Creating custom environments
- Geospatial data analysis
- Natural language processing
- Using R

Clone a GitHub repo

To clone a GitHub repo to your Studio Lab project, follow these steps.

1. Start your Studio Lab project runtime. For more information on launching Studio Lab project runtime, see Start your project runtime (p. 346).
2. In Studio Lab, choose the File Browser icon ( ) on the left menu, so that the File Browser panel shows on the left.
3. Navigate to your user directory by choosing the file icon beneath the file search bar.
4. Select the Git icon ( ) from the left menu to open a new dropdown menu.
5. Choose Clone a Repository.
6. Paste the repository’s URL under Git repository URL (.git).
7. Select Clone.

Clone individual notebooks from GitHub

To open a notebook in Studio Lab, you must have access to the repo that the notebook is in. The following examples describe Studio Lab permission-related behavior in various situations.

- If a repo is public, you can automatically clone the notebook into your project from the Studio Lab preview page.
- If a repo is private, you are prompted to sign in to GitHub from the Studio Lab preview page. If you have access to a private repo, you can clone the notebook into your project.
- If you don’t have access to a private repo, you cannot clone the notebook from the Studio Lab preview page.

The following sections show two options for you to copy a GitHub notebook in your Studio Lab project. These options depend on whether the notebook has an Open in Studio Lab button.
Option 1: Copy notebook with an Open in Studio Lab button

The following procedure shows how to copy a notebook that has an Open in Studio Lab button. If you want to add this button to your notebook, see Add an Open in Studio Lab button to your notebook (p. 360).

1. Sign in to Studio Lab following the steps in Sign in to Studio Lab (p. 345).
2. In a new browser tab, navigate to the GitHub notebook that you want to clone.
3. In the notebook, select the Open in Studio Lab button to open a new page in Studio Lab with a preview of the notebook.
4. If your project runtime is not already running, start it by choosing the Start runtime button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.
5. After your project runtime has started, select Copy to project to open your project runtime in a new browser tab.
6. In the Copy from GitHub? dialog box, select Copy notebook only. This copies the notebook file to your project.

Option 2: Clone any GitHub notebook

The following procedure shows how to copy any notebook from GitHub.

1. Navigate to the notebook in GitHub.
2. In the browser’s address bar, modify the notebook URL, as follows.

<table>
<thead>
<tr>
<th># Original URL</th>
<th><a href="https://github.com/">https://github.com/</a>&lt;PATH_TO_NOTEBOOK&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td># Modified URL</td>
<td><a href="https://studiolab.sagemaker.aws/import/github/">https://studiolab.sagemaker.aws/import/github/</a>&lt;PATH_TO_NOTEBOOK&gt;</td>
</tr>
</tbody>
</table>

3. Navigate to the modified URL. This opens a preview of the notebook in Studio Lab.
4. If your project runtime is not already running, start it by choosing the Start runtime button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.
5. After your project runtime has started, select Copy to project to open your project runtime in a new browser tab.
6. In the Copy from GitHub? dialog box, select Copy notebook only to copy the notebook file to your project.

Add an Open in Studio Lab button to your notebook

When you add the Open in Studio Lab button to your notebooks, others can clone your notebooks or repositories directly to their Studio Lab projects. If you are sharing your notebook within a public GitHub repository, your content will be publicly readable. Do not share private content, such as AWS access keys or AWS Identity and Access Management credentials, in your notebook.

To add the functional Open in Studio Lab button to your Jupyter notebook or repository, add the following markdown to the top of your notebook or repository.

```
```

Import files from your computer

The following steps show how to import files from your computer to your Studio Lab project.
1. Open the Studio Lab project runtime.
2. Open the File Browser panel.
3. In the actions bar of the File Browser panel, select the Upload Files button.
4. Select the files that you want to upload from your local machine.
5. Select Open.

Alternatively, you can drag and drop files from your computer into the File Browser panel.

**Connect to Amazon S3**

The AWS CLI enables AWS integration in your Studio Lab project. With this integration, you can pull resources from Amazon S3 to use with your Jupyter notebooks.

To use AWS CLI with Studio Lab, complete the following steps. For a notebook that outlines this integration, see Using Studio Lab with AWS Resources.

1. Install the AWS CLI following the steps in Installing or updating the latest version of the AWS CLI.
2. Configure your AWS credentials by following the steps in Quick setup. The role for your AWS account must have permissions to access the Amazon S3 bucket that you are copying data from.
3. From your Jupyter notebook, clone resources from the Amazon S3 bucket, as needed. The following command shows how to clone all resources from an Amazon S3 path to your project. For more information, see the AWS CLI Command Reference.

   ```bash
   !aws s3 cp s3://<BUCKET_NAME>/<PATH_TO_RESOURCES>/ <PROJECT_DESTINATION_PATH>/ --recursive
   ```

**Get notebook differences**

You can display the difference between the current notebook and the last checkpoint, or the last Git commit, using the Amazon SageMaker Studio Lab project UI.

**Topics**

- Get the difference between the last checkpoint (p. 361)
- Get the difference between the last commit (p. 362)

**Get the difference between the last checkpoint**

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file, or revert the notebook to match the checkpoint file.

To save the Studio Lab notebook and update the checkpoint file to match: Choose the Save notebook and create checkpoint icon (.embeddingImage). This is located on the Studio Lab menu's left side. The keyboard shortcut for Save notebook and create checkpoint is Ctrl + s.

To view changes between the Studio Lab notebook and the checkpoint file: Choose the Checkpoint diff icon (.embeddingImage), located in the center of the Studio Lab menu.

To revert the Studio Lab notebook to the checkpoint file: On the main Studio Lab menu, choose File, and then Revert Notebook to Checkpoint.
Get the difference between the last commit

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit: Choose the **Git diff** icon (`,`) in the center of the notebook menu.

Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio

Amazon SageMaker Studio offers many features for machine learning and deep learning work flows that are unavailable in Amazon SageMaker Studio Lab. This page shows how to migrate a Studio Lab environment to Studio to take advantage of more compute capacity, storage, and features. However, you may want to familiarize yourself with Studio's prebuilt containers, which are optimized for the full MLOP pipeline. For more information, see Amazon SageMaker Studio Lab (p. 340)

To migrate your Studio Lab environment to Studio, you must first onboard to Studio following the steps in Onboard to Amazon SageMaker Domain (p. 10).

Topics

- Step 1: Export your Studio Lab conda environment (p. 362)
- Step 2: Save your Studio Lab artifacts (p. 363)
- Step 3: Import your Studio Lab artifacts to Studio (p. 364)
- Step 4: Install your Studio Lab conda environments in Studio (p. 365)

Step 1: Export your Studio Lab conda environment

You can export a conda environment and add libraries or packages to the environment by following the steps in Manage your environment (p. 355). The following example demonstrates using the default environment to be exported to Studio.

1. Open the Studio Lab terminal by opening the **File Browser** panel, choose the plus (++) sign on the menu at the top of the file browser to open the **Launcher**, then choose **Terminal**. From the Studio Lab terminal, list the conda environments by running the following.

```
conda env list
```

This command outputs a list of the conda environments and their locations in the file system. When you onboard to Studio Lab, you automatically activate the `studiolab` conda environment.

```
# conda environments: #
   default                  /home/studio-lab-user/.conda/envs/default
   studiolab             *  /home/studio-lab-user/.conda/envs/studiolab
   studiolab-safemode       /opt/amazon/sagemaker/safemode-home/.conda/envs/studiolab-safemode
   studiolab-safemode       /opt/amazon/sagemaker/safemode-home/.conda/envs/studiolab-safemode
   base                     /opt/conda
```

We recommend that you do not export the `studiolab`, `studiolab-safemode`, and `base` environments. These environments are not usable in Studio for the following reasons:

- **studiolab**: This sets up the JupyterLab environment for Studio Lab. Studio Lab runs a different major version of JupyterLab than Studio, so it is not usable in Studio.
Use the Studio Lab project runtime

- **studiolab-safemode**: This also sets up the JupyterLab environment for Studio Lab. Studio Lab runs a different major version of JupyterLab than Studio, so it is not usable in Studio.
- **base**: This environment comes with conda by default. The base environment in Studio Lab and the base environment in Studio have incompatible versions of many packages.

2. For the conda environment that you want to migrate to Studio, first activate the conda environment. The `conda env list` command shows the list of environments in the current conda environment. To get the exact state of the environment, export it into a YAML file using the command line. The following command lines export the default environment into a YAML file, creating a file called `myenv.yml`.

   ```bash
   conda activate default
   conda env export > ~/myenv.yml
   ```

**Step 2: Save your Studio Lab artifacts**

Now that you have saved your environment to a YAML file, you can move the environment file to any platform.

**Save to a local machine using Studio Lab GUI**

`Note`

Downloading a directory from the Studio Lab GUI by right-clicking on the directory is currently unavailable. If you wish to export a directory, please follow the steps using the **Save to Git repository** tab.

One option is to save the environment onto your local machine. To do this, use the following procedure.

1. In Studio Lab, choose the **File Browser** icon on the left menu, so that the **File Browser** panel shows on the left.
2. Navigate to your user directory by choosing the file icon beneath the file search bar.
3. Choose (right-click) the `myenv.yml` file and then choose **Download**. You can repeat this process for other files you want to import to Studio.

**Save to a Git repository**

Another option is to save your environment to a Git repository. This option uses GitHub as an example. These steps require a GitHub account and repository. For more information, visit [GitHub](https://github.com).

The following procedure shows how to synchronize your content with GitHub using the Studio Lab terminal.

1. From the Studio Lab terminal, navigate to your user directory and make a new directory to contain the files you want to export.

   ```bash
   cd ~
mkdir <NEW_DIRECTORY_NAME>
   ```

2. After you create a new directory, copy any file or directory you want to export to `<NEW_DIRECTORY_NAME>`.

   Copy a file using the following code format:

   ```bash
   cp <FILE_NAME> <NEW_DIRECTORY_NAME>
   ```
For example, replace `<FILE_NAME>` with `myenv.yml`.

Copy any directory using the following code format:

```bash
cp -r <DIRECTORY_NAME> <NEW_DIRECTORY_NAME>
```

For example, replace `<DIRECTORY_NAME>` with any directory name in your user directory.

3. Navigate to the new directory and initialize the directory as a Git repository using the following command. For more information, see the [git-init documentation](#).

```bash
cd <NEW_DIRECTORY_NAME>
git init
```

4. Using Git, add all relevant files and then commit your changes.

```bash
git add .
git commit -m "<COMMIT_MESSAGE>"
```

For example, replace `<COMMIT_MESSAGE>` with `Add Amazon SageMaker Studio Lab artifacts to GitHub repository to migrate to Amazon SageMaker Studio`.

5. Push the commit to your remote repository. This repository has the format `https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git` where `<GITHUB_USERNAME>` is your GitHub user name and the `<REPOSITORY_NAME>` is your remote repository name. Create a branch `<BRANCH_NAME>` to push the content to the GitHub repository.

```bash
git branch -M <BRANCH_NAME>
git remote add origin https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git
git push -u origin <BRANCH_NAME>
```

---

**Step 3: Import your Studio Lab artifacts to Studio**

The following procedure shows how to import artifacts to Studio. You first have to open Amazon SageMaker Studio. For more information, see [Launch Amazon SageMaker Studio](#).

From Studio, you can import files from your local machine or from a Git repository. You can do this using the Studio GUI or terminal. The following procedure uses the examples from [Step 2: Save your Studio Lab artifacts](#).

**Import using the Studio GUI**

If you saved the files to your local machine, you can import the files to Studio using the following steps.

1. Open the **File Browser** panel at the top left of Studio.
2. Choose the **Upload Files** icon on the menu at the top of the **File Browser** panel.
3. Navigate to the file you want to import, then choose **Open**.

**Note**

If you wish to import a directory into Studio, first compress the directory on your local machine to a file. On a Mac, right-click the directory and choose **Compress**.
"<DIRECTORY_NAME>". In Windows, right-click the directory and choose Send to, and then choose Compressed (zipped) folder. After the directory is compressed, import the compressed file using the preceding steps. Unzip the compressed file by navigating to the Studio terminal and running the command `<DIRECTORY_NAME>.zip`.

Import using a Git repository

This example provides two options for how to clone a GitHub repository into Studio. You can use the Studio GUI by choosing the Git tab on the left side of Studio. Choose Clone a Repository, then paste your GitHub repository URL from Step 2: Save your Studio Lab artifacts (p. 363).

Another option is to use the Studio terminal by using the following procedure.

1. Open the Studio Launcher. For more information on opening the Launcher, see Amazon SageMaker Studio Launcher.
2. In the Launcher, in the Notebooks and compute resources section, choose Change environment.
3. In Studio, open the Launcher. To open the Launcher, choose Amazon SageMaker Studio at the top-left corner of Studio.

To learn about all the available ways to open the Launcher, see Use the Amazon SageMaker Studio Launcher (p. 218).

4. In the Change environment dialog, use the Image dropdown list to select the Data Science image and choose Select. This image comes with conda pre-installed.
5. In the Studio Launcher, choose Open image terminal.
6. From the image terminal, run the following command to clone your repository. This command creates a directory named after `<REPOSITORY_NAME>` in your Studio instance and clones your artifacts in that repository.

```
git clone https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git
```

Step 4: Install your Studio Lab conda environments in Studio

You can now recreate your conda environment by using your YAML file in your Studio instance. Open the Studio Launcher. For more information on opening the Launcher, see Amazon SageMaker Studio Launcher. From the Launcher, choose Open image terminal. In the terminal navigate to the directory that contains the YAML file, then run the following commands.

```
conda env create --file <ENVIRONMENT_NAME>.yml
conda activate <ENVIRONMENT_NAME>
```

After these commands are complete, you can select your environment as the kernel for your Studio notebook instances. To view the available environment, run conda env list. To activate your environment, run conda activate `<ENVIRONMENT_NAME>`.

Shut down resources

In this guide, you will learn how to shut down individual resources, including notebooks, terminals, and kernels. You can also shut down all resources in one of these categories at the same time.

Topics

- Shut down an open notebook (p. 366)
- Shut down resources (p. 366)
Shut down an open notebook

You can shut down an open notebook from the Amazon SageMaker Studio Lab File menu or from the Running Terminals and Kernels pane.

Note
When you shut down a notebook, any unsaved information in the notebook is lost. The notebook is not deleted.

To shut down an open notebook from the File menu

1. Save the notebook contents by choosing the icon, located in the notebook menu.
2. Choose File then Close and Shutdown Notebook.
3. Choose OK.

Shut down resources

On the left sidebar of Studio Lab, you will find the Running Terminals and Kernels pane and icon. The Running Terminals and Kernels pane has three sections. Each section lists all of the resources of that type. You can shut down each resource individually, or shut down all resources in a section simultaneously.

When you shut down all resources in a section, the following occurs:

- KERNELS – All kernels, notebooks, and consoles are shut down.
- TERMINALS – All terminals are shut down.

To shut down resources

1. In the left sidebar, choose the Running Terminals and Kernels icon ( ).
2. Do either of the following:
   - To shut down a specific resource: Choose the SHUT DOWN icon on the same row as the resource.
   - To shut down all resources in a section: Choose Shut Down All, which is located to the right of the section label. After a confirmation dialog box appears, choose Shut down all to proceed.

Troubleshooting

The guide shows common errors that might occur when using Amazon SageMaker Studio Lab. Each error contains a description, as well as a solution to the error.

Note
You cannot share your password with multiple users or use Studio Lab to mine cryptocurrency. We don’t recommend using Studio Lab for production tasks because of runtime limits.

Can’t access account

If you can’t access your account, verify that you are using the correct email and password. If you have forgotten your password, use the following steps to reset your password. If you still cannot access your account, you must request and register for a new account using the instructions in Onboard to Amazon SageMaker Studio Lab (p. 344).

**Forgot password**

If you forget your password, you must reset it using the following steps.

1. Navigate to the [Studio Lab landing page](#).
2. Select **Sign in**.
3. Select **Forgot password?** to open a new page.
4. Enter the email address that you used to sign up for an account.
5. Select **Send reset link** to send an email with a password reset link.
6. From the password reset email, select **Reset your password**.
7. Enter your new password.
8. Select **Submit**.

**Can't launch project runtime**

If the Studio Lab project runtime does not launch, try launching it again. If this doesn't work, switch the instance type from CPU to GPU (or in reverse). For more information, see [Change your compute type](#).

**Runtime stopped running unexpectedly**

If there is an issue with the environment used to run JupyterLab, then Studio Lab will automatically recreate the environment. Studio Lab does not support manual activation of this process.

**Conflicting versions**

Because you can add packages and modify your environment as needed, you may run into conflicts between packages in your environment. If there are conflicts between packages in your environment, you must remove the conflicting package.

**Environment build fails**

When you build an environment from a YAML file, a package-version conflict or file issue might cause a build to fail. To resolve this, remove the environment by running the following command. Do this before attempting to build it again.

```sh
conda remove --name <YOUR_ENVIRONMENT> --all
```

**Error message about allowing to download script from domain *.awswaf.com**

Studio uses the web application firewall service AWS WAF to protect your resources, which uses JavaScript. If you are using a browser security plugin that prevents JavaScript from downloading, this error may pop up. To use Studio, allow the JavaScript download from *.awswaf.com as a trusted domain. For more information on AWS WAF, see [AWS WAF](#) from the AWS WAF, AWS Firewall Manager, and AWS Shield Advanced. Developer Guide.

**Disk space is full**

If you run into a notification saying mentioning that your disk space is full or **File Load Error for <FILE_NAME>** while attempting to open a file, you can remove files, directories, libraries, or environments to increase space. For more information on managing your libraries and environments, see [Manage your environment](#).

**Project runtime is in safe mode notification**

If you run into a notification that **Project runtime is in safe mode**, you must free up some disk space to resume using the Studio Lab project runtime. Follow the instructions in the preceding troubleshoot item.
Disk space is full. Once up to at least 500 MB of space has been cleared, you may restart the project runtime to use Studio Lab. This can be done by choosing Amazon SageMaker Studio Lab in the top menu of Studio Lab and choosing Restart JupyterLab....

**git Cannot import cv2**

If you run into an error when importing cv2 after installing opencv-python, you must uninstall opencv-python and install opencv-python-headless as follows.

```bash
%pip uninstall opencv-python --yes
%pip install opencv-python-headless
```

You can then import cv2 as expected.

**Studio Lab becomes unresponsive when opening large files**

The Studio Lab IDE may fail to render when large files are opened, resulting in blocked access to Studio Lab resources. To resolve this, reset the Studio Lab workspace using the following procedure.

1. After you open the IDE, copy the URL in your browser's address bar. This URL should be in the https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab format. Close the tab.
2. In a new tab, paste the URL and remove anything after https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab.
3. Add ?reset to the end of the URL, so it is in the https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab?reset format.
4. Navigate to the updated URL. This resets the saved UI state and makes the Studio Lab IDE responsive.

---

**Amazon SageMaker Canvas**

Amazon SageMaker Canvas gives you the ability to use machine learning to generate predictions without needing to write any code. The following are some use cases where you can use SageMaker Canvas:

- Predict customer churn
- Plan inventory efficiently
- Optimize price and revenue
- Improve on-time deliveries
- Classify text or images based on custom categories
- Identify objects and text in images
- Extract information from documents

With Canvas, you can chat with popular large language models (LLMs), access Ready-to-use models, or build a custom model trained on your data.

Canvas chat is a functionality that leverages open-source and Amazon LLMs to help you boost your productivity. You can prompt the models to get assistance with tasks such as generating content, summarizing or categorizing documents, and answering questions. To learn more, see [Use generative AI with foundation models](#).

The Ready-to-use models in Canvas can extract insights from your data for a variety of use cases. You don’t have to build a model to use Ready-to-use models because they are powered by Amazon AI services, including Amazon Rekognition, Amazon Textract, and Amazon Comprehend. You only have to import your data and start using a solution to generate predictions.
If you want a model that is customized to your use case and trained with your data, you can **build a model** (p. 427). You can get predictions customized to your data by doing the following:

1. Import your data from one or more data sources.
2. Build a predictive model.
3. Evaluate the model’s performance.
4. Generate predictions with the model.

Canvas supports the following types of custom models:

- Numeric prediction (also known as *regression*)
- Categorical prediction for 2 and 3+ categories (also known as *binary* and *multi-class classification*)
- Time series forecasting
- Single-label image prediction (also known as *image classification*)
- Multi-category text prediction (also known as *multi-class text classification*)

You can also **bring your own models** into Canvas from Amazon SageMaker Studio.

To learn more about pricing, see the [SageMaker Canvas pricing page](#). You can also see **Manage billing and cost in SageMaker Canvas** (p. 547) for more information.

SageMaker Canvas is currently available in the following Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)

**Are you a first-time SageMaker Canvas user?**

If you are a first-time user of SageMaker Canvas, we recommend that you begin by reading the following sections:
Getting started with using Amazon SageMaker Canvas

This guide tells you how to get started with using SageMaker Canvas. If you're an IT administrator, see Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators) to set up SageMaker Canvas for your users.

If you're a business user or analyst, read the following sections.

Topics

• Prerequisites for setting up Amazon SageMaker Canvas
• Step 1: Log in to Amazon SageMaker Canvas as a business user
• Step 2: Use SageMaker Canvas to get predictions

Prerequisites for setting up Amazon SageMaker Canvas

To set up Amazon SageMaker Canvas, you can either contact your administrator or do the following:

• Set up an Amazon SageMaker Domain
• Configure the Amazon S3 location for storing Canvas data
• Give yourself permissions to use specific features in Canvas
  • Optional: Give yourself permissions to upload local files
  • Optional: Give yourself permissions to build custom image and text prediction models
  • Optional: Give yourself permissions to use Ready-to-use models and foundation models
  • Optional: Give yourself permissions to do time series forecasts
  • Optional: Give yourself permissions to send batch predictions to Amazon QuickSight
  • Optional: Give yourself permissions to deploy models to endpoints
  • Optional: Give yourself permissions to register models to the model registry
  • Optional: Give yourself permissions to collaborate with Amazon SageMaker Studio
  • Optional: Give yourself permissions to import Amazon Redshift data

The following sections describe how to set up an Amazon SageMaker Domain and give yourself SageMaker Canvas permissions.

Important
For you to set up Amazon SageMaker Canvas, your version of Amazon SageMaker Studio must be 3.19.0 or later. For information about updating Amazon SageMaker Studio, see Shut down and Update SageMaker Studio.

Onboard to Domain using IAM Identity Center

To onboard to Domain use the following procedure:

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. On the Domains page, choose Create domain
5. Choose Standard setup.
6. Choose Configure.

Use the following procedure to configure the general settings for the Domain:

1. Under Permission, for IAM role, choose an option from the role selector.

   If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3387).

   If you choose Create a new role, the Create an IAM role dialog opens:
   - Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the AmazonSageMakerFullAccess policy attached.

2. Under Network and storage, specify the following:
   - Your VPC information – For more information, see Choose an Amazon VPC (p. 42) and Configure Amazon SageMaker Canvas in a VPC without internet access (p. 403).
   - (Optional) Encryption key – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see Protect Data at Rest Using Encryption (p. 3344).

   **Note**
   Encryption in transit is only available for Amazon SageMaker Studio.

3. Select Next.

Use the following procedure to configure the SageMaker Canvas settings for the Domain:

1. For the Canvas base permissions configuration, leave the Enable Canvas base permissions option turned on (it is turned on by default). This attaches the AmazonSageMakerCanvasFullAccess policy to your user's execution role and establishes the minimum required permissions to use the SageMaker Canvas app.

2. For the Canvas storage configuration, specify where you want Canvas to store the application data, such as model artifacts, datasets, and logs. For more information, see Configure your Amazon S3 storage (p. 382). For this section, do the following:
   - Select System managed if you want to set the location to the default SageMaker-created bucket that follows the pattern s3://sagemaker-{Region}-{your-account-id}.
   - Select Custom S3 to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
   - (Optional) For Encryption key, specify a KMS key for encrypting Canvas artifacts stored at the specified location.

3. (Optional) For the Canvas Ready-to-use models configuration, do the following:
   - Leave the Enable Canvas Ready-to-use models option turned on to give your users permissions to generate predictions with Ready-to-use models in Canvas (it is turned on by default). This option also gives you permissions to chat with generative-AI powered models. For more information, see Use generative AI with foundation models (p. 410).
   - Leave the Enable document query using Amazon Kendra option turned on to give your users permissions to use foundation models for querying documents stored in an Amazon Kendra index. Then enter the existing indexes to which you want to grant access. For more information, see Use generative AI with foundation models (p. 410).
4. (Optional) For the **ML Ops permissions configuration** section, do the following:

   a. Leave the **Enable direct deployment of Canvas models** option turned on to give your users permissions to deploy their models from Canvas to a SageMaker endpoint. For more information about model deployment in Canvas, see *Deploy your models to an endpoint* (p. 516).

   b. Leave the **Enable Model Registry registration permissions for all users** option turned on to give your users permissions to register their model version to the SageMaker model registry (it is turned on by default). For more information, see *Register a model version in the SageMaker model registry* (p. 513).

5. (Optional) For the **Time series forecasting configuration**, leave the **Enable time series forecasting** option turned on to give your users permissions to do time series forecasting in SageMaker Canvas (it is turned on by default).

   • If you left **Enable time series forecasting** turned on, select **Create and use a new execution role**, or select **Use an existing execution role** if you already have an IAM role with the required Amazon Forecast permissions attached (for more information, see the **IAM role setup method**).

6. (Optional) If you left **Enable time series forecasting** turned on, select **Create and use a new execution role**, or select **Use an existing execution role** if you already have an IAM role with the required Amazon Forecast permissions attached (for more information, see the **IAM role setup method** (p. 396)).

7. (Optional) Add **Tags** to track your cost and usage trends in AWS Billing and Cost Management. SageMaker adds the tags you specify in the Domain to all of the SageMaker Canvas apps you create in the Domain. For more information about billing and tags, see *Manage billing and cost in SageMaker Canvas* (p. 547).

8. Finish making any other changes to your Domain setup, and then choose **Submit**.

   **Note**

   If you encounter any issues with granting permissions through the console, such as permissions for Ready-to-use models, see the topic *Troubleshooting issues with granting permissions through the SageMaker console* (p. 540).

When you set up the Domain, SageMaker Canvas creates a Canvas/ folder in the Amazon S3 bucket that you specified in the **Canvas storage configuration**. Your Canvas application data, such as imported datasets and batch predictions, are stored in this folder.

**Give yourself permissions to use specific features in Canvas**

The following information outlines the permissions that you can grant to a Canvas user to allow the use of various features and functionalities within Canvas:

- **Local file upload.** The permissions for local file upload are turned on by default in the Canvas base permissions when setting up your Domain. If you don't have the ability to upload local files from your machine to SageMaker Canvas, you can attach a CORS policy to the Amazon S3 bucket that you specified in the Canvas storage configuration. If you allowed SageMaker to use the default bucket, the bucket follows the naming pattern s3://sagemaker-{Region}-{your-account-id}. For more information, see *Grant Your Users Permissions to Upload Local Files*.

- **Custom image and text prediction models.** The permissions for building custom image and text prediction models are turned on by default in the Canvas base permissions when setting up your Domain. However, if you have a custom IAM configuration and don't want to attach the **AmazonSageMakerCanvasFullAccess** policy to your user's IAM execution role, then you must explicitly grant your user the necessary permissions. For more information, see *Grant Your Users Permissions to Build Custom Image and Text Prediction Models* (p. 393).

- **Ready-to-use models and foundation models.** You might want to have the ability to use the Canvas Ready-to-use models to make predictions for your data. The Ready-to-use models permissions also include the ability to chat with generative AI-powered models. The permissions
are turned on by default when setting up your Domain, or you can edit the permissions for a Domain that you’ve already created. The Canvas Ready-to-use models permissions option adds the AmazonSageMakerCanvasAIServicesAccess policy to your execution role. For more information, see the Get started (p. 419) section of the Ready-to-use models documentation.

For more information about getting started with generative AI foundation models, see Use generative AI with foundation models (p. 410).

- **Time series forecasting.** If you’d like to have the ability to perform forecasts on time series data, you can add time series forecasting permissions when setting up your Domain, or you can edit the permissions for a Domain or user profile after creating your Domain. The required permissions are the AmazonSageMakerCanvasForecastAccess managed policy and a trust relationship with Amazon Forecast to the AWS IAM role you chose when setting up the user profile. For instructions on how to add these permissions to your IAM role, see Grant Your Users Permissions to Perform Time Series Forecasting.

- **Send batch predictions to Amazon QuickSight.** You might want to have the ability to send batch predictions, or datasets of predictions you generate from a custom model, to Amazon QuickSight for analysis. In QuickSight, you can build and publish predictive dashboards with your prediction results. For instructions on how to add these permissions to your Canvas user’s IAM role, see Grant Your Users Permissions to Send Predictions to Amazon QuickSight.

- **Deploy Canvas models to a SageMaker endpoint.** SageMaker Hosting offers endpoints which you can use to deploy your model for use in production. You can deploy models built in Canvas to a SageMaker endpoint and then make predictions programmatically in a production environment. For more information, see Deploy your models to an endpoint (p. 516).

- **Register model versions to the model registry.** You might want to register versions of your model to the SageMaker model registry, which is a repository for tracking the status of updated versions of your model. A data scientist or MLOps team working in the SageMaker model registry can view the versions of your model that you’ve built and approve or reject them. Then, they can deploy your model version to production or kick off an automated workflow. Model registration permissions are turned on by default for your Domain. You can manage permissions at the user profile level and grant or remove permissions to specific users. For more information, see Register a model version in the SageMaker model registry (p. 513).

- **Collaboration with data scientists.** If you want to collaborate with Studio users and share models, you must add additional permissions to the AWS IAM role you chose when setting up the user profile. For instructions on how to add the policy to the role, see Grant Users Permissions to Collaborate with Studio.

- **Import data from Amazon Redshift.** If you want to import data from Amazon Redshift, you must give yourself additional permissions. You must add the AmazonRedshiftFullAccess managed policy to the AWS IAM role you chose when setting up the user profile. For instructions on how to add the policy to the role, see Grant Users Permissions to Import Amazon Redshift Data.

**Note**

The necessary permissions to import through other data sources, such as Amazon Athena and SaaS platforms, are included in the AmazonSageMakerFullAccess and AmazonSageMakerCanvasFullAccess policies. If you followed the standard setup instructions, these policies should already be attached to your execution role. For more information about these data sources and their permissions, see Connect to data sources (p. 440).

**Step 1: Log in to Amazon SageMaker Canvas as a business user**

Contact your administrator to guide you through the process of setting up Amazon SageMaker Canvas.

When the initial setup is complete, you can access SageMaker Canvas by doing the following.

1. Navigate to the SageMaker console.
2. In the navigation pane, choose Canvas.
3. In the **Get Started** box, select your user profile from the dropdown.
4. Choose **Open Canvas** to open the application.

When you log into SageMaker Canvas for the first time, there is a welcome message with quick getting started tutorials that you can follow for a walkthrough of the SageMaker Canvas application.

You can follow the **Get started with Canvas** tutorial for a high-level overview of the SageMaker Canvas application. There are also shorter tutorials that guide you through the individual steps of using SageMaker Canvas. These tutorials show you how to import a dataset, build a model, analyze the results of a built model, and generate predictions with your model. You can revisit the tutorials at any time by choosing the **Help** button and then choosing one of the tutorials.
Step 2: Use SageMaker Canvas to get predictions

After you’ve logged in to Canvas, you can start building models and generating predictions for your data.

You can either use Canvas Ready-to-use models to make predictions without building a model, or you can build a custom model for your specific business problem. Review the following information to decide whether Ready-to-use models or custom models are best for your use case.

- **Ready-to-use models.** With Ready-to-use models, you can use pre-built models to extract insights from your data. The Ready-to-use models cover a variety of use cases, such as language detection and document analysis. To get started making predictions with Ready-to-use models, see [Use Ready-to-use models](#).

- **Custom models.** With custom models, you can build a variety of model types that are customized to make predictions for your data. Use custom models if you’d like to build a model that is trained on your business-specific data and if you’d like to use features such as collaborating with data scientists and evaluating your model’s performance. To get started with building a custom model, see [Use custom models](#).

You can also bring your own model (BYOM) from other features in SageMaker. An Amazon SageMaker Studio user can share their model with a Canvas user, and the Canvas user can generate predictions with the model. To learn more, see [Bring your own model to SageMaker Canvas](#).

Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators)

You can use the information in this section to help your users do the following:

- Optional: Grant your users permissions to upload their files locally.
- Set up Okta SSO for your users.
- Update SageMaker Canvas.
• Clean up or delete the installation of SageMaker Canvas.
• Optional: Set up Amazon Forecast so users can do time series forecasting.
• Optional: Set up an Amazon Virtual Private Cloud.
• Optional: Encrypt data using AWS Key Management Service.
• Optional: Grant your users permissions to import Amazon Redshift data.

You can also set up SageMaker Canvas for your users with AWS CloudFormation. For more information, see AWS::SageMaker::App in the AWS CloudFormation User Guide.

Topics
• Grant Your Users Permissions to Upload Local Files (p. 376)
• Set Up SageMaker Canvas for Your Users (p. 378)
• Configure your Amazon S3 storage (p. 382)
• Grant permissions for cross-account Amazon S3 storage (p. 385)
• Encrypt Your SageMaker Canvas Data with AWS KMS (p. 389)
• Grant Your Users Permissions to Build Custom Image and Text Prediction Models (p. 393)
• Grant Your Users Permissions to Perform Time Series Forecasting (p. 393)
• Update SageMaker Canvas for Your Users (p. 397)
• Request a Quota Increase (p. 398)
• Grant Users Permissions to Import Amazon Redshift Data (p. 399)
• Grant Users Permissions to Collaborate with Studio (p. 400)
• Grant Your Users Permissions to Send Predictions to Amazon QuickSight (p. 401)
• Manage apps (p. 402)
• Configure Amazon SageMaker Canvas in a VPC without internet access (p. 403)
• Set up connections to data sources with OAuth (p. 407)

Grant Your Users Permissions to Upload Local Files

If your users are uploading files from their local machines to SageMaker Canvas, you must attach a CORS configuration to the Amazon S3 bucket that they’re using. When setting up the SageMaker Domain or user profile, you can specify either a custom Amazon S3 location or the default location, which is a SageMaker-created Amazon S3 bucket with a name that uses the following pattern: s3://sagemaker-{Region}-{your-account-id}. SageMaker Canvas adds your users’ data to the bucket whenever they upload a file.

To grant users permissions to upload local files to the bucket, you can attach a CORS configuration to it using either of the following procedures. You can use the first method when setting up your Domain or editing the existing Domain settings, where you opt in to allow SageMaker to attach the CORS configuration to the bucket for you. The second method is the manual method, where you can attach the CORS configuration to the bucket yourself.

Domain setup method

To grant your users permissions to upload local files, you can choose Enable Canvas permissions when setting up your Domain. This attaches a Cross-Origin Resource Sharing (CORS) configuration to the Canvas storage configuration's Amazon S3 bucket and grants all users in the Domain permission to upload local files into SageMaker Canvas. By default, the permissions option is turned on when you set up a Domain, but you can turn off this option if you don’t want to grant your users permission to upload files.
Note
If you have an existing CORS configuration on the storage configuration Amazon S3 bucket, turning on Enable Canvas permissions overwrites the existing configuration with the new configuration.

The following procedure shows how you can turn on this option when doing a Quick setup for your Domain in the console.

1. In the User profile section, enter a Name for the user.
2. Select an Execution role for the user.
3. Turn on Enable SageMaker Canvas permissions. (By default, this option is turned on.)
4. Finish setting up the Domain.

If you are doing a Standard setup for your Domain, then use the following procedure for the Canvas settings section to turn on local file upload.

1. For Enable and configure Canvas permissions, select Local file upload. (It's already checked by default.)
2. Choose Next.
3. Finish setting up the Domain.

Your users can now upload local files into their SageMaker Canvas application.

You can also turn on or turn off local upload permissions for an existing Domain by using the following procedure.

1. Go to the Amazon SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, choose your Domain.
6. Choose Edit.
7. In the navigation pane, choose Canvas settings.
8. Select or deselect Enable local file upload.
9. Finish any other modifications you want to make to the Domain, and then choose Submit to submit your changes.

Amazon S3 bucket method

If you want to manually attach the CORS configuration to the SageMaker Amazon S3 bucket, use the following procedure.

2. Choose your bucket. If your Domain uses the default SageMaker-created bucket, the bucket's name uses the following pattern: s3://sagemaker-{Region}-{your-account-id}.
3. Choose Permissions.
4. Navigate to Cross-origins resource sharing (CORS).
5. Choose Edit.
6. Add the following CORS policy:
7. Choose **Save changes**.

In the preceding procedure, the CORS policy must have "POST" listed under **AllowedMethods**.

After you've gone through the procedure, you should have:

- An IAM role assigned to each of your users.
- Amazon SageMaker Studio runtime permissions for each of your users. SageMaker Canvas uses Studio to run the commands from your users.
- If the users are uploading files from their local machines, a CORS policy attached to their Amazon S3 bucket.

If your users still can't upload the local files after you update the CORS policy, the browser might be caching the CORS settings from a previous upload attempt. If they're running into issues, instruct them to clear their browser cache and try again.

**Set Up SageMaker Canvas for Your Users**

To set up Amazon SageMaker Canvas, do the following:

- Create an Amazon SageMaker Domain.
- Create user profiles for the Domain
- Set up Okta Single Sign On (Okta SSO) for your users.
- Activate link sharing for models.

Use Okta Single-Sign On (Okta SSO) to grant your users access to Amazon SageMaker Canvas. SageMaker Canvas supports SAML 2.0 SSO methods. The following sections guide you through procedures to set up Okta SSO.

To set up a Domain, see **Onboard to Amazon SageMaker Runtime Studio Using IAM**. You can use the following information to help you complete the procedure in the section:

- You can ignore the step about creating projects.
- You don't need to provide access to additional Amazon S3 buckets. Your users can use the default bucket that we provide when we create a role.
- To grant your users access to share their notebooks with data scientists, turn on **Notebook Sharing Configuration**.

```json
{
    "AllowedHeaders": [
        "*
    ],
    "AllowedMethods": [
        "POST"
    ],
    "AllowedOrigins": [
        "*
    ],
    "ExposeHeaders": []
}
```
- Use Amazon SageMaker Studio version 3.19.0 or later. For information about updating Amazon SageMaker Studio, see Shut down and Update SageMaker Studio (p. 292).

Use the following procedure to set up Okta. For all of the following procedures, you specify the same IAM role for IAM-role.

**Add the SageMaker Canvas application to Okta**

Set up the sign-on method for Okta.

1. Sign in to the Okta Admin dashboard.
2. Choose **Add application**. Search for **AWS Account Federation**.
3. Choose **Add**.
4. Optional: Change the name to **Amazon SageMaker Canvas**.
5. Choose **Next**.
6. Choose **SAML 2.0** as the **Sign-On** method.
7. Choose **Identity Provider Metadata** to open the metadata XML file. Save the file locally.
8. Choose **Done**.

**Set up ID federation in IAM**

AWS Identity and Access Management (IAM) is the AWS service that you use to gain access to your AWS account. You gain access to AWS through an IAM account.

1. Sign in to the AWS console.
2. Choose **AWS Identity and Access Management (IAM)**.
3. Choose **Identity Providers**.
4. Choose **Create Provider**.
5. For **Configure Provider**, specify the following:
   - **Provider Type** – From the dropdown list, choose **SAML**.
   - **Provider Name** – Specify **Okta**.
   - **Metadata Document** – Upload the XML document that you've saved locally from step 7 of Add the SageMaker Canvas application to Okta (p. 379).
6. Find your identity provider under **Identity Providers**. Copy its **Provider ARN** value.
7. For **Roles**, choose the IAM role that you're using for Okta SSO access.
8. Under **Trust Relationship** for the IAM role, choose **Edit Trust Relationship**.
9. Modify the IAM trust relationship policy by specifying the **Provider ARN** value that you've copied and add the following policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::123456789012:saml-provider/Okta"
      },
      "Action": [
        "sts:AssumeRoleWithSAML",
        "sts:SetSourceIdentity"
      ]
    }
  ]
}
```
For Permissions, add the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AmazonSageMakerPresignedUrlPolicy",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:CreatePresignedDomainUrlWithPrincipalTag"
      ],
      "Resource": "*"
    }
  ]
}
```

### Configure SageMaker Canvas in Okta

Configure Amazon SageMaker Canvas in Okta using the following procedure.

To configure Amazon SageMaker Canvas to use Okta, follow the steps in this section. You must specify unique user names for each `SageMakerStudioProfileName` field. For example, you can use `user.login` as a value. If the username is different from the SageMaker Canvas profile name, choose a different uniquely identifying attribute. For example, you can use an employee's ID number for the profile name.

For an example of values that you can set for Attributes, see the code following the procedure.

2. Add a group with the following pattern: `sagemaker#canvas#IAM-role#AWS-account-id`.
3. In Okta, open the AWS Account Federation application integration configuration.
4. Select Sign On for the AWS Account Federation application.
5. Choose Edit and specify the following:
   - SAML 2.0
6. Choose Attributes.
7. In the `SageMakerStudioProfileName` fields, specify unique values for each username. The usernames must match the usernames that you've created in the AWS console.

Attribute 1:
Name: https://aws.amazon.com/SAML/Attributes/PrincipalTag:SageMakerStudioUserProfileName
   Value: ${user.login}

Attribute 2:
Name: https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys
   Value: {"SageMakerStudioUserProfileName"}

8. Select Environment Type. Choose Regular AWS.
   • If your environment type isn't listed, you can set your ACS URL in the ACS URL field. If your
     environment type is listed, you don't need to enter your ACS URL.

9. For Identity Provider ARN, specify the ARN used in step 6 of the preceding procedure.

10. Specify a Session Duration.

11. Choose Join all roles.

12. Turn on Use Group Mapping by specifying the following fields:
   • App Filter – okta
   • Group Filter – ^aws\#\S+\$\((?IAM-role[\w-]+)\$\((?accountid)\d+)$

13. Choose Save/Next.

14. Under Assignments, assign the application to the group that you've created.

Add optional policies on access control in IAM

In IAM, you can apply the following policy to the administrator user who creates the user profiles.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "CreateSageMakerStudioUserProfilePolicy",
         "Effect": "Allow",
         "Action": "sagemaker:CreateUserProfile",
         "Resource": "*",
         "Condition": {
            "ForAnyValue:StringEquals": {
               "aws:TagKeys": [
                  "studiouserid"
               ]
            }
         }
      }
   ]
}
```

If you choose to add the preceding policy to the admin user, you must use the following permissions from Set up ID federation in IAM (p. 379).

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AmazonSageMakerPresignedUrlPolicy",
```
Configure your Amazon S3 storage

When you set up your SageMaker Canvas application, the default storage location for model artifacts, datasets, and other application data is an Amazon S3 bucket that Canvas creates. This default Amazon S3 bucket follows the naming pattern `s3://sagemaker-{Region}-{your-account-id}` and exists in the same Region as your Canvas application.

However, you can customize the storage location and specify your own Amazon S3 bucket for storing Canvas application data. You might want to use your own Amazon S3 bucket for storing application data for any of the following reasons:

- Your organization has internal naming conventions for Amazon S3 buckets.
- You want to enable cross-account access to model artifacts or other Canvas data.
- You want to be compliant with internal security guidelines, such as restricting users to specific Amazon S3 buckets or model artifacts.
- You want enhanced visibility and access to logs produced by Canvas, independent of the AWS console or SageMaker Studio.

By specifying your own Amazon S3 bucket, you can have increased control over your own storage and be compliant with your organization.

To get started, you can either create a new SageMaker Domain or user profile, or you can update an existing Domain or user profile. Note that the user profile settings override the Domain-level settings. For example, you can use the default bucket configuration at the Domain level, but you can specify a custom Amazon S3 bucket for an individual user. After specifying your own Amazon S3 bucket for the Domain or user profile, Canvas creates a subfolder called `Canvas/<UserProfileName>` under the input Amazon S3 URI and saves all artifacts generated in the Canvas application under this subfolder.

**Important**

If you update an existing Domain or user profile, you no longer have access to your Canvas artifacts from the previous location. Your files are still in the old Amazon S3 location, but you can no longer view them from Canvas. The new configuration takes effect the next time you log into the application.

For more information about granting cross-account access to your Amazon S3 bucket, see Granting cross-account object permissions in the Amazon S3 User Guide.

The following sections describe how to specify a custom Amazon S3 bucket for your Canvas storage configuration. If you're setting up a new SageMaker Domain (or a new user in a Domain), then use the New Domain setup method (p. 383) or the New user profile setup method (p. 383). If you have an existing Canvas user profile and would like to update the profile's storage configuration, use the Existing user method (p. 384).
Before you begin

If you're specifying an Amazon S3 URI from a different AWS account, or if you're using a bucket that is encrypted with AWS KMS, then you must configure permissions before proceeding. You must grant AWS IAM permissions to ensure that Canvas can download and upload objects to and from your bucket. For detailed information on how to grant the required permissions, see Grant permissions for cross-account Amazon S3 storage (p. 385).

Additionally, the final Amazon S3 URI for the training folder in your Canvas storage location must be 128 characters or less. The final Amazon S3 URI consists of your bucket path s3://<your-bucket-name>/<folder-name>/ plus the path that Canvas adds to your bucket: Canvas/<user-profile-name>/Training. For example, an acceptable path that is less than 128 characters is s3://<my-bucket>/<machine-learning>/Canvas/<user-1>/Training.

New Domain setup method

If you're setting up a new Domain and Canvas application, use this section to configure the storage location at the Domain level. This configuration applies to all new users you create in the Domain, unless you specify a different storage location for individual user profiles.

When doing a Standard setup for your Domain, use the following procedure for the Canvas settings section:

1. For the Canvas storage configuration, do the following:
   a. Select System managed if you want to set the location to the default SageMaker-created bucket that follows the pattern s3://sagemaker-{Region}-{your-account-id}.
   b. Select Custom S3 to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
   c. (Optional) For Encryption key, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
2. Finish setting up the Domain and choose Submit.

Your Domain is now configured to use the Amazon S3 location you specified for SageMaker Canvas application storage.

New user profile setup method

If you're setting up a new user profile in your Domain, use this section to configure the storage location for the user. This configuration overrides the Domain-level configuration.

When adding a user profile to your Domain, use the following procedure for the Canvas settings section:

1. For the Canvas storage configuration, do the following:
   a. Select System managed if you want to set the location to the default SageMaker created bucket that follows the pattern s3://sagemaker-{Region}-{your-account-id}.
   b. Select Custom S3 to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
   c. (Optional) For Encryption key, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
2. Finish setting up the user profile and choose Submit.

Your user profile is now configured to use the Amazon S3 location you specified for SageMaker Canvas application storage.
Existing user method

If you have an existing Canvas user profile and would like to update the Amazon S3 storage location, you can edit the SageMaker Domain or user profile settings. The change takes effect the next time you log into the Canvas application.

**Note**
When you change the storage location for an existing Canvas application, you lose access to your Canvas artifacts from the previous storage location. The artifacts are still stored in the old Amazon S3 location, but you can no longer view them from Canvas.

Remember that the user profile settings override the general Domain settings, so you can update the Amazon S3 storage location for specific user profiles without changing it for all of the users. You can update the storage configuration for an existing Domain or user by using the following procedures.

Update an existing Domain

Use the following procedure to update the storage configuration for a Domain.

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of **Domains**, choose your Domain.
5. On the **Domain settings** page, choose the **Domain settings** tab.
6. Choose **Edit**.
7. In the navigation pane, choose **Canvas settings**.
8. For the **Canvas storage configuration**, do the following:
   a. Select **System managed** if you want to set the location to the default SageMaker-created bucket that follows the pattern s3://sagemaker-{Region}-{your-account-id}.
   b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
   c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
9. Finish any other modifications you want to make to the Domain, and then choose **Submit** to save your changes.

Update an existing user profile

Use the following procedure to update the storage configuration for a user profile.

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of **Domains**, choose your Domain.
5. From the list of users in the Domain, choose the user whose configuration you want to edit.
6. On the **User Details** page, choose **Edit**.
7. In the navigation pane, choose **Canvas settings**.
8. For the **Canvas storage configuration**, do the following:
   a. Select **System managed** if you want to set the location to the default SageMaker-created bucket that follows the pattern s3://sagemaker-{Region}-{your-account-id}. 

384
b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.

c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.

9. Finish any other modifications you want to make to the user profile, and then choose **Submit** to save your changes.

The storage location for your Canvas user profile should now be updated. The next time you log into the Canvas application, you receive a notification that the storage location has been updated. You lose access to any previous artifacts that you created in Canvas. You can still access the files in Amazon S3, but you can no longer view them in Canvas.

**Grant permissions for cross-account Amazon S3 storage**

When setting up your SageMaker Domain or user profile for users to access SageMaker Canvas, you specify an Amazon S3 storage location for Canvas artifacts. These artifacts include saved copies of your input datasets, model artifacts, predictions, and other application data. You can either use the default SageMaker created Amazon S3 bucket, or you can customize the storage location and specify your own bucket for storing Canvas application data.

You can specify an Amazon S3 bucket in another AWS account for storing your Canvas data, but first you must grant cross-account permissions so that Canvas can access the bucket.

The following sections describe how to grant permissions to Canvas for uploading and downloading objects to and from an Amazon S3 bucket in another account. There are additional permissions for when your bucket is encrypted with AWS KMS.

**Requirements**

Before you begin, review the following requirements:

- Cross-account Amazon S3 buckets (and any associated AWS KMS keys) must be in the same AWS Region as the Canvas user Domain or user profile.
- The final Amazon S3 URI for the training folder in your Canvas storage location must be 128 characters or less. The final S3 URI consists of your bucket path `s3://<your-bucket-name>/<folder-name>/` plus the path that Canvas adds to your bucket: `Canvas/<user-profile-name>/Training`. For example, an acceptable path that is less than 128 characters is `s3://<my-bucket>/<machine-learning>/Canvas/<user-1>/Training`.

**Permissions for cross-account Amazon S3 buckets**

The following section outlines the basic steps for granting the necessary permissions so that Canvas can access your Amazon S3 bucket in another account. For more detailed instructions, see Example 2: Bucket owner granting cross-account bucket permissions in the Amazon S3 User Guide.

1. Create an Amazon S3 bucket, `bucketA`, in Account A.
2. The Canvas user exists in another account called Account B. In the following steps, we refer to the Canvas user's IAM role as `roleB` in Account B.

   Give the IAM role `roleB` in Account B permission to download (GetObject) and upload (PutObject) objects to and from `bucketA` in Account A by attaching an IAM policy.

   To limit access to a specific bucket folder, define the folder name in the resource element, such as `arn:aws:s3:::<bucketA>/FolderName/*`. For more information, see How can I use IAM policies to grant user-specific access to specific folders?
Bucket-level actions, such as GetBucketCors and GetBucketLocation, should be added on bucket-level resources, not folders.

The following example IAM policy grants the required permissions for roleB to access objects in bucketA:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject"
            ],
            "Resource": [
                "arn:aws:s3:::bucketA/FolderName/*",
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketCors",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::bucketA",
            ]
        }
    ]
}
```

3. Configure the bucket policy for bucketA in Account A to grant permissions to the IAM role roleB in Account B.

**Note**
Admins must also turn off Block all public access under the bucket Permissions section.

The following is an example bucket policy for bucketA to grant the necessary permissions to roleB:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::accountB:role/roleB"
            },
            "Action": [
                "s3:DeleteObject",
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::bucketA/FolderName/*"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::accountB:role/roleB"
            },
            "Action": [
                "s3:DeleteObject",
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::bucketA/FolderName/*"
        }
    ]
}
```
After configuring the preceding permissions, your Canvas user profile in Account B can now use the Amazon S3 bucket in Account A as the storage location for Canvas artifacts.

Permissions for cross-account Amazon S3 buckets encrypted with AWS KMS

The following procedure shows you how to grant the necessary permissions so that Canvas can access your Amazon S3 bucket in another account that is encrypted with AWS KMS. The steps are similar to the procedure above, but with additional permissions. For more information about granting cross-account KMS key access, see Allowing users in other accounts to use a KMS key in the AWS KMS Developer Guide.

1. Create an Amazon S3 bucket bucketA and an Amazon S3 KMS key s3KmsInAccountA in Account A.
2. The Canvas user exists in another account called Account B. In the following steps, we refer to the Canvas user's IAM role as roleB in Account B.

   Give the IAM role roleB in Account B permission to do the following:
   - Download (GetObject) and upload (PutObject) objects to and from bucketA in Account A.
   - Access the AWS KMS key s3KmsInAccountA in Account A.

The following example IAM policy grants the required permissions for roleB to access objects in bucketA and use the KMS key s3KmsInAccountA:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject"
            ],
            "Resource": [
                "arn:aws:s3:::bucketA/FolderName/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketCors",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::bucketA"
            ]
        },
        {
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketCors",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucketA"
        }
    ]
}
```
3. Configure the bucket policy for bucketA and the key policy for s3KmsInAccountA in Account A to grant permissions to the IAM role roleB in Account B.

The following is an example bucket policy for bucketA to grant the necessary permissions to roleB:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::accountB:role/roleB"
            },
            "Action": [
                "s3:DeleteObject",
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::bucketA/FolderName/*"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::accountB:role/roleB"
            },
            "Action": [
                "s3:GetBucketCors",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucketA"
        }
    ]
}
```

The following example is a key policy that you attach to the KMS key s3KmsInAccountA in Account A to grant roleB access. For more information about how to create and attach a key policy statement, see Creating a key policy in the AWS KMS Developer Guide.

```json
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::accountB:role/roleB"
        ]
    },
    "Action": [
        "kms:DescribeKey",
        "kms:CreateGrant",
        "kms:RetireGrant",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyWithoutPlainText",
        "kms:Decrypt"
    ],
    "Effect": "Allow",
    "Resource": "arn:aws:kms:{region}:accountA:key/s3KmsInAccountA"
}
```
After configuring the preceding permissions, your Canvas user profile in Account B should now be able to use an encrypted Amazon S3 bucket in Account A as the storage location for Canvas artifacts.

Encrypt Your SageMaker Canvas Data with AWS KMS

You might have data that you want to encrypt while using Amazon SageMaker Canvas, such as your private company information or customer data. SageMaker Canvas uses AWS Key Management Service to protect your data. AWS KMS is a service that you can use to create and manage cryptographic keys for encrypting your data. For more information about AWS KMS, see AWS Key Management Service in the AWS KMS Developer Guide.

Amazon SageMaker Canvas provides you with several options for encrypting your data. SageMaker Canvas provides default encryption within the application for tasks such as building your model and generating insights. You can also choose to encrypt data stored in Amazon S3 to protect your data at rest. SageMaker Canvas supports importing encrypted datasets, so you can establish an encrypted workflow. The following sections describe how you can use AWS KMS encryption to protect your data while building models with SageMaker Canvas.

Encrypt your data in SageMaker Canvas

With SageMaker Canvas, you can use two different AWS KMS encryption keys to encrypt your data in SageMaker Canvas, which you can specify when setting up your Domain. These two keys can be the same or different. SageMaker Canvas uses one key for temporary application storage, visualizations, or compute purposes (such as building models). You can use either the default AWS managed key or specify your own. You can also specify an optional key that SageMaker Canvas uses for long-term storage of model objects and datasets, which are stored in the Region's default SageMaker S3 bucket for your account.

Prerequisites

To use your own KMS key for either of the previously described purposes, you must first grant your user's IAM role permission to use the key. Then, you can specify the KMS key when setting up your Domain.

The simplest way to grant your role permission to use the key is to modify the key policy. Use the following procedure to grant your role the necessary permissions.

1. Open the AWS KMS console.
2. In the Key Policy section, choose Switch to policy view.
3. Modify the key's policy to grant permissions for the kms:GenerateDataKey and kms:Decrypt actions to the IAM role. You can add a statement that's similar to the following:

```json
{
    "Sid": "ExampleStmt",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Effect": "Allow",
    "Principal": {
        "AWS": "<arn:aws:iam::<account_id>:role/Jane>"
    }
}
```
4. Choose **Save changes**.

The less preferred method is to modify the user's IAM role to grant the user permissions to use or manage the KMS key. If you use this method, the KMS key policy must also allow access management through IAM. To learn how to grant permission to a KMS key through the user's IAM role, see *Specifying KMS keys in IAM policy statements* in the *AWS KMS Developer Guide*.

**Prerequisites for time series forecasting**

To use your AWS KMS key to encrypt time series forecasting models in SageMaker Canvas, you must modify the key policy for the KMS key used to store objects to Amazon S3. Your key policy must grant permissions to the **AmazonSagemakerCanvasForecastRole**, which SageMaker creates when you **grant time series forecasting permissions for your users**. Amazon Forecast uses the **AmazonSagemakerCanvasForecastRole** to perform time series forecasting operations in SageMaker Canvas. Your KMS key must grant permissions to this role in order to ensure data is encrypted for time series forecasting.

To modify the permissions of your KMS key policy to allow encrypted time series forecasting, do the following.

1. Open the *AWS KMS console*.
2. In the **Key Policy** section, choose **Switch to policy view**.
3. Modify the key's policy to have the permissions specified in the following example:

   ```json
   {  
     "Sid": "Enable IAM Permissions for Amazon Forecast KMS access",
     "Effect": "Allow",
     "Principal": {  
       "AWS": "<arn:aws:iam::111122223333:role/service-role/AmazonSagemakerCanvasForecastRole-111122223333>"
     },
     "Action": [  
       "kms:DescribeKey",
       "kms:CreateGrant",
       "kms:RetireGrant",
       "kms:GenerateDataKey",
       "kms:GenerateDataKeyWithoutPlainText",
       "kms:Decrypt"
     ],
     "Resource": "*"
   }
   
   4. Choose **Save changes**.

You can now use your KMS key to encrypt time series forecasting operations in SageMaker Canvas.

**Note**

The following permissions are only required if you are using the **IAM role setup method** to configure time series forecasting. Add the following permissions policy to your user's IAM role. You must also update the key policy with updated policies required for Amazon Forecast. For more information about the permissions required for time series forecasting, see *Grant Your Users Permissions to Perform Time Series Forecasting (p. 393)*.

```json
{  
  "Sid": "Enable IAM Permissions for Amazon Forecast KMS access",
  "Effect": "Allow",
  "Principal": {
```
Encrypt your data in the SageMaker Canvas application

The first KMS key you can use in SageMaker Canvas is used for encrypting application data stored on Amazon Elastic Block Store (Amazon EBS) volumes and in the Amazon Elastic File System that SageMaker creates in your Domain. SageMaker Canvas encrypts your data with this key in the underlying application and temporary storage systems created when using compute instances for building models and generating insights. SageMaker Canvas passes the key to other AWS services, such as Autopilot, whenever SageMaker Canvas initiates jobs with them to process your data.

You can specify this key by setting the `KmsKeyID` in the `CreateDomain` API call or while doing the Standard Domain setup in the console. If you don't specify your own KMS key, SageMaker uses a default AWS managed KMS key to encrypt your data in the SageMaker Canvas application.

To specify your own KMS key for use in the SageMaker Canvas application through the console, first set up your Amazon SageMaker Domain using the Standard setup. Use the following procedure to complete the Network and Storage Section for the Domain.

1. Fill out your desired Amazon VPC settings.
2. For Encryption key, choose Enter a KMS key ARN.
3. For KMS ARN, enter the ARN for your KMS key, which should have a format similar to the following:
   arn:aws:kms:example-region-1:123456789098:key/111aa2bb-333c-4d44-5555-a111bb2c33dd

Encrypt your SageMaker Canvas data saved in Amazon S3

The second KMS key you can specify is used for data that SageMaker Canvas stores to Amazon S3. SageMaker Canvas saves duplicates of your input datasets, application and model data, and output data to the Region's default SageMaker S3 bucket for your account. The naming pattern for this bucket is s3://sagemaker-{Region}-{your-account-id}, and SageMaker Canvas stores data in the Canvas/ folder.

1. Turn on Enable notebook resource sharing.
2. For S3 location for shareable notebook resources, leave the default Amazon S3 path. Note that SageMaker Canvas does not use this Amazon S3 path; this Amazon S3 path is used for Studio notebooks.
3. For Encryption key, choose Enter a KMS key ARN.
4. For KMS ARN, enter the ARN for your KMS key, which should have a format similar to the following:
   arn:aws:kms:us-east-1:111122223333:key/111aa2bb-333c-4d44-5555-a111bb2c33dd

Import encrypted datasets from Amazon S3

Your users might have datasets that have been encrypted with a KMS key. While the preceding section shows you how to encrypt data in SageMaker Canvas and data stored to Amazon S3, you must grant
your user's IAM role additional permissions if you want to import data from Amazon S3 that is already encrypted with AWS KMS.

To grant your user permissions to import encrypted datasets from Amazon S3 into SageMaker Canvas, add the following permissions to the IAM execution role that you've used for the user profile:

"kms:Decrypt",
"kms:GenerateDataKey"

To learn how to edit the IAM permissions for a role, see Adding and removing IAM identity permissions in the IAM User Guide. For more information about KMS keys, see Key policies in AWS Key Management Service in the AWS KMS Developer Guide.

FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Canvas AWS KMS support.

Q: Does SageMaker Canvas retain my KMS key?

A: No. SageMaker Canvas may temporarily cache your key or pass it on to other AWS services (such as Autopilot), but SageMaker Canvas does not retain your KMS key.

Q: I specified a KMS key when setting up my Domain. Why did my dataset fail to import in SageMaker Canvas?

A: Your user's IAM role may not have permissions to use that KMS key. To grant your user permissions, see the Prerequisites (p. 389). Another possible error is that you have a bucket policy on your Amazon S3 bucket that requires the use of a specific KMS key that doesn't match the KMS key you specified in your Domain. Make sure that you specify the same KMS key for your Amazon S3 bucket and your Domain.

Q: How do I find the Region's default SageMaker Amazon S3 bucket for my account?

A: The default Amazon S3 bucket follows the naming pattern s3://sagemaker-{Region}-{your-account-id}. The Canvas/ folder in this bucket stores your SageMaker Canvas application data.

Q: Can I change the default SageMaker Amazon S3 bucket used to store SageMaker Canvas data?

A: No, SageMaker creates this bucket for you.

Q: What does SageMaker Canvas store in the default SageMaker Amazon S3 bucket?

A: SageMaker Canvas uses the default SageMaker Amazon S3 bucket to store duplicates of your input datasets, model artifacts, and model outputs.

Q: What use cases are supported for using KMS keys with SageMaker Canvas?

A: With SageMaker Canvas, you can use your own encryption keys with AWS KMS for building regression, binary and multi-class classification, and time series forecasting models, as well as for batch inference with your model.

Q: Can I encrypt time series forecasting models in SageMaker Canvas?

A: Yes. You must give your KMS key additional permissions in order to perform encrypted time series forecasting. For more information about how to modify your key's policy in order to grant time series forecasting permissions, see Prerequisites for time series forecasting (p. 390).
Grant Your Users Permissions to Build Custom Image and Text Prediction Models

In Amazon SageMaker Canvas, you can build custom models to meet your specific business need. Two of these custom model types are single-label image prediction and multi-category text prediction. The permissions to build these model types are included in the AWS Identity and Access Management (IAM) policy called AmazonSageMakerCanvasFullAccess, which SageMaker attaches by default to your user's IAM execution role if you leave the Canvas base permissions turned on.

However, if you are using a custom IAM configuration, then you must explicitly add permissions to your user's IAM execution role so that they can build custom image and text prediction model types. To grant the necessary permissions to build image and text prediction models, read the following section to learn how to attach a least-permissions policy to your role.

To add the permissions to the user's IAM role, do the following:

1. Go to the IAM console.
2. Choose Roles.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under Permissions, choose Add permissions.
5. Choose Create inline policy.
6. Select the JSON tab, and then paste the following least-permissions policy into the editor.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateAutoMLJobV2",
                "sagemaker:DescribeAutoMLJobV2"
            ],
            "Resource": "*
        }
    ]
}
```

7. Choose Review policy.
8. Enter a Name for the policy.
9. Choose Create policy.

For more information about AWS managed policies, see Managed policies and inline policies in the IAM User Guide.

Grant Your Users Permissions to Perform Time Series Forecasting

In order to perform time series forecasts in Amazon SageMaker Canvas, your users must have the necessary permissions. The preferred method to give your users these permissions is to turn on the time series forecasting option when setting up the Amazon SageMaker Domain, or when editing the settings for a specific user profile. You can also use the manual method of attaching a policy and trust relationship for Amazon Forecast to the AWS Identity and Access Management (IAM) role.

If you want to encrypt your time series forecasts with your own key, you must use an AWS KMS key and modify your KMS key's policy to grant permissions to the role used by Amazon Forecast. For more
information about setting up your KMS key and modifying the policy for time series forecasting, see
Prerequisites for time series forecasting (p. 390).

Domain setup method

SageMaker provides you with the option to grant time series forecasting permissions to users through
the Domain settings. You can toggle the permissions for all of the users in your Domain, and SageMaker
manages attaching the required IAM policy and trust relationship for you.

If you are setting up your Amazon SageMaker Domain for the first time and want to turn on time series
forecasting permissions for all users in the Domain, then use the following procedures.

Quick setup

Use the following procedure to turn on SageMaker Canvas time series forecasting permissions when
doing a Quick setup for your Domain.

1. In the Amazon SageMaker Domain Quick setup, fill out the Name and Default execution role
   fields in the User profile section.
2. Leave the Enable SageMaker Canvas permissions option turned on. It is turned on by default.
3. Choose Submit to finish setting up your Domain.

Standard setup

Use the following procedure to turn on SageMaker Canvas time series forecasting permissions when
doing a Standard setup for your Domain.

1. In the Amazon SageMaker Domain Standard setup, fill out the General settings, Studio
   settings, and RStudio settings pages.
2. Choose the Canvas settings page.
3. For the Canvas base permissions configuration, leave the Enable Canvas base permissions
   option turned on. It is turned on by default. These permissions are required in order to turn on
time series forecasting permissions.
4. For the Time series forecasting configuration, leave the Enable time series forecasting
   option turned on. It is turned on by default.
5. Select Create and use a new execution role, or select Use an existing execution role if you
   already have an IAM role with the required Amazon Forecast permissions attached. For more
   information, see the IAM role setup method (p. 396).
6. Finish making any other changes to your Domain setup, and then choose Submit.

Your users should now have the necessary permissions to perform time series forecasting in SageMaker
Canvas.

User setup method

You can configure time series forecasting permissions for individual users in an existing Domain. The
user profile settings override the general Domain settings, so you can grant permissions to specific users
without giving permissions to all of your users. To grant time series forecasting permissions to a specific
user that doesn’t already have permissions, use the following procedure.

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. On the Domains page, choose your Domain.
5. In the **User profiles** tab, select the name of the user whose permissions you want to edit.
6. On the **User Details** page, choose **Edit**.
7. Choose the **Canvas settings** page.
8. Turn on **Enable Canvas base permissions**. These permissions are required in order to turn on time series forecasting permissions.
9. Turn on the **Enable time series forecasting** option.
10. If you want to use a different execution role for the user than the role specified in the Domain, select **Create and use a new execution role**, or **Use an existing execution role** if you already have an IAM role ready to use.

**Note**

If you want to use an existing IAM role, make sure that it has the IAM policy `AmazonSageMakerCanvasForecastAccess` attached and has a trust relationship that establishes Amazon Forecast as a service principal. For more information, see the section **IAM role setup method (p. 396)**.

11. The **Canvas settings** page should look like the following screenshot. Finish making any other changes to your user profile, and then choose **Submit** to save your changes.

Your user should now have permission to do time series forecasting in SageMaker Canvas.
You can also remove your user’s permissions by using the preceding procedure and turning off the **Enable time series forecasting** option.

**IAM role setup method**

You can manually grant your users permissions to perform time series forecasting in Amazon SageMaker Canvas by adding additional permissions to the AWS Identity and Access Management (IAM) role specified for the user’s profile. The IAM role must have a trust relationship with Amazon Forecast and an attached policy that gives permissions to Forecast.

The following section shows you how to create the trust relationship and attach the **AmazonSageMakerCanvasForecastAccess** managed policy to your IAM role, which grants the minimum permissions necessary for time series forecasting to work in SageMaker Canvas.

**Note**

The **AmazonSageMakerCanvasForecastAccess** policy grants permissions to access the SageMaker-created Amazon S3 bucket, which is the default storage location for Canvas application data. If you’ve specified a custom Amazon S3 storage location for Canvas application data, you must update the permissions in the policy to your own Amazon S3 bucket. For more information about custom Amazon S3 storage locations for Canvas, see **Configure your Amazon S3 storage** (p. 382).

To configure an IAM role with the manual method, use the following procedure.

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. On the **Domains** page, choose your Domain.
5. From the list of **User profiles**, select the profile of the user you want to grant time series forecasting permissions.
6. Under **Details**, copy or make a note of the name of the user’s **Execution role**. The name of the IAM role should be similar to the following: 111122223333.
7. Once you have the name of the user’s IAM role, go to the **IAM console**.
8. Choose **Roles**.
9. Search for the user’s IAM role by name from the list of roles and select it.
10. Under **Permissions**, choose **Add permissions**.
11. Choose **Attach policies**.

   After attaching the policy, the role's **Permissions** section should now include AmazonSageMakerCanvasForecastAccess.

13. Return to the IAM role's page, and under **Trust relationships**, choose **Edit trust policy**.

14. In the **Edit trust policy** editor, update the trust policy to add Forecast as a service principal. The policy should look like the following example.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Service": [
   "sagemaker.amazonaws.com",
   "forecast.amazonaws.com"
   ],
   "Action": "sts:AssumeRole"
   }]
   }
   }
   ```

15. After editing the trust policy, choose **Update policy**.

You should now have an IAM role that has the policy [AmazonSageMakerCanvasForecastAccess](https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_service.html) attached to it and a trust relationship established with Amazon Forecast, giving users permission to perform time series forecasting in SageMaker Canvas. For information about AWS managed policies, see [Managed policies and inline policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html).

**Note**

If you use this method to set up time series forecasting and want to use AWS KMS encryption for your forecasts, then you must configure your KMS key's policy to grant additional permissions. For more information, see [Prerequisites for time series forecasting](https://docs.aws.amazon.com/forecast/latest/dg/00 entrenamiento dir hdpt .390).

### Update SageMaker Canvas for Your Users

You can update to the latest version of Amazon SageMaker Canvas as either a user or an IT administrator. You can update Amazon SageMaker Canvas for a single user at a time.

To update the Amazon SageMaker Canvas application, you must delete the previous version.

**Important**

Deleting the previous version of Amazon SageMaker Canvas doesn't delete the data or models that the users have created.

Use the following procedure to log in to AWS, open Amazon SageMaker Domain, and update Amazon SageMaker Canvas. The users can start using the SageMaker Canvas application when they log back in.

1. Sign in to the Amazon SageMaker console at [Amazon SageMaker Runtime](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-canvas.html).

2. On the left navigation pane, choose **Admin configurations**.

3. Under **Admin configurations**, choose **Domains**.

4. On the **Domains** page, choose your Domain.

5. From the list of **User profiles**, choose a user profile.
6. For the list of Apps, find the Canvas application (the App type says Canvas) and choose Delete app.
7. Complete the dialog box and choose Confirm action.

The following image shows the user profile page and highlights the Delete app action from the preceding procedure.

Request a Quota Increase

Your users might use AWS resources in amounts that exceed those specified by their quotas. If your users are resource constrained, you can request a quota increase for them.

Amazon SageMaker Canvas uses the following services to process the requests of your users:

- Amazon SageMaker Autopilot
- Amazon SageMaker Studio Domain
- Amazon Forecast

For information about increasing quotas for SageMaker Canvas operations that aren’t used to forecast time series data, see Amazon SageMaker endpoints and quotas.

For information about increasing quotas for SageMaker Canvas operations that are used to forecast time series data, see Amazon Forecast endpoints and quotas.

Request an increase for instances to build custom models

When building a custom model, if you encounter an error during post-building analysis that tells you to increase your quota for ml.m5.2xlarge instances, use the following information to resolve the issue.

To allow SageMaker Canvas to complete post-building analysis of models, you must increase the SageMaker Hosting endpoint quota for the ml.m5.2xlarge instance type to a non-zero value in your AWS account. After building a model, SageMaker Canvas hosts the model on a SageMaker Hosting endpoint and uses the endpoint to generate the post-building analysis. If you don’t increase the default account quota of 0 for ml.m5.2xlarge instances, SageMaker Canvas cannot complete this step and generates an error during post-building analysis.

Use the following procedure to request a quota increase for your account.

1. Open the AWS Support Center console.
2. On the AWS Support Center page, choose Create Case and then choose Service limit increase.
3. In the Case classification panel under Limit type, search for SageMaker.
4. In the Request panel, choose the Region that you are working in. For Resource Type, choose SageMaker Hosting.
5. For Limit, choose ml.m5.2xlarge instances.
6. For New Limit Value, verify that the value is at least 1.
7. In Case description, provide a brief explanation of why you need the Service limit increase. For example, "SageMaker Canvas uses this instance type for model analysis."
8. In Contact options, provide some details about how you would like to be contacted by the AWS service support team on the status of your Service limit increase request.
9. Choose Submit.

Grant Users Permissions to Import Amazon Redshift Data

Your users might have datasets stored in Amazon Redshift. Before users can import data from Amazon Redshift into SageMaker Canvas, you must add the AmazonRedshiftFullAccess managed policy to the IAM execution role that you've used for the user profile and add Amazon Redshift as a service principal to the role's trust policy. You must also associate the IAM execution role with your Amazon Redshift cluster. Complete the procedures in the following sections to give your users the required permissions to import Amazon Redshift data.

Add Amazon Redshift permissions to your IAM role

You must grant Amazon Redshift permissions to the IAM role specified in your user profile.

To add the AmazonRedshiftFullAccess policy to the user's IAM role, do the following.

2. Choose Roles.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under Permissions, choose Add permissions.
5. Choose Attach policies.
6. Search for the AmazonRedshiftFullAccess managed policy and select it.
7. Choose Attach policies to attach the policy to the role.

After attaching the policy, the role's Permissions section should now include AmazonRedshiftFullAccess.

To add Amazon Redshift as a service principal to the IAM role, do the following.

1. On the same page for the IAM role, under Trust relationships, choose Edit trust policy.
2. In the Edit trust policy editor, update the trust policy to add Amazon Redshift as a service principal. An IAM role that allows Amazon Redshift to access other AWS services on your behalf has a trust relationship as follows:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "redshift.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```
3. After editing the trust policy, choose **Update policy**.

You should now have an IAM role that has the policy `AmazonRedshiftFullAccess` attached to it and a trust relationship established with Amazon Redshift, giving users permission to import Amazon Redshift data into SageMaker Canvas. For more information about AWS managed policies, see [Managed policies and inline policies](https://docs.aws.amazon.com/iam/latest/userguide/data-share.html) in the **IAM User Guide**.

**Associate the IAM role with your Amazon Redshift cluster**

In the settings for your Amazon Redshift cluster, you must associate the IAM role that you granted permissions to in the preceding section.

To associate an IAM role with your cluster, do the following.

2. On the navigation menu, choose **Clusters**, and then choose the name of the cluster that you want to update.
3. In the **Actions** dropdown menu, choose **Manage IAM roles**. The **Cluster permissions** page appears.
4. For **Available IAM roles**, enter either the ARN or the name of the IAM role, or choose the IAM role from the list.
5. Choose **Associate IAM role** to add it to the list of **Associated IAM roles**.
6. Choose **Save changes** to associate the IAM role with the cluster.

Amazon Redshift modifies the cluster to complete the change, and the IAM role to which you previously granted Amazon Redshift permissions is now associated with your Amazon Redshift cluster. Your users now have the required permissions to import Amazon Redshift data into SageMaker Canvas.

**Grant Users Permissions to Collaborate with Studio**

Your Amazon SageMaker Canvas users might want to share their models with users in Amazon SageMaker Studio to receive feedback and model updates, and Studio users might want to share models with Canvas users so that they can generate predictions in Canvas. The following permissions grant Canvas users and Studio users access to share models with each other.

For more information about how Canvas users can share models with Studio users, see [Collaborate with data scientists (p. 524)](https://docs.aws.amazon.com/sagemaker/latest/dg/external-data-access.html). For more information about how Canvas users can bring a model shared from Studio, see [Bring your own model to SageMaker Canvas (p. 531)](https://docs.aws.amazon.com/sagemaker/latest/dg/bring-your-own-model.html).

Before Canvas and Studio users can collaborate, the users must be in the same Amazon SageMaker Domain. Add the following IAM permissions added to the same IAM execution role that you've used for their profiles.

To add the permissions to the users' IAM role, do the following:

1. Go to the **IAM console**.
2. Choose **Roles**.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under **Permissions**, choose **Add permissions**.
5. Choose **Create inline policy**.
6. In the **Policy editor**, choose **JSON** and enter the following IAM policy:

```json
{

```
7. Choose Next.
8. Enter a name for the policy in the Policy name field.
9. Choose Create policy to create the policy and attach it to the role.

For more information about AWS managed policies, see Managed policies and inline policies in the IAM User Guide.

Grant Your Users Permissions to Send Predictions to Amazon QuickSight

You must grant your SageMaker Canvas users permissions to send batch predictions to Amazon QuickSight. In Amazon QuickSight, users can create analyses and reports with a dataset and prepare dashboards to share their results. For more information about sending prediction to QuickSight for analysis, see Send predictions to Amazon QuickSight (p. 503).

To grant the necessary permissions to share batch predictions with users in QuickSight, you must add a permissions policy to the AWS Identity and Access Management (IAM) execution role that you've used for the user profile. The following section shows you how to attach a least-permissions policy to your role.

Add the permissions policy to your IAM role

To add the permissions policy, use the following procedure:

2. Choose Roles.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under Permissions, choose Add permissions.
5. Choose Create inline policy.
6. Select the JSON tab, and then paste the following least-permissions policy into the editor. Replace the placeholders <your-account-number> with your own AWS account number.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateSharedModel",
            "sagemaker:DescribeSharedModel",
            "sagemaker:ListSharedModelEvents",
            "sagemaker:ListSharedModels",
            "sagemaker:ListSharedModelVersions",
            "sagemaker:SendSharedModelEvent",
            "sagemaker:UpdateSharedModel"
         ],
         "Resource": "*"
      }
   ]
}
```

401
Amazon SageMaker Developer Guide
Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators)

```
"quicksight:CreateDataSource",
"quicksight:PassDataSet",
"quicksight:PassDataSource"
],
"Resource": [
  "arn:aws:quicksight:*:<your-account-number>:datasource/**",
  "arn:aws:quicksight:*:<your-account-number>:user/**",
  "arn:aws:quicksight:*:<your-account-number>:namespace/**",
  "arn:aws:quicksight:*:<your-account-number>:dataset/**"
]
```

7. Choose **Review policy**.
8. Enter a **Name** for the policy.
9. Choose **Create policy**.

You should now have a customer-managed IAM policy attached to your execution role that grants your Canvas users the necessary permissions to send batch predictions to users in QuickSight.

**Manage apps**

The following sections describe how you can manage your SageMaker Canvas applications. You can view, delete, or relaunch your apps from the **Domains** section of the SageMaker console.

**Check for active apps**

To check if you have any actively running SageMaker Canvas apps, use the following procedure.

1. Open the **SageMaker console**.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. On the **Domains** page, choose your Domain.
5. On the **Domain details** page, under **User profiles**, select the user profile name for the Canvas application that you want to view.
6. Under **Apps**, find the app that says **Canvas** in the **App type** column.

The **Status** column displays the status of the app, such as **Ready**, **Pending**, or **Deleted**. If the app is **Ready**, then your SageMaker Canvas workspace instance is active. You can delete the app from the console or log out from the SageMaker Canvas interface.

**Delete app**

If you want to end your SageMaker Canvas workspace instance, you can either log out from the SageMaker Canvas application or delete your application from the SageMaker console. A **workspace instance** is dedicated for your use from when you start using SageMaker Canvas to the point when you stop using it. Deleting the application only ends the workspace instance. Models and datasets aren't affected, but Quick build tasks automatically restart when you log in again. The billing for the workspace instance also stops.

To delete your Canvas app through the AWS console, first close the browser tab in which your Canvas app was open. Then, use the following procedure to delete your SageMaker Canvas application.

1. Open the **SageMaker console**.
2. On the left navigation pane, choose **Admin configurations**.

402
3. Under Admin configurations, choose Domains.
4. On the Domains page, choose your Domain.
5. On the Domain details page, under User profiles, select the user profile name for the Canvas application you want to view.
6. Under Apps, find the application that says Canvas in the App type column.
7. In the Action column, choose Delete app.
8. In the Delete app dialog box, select the Yes, delete app prompt, confirm the deletion by typing delete in the text field, and then choose Delete.

After you've successfully deleted the application, the Status column says Deleted. Otherwise, your application is still active.

You can also end the workspace instance by logging out (p. 539) from within the SageMaker Canvas application.

Relaunch app

If you delete or log out of your SageMaker Canvas application and want to relaunch the application, use the following procedure.

1. Navigate to the SageMaker console.
2. In the navigation pane, choose Canvas.
3. On the SageMaker Canvas landing page, in the Get Started box, select your user profile from the dropdown.
4. Choose Open Canvas to open the application.

SageMaker Canvas begins launching the app.

You can also use the following secondary procedure if you encounter any issues with the previous procedure.

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. On the Domains page, choose your Domain.
5. On the Domain details page, under User profiles, select the user profile name for the SageMaker Canvas application you want to view.
6. Choose Launch and select Canvas from the dropdown list.

SageMaker Canvas begins launching the app.

Configure Amazon SageMaker Canvas in a VPC without internet access

The Amazon SageMaker Canvas application runs in a container in an AWS managed Amazon Virtual Private Cloud (VPC). If you want to further control access to your resources or run SageMaker Canvas without public internet access, you can configure your Amazon SageMaker Domain and VPC settings. Within your own VPC, you can configure settings such as security groups (virtual firewalls that control inbound and outbound traffic from Amazon EC2 instances) and subnets (ranges of IP addresses in your VPC). To learn more about VPCs, see How Amazon VPC works.

When the SageMaker Canvas application is running in the AWS managed VPC, it can interact with other AWS services using either an internet connection or through VPC endpoints created in a customer-
managed VPC (without public internet access). SageMaker Canvas applications can access these VPC endpoints through a Studio-created network interface that provides connectivity to the customer-managed VPC. The default behavior of the SageMaker Canvas application is to have internet access. When using an internet connection, the containers for the preceding jobs access AWS resources over the internet, such as the Amazon S3 buckets where you store training data and model artifacts.

However, if you have security requirements to control access to your data and job containers, we recommend that you configure SageMaker Canvas and your VPC so that your data and containers aren't accessible over the internet. SageMaker uses the VPC configuration settings you specify when setting up your Domain for SageMaker Canvas.

If you want to configure your SageMaker Canvas application without internet access, you must configure your VPC settings when you onboard to Amazon SageMaker Domain (p. 10), set up VPC endpoints, and grant the necessary AWS Identity and Access Management permissions. For information about configuring a VPC in Amazon SageMaker, see Choose an Amazon VPC (p. 42). The following sections describe how to run SageMaker Canvas in a VPC without public internet access.

**Configure Amazon SageMaker Canvas in a VPC without internet access**

You can send traffic from SageMaker Canvas to other AWS services through your own VPC. If your own VPC doesn't have public internet access and you've set up your Domain in VPC only mode, then SageMaker Canvas won't have public internet access as well. This includes all requests, such as accessing datasets in Amazon S3 or training jobs for standard builds, and the requests go through VPC endpoints in your VPC instead of the public internet. When you onboard to Domain and Choose an Amazon VPC (p. 42), you can specify your own VPC as the default VPC for the Domain, along with your desired security group and subnet settings. Then, SageMaker creates a network interface in your VPC that SageMaker Canvas uses to access VPC endpoints in your VPC. Note that the security group and subnet settings are set after you finish onboarding to Domain.

When onboarding to Domain, if you choose Public internet only as the network access type, the VPC is SageMaker managed and allows internet access.

You can change this behavior by choosing VPC only so that SageMaker sends all traffic to a network interface that SageMaker creates in your specified VPC. When you choose this option, you must provide the subnets, security groups, and VPC endpoints that are necessary to communicate with the SageMaker API and SageMaker Runtime, and various AWS services, such as Amazon S3 and Amazon CloudWatch, that are used by SageMaker Canvas. Note that you can only import data from Amazon S3 buckets located in the same Region as your VPC.

The following procedures show how you can configure these settings to use SageMaker Canvas without the internet.

**Step 1: Onboard to Amazon SageMaker Domain**

To send SageMaker Canvas traffic to a network interface in your own VPC instead of over the internet, specify the VPC you want to use when onboarding to Amazon SageMaker Domain (p. 10). You must also specify at least two subnets in your VPC that SageMaker can use. Choose Standard setup and do the following procedure when configuring the Network and Storage Section for the Domain.

1. Select your desired VPC.
2. Choose two or more Subnets. If you don't specify the subnets, SageMaker uses all of the subnets in the VPC.
3. Choose one or more Security group(s).
4. Choose VPC Only to turn off direct internet access in the AWS managed VPC where SageMaker Canvas is hosted.

After disabling internet access, finish the onboarding process to set up your Domain. For more information about the VPC settings for Amazon SageMaker Domain, see Choose an Amazon VPC (p. 42).
Step 2: Configure VPC endpoints and access

**Note**
In order to configure Canvas in your own VPC, you must enable private DNS hostnames for your VPC endpoints. For more information, see [Connect to SageMaker Through a VPC Interface Endpoint](#).

SageMaker Canvas only accesses other AWS services to manage and store data for its functionality. For example, it connects to Amazon Redshift if your users access an Amazon Redshift database. It can connect to an AWS service such as Amazon Redshift using an internet connection or a VPC endpoint. Use VPC endpoints if you want to set up connections from your VPC to AWS services that don’t use the public internet.

A VPC endpoint creates a private connection to an AWS service that uses a networking path that is isolated from the public internet. For example, if you set up access to Amazon S3 using a VPC endpoint from your own VPC, then the SageMaker Canvas application can access Amazon S3 by going through the network interface in your VPC and then through the VPC endpoint that connects to Amazon S3. The communication between SageMaker Canvas and Amazon S3 is private.

For more information about configuring VPC endpoints for your VPC, see [AWS PrivateLink](#). If you are using Amazon Bedrock models in Canvas with a VPC, for more information about controlling access to your data, see [Protect jobs using a VPC](#) in the [Amazon Bedrock User Guide](#).

The following are the VPC endpoints for each service you can use with SageMaker Canvas:

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint</th>
<th>Endpoint type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Athena</td>
<td>com.amazonaws.Region.athena</td>
<td>Interface</td>
</tr>
<tr>
<td>Amazon SageMaker</td>
<td>com.amazonaws.Region.sagemaker</td>

<td>com.amazonaws.Region.rekognition</td>
</tr>
<tr>
<td>AWS Glue</td>
<td>Interface</td>
<td>com.amazonaws.Region.glue</td>
</tr>
<tr>
<td>AWS Application Auto Scaling</td>
<td>Interface</td>
<td>com.amazonaws.Region.application.autoscaling</td>
</tr>
<tr>
<td>Amazon Relational Database Service (Amazon RDS)</td>
<td>Interface</td>
<td>com.amazonaws.Region.rds</td>
</tr>
<tr>
<td>Amazon Bedrock</td>
<td>Interface</td>
<td>com.amazonaws.Region.bedrock-runtime</td>
</tr>
<tr>
<td>Amazon Kendra</td>
<td>Interface</td>
<td>com.amazonaws.Region.kendra</td>
</tr>
</tbody>
</table>

**Note**

For Amazon Bedrock, the interface endpoint service name `com.amazonaws.Region.bedrock` has been deprecated. Create a new VPC endpoint with the service name listed in the preceding table.

You must also add the following endpoint policy for Amazon S3 to control AWS principal access to your VPC endpoint. For information about how to update your VPC endpoint policy, see [Control access to VPC endpoints using endpoint policies](#).

```json
{
   "Effect": "Allow",
   "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:DeleteObject",
      "s3:CreateBucket",
      "s3:GetBucketCors",
      "s3:GetBucketLocation"
   ],
   "Resource": [
      "arn:aws:s3:::*SageMaker*",
      "arn:aws:s3:::*Sagemaker*",
      "arn:aws:s3:::*sagemaker*
   ]
},
{
   "Effect": "Allow",
   "Action": [
      "s3:ListBucket",
      "s3:ListAllMyBuckets"
   ],
   "Resource": "*"
}
```

### Step 3: Grant IAM permissions

The SageMaker Canvas user must have the necessary AWS Identity and Access Management permissions to allow connection to the VPC endpoints. The IAM role to which you give permissions must be the same one you used when onboarding to Amazon SageMaker Domain. You can attach the SageMaker
managed AmazonSageMakerFullAccess policy to the IAM role for the user to give the user the required permissions. If you require more restrictive IAM permissions and use custom policies instead, then give the user's role the ec2:DescribeVpcEndpointServices permission. SageMaker Canvas requires these permissions to verify the existence of the required VPC endpoints for standard build jobs. If it detects these VPC endpoints, then standard build jobs run by default in your VPC. Otherwise, they will run in the default AWS managed VPC.

For instructions on how to attach the AmazonSageMakerFullAccess IAM policy to your user's IAM role, see Adding and removing IAM identity permissions.

To grant your user's IAM role the granular ec2:DescribeVpcEndpointServices permission, use the following procedure.

1. Sign in to the AWS Management Console and open the IAM console.
2. In the navigation pane, choose Roles.
3. In the list, choose the name of the role to which you want to grant permissions.
4. Choose the Permissions tab.
5. Choose Add permissions and then choose Create inline policy.
6. Choose the JSON tab and enter the following policy, which grants the ec2:DescribeVpcEndpointServices permission:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": "ec2:DescribeVpcEndpointServices",
   "Resource": "*"
   }
   ]
   }
   ```

7. Choose Review policy, and then enter a Name for the policy (for example, VPCEndpointPermissions).
8. Choose Create policy.

The user's IAM role should now have permissions to access the VPC endpoints configured in your VPC.

(Optional) Step 4: Override security group settings for specific users

If you are an administrator, you might want different users to have different VPC settings, or user-specific VPC settings. When you override the default VPC's security group settings for a specific user, these settings are passed on to the SageMaker Canvas application for that user.

You can override the security groups that a specific user has access to in your VPC when you set up a new user profile in Studio. You can use the CreateUserProfile SageMaker API call (or create_user_profile with the AWS CLI), and then in the UserSettings, you can specify the SecurityGroups for the user.

Set up connections to data sources with OAuth

The following section describes the steps you must take to set up OAuth connections to data sources from SageMaker Canvas. OAuth is a common authentication platform for granting access to resources without sharing passwords. With OAuth, you can quickly connect to your data from Canvas and import it for building models. Canvas currently supports OAuth for Snowflake and Salesforce Data Cloud.

**Note**

You can only establish one OAuth connection for each data source.
Set up OAuth for Salesforce Data Cloud

To set up OAuth for Salesforce Data Cloud, follow these general steps:

1. Sign in to Salesforce Data Cloud.
2. In Salesforce Data Cloud, create a new app connection and do the following:
   a. Enable OAuth settings.
   b. When prompted for a callback URL (or the URL of the resource accessing your data), specify the URL for your Canvas application. The Canvas application URL follows this format:
      https://<domain-id>.studio.<region>.sagemaker.aws/canvas/default
   c. Copy the consumer key and secret.
   d. Copy your authorization URL and token URL.

For more detailed instructions about performing the preceding tasks in Salesforce Data Cloud, see Import data from Salesforce Data Cloud (p. 1200) in the Data Wrangler documentation for importing data from Salesforce Data Cloud.

After enabling access from Salesforce Data Cloud and getting your connection information, you must create an AWS Secrets Manager secret to store the information and add it to your Amazon SageMaker Domain or user profile. Note that you can add a secret to both a Domain and user profile, but Canvas looks for secrets in the user profile first.

To add a secret to your Domain or user profile, do the following:

1. Go to the Amazon SageMaker console.
2. Choose Domains in the navigation pane.
3. From the list of Domains, choose your Domain.
   a. If adding your secret to your Domain, do the following:
      i. Choose the Domain.
      ii. On the Domain settings page, choose the Domain settings tab.
      iii. Choose Edit.
   b. If adding the secret to your user profile, do the following:
      i. Choose the user’s Domain.
      ii. On the Domain settings page, choose the user profile.
      iii. On the User Details page, choose Edit.
4. In the navigation pane, choose Canvas settings.
5. For OAuth settings, choose Add OAuth configuration.
6. For Data source, select Salesforce Data Cloud.
7. For Secret Setup, select Create a new secret. Alternatively, if you already created an AWS Secrets Manager secret with your credentials, enter the ARN for the secret. If creating a new secret, do the following:
   a. For Identity Provider, select SALESFORCE.
   b. For Client ID, Client Secret, Authorization URL, and Token URL, enter all of the information you gathered from Salesforce Data Cloud in the previous procedure.
8. Save your Domain or user profile settings.

You should now be able to create a connection to your data in Salesforce Data Cloud from Canvas.
Set up OAuth for Snowflake

To set up authentication for Snowflake, Canvas supports identity providers that you can use instead of having users directly enter their credentials into Canvas.

The following are links to the Snowflake documentation for the identity providers that Canvas supports:

- Azure AD
- Okta
- Ping Federate

The following process describes the general steps you must take. For more detailed instructions about performing these steps, you can refer to the Setting up Snowflake OAuth Access (p. 1209) section in the Data Wrangler documentation for importing data from Snowflake.

To set up OAuth for Snowflake, do the following:

1. Register Canvas as an application with the identity provider. This requires specifying a redirect URL to Canvas, which should follow this format: https://<domain-id>.studio.<region>.sagemaker.aws/canvas/default

2. Within the identity provider, create a server or API that sends OAuth tokens to Canvas so that Canvas can access Snowflake. When setting up the server, use the authorization code and refresh token grant types, specify the access token lifetime, and set a refresh token policy. Additionally, within the External OAuth Security Integration for Snowflake, enable external_oauth_any_role_mode.

3. Get the following information from the identity provider: token URL, authorization URL, client ID, client secret. For Azure AD, also retrieve the OAuth scope credentials.

4. Store the information retrieved in the previous step in an AWS Secrets Manager secret.

   a. For Okta and Ping Federate, the secret should look like the following format:

   ```json
   ```

   b. For Azure AD, the secret should also include the OAuth scope credentials as the datasource_oauth_scope field.

After configuring the identity provider and the secret, you must create an AWS Secrets Manager secret to store the information and add it to your Amazon SageMaker Domain or user profile. Note that you can add a secret to both a Domain and user profile, but Canvas looks for secrets in the user profile first.

To add a secret to your Domain or user profile, do the following:

1. Go to the Amazon SageMaker console.

2. Choose Domains in the navigation pane.

3. From the list of Domains, choose your Domain.

   a. If adding your secret to your Domain, do the following:

      i. Choose the Domain.
      ii. On the Domain settings page, choose the Domain settings tab.
      iii. Choose Edit.

   b. If adding the secret to your user profile, do the following:
Use generative AI with foundation models

Amazon SageMaker Canvas provides generative AI foundation models that you can use to start conversational chats. These content generation models are trained on large amounts of text data to learn the statistical patterns and relationships between words, and they can produce coherent text that is statistically similar to the text on which they were trained. You can use this capability to increase your productivity by doing the following:

- Generate content, such as document outlines, reports, and blogs
- Summarize text from large corpuses of text, such as earnings call transcripts, annual reports, or chapters of user manuals
- Extract insights and key takeaways from large passages of text, such as meeting notes or narratives
- Improve text and catch grammatical errors or typos

The foundation models are a combination of Amazon SageMaker JumpStart and Amazon Bedrock large language models (LLMs). Canvas offers the following models:

<table>
<thead>
<tr>
<th>Model</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon-7B-Instruct</td>
<td>SageMaker JumpStart model</td>
<td>Falcon-7B-Instruct has 7 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-40B-Instruct, Falcon-7B-</td>
</tr>
</tbody>
</table>

You should now be able to create a connection to your data in Snowflake from Canvas.
<table>
<thead>
<tr>
<th>Model</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Falcon-40B-Instruct</td>
<td>SageMaker JumpStart model</td>
<td>Falcon-40B-Instruct has 40 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-7B-Instruct, Falcon-40B-Instruct is a slightly larger and more powerful model.</td>
</tr>
<tr>
<td>MPT-7B-Instruct</td>
<td>SageMaker JumpStart model</td>
<td>MPT-7B-Instruct is a model for long-form instruction following tasks and can assist you with writing tasks including text summarization and question-answering to save you time and effort. This model was trained on large amounts of fine-tuned data and can handle larger inputs, such as complex documents. Use this model when you want to process large bodies of text or want the model to generate long responses.</td>
</tr>
<tr>
<td>Model</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Amazon Titan</td>
<td>Amazon Bedrock model</td>
<td>Amazon Titan is a powerful, general-purpose language model that you can use for tasks such as summarization, text generation (such as creating a blog post), classification, open-ended Q&amp;A, and information extraction. It is pretrained on large datasets, making it suitable for complex tasks and reasoning. To continue supporting best practices in the responsible use of AI, Titan foundation models are built to detect and remove harmful content in the data, reject inappropriate content in the user input, and filter model outputs that contain inappropriate content (such as hate speech, profanity, and violence).</td>
</tr>
<tr>
<td>Jurassic-2 Mid</td>
<td>Amazon Bedrock model</td>
<td>Jurassic-2 Mid is a high performance text generation model trained on a massive corpus of text (current up to mid 2022). It is highly versatile, general-purpose, and capable of composing human-like text and solving complex tasks such as question answering, text classification, and many others. This model offers zero-shot instruction capabilities, allowing it to be directed with only natural language and without the use of examples. It performs up to 30% faster than its predecessor, the Jurassic-1 model. Jurassic-2 Mid is AI21’s mid-sized model, carefully designed to strike the right balance between exceptional quality and affordability.</td>
</tr>
<tr>
<td>Model</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Jurassic-2 Ultra</td>
<td>Amazon Bedrock model</td>
<td>Jurassic-2 Ultra is a high performance text generation model trained on a massive corpus of text (current up to mid 2022). It is highly versatile, general-purpose, and capable of composing human-like text and solving complex tasks such as question answering, text classification, and many others. This model offers zero-shot instruction capabilities, allowing it to be directed with only natural language and without the use of examples. It performs up to 30% faster than its predecessor, the Jurassic-1 model. Compared to Jurassic-2 Mid, Jurassic-2 Ultra is a slightly larger and more powerful model.</td>
</tr>
<tr>
<td>Anthropic Claude Instant</td>
<td>Amazon Bedrock model</td>
<td>Anthropic's Claude Instant is a faster and more cost-effective yet still very capable model. This model can handle a range of tasks including casual dialogue, text analysis, summarization, and document question answering. Just like Claude-2, Claude Instant can support up to 100,000 tokens in each prompt, equivalent to about 200 pages of information.</td>
</tr>
</tbody>
</table>
Use generative AI with foundation models

<table>
<thead>
<tr>
<th>Model</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anthropic Claude-2</td>
<td>Amazon Bedrock model</td>
<td>Claude-2 is Anthropic's most powerful model, which excels at a wide range of tasks from sophisticated dialogue and creative content generation to detailed instruction following. Claude-2 can take up to 100,000 tokens in each prompt, equivalent to about 200 pages of information. It can generate longer responses compared to its prior version. It supports use cases such as question answering, information extraction, removing PII, content generation, multiple-choice classification, roleplay, comparing text, summarization, and document Q&amp;A with citation.</td>
</tr>
</tbody>
</table>

The foundation models from Amazon Bedrock are currently only available in the US East (N. Virginia) and US West (Oregon) Regions. Additionally, when using foundation models from Amazon Bedrock, you are charged based on the volume of input tokens and output tokens, as specified by each model provider. For more information, see the Amazon Bedrock pricing page. The SageMaker JumpStart foundation models are deployed on SageMaker Hosting instances, and you are charged for the duration of usage based on the instance type used. For more information about the cost of different instance types, see the Amazon SageMaker Hosting: Real-Time Inference section on the SageMaker pricing page.

Document querying is an additional feature that you can use to query and get insights from documents stored in indexes using Amazon Kendra. With this functionality, you can generate content from the context of those documents and receive responses that are specific to your business use case, as opposed to responses that are generic to the large amounts of data on which the foundation models were trained. For more information about indexes in Amazon Kendra, see the Amazon Kendra Developer Guide.

To get started, see the following sections.

**Prerequisites**

The following sections outline the prerequisites for interacting with foundation models and using the document query feature in Canvas. The rest of the content on this page assumes that you've met the prerequisites for foundation models. The document query feature requires additional permissions.

**Prerequisites for foundation models**

The permissions you need for interacting with models are included in the Canvas Ready-to-use models permissions. To use the generative AI-powered models in Canvas, you must turn on the Canvas Ready-to-use models configuration permissions when setting up your Amazon SageMaker Domain. For more information, see Prerequisites for setting up Amazon SageMaker Canvas (p. 370). The Canvas Ready-to-use models configuration attaches the AmazonSageMakerCanvasAIOutputsAccess policy to your Canvas user's AWS Identity and Access Management (IAM) execution role. If you encounter any issues with granting permissions, see the topic Troubleshooting issues with granting permissions through the SageMaker console (p. 540).
If you've already set up your Domain, you can edit your Domain settings and turn on the permissions. For instructions on how to edit your Domain settings, see View and Edit Domains (p. 20). When editing the settings for your Domain, go to the Canvas settings and turn on the Enable Canvas Ready-to-use models option.

Certain SageMaker JumpStart foundation models also require that you request a SageMaker instance quota increase. Canvas hosts the models that you're currently interacting with on these instances, but the default quota for your account may be insufficient. If you run into an error while running any of the following models, request a quota increase for the associated instance types:

- Falcon-40B – ml.g5.12xlarge, ml.g5.24xlarge
- Falcon-13B – ml.g5.2xlarge, ml.g5.4xlarge, ml.g5.8xlarge
- MPT-7B-Instruct – ml.g5.2xlarge, ml.g5.4xlarge, ml.g5.8xlarge

For the preceding instances types, request an increase from 0 to 1 for the endpoint usage quota. For more information about how to increase an instance quota for your account, see Requesting a quota increase in the Service Quotas User Guide.

**Prerequisites for document querying**

**Note**
Document querying is supported in the following AWS Regions: US East (N. Virginia), US East (Ohio), US West (Oregon), Europe (Ireland), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Asia Pacific (Mumbai).

The document querying feature requires that you already have an Amazon Kendra index that stores your documents and document metadata. For more information about Amazon Kendra, see the Amazon Kendra Developer Guide. To learn more about the quotas for querying indexes, see Quotas in the Amazon Kendra Developer Guide.

You must also make sure that your Canvas user profile has the necessary permissions for document querying. The AmazonSageMakerCanvasFullAccess policy must be attached to the AWS IAM execution role for the SageMaker Domain that hosts your Canvas application (this policy is attached by default to all new and existing Canvas user profiles). You must also specifically grant document querying permissions and specify access to one or more Amazon Kendra indexes.

If your Canvas administrator is setting up a new Domain or user profile, have them set up the Domain by following the instructions in Prerequisites for setting up Amazon SageMaker Canvas (p. 370). While setting up the Domain, they can turn on the document querying permissions through the Canvas Ready-to-use models configuration.

The Canvas administrator can manage document querying permissions at the user profile level as well. For example, if the administrator wants to grant document querying permissions to some user profiles but remove permissions for others, they can edit the permissions for a specific user.

The following procedure shows how to turn on document querying permissions for a specific user profile:

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the user profile's Domain.
5. On the Domain details page, choose the User profile whose permissions you want to edit.
6. On the User Details page, choose Edit.
7. In the left navigation pane, choose Canvas settings.
8. In the Canvas Ready-to-use models configuration section, turn on the Enable document query using Amazon Kendra toggle.
9. In the dropdown, select one or more Amazon Kendra indexes to which you want to grant access.
10. Choose Submit to save the changes to your Domain settings.

You should now be able to use Canvas foundation models to query documents in the specified Amazon Kendra indexes.

**Start a new conversation to generate, extract, or summarize content**

To get started with generative AI foundation models in Canvas, you can initiate a new chat session with one of the models. For SageMaker JumpStart models, you are charged while the model is active, so you must start up models when you want to use them and shut them down when you are done interacting. If you do not shut down a SageMaker JumpStart model, Canvas shuts it down after 2 hours of inactivity. For Bedrock models (such as Amazon Titan), you are charged by prompt; the models are already active and don’t need to be started up or shut down. You are charged directly for use of these models by Amazon Bedrock.

To open a chat with a model, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose Ready-to-use models.
3. Choose Generate, extract and summarize content.
4. On the welcome page, you’ll receive a recommendation to start up the default model. You can start the recommended model, or you can choose Select another model from the dropdown to choose a different one.
5. If you selected a SageMaker JumpStart foundation model, you have to start it up before it is available for use. Choose Start up the model, and then the model is deployed to a SageMaker instance. It might take several minutes for this to complete. When the model is ready, you can enter prompts and ask the model questions.

   If you selected a foundation model from Amazon Bedrock, you can start using it instantly by entering a prompt and asking questions.

Depending on the model, you can perform various tasks. For example, you can enter a passage of text and ask the model to summarize it. Or, you can ask the model to come up with a short summary of the market trends in your domain.

The model’s responses in a chat are based on the context of your previous prompts. If you want to ask a new question in the chat that is unrelated to the previous conversation topic, we recommend that you start a new chat with the model.

**Extract information from documents with document querying**

*Note
This section assumes that you’ve completed the section above Prerequisites for document querying (p. 415).

Document querying is a feature that you can use while interacting with foundation models in Canvas. With document querying, you can access a corpus of documents stored in an Amazon Kendra index, which holds the contents of your documents and is structured in a way to make documents searchable. You can ask specific questions that are targeted to the data in your Amazon Kendra index, and the foundation model returns answers to your questions. For example, you can query an internal knowledge base of IT information and ask questions such as “How do I connect to my company’s network?” For more information about setting up an index, see the Amazon Kendra Developer Guide.
When using the document query feature, the foundation models restrict their responses to the content of the documents in your index with a technique called Retrieval Augmented Generation (RAG). This technique bundles the most relevant information from the index along with the user's prompt and sends it to the foundation model to get a response. Responses are limited to what can be found in your index, preventing the model from giving you incorrect responses based on external data. For more information about this process, see the blog post "Quickly build high-accuracy Generative AI applications on enterprise data."

To get started, in a chat with a foundation model in Canvas, turn on the Document query toggle at the top of the page. From the dropdown, select the Amazon Kendra index that you want to query. Then, you can begin asking questions related to the documents in your index.

**Important**

Document querying supports the Compare model outputs (p. 417) feature. Any existing chat history is overwritten when you start a new chat to compare model outputs.

**Model management**

**Note**

The following section describes starting up and shutting down models, which only applies to the SageMaker JumpStart foundation models, such as Falcon-40B-Instruct. You can access Amazon Bedrock models, such as Amazon Titan, instantly at any time.

You can start up as many SageMaker JumpStart models as you like. Each active SageMaker JumpStart model incurs charges on your account, so we recommend that you don’t start up more models than you are currently using.

To start up another model, you can do the following:

1. On the Generate, extract and summarize content page, choose New chat.
2. Choose the model from the dropdown menu. If you want to choose a model not displayed in the dropdown, choose Start up another model, and then select the model that you want to start up.
3. Choose Start up model.

The model should begin starting up, and within a few minutes you can chat with the model.

We highly recommend that you shut down models that you aren’t using. The models automatically shut down after 2 hours of inactivity. However, to manually shut down a model, you can do the following:

1. On the Generate, extract and summarize content page, open the chat for the model that you want to shut down.
2. On the chat page, choose the More options icon ( ).
3. Choose Shut down model.
4. In the Shut down model confirmation box, choose Shut down.

The model begins shutting down. If your chat compares two or more models, you can shut down an individual model from the chat page by choosing the model's More options icon ( ) and then choosing Shut down model.

**Compare model outputs**

You might want to compare the output of different models side by side to see which model output you prefer. This can help you decide which model is best suited to your use case. You can compare up to three models in chats.
Use Ready-to-use models

Note
Each individual model incurs charges on your account.

You must start a new chat to add models for comparison. To compare the output of models side by side in a chat, do the following:

1. In a chat, choose New chat.
2. Choose Compare, and use the dropdown menu to select the model that you want to add. To add a third model, choose Compare again to add another model.

Note
If you want to use a SageMaker JumpStart model that isn’t currently active, you are prompted to start up the model.

When the models are active, you see the two models side by side in the chat. You can submit your prompt, and each model responds in the same chat, as shown in the following screenshot.

When you're done interacting, make sure to shut down any SageMaker JumpStart models individually to avoid incurring further charges.

Use Ready-to-use models

With Amazon SageMaker Canvas Ready-to-use models, you can make predictions on your data without writing a single line of code or having to build a model—all you have to bring is your data. The Ready-to-use models use pre-built models to generate predictions without requiring you to spend the time, expertise, or cost required to build a model, and you can choose from a variety of use cases ranging from language detection to expense analysis.

Canvas integrates with existing AWS services, such as Amazon Textract, Amazon Rekognition, and Amazon Comprehend, to analyze your data and make predictions or extract insights. You can use the predictive power of these services from within the Canvas application to get high quality predictions for your data.

Canvas supports the following Ready-to-use models types:
<table>
<thead>
<tr>
<th>Ready-to-use model</th>
<th>Description</th>
<th>Supported data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentiment analysis</td>
<td>Detect sentiment in lines of text, which can be positive, negative, neutral, or mixed. Currently, you can only do sentiment analysis for English language text.</td>
<td>Plain text or tabular (CSV, Parquet)</td>
</tr>
<tr>
<td>Entities extraction</td>
<td>Extract entities, which are real-world objects such as people, places, and commercial items, or units such as dates and quantities, from text.</td>
<td>Plain text or tabular (CSV, Parquet)</td>
</tr>
<tr>
<td>Language detection</td>
<td>Determine the dominant language in text such as English, French, or German.</td>
<td>Plain text or tabular (CSV, Parquet)</td>
</tr>
<tr>
<td>Personal information detection</td>
<td>Detect personal information that could be used to identify an individual, such as addresses, bank account numbers, and phone numbers, from text.</td>
<td>Plain text or tabular (CSV, Parquet)</td>
</tr>
<tr>
<td>Object detection in images</td>
<td>Detect objects, concepts, scenes, and actions in your images.</td>
<td>Image (JPG, PNG)</td>
</tr>
<tr>
<td>Text detection in images</td>
<td>Detect text in your images.</td>
<td>Image (JPG, PNG)</td>
</tr>
<tr>
<td>Expense analysis</td>
<td>Extract information from invoices and receipts, such as date, number, item prices, total amount, and payment terms.</td>
<td>Document (PDF, JPG, PNG, TIFF)</td>
</tr>
<tr>
<td>Identity document analysis</td>
<td>Extract information from passports, driver licenses, and other identity documentation issued by the US Government.</td>
<td>Document (PDF, JPG, PNG, TIFF)</td>
</tr>
<tr>
<td>Document analysis</td>
<td>Analyze documents and forms for relationships among detected text.</td>
<td>Document (PDF, JPG, PNG, TIFF)</td>
</tr>
<tr>
<td>Document queries</td>
<td>Extract information from structured documents such as paystubs, bank statements, W-2s, and mortgage application forms by asking questions using natural language.</td>
<td>Document (PDF)</td>
</tr>
</tbody>
</table>

**Get started**

To get started with Ready-to-use models, review the following information.

**Prerequisites**

To use Ready-to-use models in Canvas, you must turn on the **Canvas Ready-to-use models configuration** permissions when **setting up your Amazon SageMaker Domain**. The **Canvas Ready-to-use models configuration** permissions must be turned on for users to...
to-use models configuration attaches the AmazonSageMakerCanvasAIOMServicesAccess policy to your Canvas user's AWS Identity and Access Management (IAM) execution role. If you encounter any issues with granting permissions, see the topic Troubleshooting issues with granting permissions through the SageMaker console (p. 540).

If you've already set up your Domain, you can edit your Domain settings and turn on the permissions. For instructions on how to edit your Domain settings, see View and Edit Domains. When editing the settings for your Domain, go to the Canvas settings and turn on the Enable Canvas Ready-to-use models option.

How to use Ready-to-use models

To get started with Ready-to-use models, do the following:

1. **(Optional) Import your data.** You can import a tabular, image, or document dataset to generate batch predictions, or a dataset of predictions, with Ready-to-use models. To get started with importing a dataset, see Import data for Ready-to-use models (p. 420).

2. **Generate predictions.** You can generate single or batch predictions with your chosen Ready-to-use model. To get started with making predictions, see Make predictions with Ready-to-use models (p. 422).

**Import data for Ready-to-use models**

*Note*

The following topic assumes that want to use Ready-to-use models to get predictions for an entire dataset. If you only want to get a single prediction with a Ready-to-use model, can you skip this section and go directly to the Make predictions with Ready-to-use models (p. 422) topic.

You can use Canvas Ready-to-use models to get predictions for an entire dataset. You only have to import your data into Canvas.

Ready-to-use models support predictions for the following dataset types:

- **Text data.** Text data for Ready-to-use models should consist of a tabular dataset with at least one column of text data entries and can be stored in CSV or Parquet format.
- **Image data.** Image datasets should consist of image files in JPG or PNG format.
- **Document data.** Document datasets should consist of files in PDF, JPG, PNG, or TIFF format.

When you import your data into Canvas, you must make sure that it meets the input requirements. For a table of requirements by data type, you can refer to the limits table on the Create a dataset (p. 431) page for custom models.

You can import data into Canvas from the following data sources:

- Local files on your computer
- Amazon S3 buckets
- Amazon Redshift
- AWS Glue Data Catalog through Amazon Athena
- Snowflake
- Over 40 external SaaS platforms, such as SAP OData

For a table of all of the supported data sources and what data types you can import from them, see the data sources table on the Import data into Canvas page in the custom models documentation.
Use the following procedures to import datasets into Canvas that you can use with Ready-to-use models.

**Import text or image data**

With tabular datasets of text data, you can generate predictions for the sentiment analysis, entities extraction, language detection, and personal information detection Ready-to-use models. With image datasets, you can generate predictions for the object detection in images and text detection in images Ready-to-use models.

The procedures for importing text and image data are the same for Ready-to-use models and custom models. You can refer to the custom model procedures for instructions on how to import these types of datasets:

- To learn how to import text data, use the [Import tabular data](p. 434) procedure within the custom model documentation.
- To learn how to import image data, use the [Import image data](p. 435) procedure within the custom model documentation.

**Note**

You can only import image datasets from local file upload or an Amazon S3 bucket.

**Import document data**

The Ready-to-use models for expense analysis, identity document analysis, document analysis, and document queries support document data. You can’t build a custom model with document data.

With document datasets, you can generate predictions for expense analysis, identity document analysis, document analysis, and document queries Ready-to-use models. Review the limitations table in the [Create a dataset](p. 431) section to ensure that your document dataset meets the requirements for document data.

**Note**

You can only import document datasets from local file upload or an Amazon S3 bucket.

Use the following procedure to import a document dataset into Canvas:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. Choose **Create**.
4. From the dropdown menu, choose **Document**.
5. In the popup dialog box, in the **Dataset name** field, enter a name for the dataset and choose **Create**.
6. On the **Import** page, open the **Data Source** dropdown menu.
7. Choose your data source. To upload files from your computer, choose **Local upload**. To import files from Amazon S3, choose **Amazon S3**.
8. From your computer or Amazon S3 bucket, select the document files that you want to upload.
9. When you’re ready to import your data, choose **Import data**.

While your dataset is importing into Canvas, you can see your datasets listed on the **Datasets** page. From this page, you can [View your dataset details](p. 436).

When the **Status** of your dataset shows as Ready, Canvas has successfully imported your data.

On the **Datasets** page, you can choose your dataset to preview it, which shows you up to the first 100 documents of your dataset.
Make predictions with Ready-to-use models

Ready-to-use models are available for text, image, and document data. Each data type has Ready-to-use models that are designed to work best for each use case. Use the following guide to determine which Ready-to-use models you can use with your input data:

- **Text data**: Sentiment analysis, entities extraction, language detection, personal information detection
- **Image data**: Object detection in images, text detection in images
- **Document data**: Expense analysis, identity document analysis, document analysis, document queries

The following screenshot shows you the landing page for Ready-to-use models, which showcases all of the different solutions.

Each Ready-to-use model supports both **Single predictions** and **Batch predictions** for your dataset. A **Single prediction** is when you only need to make one prediction. For example, you have one image from which you want to extract text, or one paragraph of text for which you want to detect the dominant language. A **Batch prediction** is when you’d like to make predictions for an entire dataset. For example, you might have a CSV file of customer reviews for which you’d like to analyze the customer sentiment, or you might have image files in which you’d like to detect objects.

When you have your data and have identified your use case, choose one of the following workflows to make predictions for your data.

**Make predictions for text data**

The following procedures describe how to make both single and batch predictions for text datasets. You can use the procedures for the following Ready-to-use model types: sentiment analysis, entities extraction, language detection, and personal information detection.

**Note**

For sentiment analysis, you can only use English language text.

**Single predictions**

To make a single prediction for Ready-to-use models that accept text data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For text data, it should be one of the following: **Sentiment analysis, Entities extraction, Language detection, or Personal information detection**.

3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Single prediction**.

4. For **Text field**, enter the text for which you’d like to get a prediction.

5. Choose **Generate prediction results** to get your prediction.

In the right pane **Prediction results**, you receive an analysis of your text in addition to a **Confidence** score for each result or label. For example, if you chose language detection and entered a passage of text in French, you might get French with a 95% confidence score and traces of other languages, like English, with a 5% confidence score.

The following screenshot shows the results for a single prediction using language detection where the model is 100% confident that the passage is English.

### Batch predictions

To make batch predictions for Ready-to-use models that accept text data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.

2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For text data, it should be one of the following: **Sentiment analysis, Entities extraction, Language detection, or Personal information detection**.

3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Batch prediction**.

4. Choose **Select dataset** if you’ve already imported your dataset. If not, choose **Import new dataset**, and then you are directed through the import data workflow.

5. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon ( ), you can **Preview** the output data. Then, you can choose **Download** to download the results.

### Make predictions for image data

The following procedures describe how to make both single and batch predictions for image datasets. You can use the procedures for the following Ready-to-use model types: object detection images and text detection in images.
Single predictions

To make a single prediction for Ready-to-use models that accept image data, do the following:

1. In the left navigation pane of the Canvas application, choose `Ready-to-use models`.
2. On the `Ready-to-use models` page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: `Object detection images` or `Text detection in images`.
3. On the `Run predictions` page for your chosen Ready-to-use model, choose `Single prediction`.
5. You are prompted to select an image to upload from your local computer. Select the image from your local files, and then the prediction results generate.

In the right pane `Prediction results`, you receive an analysis of your image in addition to a `Confidence` score for each object or text detected. For example, if you chose object detection in images, you receive a list of objects in the image along with a confidence score of how certain the model is that each object was accurately detected, such as 93%.

The following screenshot shows the results for a single prediction using the object detection in images solution, where the model predicts objects such as a clock tower and bus with 100% confidence.

Batch predictions

To make batch predictions for Ready-to-use models that accept image data, do the following:

1. In the left navigation pane of the Canvas application, choose `Ready-to-use models`.
2. On the `Ready-to-use models` page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: `Object detection images` or `Text detection in images`.
3. On the `Run predictions` page for your chosen Ready-to-use model, choose `Batch prediction`.
4. Choose `Select dataset` if you’ve already imported your dataset. If not, choose `Import new dataset`, and then you are directed through the import data workflow.
5. From the list of available datasets, select your dataset and choose `Generate predictions` to get your predictions.

After the prediction job finishes running, on the `Run predictions` page, you see an output dataset listed under `Predictions`. This dataset contains your results, and if you select the `More options` icon ( ), you can choose `View prediction results` to preview the output data. Then, you can choose `Download prediction` and download the results as a CSV or a ZIP file.
Make predictions for document data

The following procedures describe how to make both single and batch predictions for document datasets. You can use the procedures for the following Ready-to-use model types: expense analysis, identity document analysis, and document analysis.

**Note**
For document queries, only single predictions are currently supported.

### Single predictions

To make a single prediction for Ready-to-use models that accept document data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For document data, it should be one of the following: **Expense analysis**, **Identity document analysis**, or **Document analysis**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Single prediction**.
4. If your Ready-to-use model is identity document analysis or document analysis, complete the following actions. If you're doing expense analysis or document queries, skip this step and go to Step 5 or Step 6, respectively.
   a. Choose **Upload document**.
   b. You are prompted to upload a PDF, JPG, or PNG file from your local computer. Select the document from your local files, and then the prediction results will generate.
5. If your Ready-to-use model is expense analysis, do the following:
   a. Choose **Upload invoice or receipt**.
   b. You are prompted to upload a PDF, JPG, PNG, or TIFF file from your local computer. Select the document from your local files, and then the prediction results will generate.
6. If your Ready-to-use model is document queries, do the following:
   a. Choose **Upload document**.
   b. You are prompted to upload a PDF file from your local computer. Select the document from your local files. Your PDF must be 1–100 pages long.

   **Note**
   If you're in the Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), or Europe (Frankfurt) regions, then the maximum PDF size for document queries is 20 pages.
   c. In the right side pane, enter queries to search for information in the document. The number of characters you can have in a single query is from 1–200. You can add up to 15 queries at a time.
   d. Choose **Submit queries**, and then the results generate with answers to your queries. You are billed once for each submissions of queries you make.

In the right pane **Prediction results**, you'll receive an analysis of your document.

The following information describes the results for each type of solution:

- For expense analysis, the results are categorized into **Summary fields**, which include fields such as the total on a receipt, and **Line item fields**, which include fields such as individual items on a receipt. The identified fields are highlighted on the document image in the output.
- For identity document analysis, the output shows you the fields that the Ready-to-use model identified, such as first and last name, address, or date of birth. The identified fields are highlighted on the document image in the output.
Use Ready-to-use models

For document analysis, the results are categorized into **Raw text**, **Forms**, **Tables**, and **Signatures**. **Raw text** includes all of the extracted text, while **Forms**, **Tables**, and **Signatures** only include information on the form that falls into those categories. For example, **Tables** only includes information extracted from tables in the document. The identified fields are highlighted on the document image in the output.

For document queries, Canvas returns answers to each of your queries. You can open the collapsible query dropdown to view a result, along with a confidence score for the prediction. If Canvas finds multiple answers in the document, then you might have more than one result for each query.

The following screenshot shows the results for a single prediction using the document analysis solution.

![Document analysis screenshot](image.png)

**Batch predictions**

To make batch predictions for Ready-to-use models that accept document data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: Expense analysis, Identity document analysis, or Document analysis.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Batch prediction**.
4. Choose **Select dataset** if you’ve already imported your dataset. If not, choose **Import new dataset**, and then you are directed through the import data workflow.
5. From the list of available datasets, select your dataset and choose **Generate predictions**. If your use case is document analysis, continue to Step 6.
6. (Optional) If your use case is Document analysis, another dialog box called **Select features to include in batch prediction** appears. You can select **Forms**, **Tables**, and **Signatures** to group the results by those features. Then, choose **Generate predictions**.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (•), you can choose **View prediction results** to preview the analysis of your document data.

The following information describes the results for each type of solution:

- For expense analysis, the results are categorized into **Summary fields**, which include fields such as the total on a receipt, and **Line item fields**, which include fields such as individual items on a receipt. The identified fields are highlighted on the document image in the output.
• For identity document analysis, the output shows you the fields that the Ready-to-use model identified, such as first and last name, address, or date of birth. The identified fields are highlighted on the document image in the output.

• For document analysis, the results are categorized into Raw text, Forms, Tables, and Signatures. Raw text includes all of the extracted text, while Forms, Tables, and Signatures only include information on the form that falls into those categories. For example, Tables only includes information extracted from tables in the document. The identified fields are highlighted on the document image in the output.

After previewing your results, you can choose Download prediction and download the results as a ZIP file.

Use custom models

With Amazon SageMaker Canvas, you can build a custom model that is trained with your data. By training a custom model on your data, you are able to capture characteristics and trends that are specific and most representative of your data. For example, you might want to create a custom time series forecasting model that you train on inventory data from your warehouse that allows you to manage your logistics operations.

You can train a Canvas custom model on the following types of datasets:

• Tabular (including Numeric, Categorical, Timeseries, and Text data)
• Image

The following table shows the types of custom models that you can build in Canvas, along with their supported data types and data sources:

<table>
<thead>
<tr>
<th>Model type</th>
<th>Example use case</th>
<th>Supported data types</th>
<th>Supported data sources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric prediction</td>
<td>Predicting house prices based on features like square footage</td>
<td>Numeric</td>
<td>Local upload, Amazon S3, SaaS connectors</td>
</tr>
<tr>
<td>2 category prediction</td>
<td>Predicting whether or not a customer is likely to churn</td>
<td>Binary or Categorical</td>
<td>Local upload, Amazon S3, SaaS connectors</td>
</tr>
<tr>
<td>3+ category prediction</td>
<td>Predicting patient outcomes after being discharged from the hospital</td>
<td>Categorical</td>
<td>Local upload, Amazon S3, SaaS connectors</td>
</tr>
<tr>
<td>Time series forecasting</td>
<td>Predicting your inventory for the next quarter</td>
<td>Timeseries</td>
<td>Local upload, Amazon S3, SaaS connectors</td>
</tr>
<tr>
<td>Single-label image prediction</td>
<td>Predicting types of manufacturing defects in images</td>
<td>Image (JPG, PNG)</td>
<td>Local upload, Amazon S3</td>
</tr>
<tr>
<td>Multi-category text prediction</td>
<td>Predicting categories of products, such as clothing, electronics, or Target column: Text</td>
<td>Source column: Text</td>
<td>Local upload, Amazon S3</td>
</tr>
</tbody>
</table>
Use custom models

Model type | Example use case | Supported data types | Supported data sources
--- | --- | --- | ---
 | household goods, based on product descriptions | | |

Get started

To get started with building and generating predictions from a custom model, do the following:

- Determine your use case and type of model that you want to build. For more information about the custom model types, see [Build a custom model](p. 452). For more information about the data types and sources supported for custom models, see [Import data into Canvas](p. 428).
- Import your data into Canvas. You can build a custom model with any tabular or image dataset that meets the input requirements. For more information about the input requirements, see [Create a dataset](p. 431).

To learn more about SageMaker-provided sample datasets you can experiment with, see [Use sample datasets].

- Build your custom model. You can do a **Quick build** to get your model and start making predictions more quickly, or you can do a **Standard build** for greater accuracy.

For numeric, categorical, and time series forecasting model types, you can clean and prepare your data with features such as advanced transforms and joins. For image prediction models, you can [Edit an image dataset](p. 460) to update your labels or add and delete images. Note that you can't use these features for multi-category text prediction models.

- Evaluate your model's performance and determine how well it might perform on real-world data.
- (Optional) For certain model types, you can [collaborate with data scientists in Amazon SageMaker Studio](p. 204) who can help review and improve your model.
- [Make single or batch predictions](p. 204) with your model.

**Note**

If you already have a trained model in Amazon SageMaker Studio that you’d like to share with Canvas, you can bring your own model to SageMaker Canvas. Review the [BYOM prerequisites](p. 204) to determine whether your model is eligible for sharing.

Import data into Canvas

Amazon SageMaker Canvas supports importing tabular, image, and document data. You can import data from both local and external data sources into Canvas. Use the datasets that you import to build models and make predictions for other datasets.

Each use case for which you can build a custom model accepts different types of input. For example, if you want to build a single-label image classification model, then you should import image data. For more information about the different model types and the data they accept, see [Build a custom model](p. 452). You can import data and build custom models in SageMaker Canvas for the following data types:

- **Tabular** (CSV, Parquet, or tables)
  - Categorical – Use categorical data to build custom categorical prediction models for 2 and 3+ category prediction.
  - Numeric – Use numeric data to build custom numeric prediction models.
  - Text – Use text data to build custom multi-category text prediction models.
  - Timeseries – Use timeseries data to build custom time series forecasting models.
• **Image** (JPG or PNG) – Use image data to build custom single-label image prediction models.

• **Document** (PDF, JPG, PNG, TIFF) – Document data is only supported for SageMaker Canvas Ready-to-use models. To learn more about Ready-to-use models that can make predictions for document data, see **Use Ready-to-use models** (p. 418).

You can import data into Canvas from the following data sources:

• Local files on your computer
• Amazon S3 buckets
• Amazon Redshift
• AWS Glue Data Catalog through Amazon Athena
• Amazon Aurora
• Amazon Relational Database Service (Amazon RDS)
• Salesforce Data Cloud
• Snowflake
• Databricks, SQLServer, MariaDB, and other popular databases through JDBC connectors
• Over 40 external SaaS platforms, such as SAP OData

For a full list of data sources you can import from, see the following table:

<table>

For instructions on how to import data and information regarding input data requirements, such as the maximum file size for images, see Create a dataset (p. 431).

Canvas also provides several sample datasets in your application to help you get started. To learn more about the SageMaker-provided sample datasets you can experiment with, see Use sample datasets.

After you import a dataset into Canvas, you can update the dataset at any time. You can do a manual update or you can set up a schedule for automatic dataset updates. For more information, see Update a dataset (p. 438).

For more information specific to each dataset type, see the following sections:

**Tabular**

To import data from an external data source (such as a Snowflake database or a SaaS platform), you must authenticate and connect to the data source in the Canvas application. For more information, see Connect to data sources (p. 440).

After creating datasets in Canvas, you can join multiple datasets into a single dataset. Joining datasets is only supported for tabular datasets. As long as your data is arranged into tables, you can join datasets from various sources, such as Amazon Redshift, Amazon Athena, or Snowflake. For information about joining datasets, see Join data that you’ve imported into SageMaker Canvas (p. 448).

**Image**

For information about how to edit an image dataset and perform tasks such as assigning or reassigning labels, adding images, or deleting images, see Edit an image dataset (p. 460).

**Create a dataset**

The following sections describe how to create a dataset in Amazon SageMaker Canvas. For custom models, you can create datasets for tabular and image data. Choose your workflow based on the following information:

- For categorical, numeric, text, and timeseries data, see Import tabular data (p. 434).
- For image data, see Import image data (p. 435).

**Note**

For information about how to import a document dataset for Ready-to-use models that accept document data, see the Import document data (p. 421) workflow in the Ready-to-use models documentation.

A dataset can consist of multiple files. For example, you might have multiple files of inventory data in CSV format. You can upload these files together as a dataset as long as the schema (or column names and data types) of the files match.
Canvas also supports managing multiple versions of your dataset. When you create a dataset, the first version is labeled as V1. You can create a new version of your dataset by updating your dataset. You can do a manual update, or you can set up an automated schedule for updating your dataset with new data. For more information, see [Update a dataset](p. 438).

When you import your data into Canvas, make sure that it meets the requirements in the following table. The limitations are specific to the type of model you’re building.

<table>
<thead>
<tr>

</tbody>
</table>

*Document data is currently only supported for Ready-to-use models (p. 418) that accept document data. You can't build a custom model with document data.

Also note the following restrictions:

- For tabular data, Canvas disallows selecting any file with extensions other than .csv, .parquet, .parq, and .pqt for both local upload and Amazon S3 import. CSV files must be comma delimited and not have newline characters except when denoting a new row.
- For tabular data using Parquet files, note the following:
  - Parquet files can't include complex types like maps and lists.
  - The column names of Parquet files can't contain spaces.
  - If using compression, Parquet files must use either gzip or snappy compression types. For more information about the preceding compression types, see the gzip documentation and the snappy documentation.
- For image data, if you have any unlabeled images, you must label them before building your model. For information about how to assign labels to images within the Canvas application, see Edit an image dataset (p. 460).
- If you set up automatic dataset updates or automatic batch prediction configurations, you can only create a total of 20 configurations in your Canvas application. For more information, see Manage automations (p. 522).

After you import a dataset, you can view your datasets on the Datasets page at any time.
Import tabular data

With tabular datasets, you can build categorical, numeric, time series forecasting, and text prediction models. Review the limitations table in the preceding Import a dataset section to ensure that your data meets the requirements for tabular data (note that the sample size limits only apply when previewing your data before building your model).

Use the following procedure to import a tabular dataset into Canvas:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose Datasets.
3. Choose Import.
4. In the popup dialog box, in the Dataset name field, enter a name for the dataset and choose Create.
5. On the Import page, open the Data Source dropdown menu.
6. Choose your data source:
   - To upload files from your computer, choose Local upload.
   - To import data from another source, such as an Amazon S3 bucket or a Snowflake database, search for your data source in the Search data source bar. Then, choose the tile for your desired data source.

   **Note**
   You can only import data from the tiles that have an active connection. If you want to connect to a data source that is unavailable to you, contact your administrator. If you're an administrator, see Connect to data sources (p. 440).

The following screenshot shows the Data Source dropdown menu.

7. (Optional) If you're connecting to an Amazon Redshift or Snowflake database for the first time, a dialog box appears to create a connection. Fill out the dialog box with your credentials and choose Create connection. If you already have a connection, choose your connection.
8. From your data source, select your files to import. For local upload and importing from Amazon S3, you can select files. For database sources, you can drag-and-drop data tables from the left navigation pane.
9. (Optional) For tabular data sources that support SQL querying (such as Amazon Redshift, Amazon Athena, or Snowflake), you can choose Edit in SQL to make SQL queries and join tables before importing them. For more information, see Join data that you've imported into SageMaker Canvas (p. 448).

   The following screenshot shows the Edit SQL view for an Amazon Athena data source.
10. (Optional) You can choose Preview to preview your dataset before importing. For tabular datasets, this shows you up to the first 100 rows of your dataset. The following screenshot shows you the Import preview screen.

11. When you're ready to import your data, choose Import data.

While your dataset is importing into Canvas, you can see your datasets listed on the Datasets page. From this page, you can View your dataset details (p. 436).

When the Status of your dataset shows as Ready, Canvas successfully imported your data and you can proceed with building a model.

If you have a connection to a data source, such as an Amazon Redshift database or a SaaS connector, you can return to that connection. For Amazon Redshift and Snowflake, you can add another connection by creating another dataset, returning to the Import data page, and choosing the Data Source tile for that connection. From the dropdown menu, you can open the previous connection or choose Add connection.

**Note**
For SaaS platforms, you can only have one connection per data source.

**Import image data**

With image datasets, you can build single-label image prediction custom models, which predict a label for an image. Review the limitations in the preceding Import a dataset section to ensure that your image dataset meets the requirements for image data.

**Note**
You can only import image datasets from local file upload or an Amazon S3 bucket. Also, for image datasets, you must have at least 25 images per label.

Use the following procedure to import an image dataset into Canvas:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose Datasets.
3. Choose Create.
4. From the dropdown menu, choose Image.
5. In the popup dialog box, in the Dataset name field, enter a name for the dataset and choose Create.
6. On the Import page, open the Data Source dropdown menu.
7. Choose your data source. To upload files from your computer, choose Local upload. To import files from Amazon S3, choose Amazon S3.
8. From your computer or Amazon S3 bucket, select the images or folders of images that you want to upload.

9. When you’re ready to import your data, choose **Import data**.

While your dataset is importing into Canvas, you can see your datasets listed on the **Datasets** page. From this page, you can [View your dataset details](p. 436).

When the **Status** of your dataset shows as Ready, Canvas successfully imported your data and you can proceed with **building a model**.

When you are building your model, you can edit your image dataset, and you can assign or re-assign labels, add images, or delete images from your dataset. For more information about how to edit your image dataset, see [Edit an image dataset](p. 460).

**View your dataset details**

For each of your datasets, you can view all of the files in a dataset, the dataset’s version history, and any auto update configurations for the dataset. From the **Datasets** page, you can also initiate actions such as [Update a dataset](p. 438) or [Build a custom model](p. 452).

To view the details for a dataset, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. From the list of datasets, choose your dataset.

On the **Data** tab, you can see a preview of your data. If you choose **Dataset details**, you can see all of the files that are part of your dataset. Choose a file to see only the data from that file in the preview. For image datasets, the preview only shows you the first 100 images of your dataset.

On the **Version history** tab, you can see a list of all of the versions of your dataset. A new version is made whenever you update a dataset. To learn more about updating a dataset, see [Update a dataset](p. 438). The following screenshot shows the **Version history** tab in the Canvas application.
On the **Auto updates** tab, you can enable auto updates for the dataset and set up a configuration to update your dataset on a regular schedule. To learn more about setting up auto updates for a dataset, see [Configure automatic updates for a dataset](p. 439). The following screenshot shows the **Auto updates** tab with auto updates turned on and a list of auto update jobs that have been performed on the dataset.
Update a dataset

After importing your initial dataset into Amazon SageMaker Canvas, you might have additional data that you want to add to your dataset. For example, you might get inventory data at the end of every week that you want to add to your dataset. Instead of importing your data multiple times, you can update your existing dataset and add or remove files from it.

**Note**

You can only update datasets that you have imported through local upload or Amazon S3.

You can update your dataset either manually or automatically. With automatic updates, you specify a location where Canvas checks for files at a frequency you specify. If you import new files during the update, the schema of the files must match the existing dataset exactly.

Every time you update your dataset, Canvas creates a new version of your dataset. You can only use the latest version of your dataset to build a model or generate predictions. For more information about viewing the version history of your dataset, see [View your dataset details](p. 436).

You can also use dataset updates with automated batch predictions, which starts a batch prediction job whenever you update your dataset. For more information, see [Make batch predictions](p. 500).

The following sections describe how to do manual and automatic updates to your dataset.

**Manually update a dataset**

To do a manual update, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose Datasets.
3. From the list of datasets, choose the dataset you want to update.
4. Choose the Update dataset dropdown menu and choose Manual update. You are taken to the import data workflow.
5. From the Data source dropdown menu, choose either Local upload or Amazon S3.
6. The page shows you a preview of your data. From here, you can add or remove files from the dataset. If you're importing tabular data, the schema of the new files (column names and data types) must match the schema of the existing files. Additionally, your new files must not exceed the maximum dataset size or file size. For more information about these limitations, see Import a dataset.
   
   Note
   If you add a file with the same name as an existing file in your dataset, the new file overwrites the old version of the file.
7. When you're ready to save your changes, choose Update dataset.

You should now have a new version of your dataset.

On the Datasets page, you can choose the Version history tab to see all of the versions of your dataset and the history of both manual and automatic updates you've made.

Configure automatic updates for a dataset

An automatic update is when you set up a configuration for Canvas to update your dataset at a given frequency. We recommend that you use this option if you regularly receive new files of data that you want to add to your dataset.

When you set up the auto update configuration, you specify an Amazon S3 location where you upload your files and a frequency at which Canvas checks the location and imports files. Each instance of Canvas updating your dataset is referred to as a job. For each job, Canvas imports all of the files in the Amazon S3 location. If you have new files with the same names as existing files in your dataset, Canvas overwrites the old files with the new files.

For automatic dataset updates, Canvas doesn’t perform schema validation. If the schema of files imported during an automatic update don’t match the schema of the existing files or exceed the size limitations (see Import a dataset for a table of file size limitations), then you get errors when your jobs run.

   Note
   You can only set up a maximum of 20 automatic configurations in your Canvas application. Additionally, Canvas only does automatic updates while you’re logged in to your Canvas application. If you log out of your Canvas application, automatic updates pause until you log back in.

To configure automatic updates for your dataset, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose Datasets.
3. From the list of datasets, choose the dataset you want to update.
4. Choose the Update dataset dropdown menu and choose Automatic update. You are taken to the Auto update tab for the dataset.
5. Turn on the Auto update enabled toggle.
6. For Specify a data source, enter the Amazon S3 path to a folder where you plan to regularly upload files.
7. For Choose a frequency, select Hourly, Weekly, or Daily.
8. For Specify a starting time, use the calendar and time picker to select when you want the first auto update job to start.
9. When you're ready to create the auto update configuration, choose Save.

Canvas begins the first job of your auto update cadence at the specified starting time.

For more information about viewing your auto update job history or making changes to your auto update configuration through the Automations page in the Canvas application, see Manage automations (p. 522).

The following sections describe how to view, update, and delete your automatic update configuration through the Datasets page in the Canvas application.

View your automatic dataset update jobs

To view the job history for your automatic dataset updates, on your dataset details page, choose the Auto updates tab.

Each automatic update to a dataset shows as a job in the Auto updates tab under the Job history section. For each job, you can see the following:

- **Job created** – The timestamp for when Canvas started updating the dataset.
- **Files** – The number of files in the dataset.
- **Cells (Columns x Rows)** – The number of columns and rows in the dataset.
- **Status** – The status of the dataset after the update. If the job was successful, the status is Ready. If the job failed for any reason, the status is Failed, and you can hover over the status for more details.

Edit your automatic dataset update configuration

You might want to make changes to your auto update configuration for a dataset, such as changing the frequency of the updates. You might also want to turn off your automatic update configuration to pause the updates to your dataset.

To make changes to your auto update configuration for a dataset, go to the Auto updates tab of your dataset and choose Edit to make changes to the configuration.

To pause your dataset updates, turn off your automatic configuration. You can turn off auto updates by going to the Auto updates tab of your dataset and turning the Enable auto updates toggle off. You can turn this toggle back on at any time to resume the update schedule.

Delete your automatic dataset update configuration

To learn how to delete your configuration, see Delete an automatic configuration (p. 524).

Connect to data sources

In Amazon SageMaker Canvas, you can import data from a location outside of your local file system through an AWS service, a SaaS platform, or other databases using JDBC connectors. For example, you might want to import tables from a data warehouse in Amazon Redshift, or you might want to import Google Analytics data.

When you go through the Import workflow to import data in the Canvas application, you can choose your data source and then select the data that you want to import. For certain data sources, like Snowflake and Amazon Redshift, you must specify your credentials and add a connection to the data source.

The following screenshot shows the data sources toolbar in the Import workflow, with all of the available data sources highlighted. You can only import data from the data sources that are available to you. Contact your administrator if your desired data source isn't available.
The following sections provide information about establishing connections to external data sources and importing data from them. Review the following section first to determine what permissions you need to import data from your data source.

Permissions

Review the following information to ensure that you have the necessary permissions to import data from your data source:

- **Amazon S3**: You can import data from any Amazon S3 bucket as long as your user has permissions to access the bucket. For more information about using AWS IAM to control access to Amazon S3 buckets, see Identity and access management in Amazon S3 in the Amazon S3 User Guide.

- **Amazon Athena**: If you have the AmazonSageMakerFullAccess policy and the AmazonSageMakerCanvasFullAccess policy attached to your user's execution role, then you’ll be able to query your AWS Glue Data Catalog with Amazon Athena. If you’re part of an Athena workgroup, make sure that the Canvas user has permissions to run Athena queries on the data. For more information, see Using workgroups for running queries in the Amazon Athena User Guide.

- **Amazon Redshift**: To give yourself the necessary permissions to import data from Amazon Redshift, see Grant Users Permissions to Import Amazon Redshift Data.

- **Amazon RDS**: If you have the AmazonSageMakerCanvasFullAccess policy attached to your user's execution role, then you’ll be able to access your Amazon RDS databases from Canvas.

- **SaaS platforms**: If you have the AmazonSageMakerFullAccess policy and the AmazonSageMakerCanvasFullAccess policy attached to your user's execution role, then you’ll have the necessary permissions to import data from SaaS platforms. See Use SaaS connectors with Canvas (p. 448) for more information about connecting to a specific SaaS connector.

- **JDBC connectors**: For database sources such as Databricks, MySQL or MariaDB, you must enable username and password authentication on the source database before attempting to connect from Canvas. If you’re connecting to a Databricks database, you must have the JDBC URL that contains the necessary credentials.

Connect to a database stored in AWS

You might want to import data that you've stored in AWS. You can import data from Amazon S3, use Amazon Athena to query a database in the AWS Glue Data Catalog, import data from Amazon RDS, or make a connection to an Amazon Redshift database.

You can create multiple connections to Amazon Redshift. For Amazon Athena, you can access any databases that you have in your AWS Glue Data Catalog. For Amazon S3, you can import data from a bucket as long as you have the necessary permissions.

Review the following sections for more detailed information.
**Connect to data in Amazon S3, Amazon Athena, or Amazon RDS**

For Amazon S3, you can import data from an Amazon S3 bucket as long as you have permissions to access the bucket.

For Amazon Athena, you can access databases in your AWS Glue Data Catalog as long as you have permissions through your [Amazon Athena workgroup](#).

For Amazon RDS, if you have the [AmazonSageMakerCanvasFullAccess](#) policy attached to your user's role, then you'll be able to import data from your Amazon RDS databases into Canvas.

To import data from an Amazon S3 bucket, or to run queries and import data tables with Amazon Athena, see [Create a dataset](#). You can only import tabular data from Amazon Athena, and you can import tabular and image data from Amazon S3.

**Connect to an Amazon Redshift database**

You can import data from Amazon Redshift, a data warehouse where your organization keeps its data. Before you can import data from Amazon Redshift, the AWS IAM role you use must have the [AmazonRedshiftFullAccess](#) managed policy attached. For instructions on how to attach this policy, see [Grant Users Permissions to Import Amazon Redshift Data](#).

To import data from Amazon Redshift, you do the following:

1. Create a connection to an Amazon Redshift database.
2. Choose the data that you're importing.
3. Import the data.

You can use the Amazon Redshift editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

SQL queries give you the ability to customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can use joins to combine multiple datasets from Amazon Redshift into a single dataset. You can drag your datasets from Amazon Redshift into the panel that gives you the ability to join the datasets.

You can use the SQL editor to edit the dataset that you've joined and convert the joined dataset into a single node. You can join another dataset to the node. You can import the data that you've selected into SageMaker Canvas.

Use the following procedure to import data from Amazon Redshift.

1. In the SageMaker Canvas application, go to the **Datasets** page.
2. Choose *Create*, and from the dropdown menu, choose *Tabular*.
3. Enter a name for the dataset and choose *Create*.
4. For **Data Source**, open the dropdown menu and choose *Redshift*.
5. Choose *Add connection*.
6. In the dialog box, specify your Amazon Redshift credentials:
   a. For **Authentication method**, choose *IAM*.
   b. Enter the **Cluster identifier** to specify to which cluster you want to connect. Enter only the cluster identifier and not the full endpoint of the Amazon Redshift cluster.
c. Enter the **Database name** of the database to which you want to connect.

d. Enter a **Database user** to identify the user you want to use to connect to the database.

e. For **ARN**, enter the IAM role ARN of the role that the Amazon Redshift cluster should assume to move and write data to Amazon S3. For more information about this role, see [Authorizing Amazon Redshift to access other AWS services on your behalf](#) in the *Amazon Redshift Management Guide*.

f. Enter a **Connection name**. This is a name used by Canvas to identify this connection.

7. From the tab that has the name of your connection, drag the .csv file that you’re importing to the **Drag and drop table to import** pane.

8. Optional: Drag additional tables to the import pane. You can use the GUI to join the tables. For more specificity in your joins, choose **Edit in SQL**.

9. Optional: If you’re using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:

   - Warehouse
   - Database
   - Schema

10. Choose **Import data**.

The following image shows an example of fields specified for an Amazon Redshift connection.

![Add a new Redshift connection](image)

The following image shows the page used to join datasets in Amazon Redshift.

![Join datasets in Amazon Redshift](image)
The following image shows an SQL query being used to edit a join in Amazon Redshift.

Connect to your data with JDBC connectors

With JDBC, you can connect to your databases from sources such as Databricks, SQLServer, MySQL, PostgreSQL, MariaDB, Amazon RDS, and Amazon Aurora.

You must make sure that you have the necessary credentials and permissions to create the connection from Canvas.

- For Databricks, you must provide a JDBC URL. The URL formatting can vary between Databricks instances. For information about finding the URL and the specifying the parameters within it, see JDBC configuration and connection parameters in the Databricks documentation. The following is an example of how a URL can be formatted:
  `jdbc:spark://aws-sagemaker-datawrangler.cloud.databricks.com:443/default;transportMode=http;ssl=1;httpPath=sql/protocolv1/o/3122619508517275/0909-200301-cut318;AuthMech=3;UID=token;PWD=personal-access-token`

- For other database sources, you must set up username and password authentication, and then specify those credentials when connecting to the database from Canvas.

Additionally, your data source must either be accessible through the public internet, or if your Canvas application is running in VPC-only mode, then the data source must run in the same VPC. For more information about configuring an Amazon RDS database in a VPC, see Amazon VPC VPCs and Amazon RDS in the Amazon RDS User Guide.

After you've configured your data source credentials, you can sign in to the Canvas application and create a connection to the data source. Specify your credentials (or, for Databricks, the URL) when creating the connection.

Connect to data sources with OAuth

Canvas supports using OAuth as an authentication method for connecting to your data in Snowflake and Salesforce Data Cloud. OAuth is a common authentication platform for granting access to resources without sharing passwords.

**Note**

You can only establish one OAuth connection for each data source.

To authorize the connection, you must following the initial setup described in Set up connections to data sources with OAuth (p. 407).
After setting up the OAuth credentials, you can do the following to add a Snowflake or Salesforce Data Cloud connection with OAuth:

1. Sign in to the Canvas application.
2. Create a tabular dataset. When prompted to upload data, choose Snowflake or Salesforce Data Cloud as your data source.
3. Create a new connection to your Snowflake or Salesforce Data Cloud data source. Specify OAuth as the authentication method and enter your connection details.

You should now be able to import data from your databases in Snowflake or Salesforce Data Cloud.

**Connect to a SaaS platform**

You can import data from Snowflake and over 40 other external SaaS platforms. For a full list of the connectors, see the table on [Import data into Canvas](p. 428).

**Note**
You can only import tabular data, such as data tables, from SaaS platforms.

**Use Snowflake with Canvas**

Snowflake is a data storage and analytics service, and you can import your data from Snowflake into SageMaker Canvas. For more information about Snowflake, see the [Snowflake documentation](#).

You can import data from your Snowflake account by doing the following:

1. Create a connection to the Snowflake database.
2. Choose the data that you're importing by dragging and dropping the table from the left navigation menu into the editor.
3. Import the data.

You can use the Snowflake editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

SQL queries give you the ability to customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can join multiple Snowflake datasets into a single dataset before you import into Canvas using SQL or the Canvas interface. You can drag your datasets from Snowflake into the panel that gives you the ability to join the datasets, or you can edit the joins in SQL and convert the SQL into a single node. You can join other nodes to the node that you've converted. You can then combine the datasets that you've joined into a single node and join the nodes to a different Snowflake dataset. Finally, you can import the data that you've selected into Canvas.

Use the following procedure to import data from Snowflake to Amazon SageMaker Canvas.

1. In the SageMaker Canvas application, go to the **Datasets** page.
2. Choose **Import**.
3. For **Data Source**, open the dropdown menu and choose **Snowflake**.
4. Choose **Add connection**.
5. In the **Add a new Snowflake connection** dialog box, specify your Snowflake credentials. For the **Authentication method**, you can choose **Basic - username password**, **ARN** or **OAuth**. OAuth lets you authenticate without providing a password but requires additional setup. For more information about setting up OAuth credentials for Snowflake, see [Set up connections to data sources with OAuth](p. 407).

6. Choose **Add connection**.

7. From the tab that has the name of your connection, drag the .csv file that you're importing to the **Drag and drop table to import** pane.

8. Optional: Drag additional tables to the import pane. You can use the user interface to join the tables. For more specificity in your joins, choose **Edit in SQL**.

9. Optional: If you're using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:
   - Warehouse
   - Database
   - Schema

Adding context to a connection makes it easier to specify future queries.

10. Choose **Import data**.

The following image shows an example of fields specified for a Snowflake connection.

![Image of Snowflake connection fields](image_url)

The following image shows the page used to add context to a connection.

![Image of context addition](image_url)
The following image shows the page used to join datasets in Snowflake.

The following image shows a SQL query being used to edit a join in Snowflake.
Use custom models

Use SaaS connectors with Canvas

Note
For SaaS platforms besides Snowflake, you can only have one connection per data source.

Before you can import data from a SaaS platform, your administrator must authenticate and create a connection to the data source. For more information about how administrators can create a connection with a SaaS platform, see Managing Amazon AppFlow connections in the Amazon AppFlow User Guide.

If you’re an administrator getting started with Amazon AppFlow for the first time, see Getting started in the Amazon AppFlow User Guide.

To import data from a SaaS platform, you can follow the standard Import tabular data (p. 434) procedure, which shows you how to import tabular datasets into Canvas.

Join data that you’ve imported into SageMaker Canvas

Note
You can only make joins for tabular datasets in SageMaker Canvas.

You can use Amazon SageMaker Canvas to join multiple datasets into a single dataset. A join combines the two datasets. By default, SageMaker Canvas automatically joins the datasets on their matching column names. The option to combine multiple datasets might give you the ability to get more insight from the models that you build.

You can make the following joins for your datasets:

- **Inner** – Returns a dataset with matching values in both datasets.
- **Left** – Returns a dataset that has:
  - All the rows from the dataset to the left of the join.
  - All the rows from the dataset to the right of the join that have matching values with the columns to the left of the join.
- **Right** – Returns a dataset that has:
  - All the rows from the dataset to the right of the join.
- All the rows from the dataset to the left of the join that have matching values with the columns to the right of the join.
- **Outer** – Returns all the rows when there is a match in either the left or the right dataset. The dataset from an outer join might have null values that SageMaker Canvas might impute when you build a model.

Use the following procedure to join your datasets.

To join datasets, do the following.

1. Navigate to the **Datasets** page.
2. Choose **Join data**.
3. Drag and drop the datasets that you're joining into the Drag and drop datasets to join box.
4. Configure the join. Amazon SageMaker Canvas shows you a preview of the joined data after you configure it.
5. Choose **Save joined data** to save the output of the join.

The following images show the workflow of the preceding procedure.
Use sample datasets

SageMaker Canvas provides sample datasets addressing unique use cases so you can start building, training, and validating models quickly without writing any code. The use cases associated with these datasets highlight the capabilities of SageMaker Canvas, and you can leverage these datasets to get started with building models. You can find the sample datasets in the **Datasets** page of your SageMaker Canvas application.

**Sample datasets**

The following datasets are the samples that SageMaker Canvas provides by default. These datasets cover use cases such as predicting house prices, loan defaults, and readmission for diabetic patients; forecasting sales; predicting machine failures to streamline predictive maintenance in manufacturing units; and generating supply chain predictions for transportation and logistics. The datasets are stored in the `sample_dataset` folder in the default Amazon S3 bucket that SageMaker creates for your account in a Region.

- **canvas-sample-diabetic-readmission.csv**: This dataset contains historical data including over fifteen features with patient and hospital outcomes. You can use this dataset to predict whether high-risk diabetic patients are likely to get readmitted to the hospital within 30 days of discharge, after 30 days, or not at all. Use the `redadmitted` column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the [SageMaker Canvas workshop page](https://docs.aws.amazon.com/sagemaker/latest/dg/). This dataset was obtained from the [UCI Machine Learning Repository](https://archive.ics.uci.edu/ml/datasets/diabetes+readmission).

- **canvas-sample-housing.csv**: This dataset contains data on the characteristics tied to a given housing price. You can use this dataset to predict housing prices. Use the `median_house_value` column as the target column, and use the Numeric prediction model type with this dataset. To learn more about building a model with this dataset, see the [SageMaker Canvas workshop page](https://docs.aws.amazon.com/sagemaker/latest/dg/). This is the California housing dataset obtained from the [StatLib repository](https://archive.ics.uci.edu/ml/datasets/housing).

- **canvas-sample-loans.csv**: This dataset contains complete loan data for all loans issued from 2007–2011, including the current loan status and latest payment information. You can use this dataset to predict whether a customer will repay a loan. Use the `loan_status` column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a
model with this dataset, see the SageMaker Canvas workshop page. This data uses the LendingClub data obtained from Kaggle.

- **canvas-sample-maintenance.csv**: This dataset contains data on the characteristics tied to a given maintenance failure type. You can use this dataset to predict which failure will occur in the future. Use the **Failure Type** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This dataset was obtained from the UCI Machine Learning Repository.

- **canvas-sample-shipping-logs.csv**: This dataset contains complete shipping data for all products delivered, including estimated time shipping priority, carrier, and origin. You can use this dataset to predict the estimated time of arrival of the shipment in number of days. Use the **ActualShippingDays** column as the target column, and use the Numeric prediction model type with this dataset. To learn more about how to build a model with this data, see the SageMaker Canvas workshop page. This is a synthetic dataset created by Amazon.

- **canvas-sample-sales-forecasting.csv**: This dataset contains historical time series sales data for retail stores. You can use this dataset to forecast sales for a particular retail store. Use the **sales** column as the target column, and use the Time series forecasting model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This is a synthetic dataset created by Amazon.

**Re-import a deleted sample dataset**

If you no longer wish to use the sample datasets, you can delete them from the Datasets page of your SageMaker Canvas application. However, these datasets are still stored in the Amazon S3 bucket that you specified as the Canvas storage location, so you can always access them later.

If you used the default Amazon S3 bucket, the bucket name follows the pattern sagemaker-{{region}}-{{account ID}}. You can find the sample datasets in the directory path Canvas/sample_dataset.

If you delete a sample dataset from your SageMaker Canvas application and want to access the sample dataset again, use the following procedure.

1. Navigate to the Datasets page in your SageMaker Canvas application.
2. Choose Import data.
3. From the list of Amazon S3 buckets, select the bucket that is your Canvas storage location. If using the default SageMaker-created Amazon S3 bucket, it follows the naming pattern sagemaker-{{region}}-{{account ID}}.
4. Select the Canvas folder.
5. Select the sample_dataset folder, which contains all of the sample datasets for SageMaker Canvas.
6. Select the dataset you want to import, and then choose Import data.

**Build a custom model**

Use Amazon SageMaker Canvas to build a custom model on the dataset that you've imported. Use the model that you've built to make predictions on new data. SageMaker Canvas uses the information in the dataset to build up to 250 models and choose the one that performs the best.

When you begin building a model, Canvas automatically recommends one or more model types. Model types fall into one of the following categories:

- **Numeric prediction** – This is known as regression in machine learning. Use the numeric prediction model type when you want to make predictions for numeric data. For example, you might want to predict the price of houses based on features such as the house's square footage.
• **Categorical prediction** – This is known as *classification* in machine learning. When you want to categorize data into groups, use the categorical prediction model types:
  
  • **2 category prediction** – Use the 2 category prediction model type (also known as *binary classification* in machine learning) when you have two categories that you want to predict for your data. For example, you might want to determine whether a customer is likely to churn.
  
  • **3+ category prediction** – Use the 3+ category prediction model type (also known as *multi-class classification* in machine learning) when you have three or more categories that you want to predict for your data. For example, you might want to predict a customer’s loan status based on features such as previous payments.
  
  • **Time series forecasting** – Use time series forecasts when you want to make predictions over a period of time. For example, you might want to predict the number of items you’ll sell in the next quarter. For information about time series forecasts, see [Time Series Forecasts in Amazon SageMaker Canvas](https://docs.aws.amazon.com/sagemaker/latest/dg/time-series-forecasts.html).
  
  • **Image prediction** – Use the single-label image prediction model type (also known as *single-label image classification* in machine learning) when you want to assign labels to images. For example, you might want to classify different types of manufacturing defects in images of your product.
  
  • **Text prediction** – Use the multi-category text prediction model type (also known as *multi-class text classification* in machine learning) when you want to assign labels to passages of text. For example, you might have a dataset of customer reviews for a product, and you want to determine whether customers liked or disliked the product. You might have your model predict whether a given passage of text is Positive, Neutral, or Neutral.

For a table of the supported input data types for each model type, see [Use custom models](#) (p. 427).

For each tabular data model that you build (which includes numeric, categorical, time series forecasting, and text prediction models), you choose the **Target column**. The **Target column** is the column that contains the information that you want to predict. For example, if you’re building a model to predict whether people have cancelled their subscriptions, the **Target column** contains data points that are either a yes or a no about someone’s cancellation status.

For image prediction models, you build the model with a dataset of images that have been assigned labels. For the unlabeled images that you provide, the model predicts a label. For example, if you’re building a model to predict whether an image is a cat or a dog, you provide images labeled as cats or dogs when building the model. Then, the model can accept unlabeled images and predict them as either cats or dogs.

**What happens when you build a model**

To build your model, you can choose either a **Quick build** or a **Standard build**. The **Quick build** has a shorter build time, but the **Standard build** generally has a higher accuracy. The following table outlines the average build times for each model and build type, along with the minimum and maximum number of data points you should have for each build type.

<table>
<thead>
<tr>
<th>Limit</th>
<th>Numeric and categorical prediction</th>
<th>Time series forecasting</th>
<th>Image prediction</th>
<th>Text prediction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quick build time</td>
<td>2-20 minutes</td>
<td>2-20 minutes</td>
<td>15-30 minutes</td>
<td>15-30 minutes</td>
</tr>
<tr>
<td>Standard build time</td>
<td>2-4 hours</td>
<td>2-4 hours</td>
<td>2-5 hours</td>
<td>2-5 hours</td>
</tr>
<tr>
<td>Maximum number of entries</td>
<td>50,000</td>
<td>50,000</td>
<td>5000</td>
<td>7500</td>
</tr>
</tbody>
</table>
If you log out while running a **Quick build**, your build might be interrupted until you log in again. When you log in again, Canvas resumes the **Quick build**.

Canvas predicts values by using the information in the rest of the dataset, depending on the model type:

- **For categorical prediction**, Canvas puts each row into one of the categories listed in the **Target column**.
- **For numeric prediction**, Canvas uses the information in the dataset to predict the numeric values in the **Target column**.
- **For time series forecasting**, Canvas uses historical data to predict values for the **Target column** in the future.
- **For image prediction**, Canvas uses images that have been assigned labels to predict labels for unlabeled images.
- **For text prediction**, Canvas analyzes text data that has been assigned labels to predict labels for passages of unlabeled text.

### Additional features to help you build your model

**Note**

The following features are available for numeric and categorical prediction and time series forecasting models.

Before building your model, you can filter your data or prepare it using advanced transforms. For more information about preparing your data for model building, see [Prepare data with advanced transformations](p. 470).

You can also use visualization and analytics to explore your data and determine which features are best to include in your model. For more information, see [Explore and analyze your data](p. 387).

To learn more about additional features such as previewing your model, validating your dataset, and changing the size of the random sample used to build your model, see [Preview your model](p. 458).

For tabular datasets with multiple columns (such as datasets for building categorical, numeric, or time series forecasting model types), you might have rows with missing data points. While Canvas builds the model, it automatically adds missing values. Canvas uses the values in your dataset to perform a mathematical approximation for the missing values. For the highest model accuracy, we recommend adding in the missing data if you can find it. Note that the missing data feature is not supported for text prediction or image prediction models.

### Get started

To get started with building a custom model, see [Build a model](p. 454) and follow the procedure for the type of model that you want to build.

### Build a model

The following sections show you how to build a model for each of the main types of custom models.

- To build numeric prediction, 2 category prediction, or 3+ category prediction models, see [Build a custom numeric or categorical prediction model](p. 455).
- To build single-label image prediction models, see [Build a custom image prediction model](p. 456).
- To build multi-category text prediction models, see [Build a custom text prediction model](p. 457).
- To get started with time-series forecasting models, see [Time Series Forecasts in Amazon SageMaker Canvas].
Build a custom numeric or categorical prediction model

Numeric and categorical prediction models support both Quick builds and Standard builds.

To build a numeric or categorical prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose My models.
3. Choose New model.
4. In the Create new model dialog box, do the following:
   a. Enter a name in the Model name field.
   b. Select the Predictive analysis problem type.
   c. Choose Create.
5. For Select dataset, select your dataset from the list of datasets. If you haven't already imported your data, choose Import to be directed through the import data workflow.
6. When you're ready to begin building your model, choose Select dataset.
7. On the Build tab, for the Target column dropdown list, select the target for your model that you would like to predict.
8. For Model type, Canvas automatically detects the problem type for you. If you want to change the type, choose Advanced settings and then do the following:
   a. For Model type, select your desired model type.
   b. (Optional) For the Objective metric dropdown menu, select the metric that you want Canvas to optimize while building your model. If you don't select a metric, Canvas chooses one for you by default. For descriptions of the available metrics, see Use advanced metrics in your analyses.
9. Select or deselect columns in your data to include or drop them from your build.
   Note
   If you make batch predictions with your model after building, Canvas adds dropped columns to your prediction results. However, Canvas does not add the dropped columns to your batch predictions for time series models.
10. (Optional) Use the visualization and analytics tools that Canvas provides to visualize your data and determine which features you might want to include in your model. For more information, see Explore and analyze your data.
11. (Optional) Use data transformations to clean, transform, and prepare your data for model building. For more information, see Prepare your data with advanced transformations. You can view and remove your transforms by choosing Model recipe to open the Model recipe side panel.
12. (Optional) For additional features such as previewing the accuracy of your model, validating your dataset, and changing the size of the random sample that Canvas takes from your dataset, see Preview your model (p. 458).
13. After reviewing your data and making any changes to your dataset, choose Quick build or Standard build to begin a build for your model. The following screenshot shows the Build page and the Quick build and Standard build options.
After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it’s ready for analysis and predictions.

**Build a custom image prediction model**

Single-label image prediction models support both **Quick builds** and **Standard builds**.

To build a single-label image prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose **New model**.
4. In the **Create new model** dialog box, do the following:
   a. Enter a name in the **Model name** field.
   b. Select the **Image analysis** problem type.
   c. Choose **Create**.
5. For **Select dataset**, select your dataset from the list of datasets. If you haven't already imported your data, choose **Import** to be directed through the import data workflow.
6. When you’re ready to begin building your model, choose **Select dataset**.
7. On the **Build** tab, you see the **Label distribution** for the images in your dataset. The **Model type** is set to **Single-label image prediction**.
8. On this page, you can preview your images and edit the dataset. If you have any unlabeled images, choose **Edit dataset** and **Assign labels to unlabeled images** (p. 461). You can also perform other tasks when you **Edit an image dataset** (p. 460), such as renaming labels and adding images to the dataset.
9. After reviewing your data and making any changes to your dataset, choose **Quick build** or **Standard build** to begin a build for your model. The following screenshot shows the **Build** page of an image prediction model that is ready to be built.
After your model begins building, you can leave the page. When the model shows as Ready on the My models page, it's ready for analysis and predictions.

Build a custom text prediction model

Multi-category text prediction models support both Quick builds and Standard builds.

To build a text prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose My models.
3. Choose New model.
4. In the Create new model dialog box, do the following:
   a. Enter a name in the Model name field.
   b. Select the Text analysis problem type.
   c. Choose Create.
5. For Select dataset, select your dataset from the list of datasets. If you haven't already imported your data, choose Import to be directed through the import data workflow.
6. When you're ready to begin building your model, choose Select dataset.
7. On the Build tab, for the Target column dropdown list, select the target for your model that you would like to predict. The target column must have a binary or categorical data type, and there must be at least 25 entries (or rows of data) for each unique label in the target column.
8. For Model type, confirm that the model type is automatically set to Multi-category text prediction.
9. For the training column, select your source column of text data. This should be the column containing the text that you want to analyze.
10. Choose Quick build or Standard build to begin building your model. The following screenshot shows the Build page of a text prediction model that is ready to be built.
After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it’s ready for analysis and predictions.

**Preview your model**

**Note**
The following functionalities are only available for custom models built with tabular datasets. Multi-category text prediction models are also excluded.

SageMaker Canvas provides you with tools to preview your model and validate data before you begin building. The following functionalities include previewing the accuracy of your model, validating your dataset to prevent issues while building the model, and changing the size of the random sample for your model.

**Preview a model**

With Amazon SageMaker Canvas, you can get insights from your data before you build a model by choosing **Preview model**. For example, you can see how the data in each column is distributed. For models built using categorical data, you can also choose **Preview model** to generate an **Estimated accuracy** prediction of how well the model might analyze your data. The accuracy of a **Quick build** or a **Standard build** represents how well the model can perform on real data and is generally higher than the **Estimated accuracy**.

Amazon SageMaker Canvas automatically handles missing values in your dataset while it builds the model. It infers the missing values by using adjacent values that are present in the dataset.
Validate data

Before you build your model, SageMaker Canvas checks your dataset for issues that will cause your build to fail. If SageMaker Canvas finds any issues, then it warns you on the Build page before you attempt to build a model.

You can choose Validate data to see a list of the issues with your dataset. You can then use the SageMaker Canvas data preparation features (p. 470), or your own tools, to fix your dataset before starting a build. If you don’t fix the issues with your dataset, then your build fails.

If you make changes to your dataset to fix the issues, you have the option to re-validate your dataset before attempting a build. We recommend that you re-validate your dataset before building.

The following table shows the issues that SageMaker Canvas checks for in your dataset and how to resolve them.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wrong model type for your data</td>
<td>Try another model type or use a different dataset.</td>
</tr>
<tr>
<td>Missing values in your target column</td>
<td>Replace the missing values, drop rows with missing values, or use a different dataset.</td>
</tr>
<tr>
<td>Too many unique labels in your target column</td>
<td>Verify that you’ve used the correct column for your target column, or use a different dataset.</td>
</tr>
<tr>
<td>Too many non-numeric values in your target column</td>
<td>Choose a different target column, select another model type, or use a different dataset.</td>
</tr>
<tr>
<td>One or more column names contain double underscores</td>
<td>Rename the columns to remove any double underscores, and try again.</td>
</tr>
<tr>
<td>None of the rows in your dataset are complete</td>
<td>Replace the missing values, or use a different dataset.</td>
</tr>
<tr>
<td>Too many unique labels for the number of rows in your data</td>
<td>Check that you’re using the right target column, increase the number of rows in your dataset, consolidate similar labels, or use a different dataset.</td>
</tr>
</tbody>
</table>

Random sample

SageMaker Canvas uses the random sampling method to sample your dataset. The random sample method means that each row has an equal chance of being picked for the sample. You can choose a column in the preview to get summary statistics for the random sample, such as the mean and the mode.

By default, SageMaker Canvas uses a random sample size of 20,000 rows from your dataset for datasets with more than 20,000 rows. For datasets smaller than 20,000 rows, the default sample size is the number of rows in your dataset. You can increase or decrease the sample size by choosing Random sample in the Build tab of the SageMaker Canvas application. You can use the slider to select your desired sample size, and then choose Update to change the sample size. The maximum sample size you can choose for a dataset is 40,000 rows, and the minimum sample size is 500 rows. If you choose a large sample size, the dataset preview and summary statistics might take a few moments to reload.

The Build page shows a preview of 100 rows from your dataset. If the sample size is the same size as your dataset, then the preview uses the first 100 rows of your dataset. Otherwise, the preview uses the first 100 rows of the random sample.
Edit an image dataset

In Amazon SageMaker Canvas, you can edit your image datasets and review your labels before building a model. You might want to perform tasks such as assigning labels to unlabeled images or adding more images to the dataset. These tasks can all be done in the Canvas application, providing you with one place to modify your dataset and build a model.

Note
Before building a model, you must assign labels to all images in your dataset. Also, you must have at least 25 images per label and a minimum of two labels. For more information about assigning labels, see the section on this page called Assign labels to unlabeled images. If you can’t determine a label for an image, you should delete it from your dataset. For more information about deleting images, see the section on this page Add or delete images from the dataset (p. 461).

To begin editing your image dataset, you should be on the Build tab while building your single-label image prediction model.

A new page opens that shows the images in your dataset along with their labels. This page categorizes your image dataset into Total images, Labeled images, and Unlabeled images. You can also review the Dataset preparation guide for best practices on building a more accurate image prediction model.

The following screenshot shows the page for editing your image dataset.

From this page, you can do the following actions.

View the properties for each image (label, size, dimensions)

To view an individual image, you can search for it by file name in the search bar. Then, choose the image to open the full view. You can view the image properties and reassign the image's label. Choose Save when you’re done viewing the image.

Add, rename, or delete labels in the dataset

Canvas lists the labels for your dataset in the left navigation pane. You can add new labels to the dataset by entering a label in the Add label text field.

To rename or delete a label from your dataset, choose the More options icon (.), next to the label and select either Rename or Delete. If you rename the label, you can enter the new label name and choose Confirm. If you delete the label, the label is removed from all images in your dataset that have that label. Any images with that label will be unlabeled.
**Assign labels to unlabeled images**

To view the unlabeled images in your dataset, choose **Unlabeled** in the left navigation pane. For each image, select it and open the label titled **Unlabeled** and select a label to assign to the image from the dropdown list. You can also select more than one image and perform this action, and all selected images are assigned the label you chose.

**Reassign labels to images**

You can reassign labels to images by selecting the image (or multiple images at a time) and opening the dropdown titled with the current label. Select your desired label, and the image or images are updated with the new label.

**Sort your images by label**

You can view all the images for a given label by choosing the label in the left navigation pane.

**Add or delete images from the dataset**

You can add more images to your dataset by choosing **Add images** in the top navigation pane. You'll be taken through the workflow to import more images. The images you import are added to your existing dataset.

You can delete images from your dataset by selecting them and then choosing **Delete** in the top navigation pane.

**Note**

After making any changes to your dataset, choose **Save dataset** to make sure that you don’t lose your changes.

**Explore and analyze your data**

**Note**

You can only use SageMaker Canvas visualizations and analytics for models built on tabular datasets. Multi-category text prediction models are also excluded.

In Amazon SageMaker Canvas, you can explore the variables in your dataset using visualizations and analytics. SageMaker Canvas provides you with the ability to create in-application visualizations and analytics. You can use these explorations to uncover relationships between your variables before building your model.

For more information about visualization techniques in Canvas, see [Explore your data using visualization techniques](p. 461).

For more information about analytics in Canvas, see [Explore your data using analytics](p. 468).

**Explore your data using visualization techniques**

**Note**

You can only use SageMaker Canvas visualizations for models built on tabular datasets. Multi-category text prediction models are also excluded.

With Amazon SageMaker Canvas, you can explore and visualize your data to gain advanced insights into your data before building your ML models. You can visualize using scatter plots, bar charts, and box plots, which can help you understand your data and discover the relationships between features that could affect the model accuracy.

In the **Build** tab of the SageMaker Canvas application, choose **Data visualizer** to begin creating your visualizations.
You can change the visualization sample size to adjust the size of the random sample taken from your dataset. A sample size that is too large might affect the performance of your data visualizations, so we recommend that you choose an appropriate sample size. To change the sample size, use the following procedure.

1. Choose **Visualization sample**.

2. Use the slider to select your desired sample size.

3. Choose **Update** to confirm the change to your sample size.

**Note**

Certain visualization techniques require columns of a specific data type. For example, you can only use numeric columns for the x and y-axes of scatter plots.

**Scatter plot**

To create a scatter plot with your dataset, choose **Scatter plot** in the **Visualization** panel. Then, you can choose the features you want to plot on the x and y-axes from the **Columns** section. You can drag and drop the columns onto the axes, or once an axis has been dropped, you can choose a column from the list of supported columns.

You can use **Color by** to color the data points on the plot with a third feature. You can also use **Group by** to group the data into separate plots based on a fourth feature.

The following image shows a scatter plot that uses **Color by** and **Group by**. In this example, each data point is colored by the **MaritalStatus** feature, and grouping by the **Department** feature results in a scatter plot for the data points of each department.
Use custom models

Department...  Distance...
Education  Education...
Employment...  Employment...
Environment...  Gender
Bar chart

To create a bar chart with your dataset, choose Bar chart in the Visualization panel. Then, you can choose the features you want to plot on the x and y-axes from the Columns section. You can drag and drop the columns onto the axes, or once an axis has been dropped, you can choose a column from the list of supported columns.

You can use Group by to group the bar chart by a third feature. You can use Stack by to vertically shade each bar based on the unique values of a fourth feature.

The following image shows a bar chart that uses Group by and Stack by. In this example, the bar chart is grouped by the MaritalStatus feature and stacked by the JobLevel feature. For each JobRole on the x axis, there is a separate bar for the unique categories in the MaritalStatus feature, and every bar is vertically stacked by the JobLevel feature.

Explore your data using analytics

**Note**
You can only use SageMaker Canvas analytics for models built on tabular datasets. Multicategory text prediction models are also excluded.

With analytics in Amazon SageMaker Canvas, you can explore your dataset and gain insight on all of your variables before building a model. You can determine the relationships between features in your dataset using correlation matrices. You can use this technique to summarize your dataset into a matrix that shows the correlations between two or more values. This helps you identify and visualize patterns in a given dataset for advanced data analysis.

The matrix shows the correlation between each feature as positive, negative, or neutral. You might want to include features that have a high correlation with each other when building your model. Features that have little to no correlation might be irrelevant to your model, and you can drop those features when building your model.

To get started with correlation matrices in SageMaker Canvas, see the following section.

**Create a correlation matrix**

You can create a correlation matrix when you are preparing to build a model in the Build tab of the SageMaker Canvas application.

For instructions on how to begin creating a model, see [Build a model](p. 454).

After you’ve started preparing a model in the SageMaker Canvas application, do the following:

1. In the Build tab, choose Data visualizer.
2. Choose Analytics.
3. Choose Correlation matrix.

You should see a visualization similar to the following screenshot, which shows up to 15 columns of the dataset organized into a correlation matrix.

![Correlation Matrix](image)

After you’ve created the correlation matrix, you can customize it by doing the following:

1. Choose your columns

For Columns, you can select the columns that you want to include in the matrix. You can compare up to 15 columns from your dataset.
Note
You can use numeric, categorical, or binary column types for a correlation matrix. The correlation matrix doesn't support datetime or text data column types.

To add or remove columns from the correlation matrix, select and deselect columns from the Columns panel. You can also drag and drop columns from the panel directly onto the matrix. If your dataset has a lot of columns, you can search for the columns you want in the Search columns bar.

To filter the columns by data type, choose the dropdown menu and select All, Numeric, or Categorical. Selecting All shows you all of the columns from your dataset, whereas the Numeric and Categorical filters only show you the numeric or categorical columns in your dataset. Note that binary column types are included in the numeric or categorical filters.

For the best data insights, include your target column in the correlation matrix. When you include your target column in the correlation matrix, it appears as the last feature on the matrix with a target symbol.

2. Choose your correlation type

SageMaker Canvas supports different correlation types, or methods for calculating the correlation between your columns.

To change the correlation type, use the Columns filter mentioned in the preceding section to filter for your desired column type and columns. You should see the Correlation type in the side panel. For numeric comparisons, you have the option to select either Pearson or Spearman. For categorical comparisons, the correlation type is set as MI. For categorical and mixed comparisons, the correlation type is set as Spearman & MI.

For matrices that only compare numeric columns, the correlation type is either Pearson or Spearman. The Pearson measure evaluates the linear relationship between two continuous variables. The Spearman measure evaluates the monotonic relationship between two variables. For both Pearson and Spearman, the scale of correlation ranges from -1 to 1, with either end of the scale indicating a perfect correlation (a direct 1:1 relationship) and 0 indicating no correlation. You might want to select Pearson if your data has more linear relationships (as revealed by a scatter plot visualization). If your data is not linear, or contains a mixture of linear and monotonic relationships, then you might want to select Spearman.

For matrices that only compare categorical columns, the correlation type is set to Mutual Information Classification (MI). The MI value is a measure of the mutual dependence between two random variables. The MI measure is on a scale of 0 to 1, with 0 indicating no correlation and 1 indicating a perfect correlation.

For matrices that compare a mix of numeric and categorical columns, the correlation type Spearman & MI is a combination of the Spearman and MI correlation types. For correlations between two numeric columns, the matrix shows the Spearman value. For correlations between a numeric and categorical column or two categorical columns, the matrix shows the MI value.

Lastly, remember that correlation does not necessarily indicate causation. A strong correlation value only indicates that there is a relationship between two variables, but the variables might not have a causal relationship. Carefully review your columns of interest to avoid bias when building your model.

3. Filter your correlations

In the side panel, you can use the Filter correlations feature to filter for the range of correlation values that you want to include in the matrix. For example, if you want to filter for features that only have positive or neutral correlation, you can set the Min to 0 and the Max to 1 (valid values are -1 to 1).

For Spearman and Pearson comparisons, you can set the Filter correlations range anywhere from -1 to 1, with 0 meaning that there is no correlation. -1 and 1 mean that the variables have a strong negative or positive correlation, respectively.
For MI comparisons, the correlation range only goes from 0 to 1, with 0 meaning that there is no correlation and 1 meaning that the variables have a strong correlation, either positive or negative.

Each feature has a perfect correlation (1) with itself. Therefore, you might notice that the top row of the correlation matrix is always 1. If you want to exclude these values, you can use the filter to set the Max less than 1.

Keep in mind that if your matrix compares a mix of numeric and categorical columns and uses the Spearman & MI correlation type, then the *categorical x numeric* and *categorical x categorical* correlations (which use the MI measure) are on a scale of 0 to 1, whereas the *numeric x numeric* correlations (which use the Spearman measure) are on a scale of -1 to 1. Review your correlations of interest carefully to ensure that you know the correlation type being used to calculate each value.

4. Choose the visualization method

In the side panel, you can use Visualize by to change the visualization method of the matrix. Choose the Numeric visualization method to show the correlation (Pearson, Spearman, or MI) value, whereas choosing the Size visualization method visualizes the correlation with differently sized and colored dots. If you choose Size, you can hover over a specific dot on the matrix to see the actual correlation value.

5. Choose a color palette

In the side panel, you can use Color selection to change the color palette used for the scale of negative to positive correlation in the matrix. Select one of the alternative color palettes to change the colors used in the matrix.

Prepare data with advanced transformations

Note

You can only use advanced transformations for models built on tabular datasets. Multi-category text prediction models are also excluded.

Your machine learning dataset might require data preparation before you build your model. You might want to clean your data due to various issues, which might include missing values or outliers, and perform feature engineering to improve the accuracy of your model. Amazon SageMaker Canvas provides ML data transforms with which you can clean, transform, and prepare your data for model building. You can use these transforms on your datasets without any code. SageMaker Canvas adds the transforms you use to the Model recipe, which is a record of the data preparation done on your data before building the model. Any data transforms you use only modify the input data for model building and do not modify your original data source.

The following transforms are available in SageMaker Canvas for you to prepare your data for building.

Note

The preview of your dataset shows the first 100 rows of the dataset. If your dataset has more than 20,000 rows, Canvas takes a random sample of 20,000 rows and previews the first 100 rows from that sample. You can only search for and specify values from the previewed rows, and the filter functionality only filters the previewed rows and not the entire dataset.

Drop columns

You can exclude a column from your model build by dropping it in the Build tab of the SageMaker Canvas application. Deselect the column you want to drop, and it isn't included when building the model.

Note

If you drop columns and then make batch predictions (p. 498) with your model, SageMaker Canvas adds the dropped columns back to the output dataset available for you to download. However, SageMaker Canvas does not add the dropped columns back for time series models.
Filter rows

The filter functionality filters the previewed rows (the first 100 rows of your dataset) according to conditions that you specify. Filtering rows creates a temporary preview of the data and does not impact the model building. You can filter to preview rows that have missing values, contain outliers, or meet custom conditions in a column you choose.

Filter rows by missing values

Missing values are a common occurrence in machine learning datasets. If you have rows with null or empty values in certain columns, you might want to filter for and preview those rows.

To filter missing values from your previewed data, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Filter by rows (Y).
2. Choose the Column you want to check for missing values.
3. For the Operation, choose Is missing.

SageMaker Canvas filters for rows that contain missing values in the Column you selected and provides a preview of the filtered rows.

Filter rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect and filter rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To filter for outliers in your data, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Filter by rows (Y).
2. Choose the Column you want to check for outliers.
3. For the Operation, choose Is outlier.
4. Set the Outlier range to either Standard deviation or Custom range.
5. If you choose Standard deviation, specify a SD (standard deviation) value from 1–3. If you choose Custom range, select either Percentile or Number, and then specify the Min and Max values.

The Standard deviation option detects and filters for outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to
be considered an outlier. For example, if you specify 3 for SD, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The *Custom range* option detects and filters for outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. You can set the *Type* of the range to either *Percentile* or *Number*. If you choose *Percentile*, the *Min* and *Max* values should be the minimum and maximum of the percentile range (0-100) that you want to allow. If you choose *Number*, the *Min* and *Max* values should be the minimum and maximum numeric values that you want to filter in the data.

Filter rows by custom values

You can filter for rows with values that meet custom conditions. For example, you might want to preview rows that have a price value greater than 100 before removing them. With this functionality, you can filter rows that exceed the threshold you set and preview the filtered data.

To use the custom filter functionality, do the following.

1. In the *Build* tab of the SageMaker Canvas application, choose *Filter by rows* (Y).
2. Choose the *Column* you want to check.
3. Select the type of *Operation* you want to use, and then specify the values for the selected condition.

For the *Operation*, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create a `is greater` operation for a column containing text values.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Supported data type</th>
<th>Supported feature type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is equal to</td>
<td>Numeric, Text</td>
<td>Binary, Categorical</td>
<td>Filters rows where the value in Column equals the values you specify.</td>
</tr>
<tr>
<td>Is not equal to</td>
<td>Numeric, Text</td>
<td>Binary, Categorical</td>
<td>Filters rows where the value in Column doesn't equal the values you specify.</td>
</tr>
<tr>
<td>Is less than</td>
<td>Numeric</td>
<td>N/A</td>
<td>Filters rows where the value in Column is less than the value you specify.</td>
</tr>
<tr>
<td>Is less than or equal to</td>
<td>Numeric</td>
<td>N/A</td>
<td>Filters rows where the value in Column is less than or equal to the value you specify.</td>
</tr>
</tbody>
</table>
### Functions and operators

You can use mathematical functions and operators to explore and distribute your data. You can use the SageMaker Canvas supported functions or create your own formula with your existing data and create a new column with the result of the formula. For example, you can add the corresponding values of two columns and save the result to a new column.

You can nest statements to create more complex functions. The following are some examples of nested functions that you might use.

- To calculate BMI, you could use the function `weight / (height ^ 2)`.
- To classify ages, you could use the function `Case(age < 18, 'child', age < 65, 'adult', 'senior')`.

You can specify functions in the data preparation stage before you build your model. To use a function, do the following.
In the Build tab of the SageMaker Canvas app, choose View all and then choose Custom formula to open the Custom formula panel.

In the Custom formula panel, you can choose a Formula to add to your Model Recipe. Each formula is applied to all of the values in the columns you specify. For formulas that accept two or more columns as arguments, use columns with matching data types; otherwise, you will get an error or null values in the new column.

After you've specified a Formula, add a column name in the New Column Name field. SageMaker Canvas uses this name for the new column that is created.

(Optional) Choose Preview to preview your transform.

To add the function to your Model Recipe, choose Add.

SageMaker Canvas saves the result of your function to a new column using the name you specified in New Column Name. You can view or remove functions from the Model Recipe panel.

SageMaker Canvas supports the following operators for functions. You can use either the text format or the in-line format to specify your function.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Supported data types</th>
<th>Text format</th>
<th>In-line format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>Returns the sum of the values</td>
<td>Numeric</td>
<td>Add(sales1, sales2)</td>
<td>sales1 + sales2</td>
</tr>
<tr>
<td>Subtract</td>
<td>Returns the difference between the values</td>
<td>Numeric</td>
<td>Subtract(sales1, sales2)</td>
<td>sales1 - sales2</td>
</tr>
<tr>
<td>Multiply</td>
<td>Returns the product of the values</td>
<td>Numeric</td>
<td>Multiply(sales1, sales2)</td>
<td>sales1 * sales2</td>
</tr>
<tr>
<td>Divide</td>
<td>Returns the quotient of the values</td>
<td>Numeric</td>
<td>Divide(sales1, sales2)</td>
<td>sales1 / sales2</td>
</tr>
<tr>
<td>Mod</td>
<td>Returns the result of the modulo operator (the remainder after dividing the two values)</td>
<td>Numeric</td>
<td>Mod(sales1, sales2)</td>
<td>sales1 % sales2</td>
</tr>
<tr>
<td>Abs</td>
<td>Returns the absolute value of the value</td>
<td>Numeric</td>
<td>Abs(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Negate</td>
<td>Returns the negative of the value</td>
<td>Numeric</td>
<td>Negate(c1)</td>
<td>-c1</td>
</tr>
<tr>
<td>Exp</td>
<td>Returns e (Euler's number) raised to the power of the value</td>
<td>Numeric</td>
<td>Exp(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Log</td>
<td>Returns the logarithm (base 10) of the value</td>
<td>Numeric</td>
<td>Log(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Ln</td>
<td>Returns the natural logarithm (base e) of the value</td>
<td>Numeric</td>
<td>Ln(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Pow</td>
<td>Returns the value raised to a power</td>
<td>Numeric</td>
<td>Pow(sales1, 2)</td>
<td>sales1 ^ 2</td>
</tr>
<tr>
<td>If</td>
<td>Returns a true or false label based on a condition you specify</td>
<td>Boolean, Numeric, Text</td>
<td>If(sales1&gt;7000, 'truelabel', 'falselabel')</td>
<td>N/A</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
<td>Supported data types</td>
<td>Text format</td>
<td>In-line format</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>----------------------</td>
<td>-------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Or</td>
<td>Returns a boolean value of whether one of the specified values/conditions is true or not</td>
<td>Boolean</td>
<td>Or(fullprice, discount)</td>
<td>fullprice</td>
</tr>
<tr>
<td>And</td>
<td>Returns a boolean value of whether two of the specified values/conditions are true or not</td>
<td>Boolean</td>
<td>And(sales1,sales2)</td>
<td>sales1 &amp;&amp; sales2</td>
</tr>
<tr>
<td>Not</td>
<td>Returns a boolean value that is the opposite of the specified value/conditions</td>
<td>Boolean</td>
<td>Not(sales1)</td>
<td>!sales1</td>
</tr>
<tr>
<td>Case</td>
<td>Returns a boolean value based on conditional statements (returns c1 if cond1 is true, returns c2 if cond2 is true, else returns c3)</td>
<td>Boolean, Numeric, Text</td>
<td>Case(cond1, c1, cond2, c2, c3)</td>
<td>N/A</td>
</tr>
<tr>
<td>Equal</td>
<td>Returns a boolean value of whether two values are equal</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 = c2 c1 == c2</td>
</tr>
<tr>
<td>Not equal</td>
<td>Returns a boolean value of whether two values are not equal</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 != c2</td>
</tr>
<tr>
<td>Less than</td>
<td>Returns a boolean value of whether c1 is less than c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &lt; c2</td>
</tr>
<tr>
<td>Greater than</td>
<td>Returns a boolean value of whether c1 is greater than c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &gt; c2</td>
</tr>
<tr>
<td>Less than or equal</td>
<td>Returns a boolean value of whether c1 is less than or equal to c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &lt;= c2</td>
</tr>
<tr>
<td>Greater than or equal</td>
<td>Returns a boolean value of whether c1 is greater than or equal to c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &gt;= c2</td>
</tr>
</tbody>
</table>

SageMaker Canvas also supports aggregate operators, which can perform operations such as calculating the sum of all the values or finding the minimum value in a column. You can use aggregate operators in combination with standard operators in your functions. For example, to calculate the difference of values from the mean, you could use the function Abs(height – avg(height)). SageMaker Canvas supports the following aggregate operators.

<table>
<thead>
<tr>
<th>Aggregate operator</th>
<th>Description</th>
<th>Format</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>Returns the sum of all the values in a column</td>
<td>sum</td>
<td>sum(c1)</td>
</tr>
<tr>
<td>minimum</td>
<td>Returns the minimum value of a column</td>
<td>min</td>
<td>min(c2)</td>
</tr>
<tr>
<td>Aggregate operator</td>
<td>Description</td>
<td>Format</td>
<td>Example</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------</td>
<td>--------</td>
<td>---------------</td>
</tr>
<tr>
<td>maximum</td>
<td>Returns the maximum value of a column</td>
<td>max</td>
<td>max(c3)</td>
</tr>
<tr>
<td>average</td>
<td>Returns the average value of a column</td>
<td>avg</td>
<td>avg(c4)</td>
</tr>
<tr>
<td>std</td>
<td>Returns the sample standard deviation of a column</td>
<td>std</td>
<td>std(c1)</td>
</tr>
<tr>
<td>stddev</td>
<td>Returns the standard deviation of the values in a column</td>
<td>stddev</td>
<td>stddev(c1)</td>
</tr>
<tr>
<td>variance</td>
<td>Returns the unbiased variance of the values in a column</td>
<td>variance</td>
<td>variance(c1)</td>
</tr>
<tr>
<td>approx_count_distinct</td>
<td>Returns the approximate number of distinct items in a column</td>
<td>approx_count_distinct</td>
<td>approx_count_distinct(c1)</td>
</tr>
<tr>
<td>count</td>
<td>Returns the number of items in a column</td>
<td>count</td>
<td>count(c1)</td>
</tr>
<tr>
<td>first</td>
<td>Returns the first value of a column</td>
<td>first</td>
<td>first(c1)</td>
</tr>
<tr>
<td>last</td>
<td>Returns the last value of a column</td>
<td>last</td>
<td>last(c1)</td>
</tr>
<tr>
<td>stddev_pop</td>
<td>Returns the population standard deviation of a column</td>
<td>stddev_pop</td>
<td>stddev_pop(c1)</td>
</tr>
<tr>
<td>variance_pop</td>
<td>Returns the population variance of the values in a column</td>
<td>variance_pop</td>
<td>variance_pop(c1)</td>
</tr>
</tbody>
</table>

**Manage rows**

With the Manage rows transform, you can perform sort, random shuffle, and remove rows of data from the dataset.

**Sort rows**

To sort the rows in a dataset by a given column, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows** and then choose **Sort rows**.
2. For **Sort Column**, choose the column you want to sort by.
3. For **Sort Order**, choose either **Ascending** or **Descending**.
4. Choose **Add** to add the transform to the **Model recipe**.

**Shuffle rows**

To randomly shuffle the rows in a dataset, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows** and then choose **Shuffle rows**.
2. Choose **Add** to add the transform to the **Model recipe**.
Drop duplicate rows

To remove duplicate rows in a dataset, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Manage rows and then choose Drop duplicate rows.
2. Choose Add to add the transform to the Model recipe.

Remove rows by missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. Use this transform if you want to drop rows with null or empty values in certain columns.

To remove rows that contain missing values in a specified column, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Manage rows.
2. Choose Drop rows by missing values.
3. Choose Add to add the transform to the Model recipe.

Remove rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. With SageMaker Canvas, you can detect and remove rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To remove outliers from your data, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Manage rows.
2. Choose Drop rows by outlier values.
3. Choose the Column you want to check for outliers.
4. Set the Operator to Standard deviation, Custom numeric range, or Custom quantile range.
5. If you choose Standard deviation, specify a Standard deviations (standard deviation) value from 1–3. If you choose Custom numeric range or Custom quantile range, specify the Min and Max values (numbers for numeric ranges, or percentiles between 0–100% for quantile ranges).
6. Choose Add to add the transform to the Model recipe.
The **Standard deviation** option detects and removes outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Custom numeric range** and **Custom quantile range** options detect and remove outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. If you choose a numeric range, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to allow in the data. If you choose a quantile range, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0–100) that you want to allow.

After removing the rows from the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the rows return to your dataset.

### Remove rows by custom values

You can remove rows with values that meet custom conditions. For example, you might want to exclude all of the rows with a price value greater than 100 when building your model. With this transform, you can create a rule that removes all rows that exceed the threshold you set.

To use the custom remove transform, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows**.
2. Choose **Drop rows by formula**.
3. Choose the **Column** you want to check.
4. Select the type of **Operation** you want to use, and then specify the values for the selected condition.
5. Choose **Add** to add the transform to the **Model recipe**.

For the **Operation**, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create an operation for a column containing text values.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Supported data type</th>
<th>Supported feature type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is equal to</td>
<td>Numeric, Text</td>
<td>Binary, Categorical</td>
<td>Removes rows where the value in <strong>Column</strong> equals the values you specify.</td>
</tr>
<tr>
<td>Operation</td>
<td>Supported data type</td>
<td>Supported feature type</td>
<td>Function</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------</td>
<td>------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>Is not equal to</td>
<td>Numeric, Text</td>
<td>Binary, Categorical</td>
<td>Removes rows where the value in Column doesn’t equal the values you specify.</td>
</tr>
<tr>
<td>Is less than</td>
<td>Numeric</td>
<td>N/A</td>
<td>Removes rows where the value in Column is less than the value you specify.</td>
</tr>
<tr>
<td>Is less than or</td>
<td>Numeric</td>
<td>N/A</td>
<td>Removes rows where the value in Column is less than or equal to the value you specify.</td>
</tr>
<tr>
<td>equal to</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Is greater than</td>
<td>Numeric</td>
<td>N/A</td>
<td>Removes rows where the value in Column is greater than the value you specify.</td>
</tr>
<tr>
<td>Is greater than or</td>
<td>Numeric</td>
<td>N/A</td>
<td>Removes rows where the value in Column is greater than or equal to the value you specify.</td>
</tr>
<tr>
<td>equal to</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Is between</td>
<td>Numeric</td>
<td>N/A</td>
<td>Removes rows where the value in Column is between or equal to two values you specify.</td>
</tr>
<tr>
<td>Contains</td>
<td>Text</td>
<td>Categorical</td>
<td>Removes rows where the value in Column contains a values you specify.</td>
</tr>
<tr>
<td>Starts with</td>
<td>Text</td>
<td>Categorical</td>
<td>Removes rows where the value in Column begins with a value you specify.</td>
</tr>
<tr>
<td>Ends with</td>
<td>Text</td>
<td>Categorical</td>
<td>Removes rows where the value in Column ends with a value you specify.</td>
</tr>
</tbody>
</table>

After removing the rows from the dataset, SageMaker Canvas adds the transform in the Model recipe section. If you remove the transform from the Model recipe section, the rows return to your dataset.
Rename columns

With the rename columns transform, you can rename columns in your data. When you rename a column, SageMaker Canvas changes the column name in the model input.

You can rename a column in your dataset by double-clicking on the column name in the Build tab of the SageMaker Canvas application and entering a new name. Pressing the Enter key submits the change, and clicking anywhere outside the input cancels the change. You can also rename a column by clicking the More options icon (.), located at the end of the row in list view or at the end of the header cell in grid view, and choosing Rename.

Your column name can't be longer than 32 characters or have double underscores (__), and you can't rename a column to the same name as another column. You also can't rename a dropped column.

The following screenshot shows how to rename a column by double-clicking the column name.

When you rename a column, SageMaker Canvas adds the transform in the Model recipe section. If you remove the transform from the Model recipe section, the column reverts to its original name.

Manage columns

With the following transforms, you can change the data type of columns and replace missing values or outliers for specific columns. SageMaker Canvas uses the updated data types or values when building your model but doesn't change your original dataset. Note that if you've dropped a column from your dataset using the Drop columns (p. 470) transform, you can't replace values in that column.

Replace missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. You can choose to drop rows that have missing values, but your model is more accurate if you choose to replace the missing values instead. With this transform, you can replace missing values in numeric columns with the mean or median of the data in a column, or you can also specify a custom value with which to replace missing values. For non-numeric columns, you can replace missing values with the mode (most common value) of the column or a custom value.

Use this transform if you want to replace the null or empty values in certain columns. To replace missing values in a specified column, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Manage columns.
2. Choose Replace missing values.
3. Choose the Column in which you want to replace missing values.
4. Set **Mode** to **Manual** to replace missing values with values that you specify. With the **Automatic (default)** setting, SageMaker Canvas replaces missing values with imputed values that best fit your data. This imputation method is done automatically for each model build, unless you specify the **Manual** mode.

5. Set the **Replace with** value:
   
   - If your column is numeric, then select **Mean**, **Median**, or **Custom. Mean** replaces missing values with the mean for the column, and **Median** replaces missing values with the median for the column. If you choose **Custom**, then you must specify a custom value that you want to use to replace missing values.
   
   - If your column is non-numeric, then select **Mode** or **Custom. Mode** replaces missing values with the mode, or the most common value, for the column. For **Custom**, specify a custom value that you want to use to replace missing values.

6. Choose **Add** to add the transform to the **Model recipe**.

After replacing the missing values in the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the missing values return to the dataset.

---

**Replace outliers**

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect outliers in numeric columns and replace the outliers with values that lie within an accepted range in your data. You can choose to define outliers with either standard deviations or a custom range, and you can replace outliers with the minimum and maximum values in the accepted range.

To replace outliers in your data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage columns**.
2. Choose **Replace outlier values**.
3. Choose the **Column** in which you want to replace outliers.
4. For **Define outliers**, choose **Standard deviation**, **Custom numeric range**, or **Custom quantile range**.
5. If you choose **Standard deviation**, specify a **Standard deviations** (standard deviation) value from 1–3. If you choose **Custom numeric range** or **Custom quantile range**, specify the **Min** and **Max** values (numbers for numeric ranges, or percentiles between 0–100% for quantile ranges).
6. For **Replace with**, select **Min/max range**.
7. Choose **Add** to add the transform to the **Model recipe**.
The **Standard deviation** option detects outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier. SageMaker Canvas replaces outliers with the minimum value or maximum value in the accepted range. For example, if you configure the standard deviations to only include values from 200–300, then SageMaker Canvas changes a value of 198 to 200 (the minimum).

The **Custom numeric range** and **Custom quantile range** options detect outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. If you choose a numeric range, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to allow. SageMaker Canvas replaces any values that fall outside of the minimum and maximum to the minimum and maximum values. For example, if your range only allows values from 1–100, then SageMaker Canvas changes a value of 102 to 100 (the maximum). If you choose a quantile range, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0–100) that you want to allow.

After replacing the values in the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the original values return to the dataset.

**Change data type**

SageMaker Canvas provides you with the ability to change the data type of your columns between numeric, text, and datetime, while also displaying the associated feature type for that data type. A **data type** refers to the format of the data and how it is stored, while the **feature type** refers to the characteristic of the data used in machine learning algorithms, such as binary or categorical. This gives you the flexibility to manually change the type of data in your columns based on the features. The ability to choose the right data type ensures data integrity and accuracy prior to building models. These data types are used when building models.

**Note**

Currently, changing the feature type (for example, from binary to categorical) is not supported.

The following table lists all of the supported data types in Canvas.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>Numeric data represents numerical values</td>
<td>1, 2, 3</td>
</tr>
</tbody>
</table>
### Data type

<table>
<thead>
<tr>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>A, B, C, D</td>
</tr>
<tr>
<td>Text data represents sequences of characters, like names or descriptions</td>
<td>apple, banana, orange</td>
</tr>
<tr>
<td>Datetime</td>
<td>2019-07-01 01:00:00, 2019-07-01 02:00:00, 2019-07-01 03:00:00</td>
</tr>
<tr>
<td>Datetime data represents dates and times in timestamp format</td>
<td></td>
</tr>
</tbody>
</table>

The following table lists all of the supported feature types in Canvas.

<table>
<thead>
<tr>
<th>Feature type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>Binary features represent two possible values</td>
<td>0, 1, 0, 1, 0 (2 distinct values)</td>
</tr>
<tr>
<td></td>
<td>true, false, true (2 distinct values)</td>
<td></td>
</tr>
<tr>
<td>Categorical</td>
<td>Categorical features represent distinct categories or groups</td>
<td>apple, banana, orange, apple (3 distinct values)</td>
</tr>
<tr>
<td></td>
<td>A, B, C, D, E, A, D, C (5 distinct values)</td>
<td></td>
</tr>
</tbody>
</table>

To modify data type of a column in a dataset, do the following.

1. In the **Build** tab of the SageMaker Canvas application, go to the **Column view** or **Grid view** and select the **Data type** dropdown for the specific column.
2. In the **Data type** dropdown, choose the data type to convert to. The following screenshot shows the dropdown menu.
3. For **Column**, choose or verify the column you want to change the data type for.
4. For **New data type**, choose or verify the new data type you want to convert to.
5. If the **New data type** is Datetime or Numeric, choose one of the following options under **Handle invalid values**:

---

483
a. **Replace with empty value** – Invalid values are substituted with an empty value
b. **Delete rows** – Rows with an invalid value are removed from the dataset
c. **Replace with custom value** – Invalid values are substituted with the Custom Value that you specify.

6. Choose **Add** to add the transform to the Model recipe.

The data type for your column should now be updated.

**Prepare time series data**

Use the following functionalities to prepare your time series data for building time series forecasting models.

**Resample time series data**

By resampling time-series data, you can establish regular intervals for the observations in your time series dataset. This is particularly useful when working with time series data containing irregularly spaced observations. For instance, you can use resampling to transform a dataset with observations recorded every one hour, two hour and three hour intervals into a regular one hour interval between observations. Forecasting algorithms require the observations to be taken at regular intervals.

To resample time series data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Time series**.
2. Choose **Resample**.
3. For **Timestamp column**, choose the column you want to apply the transform to. You can only select columns of the **Datetime** type.
4. In the **Frequency settings** section, choose a **Frequency** and **Rate**. **Frequency** is the unit of frequency and **Rate** is the interval of the unit of frequency to be applied to the column. For example, choosing Calendar Day for **Frequency value** and 1 for **Rate** sets the interval to increase every 1 calendar day, such as 2023-03-26 00:00:00, 2023-03-27 00:00:00, 2023-03-28 00:00:00. See the table after this procedure for a complete list of **Frequency value**.
5. Choose **Add** to add the transform to the Model recipe.

The following table lists all of the **Frequency** types you can select when resampling time series data.

<table>
<thead>
<tr>
<th>Frequency</th>

When applying the resampling transform, you can use the **Advanced** option to specify how the resulting values of the rest of the columns (other than the timestamp column) in your dataset are modified. This can be achieved by specifying the resampling methodology, which can either be downsampling or upsampling for both numeric and non-numeric columns.

**Downsampling** increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The values of other columns of the hourly observations are aggregated into a single value using a combination method. The following tables show an example of downsampling time series data by using mean as the combination method. The data is downsampled from every two hours to every hour.

The following table shows the hourly temperature readings over a day before downsampling.

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00 pm</td>
<td>30</td>
</tr>
<tr>
<td>1:00 am</td>
<td>32</td>
</tr>
<tr>
<td>2:00 am</td>
<td>35</td>
</tr>
<tr>
<td>3:00 am</td>
<td>32</td>
</tr>
<tr>
<td>4:00 am</td>
<td>30</td>
</tr>
</tbody>
</table>

The following table shows the temperature readings after downsampling to every two hours.

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00 pm</td>
<td>30</td>
</tr>
<tr>
<td>2:00 am</td>
<td>33.5</td>
</tr>
<tr>
<td>2:00 am</td>
<td>35</td>
</tr>
<tr>
<td>4:00 am</td>
<td>32.5</td>
</tr>
</tbody>
</table>

To downsample time series data, do the following:

1. Expand the **Advanced** section under the **Resample** transform.
2. Choose **Non-numeric combination** to specify the combination method for non-numeric columns. See the table below for a complete list of combination methods.
3. Choose **Numeric combination** to specify the combination method for numeric columns. See the table below for a complete list of combination methods.
If you don’t specify combination methods, the default values are Most Common for **Non-numeric combination** and Mean for **Numeric combination**. The following table lists the methods for numeric and non-numeric combination.

<table>
<thead>
<tr>
<th>Downsampling methodology</th>
<th>Combination method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-numeric combination</td>
<td>Most Common</td>
<td>Aggregate values in the non-numeric column by the most commonly occurring value</td>
</tr>
<tr>
<td>Non-numeric combination</td>
<td>Last</td>
<td>Aggregate values in the non-numeric column by the last value in the column</td>
</tr>
<tr>
<td>Non-numeric combination</td>
<td>First</td>
<td>Aggregate values in the non-numeric column by the first value in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Mean</td>
<td>Aggregate values in the numeric column by the taking the mean of all the values in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Median</td>
<td>Aggregate values in the numeric column by the taking the median of all the values in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Min</td>
<td>Aggregate values in the numeric column by the taking the minimum of all the values in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Max</td>
<td>Aggregate values in the numeric column by the taking the maximum of all the values in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Sum</td>
<td>Aggregate values in the numeric column by adding all the values in the column</td>
</tr>
<tr>
<td>Numeric combination</td>
<td>Quantile</td>
<td>Aggregate values in the numeric column by the taking the quantile of all the values in the column</td>
</tr>
</tbody>
</table>

**Upsampling** reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, the values of other columns of the hourly observations are interpolated from the ones that have been taken every two hours.

To upsample time series data, do the following:

1. Expand the **Advanced** section under the **Resample** transform.
2. Choose **Non-numeric estimation** to specify the estimation method for non-numeric columns. See the table after this procedure for a complete list of methods.
3. Choose **Numeric estimation** to specify the estimation method for numeric columns. See the table below for a complete list of methods.
Use custom models

4. (Optional) Choose **ID Column** to specify the column that has the IDs of the observations of the time series. Specify this option if your dataset has two time series. If you have a column representing only one time series, don’t specify a value for this field. For example, you can have a dataset that has the columns `id` and `purchase`. The `id` column has the following values: [1, 2, 2, 1]. The `purchase` column has the following values: [$2, $3, $4, $1]. Therefore, the dataset has two time series—one time series is 1: [$2, $1], and the other time series is 2: [$3, $4].

If you don’t specify estimation methods, the default values are **Forward Fill** for **Non-numeric estimation** and **Linear** for **Numeric estimation**. The following table lists the methods for estimation.

<table>
<thead>
<tr>
<th>Upsampling methodology</th>
<th>Estimation method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-numeric estimation</td>
<td>Forward Fill</td>
<td>Interpolate values in the non-numeric column by taking the consecutive values after all the values in the column</td>
</tr>
<tr>
<td>Non-numeric estimation</td>
<td>Backward Fill</td>
<td>Interpolate values in the non-numeric column by taking the consecutive values before all the values in the column</td>
</tr>
<tr>
<td>Non-numeric estimation</td>
<td>Keep Missing</td>
<td>Interpolate values in the non-numeric column by showing empty values</td>
</tr>
<tr>
<td>Numeric estimation</td>
<td>Linear, Time, Index, Zero, S-Linear, Nearest, Quadratic, Cubic, Barycentric, Polynomial, Krogh, Piecewise Polynomial, Spline, P-chip, Akima, Cubic Spline, From Derivatives</td>
<td>Interpolate values in the numeric column by using the specified interpolator. For information on interpolation methods, see <code>pandas.DataFrame.interpolate</code> in the pandas documentation.</td>
</tr>
</tbody>
</table>

The following screenshot shows the **Advanced** settings with the fields for downsampling and upsampling filled out.
Use datetime extraction

With the datetime extraction transform, you can extract values from a datetime column to a separate column. For example, if you have a column containing dates of purchases, you can extract the month value to a separate column and use the new column when building your model. You can also extract multiple values to separate columns with a single transform.

Your datetime column must use a supported timestamp format. For a list of the formats that SageMaker Canvas supports, see Time Series Forecasts in Amazon SageMaker Canvas (p. 507). If your dataset does not use one of the supported formats, update your dataset to use a supported timestamp format and re-import it to Amazon SageMaker Canvas before building your model.

To perform a datetime extraction, do the following.
1. In the Build tab of the SageMaker Canvas application, on the transforms bar, choose View all.
2. Choose Extract features.
3. Choose the Timestamp column from which you want to extract values.
4. For Values, select one or more values to extract from the column. The values you can extract from a timestamp column are Year, Month, Day, Hour, Week of year, Day of year, and Quarter.
5. (Optional) Choose Preview to preview the transform results.
6. Choose Add to add the transform to the Model recipe.

SageMaker Canvas creates a new column in the dataset for each of the values you extract. Except for Year values, SageMaker Canvas uses a 0-based encoding for the extracted values. For example, if you extract the Month value, January is extracted as 0, and February is extracted as 1.

You can see the transform listed in the Model recipe section. If you remove the transform from the Model recipe section, the new columns are removed from the dataset.

Evaluate Your Model's Performance in Amazon SageMaker Canvas

After you've built your model, you can evaluate how well your model performed on your data before using it to make predictions. You can use information, such as the model's accuracy when predicting labels and advanced metrics, to determine whether your model can make sufficiently accurate predictions for your data.

The section Evaluate your model's performance (p. 490) describes how to view your model's accuracy score, broken down by model type. For each model, there is an Overview tab, which gives you a general overview of the model's performance, depending on the model type. There is also a Scoring tab, which
shows visualizations that you can use to get more insights into your model's performance beyond the overall accuracy metric.

The Advanced metrics for your model contain information that you can use for a deeper understanding of your model's performance. For information about how to view metrics you can use to quantify your model's accuracy, see Use advanced metrics in your analyses (p. 494).

Evaluate your model's performance

Amazon SageMaker Canvas provides overview and scoring information for the different types of model. Your model's score can help you determine how accurate your model is when it makes predictions. The additional scoring insights can help you quantify the differences between the actual and predicted values.

To view the analysis of your model, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose My models.
3. Choose the model that you built.
4. In the top navigation pane, choose the Analyze tab.
5. Within the Analyze tab, you can view the overview and scoring information for your model.

The following sections describe how to interpret the scoring for each model type.

Evaluate categorical prediction models

The Overview tab shows you the column impact for each column. Column impact is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weights the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the Accuracy score for the model, along with the Optimization metric, which is the metric that you choose to optimize when building the model. In this case, the Optimization metric is F1. You can specify a different optimization metric if you build a new version of your model.

The Scoring tab for a categorical prediction model gives you the ability to visualize all the predictions. Line segments extend from the left of the page, indicating all the predictions the model has made. In the middle of the page, the line segments converge on a perpendicular segment to indicate the proportion of each prediction to a single category. From the predicted category, the segments branch out to the actual category. You can get a visual sense of how accurate the predictions were by following each line segment from the predicted category to the actual category.

The following image gives you an example Scoring section for a 2 category prediction model.
The following image gives you an example **Scoring** section for a 3+ category prediction model.

Evaluate numeric prediction models

The **Overview** tab shows you the column impact for each column. **Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weighs the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the **RMSE** score for the model on the **Overview** tab, which in this case is the **Optimization metric**. The **Optimization metric** is the metric that you choose to optimize when building the model. You can specify a different optimization metric if you build a new version of your model.
The **Scoring** tab for numeric prediction shows a line to indicate the model's predicted value in relation to the data used to make predictions. The values of the numeric prediction are often +/- the RMSE (root mean squared error) value. The value that the model predicts is often within the range of the RMSE. The width of the purple band around the line indicates the RMSE range. The predicted values often fall within the range.

The following image shows the **Scoring** section for numeric prediction.

---

**Evaluate time series forecasting models**

On the **Analyze** page for time series forecasting models, you can see an overview of the model's metrics. You can hover over each metric for more information, or you can see *Use advanced metrics in your analyses (p. 494)*.

In the **Column impact** section, you can see the score for each column. **Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weighs the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the time series metrics scores for the model, along with the **Optimization metric**, which is the metric that you choose to optimize when building the model. In this case, the **Optimization metric** is **RMSE**. You can specify a different optimization metric if you build a new version of your model.
Evaluate image prediction models

The Overview tab shows you the Per label performance, which gives you an overall accuracy score for the images predicted for each label. You can choose a label to see more specific details, such as the Correctly predicted and Incorrectly predicted images for the label.

You can turn on the Heatmap toggle to see a heatmap for each image. The heatmap shows you the areas of interest that have the most impact when your model is making predictions. For more information about heatmaps and how to use them to improve your model, choose the More info icon next to the Heatmap toggle.

The Scoring tab for single-label image prediction models shows you a comparison of what the model predicted as the label versus what the actual label was. You can select up to 10 labels at a time. You can change the labels in the visualization by choosing the labels dropdown menu and selecting or deselecting labels.

You can also view insights for individual labels or groups of labels, such as the three labels with the highest or lowest accuracy, by choosing the View scores for dropdown menu in the Model accuracy insights section.

The following screenshot shows the Scoring information for a single-label image prediction model.

Evaluate text prediction models

The Overview tab shows you the Per label performance, which gives you an overall accuracy score for the passages of text predicted for each label. You can choose a label to see more specific details, such as the Correctly predicted and Incorrectly predicted passages for the label.

The Scoring tab for multi-category text prediction models shows you a comparison of what the model predicted as the label versus what the actual label was.

In the Model accuracy insights section, you can see the Most frequent category, which tells you the category that the model predicted most frequently and how accurate those predictions were. If you
model predicts a label of **Positive** correctly 99% of the time, then you can be fairly confident that your model is good at predicting positive sentiment in text.

The following screenshot shows the **Scoring** information for a multi-category text prediction model.

Use advanced metrics in your analyses

The advanced metrics that SageMaker Canvas shows you depend on whether your model performs numeric, categorical, image, text, or time series forecasting predictions on your data.

**Numeric prediction** refers to the mathematical concept of regression. When your **Target column** has values that can be measured, such as yearly revenue or the number of items sold by a department store, Canvas builds a model on your data using regression.

**Categorical prediction**, such as 2 category prediction or 3 category prediction, refers to the mathematical concept of classification. Categorical prediction can be performed on data that can be put into a category, such as the following:

- The colors on a color wheel
- Instances where the data is either a 0 or 1
- Instances where the data is either a Yes or a No
- A list of responses to a survey question

**Image prediction**, such as single-label image prediction, refers to using computer vision to identify and classify information in images. For example, you can use image prediction to predict whether an image is of a dog or a cat.

**Text prediction**, such as multi-category text prediction, refers to using natural language processing (NLP) to analyze language data. You can use multi-category text prediction on text data to analyze the sentiment of text, or the overall mood of a text, such as **Positive**, **Negative**, **Neutral**, or **Mixed**.

**Time series forecasting** refers to making predictions that vary over time. You can perform time series forecasts on data with timestamps that correlate to a value you want to predict. For example, you can make a time series forecast that takes daily sales data and makes sales predictions for the next month.

SageMaker Canvas uses confusion matrices to help you visualize when a model makes predictions correctly. In a confusion matrix, your results are arranged to compare the predicted values against the actual values. The following example explains how a confusion matrix works for a 2 category prediction model that predicts positive and negative labels:
• True positive – The model correctly predicted positive when the true label was positive.
• True negative – The model correctly predicted negative when the true label was negative.
• False positive – The model incorrectly predicted positive when the true label was negative.
• False negative – The model incorrectly predicted negative when the true label was positive.

The following image is an example of a confusion matrix for 2 categories.

![Confusion Matrix for 2 Categories](image1)

The following image is an example of a confusion matrix for 3+ categories.

![Confusion Matrix for 3+ Categories](image2)

**Metrics for numeric prediction**

The following defines the advanced metrics for numeric prediction in Amazon SageMaker Canvas and gives you information about how you can use them.

• R2 – The percentage of the difference in the target column that can be explained by the input column.
• MAE – Mean absolute error. On average, the prediction for the target column is +/- \{MAE\} from the actual value.
• MAPE – Mean absolute percent error. On average, the prediction for the target column is +/- \{MAPE\}% from the actual value.
• RMSE – Root Mean Square Error. The standard deviation of the errors.

The following image shows a graph of the residuals or errors. The horizontal line indicates an error of 0 or a perfect prediction. The blue dots are the errors. Their distance from the horizontal line indicates the magnitude of the errors.

The following image shows an error density plot.

Metrics for categorical, image, and text prediction

The following defines the advanced metrics for categorical, image, and text prediction in Canvas and gives you information about how you can use them.

• Missing – A missing value contains no content or is non-existent. Missing values are automatically inferred.
• Mismatched – A mismatched value has a different data type from the type specified for its column. SageMaker Canvas categorizes these values as missing and infers values for them.
• Unique – The number and percentage of values that are unique.
• Target correlation – A value between -1 and 1 that represents strength of the linear relationship between a column and the target column. 0 represents no detectable relationship. 1 represents a strong positive relationship. -1 represents a strong negative relationship.
• Column impact – Identifies the relative impact of the column in predicting the target column.

The following is a list of available metrics for 2 category prediction.

• F1 – A balanced measure of accuracy that takes class balance into account.
• Accuracy – The percentage of correct predictions.
• Precision – Of all the times that {category-1} was predicted, the prediction was correct {precision}% of the time.
• Recall – The model correctly predicted {recall}% to be {category-1} when {target_column} was actually {category-1}.
• AUC – A value between 0 and 1 that indicates how well your model is able to separate the categories in your dataset. A value of 1 indicates that it was able to separate the categories perfectly.

The following is a list of available metrics for 3+ category prediction, image prediction, and text prediction.

• F1 – A balanced measure of accuracy that takes class balance into account.
• Accuracy – The percentage of correct predictions.
• Precision – Of all the times that {category-1} was predicted, the prediction was correct {precision}% of the time.
• Recall – The model correctly predicted {recall}% to be {category-1} when {target_column} was actually {category-1}.
• AUC – A value between 0 and 1 that indicates how well your model is able to separate the categories in your dataset. A value of 1 indicates that it was able to separate the categories perfectly.
• Average F1 – The F1 averaged for all categories.
• Average Accuracy – The percentage of correct predictions out of all the predictions that are made.
• Average Precision – The precision averaged for all categories.
• Average Recall – The recall averaged for all categories.
• Average AUC – The AUC averaged for all categories.

**Metrics for time series forecasts**

The following defines the advanced metrics for time series forecasts in Amazon SageMaker Canvas and gives you information about how you can use them.

• Average Weighted Quantile Loss (wQL) – Evaluates the forecast by averaging the accuracy at the P10, P50, and P90 quantiles. A lower value indicates a more accurate model.
• Weighted Absolute Percent Error (WAPE) – The sum of the absolute error normalized by the sum of the absolute target, which measure the overall deviation of forecasted values from observed values. A lower value indicates a more accurate model, where WAPE = 0 is a model with no errors.
• Root Mean Square Error (RMSE) – The square root of the average squared errors. A lower RMSE indicates a more accurate model, where RMSE = 0 is a model with no errors.
• Mean Absolute Percent Error (MAPE) – The percentage error (percent difference of the mean forecasted value versus the actual value) averaged over all time points. A lower value indicates a more accurate model, where MAPE = 0 is a model with no errors.
• Mean Absolute Scaled Error (MASE) – The mean absolute error of the forecast normalized by the mean absolute error of a simple baseline forecasting method. A lower value indicates a more accurate model, where MASE < 1 is estimated to be better than the baseline and MASE > 1 is estimated to be worse than the baseline.
Make predictions for your data

Use the custom model that you’ve built in SageMaker Canvas to make predictions for your data. The following sections show you how to make predictions for numeric and categorical prediction models, image prediction models, and text prediction models. For information about how to make predictions with a time series forecast model, see Make a time series forecast.

Numeric and categorical prediction, image prediction, and text prediction custom models support making the following types of predictions for your data:

- **Single predictions** — A **Single prediction** is when you only need to make one prediction. For example, you have one image or passage of text that you want to classify.
- **Batch predictions** — A **Batch prediction** is when you’d like to make predictions for an entire dataset. For example, you have a CSV file of customer reviews for which you’d like to predict the customer sentiment, or you have a folder of image files that you’d like to classify. You should make predictions with a dataset that matches your input dataset. Canvas provides you with the ability to do manual batch predictions, or you can configure automatic batch predictions that initiate whenever a specified dataset is updated in Canvas.

For each prediction or set of predictions, SageMaker Canvas returns the following:

- The predicted values
- The probability of the predicted value being correct

Get started

Choose one of the following workflows to make predictions with your custom model:

- Make batch predictions (p. 500)
- Make single predictions (p. 498)

After generating predictions with your model, you can also do the following:

- **Update your model by creating a new version.** If you want to try to improve the prediction accuracy of your model, you can build new versions of your model. You can update your data or change any advanced transformations you used, and then you can review and compare the versions of your model to choose the best one.
- **Register a model version in the SageMaker model registry (p. 513).** You can register versions of your model to the SageMaker model registry, which is a feature for tracking and managing the status of model versions and machine learning pipelines. A data scientist or MLOps team user with access to the SageMaker model registry can review your model versions and approve or reject them before deploying them to production.
- **Send your batch predictions to Amazon QuickSight.** In Amazon QuickSight, you can build and publish dashboards with your batch prediction datasets. This can help you analyze and share results generated by your custom model.

Make single predictions

**Note**
This section describes how to get single predictions from your model inside the Canvas application. For information about making real-time invocations in a production environment by deploying your model to an endpoint, see Deploy your models to an endpoint (p. 516).
Make single predictions if you want to get a prediction for a single data point. You can use this feature to get real-time predictions or to experiment with changing individual values to see how they impact the prediction outcome.

Choose one of the following procedures based on your model type.

**Make single predictions with numeric and categorical prediction models**

To make a single prediction for a numeric or categorical prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Single prediction**.
5. For each **Column** field, which represents the columns of your input data, you can change the **Value**. Select the dropdown menu for the **Value** you want to change. For numeric fields, you can enter a new number. For fields with labels, you can select a different label.
6. When you're ready to generate the prediction, in the right **Prediction** pane, choose **Update**.

In the right **Prediction** pane, you'll see the prediction result. You can **Copy** the prediction result chart, or you can also choose **Download** to either download the prediction result chart as an image or to download the values and prediction as a CSV file.

**Make single predictions with image prediction models**

To make a single prediction for a single-label image prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Single prediction**.
5. Choose **Import image**.
6. You'll be prompted to upload an image. You can upload an image from your local computer or from an Amazon S3 bucket.
7. Choose **Import** to import your image and generate the prediction.

In the right **Prediction results** pane, the model lists the possible labels for the image along with a **Confidence** score for each label. For example, the model might predict the label **Sea** for an image, with a confidence score of 96%. The model may have predicted the image as a **Glacier** with only a confidence score of 4%. Therefore, you can determine that your model is fairly confident in predicting images of the sea.

**Make single predictions with text prediction models**

To make a single prediction for a multi-category text prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Single prediction**.
5. For the **Text field**, enter the text for which you'd like to get a prediction.
6. Choose **Generate prediction results** to get your prediction.

In the right **Prediction results** pane, you receive an analysis of your text in addition to a **Confidence** score for each possible label. For example, if you entered a good review for a product, you might get **Positive** with a confidence score of 85%, while the confidence score for **Neutral** might be 10% and the confidence score for **Negative** only 5%.

**Make batch predictions**

Make batch predictions when you have an entire dataset for which you’d like to generate predictions.

There are two types of batch predictions you can make:

- **Manual** batch predictions are when you have a dataset for which you want to make one-time predictions.
- **Automatic** batch predictions are when you set up a configuration that runs a batch prediction whenever a specific dataset is updated. For example, if you’ve configured weekly updates to a SageMaker Canvas dataset of inventory data, you can set up automatic batch predictions that run whenever you update the dataset. After setting up an automated batch predictions workflow, see **Manage automations** (p. 522) for more information about viewing and editing the details of your configuration. For more information about setting up automatic dataset updates, see **Configure automatic updates for a dataset** (p. 439).

**Note**

You can only set up automatic batch predictions for datasets imported through local upload or Amazon S3. Additionally, automatic batch predictions can only run while you’re logged in to the Canvas application. If you log out of Canvas, automatic batch prediction jobs resume when you log back in.

To get started, reviewing the following section for batch prediction dataset requirements, and then choose one of the following manual or automatic batch prediction workflows.

**Batch prediction dataset requirements**

For batch predictions, make sure that your datasets meet the requirements outlined in **Create a dataset** (p. 431).

You might not be able to make predictions on some datasets because they have incompatible schemas. A **schema** is an organizational structure. For a tabular dataset, the schema is the names of the columns and the data type of the data in the columns. An incompatible schema might happen for one of the following reasons:

- The dataset that you're using to make predictions has fewer columns than the dataset that you're using to build the model.
- The data types in the columns you used to build the dataset might be different from the data types in dataset that you're using to make predictions.
- The dataset that you're using to make predictions and the dataset that you've used to build the model have column names that don't match. The column names are case sensitive. Column1 is not the same as column1.

To ensure that you can successfully generate batch predictions, match the schema of your batch predictions dataset to the dataset you used to train the model.

**Note**

For batch predictions, if you dropped any columns when building your model, Canvas adds the dropped columns back to the prediction results. However, Canvas does not add the dropped columns to your batch predictions for time series models.
Make manual batch predictions

Choose one of the following procedures to make manual batch predictions based on your model type.

Make manual batch predictions with numeric and categorical prediction models

To make manual batch predictions for a numeric or categorical prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Batch prediction**.
5. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you'll be directed through the import data workflow.
6. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (†), you can choose **Preview** to preview the output data. You can see the input data matched to the prediction and the probability that the prediction is correct. Then, you can choose **Download prediction** to download the results as a file.

Make manual batch predictions with image prediction models

To make manual batch predictions for a single-label image prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Batch prediction**.
5. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you'll be directed through the import data workflow.
6. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (†), you can choose **View prediction results** to see the output data. You can see the images along with their predicted labels and confidence scores. Then, you can choose **Download prediction** to download the results as a CSV or a ZIP file.

Make manual batch predictions with text prediction models

To make manual batch predictions for a multi-category text prediction model, do the following:

1. In the left navigation pane of the Canvas application, choose **My models**.
2. On the **My models** page, choose your model.
3. After opening your model, choose the **Predict** tab.
4. On the **Run predictions** page, choose **Batch prediction**.
5. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you'll be directed through the import data workflow. The dataset you choose must have the same source column as the dataset with which you built the model.
6. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (†), you can choose **Preview** to see the output data. You can see the images along with their predicted labels and confidence scores. Then, you can choose **Download prediction** to download the results.

**Make automatic batch predictions**

To set up a schedule for automatic batch predictions, do the following:

1. In the left navigation pane of Canvas, choose **My models**.
2. Choose your model.
3. Choose the **Predict** tab.
4. Choose **Batch prediction**.
5. For **Generate predictions**, choose **Automatic**.
6. The **Automatic batch predictions** dialog box pops up. Choose **Select dataset** and choose the dataset for which you want to automate predictions. Note that you can only select a dataset that was imported through local upload or Amazon S3.
7. After selecting a dataset, choose **Set up**.

Canvas runs a batch predictions job for the dataset after you set up the configuration. Then, every time you update a dataset (p. 438), either manually or automatically, another batch predictions job runs.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (†), you can choose **Preview** to preview the output data. You can see the input data matched to the prediction and the probability that the prediction is correct. Then, you can choose **Download** to download the results.

The following sections describe how to view, update, and delete your automatic batch prediction configuration through the **Datasets** page in the Canvas application. You can only set up a maximum of 20 automatic configurations in Canvas. For more information about viewing your automated batch predictions job history or making changes to your automatic configuration through the **Automations** page, see **Manage automations** (p. 522).

**View your automatic batch prediction jobs**

To view your job history for your automatic batch predictions, go to the **Predict** tab of your model.

Each automatic batch prediction job shows up in the **Predict** tab of your model. Under **Predictions**, you can see the **All jobs** tab and the **Configuration** tabs:

- **All jobs** – In this tab, you can see all of the batch prediction jobs for this model. You can filter the jobs by configuration name. For each job, you can see fields such as the **Input dataset**, which includes the version of the dataset, and the **Prediction type**, such as whether the predictions were automatic or manual. If you choose the **More options** icon (†), you can choose **View prediction** or **Download prediction**.

- **Configuration** – In this tab, you can see all of the automatic batch prediction configurations you've created for this model. For each configuration, you can see fields such as the timestamp for when it was **Created**, the **Input dataset** it tracks for updates, and the **Next job scheduled**. If you choose the
More options icon (†), you can choose View all jobs to see the job history and in progress jobs for the configuration.

Edit your automatic batch prediction configuration

You might want to make changes to your auto update configuration for a dataset, such as changing the frequency of the updates. You might also want to turn off your automatic update configuration to pause the updates to your dataset.

When you edit a batch prediction configuration, you can change the target dataset but not the frequency (since automatic batch predictions occur whenever the dataset is updated).

To edit your auto update configuration, do the following:

1. Go to the Predict tab of your model.
2. Under Predictions, choose the Configuration tab.
3. Find your configuration and choose the More options icon (†).
4. From the dropdown menu, choose Update configuration.
5. The Automate batch prediction dialog box opens. You can select another dataset and choose Set up to save your changes.

Your automatic batch predictions configuration is now updated.

To pause your automatic batch predictions, turn off your automatic configuration by doing the following:

1. Go to the Predict tab of your model.
2. Under Predictions, choose the Configuration tab.
3. Find your configuration from the list and turn off the Auto update toggle.

Automatic batch predictions are now paused. You can turn the toggle back on at any time to resume the update schedule.

Delete your automatic batch prediction configuration

To learn how to delete your automatic batch prediction configuration, see Delete an automatic configuration (p. 524).

You can also delete your configuration by doing the following:

1. Go to the Predict tab of your model.
2. Under Predictions, choose the Configuration tab.
3. Find your configuration from the list and choose the More options icon (†).
4. From the dropdown menu, choose Delete configuration.

Your configuration should now be deleted.

Send predictions to Amazon QuickSight

Note

You can send batch predictions to Amazon QuickSight for numeric and categorical prediction and time series forecasting models. You can also send predictions generated with BYOM models. Single-label image prediction and multi-category text prediction models are excluded.
Once you generate batch predictions with custom tabular models in SageMaker Canvas, you can send those predictions as CSV files to Amazon QuickSight, which is a business intelligence (BI) service to build and publish predictive dashboards.

For example, if you built a 2 category prediction model to determine whether a customer will churn, you can create a visual, predictive dashboard in QuickSight to show the percentage of customers that are expected to churn. To learn more about Amazon QuickSight, see the Amazon QuickSight User Guide.

The following sections show you how to send your batch predictions to QuickSight for analysis.

**Before you begin**

Your user must have the necessary AWS Identity and Access Management (IAM) permissions to send your predictions to QuickSight. Your administrator can set up the IAM permissions for your user. For more information, see [Grant Your Users Permissions to Send Predictions to Amazon QuickSight](p. 401).

Your QuickSight account must contain the default namespace, which is set up when you first create your QuickSight account. Contact your administrator to help you get access to QuickSight. For more information, see [Setting up for Amazon QuickSight](in the Amazon QuickSight User Guide).

Your QuickSight account must be created in the same Region as your Canvas application. If your QuickSight account's home Region differs from your Canvas application's Region, you must either close and recreate your QuickSight account, or set up a Canvas application in the same Region as your QuickSight account. You can check your QuickSight home Region by doing the following (assuming you already have a QuickSight account):

1. Open your QuickSight console.
2. When the page loads, your QuickSight home Region is appended to the URL in the following format: https://<your-home-region>.quicksight.aws.amazon.com/.

You must know the usernames of the QuickSight users to whom you want to send your predictions. You can send predictions to yourself or other users who have the right permissions. Any users to whom you send predictions must be in the default namespace of your QuickSight account and have the Author or Admin role in QuickSight.

Additionally, QuickSight must have access to the SageMaker default Amazon S3 bucket for your Domain, which is named with the following format: sagemaker-{REGION}-{ACCOUNT_ID}. The Region should be the same as your QuickSight account's home Region and your Canvas application's Region. To learn how to give QuickSight access to the batch predictions stored in your Amazon S3 bucket, see the topic I can't connect to Amazon S3 in the Amazon QuickSight User Guide.

**Supported data formats**

Before sending your predictions, check that the data format of your batch predictions is compatible with QuickSight.

- To learn more about the accepted data formats for timeseries data, see [Supported date formats](in the Amazon QuickSight User Guide).
- To learn more about data values that might prevent you from sending to QuickSight, see [Unsupported values in data](in the Amazon QuickSight User Guide).

Also note that Amazon QuickSight uses the character " as a text qualifier, so if your Canvas data contains any " characters, make sure that you close all matching quotes. Any mismatching quotes can cause issues with sending your dataset to QuickSight.

**Send your batch predictions to QuickSight**

Use the following procedure to send your predictions to QuickSight:
1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. On the **My models** page, choose your model.
4. Choose the **Predict** tab.
5. Under **Predictions**, select the dataset (or datasets) of batch predictions that you'd like to share. You can share up to 5 datasets of batch predictions at a time.
6. After you select your dataset, choose **Send to Amazon QuickSight**.

**Note**
The **Send to Amazon QuickSight** button doesn’t activate unless you select one or more datasets.

Alternatively, you can preview your predictions by choosing the **More options** icon ( ) and then **View prediction results**. From the dataset preview, you can choose **Send to Amazon QuickSight**. The following screenshot shows you the **Send to Amazon QuickSight** button in a dataset preview.

7. In the **Send to Amazon QuickSight** dialog box, do the following:
   a. For **QuickSight users**, enter the name of the QuickSight users to whom you want to send your predictions. If you want to send them to yourself, enter your own username. You can only send predictions to users in the default namespace of the QuickSight account, and the user must have the **Author** or **Admin** role in QuickSight.
   b. Choose **Send**.

The following screenshot shows the **Send to Amazon QuickSight** dialog box:
After you send your batch predictions, the **QuickSight** field for the datasets you sent shows as Sent. In the confirmation box that confirms your predictions were sent, you can choose **Open Amazon QuickSight** to open your QuickSight application. If you're done using Canvas, you should **log out** of the Canvas application.

The QuickSight users that you've sent datasets to can open their QuickSight application and view the Canvas datasets that have been shared with them. Then, they can create predictive dashboards with the data. For more information, see [Getting started with Amazon QuickSight data analysis](https://docs.aws.amazon.com/quicksight/latest/userguide/qs-data-analysis-getting-started.html) in the *Amazon QuickSight User Guide*.

By default, all of the users to whom you send predictions have owner permissions for the dataset in QuickSight. Owners are able to create analyses, refresh, edit, delete, and re-share datasets. The changes that owners make to a dataset change the dataset for all users with access. To change the permissions, go to the dataset in QuickSight and manage its permissions. For more information, see [Viewing and editing the permissions users that a dataset is shared with](https://docs.aws.amazon.com/quicksight/latest/userguide/qs-data-sharing-permissions.html) in the *Amazon QuickSight User Guide*.

### Send to Amazon QuickSight

Send your model to Amazon QuickSight

If you use Amazon QuickSight and want to leverage SageMaker Canvas in your QuickSight visualizations, you can build an Amazon SageMaker Canvas model and use it as a **predictive field** in your QuickSight dataset. A **predictive field** is a field in your QuickSight dataset that can make predictions for a given column in your dataset, similar to how Canvas users make single or batch predictions with a model. To learn more about how to integrate Canvas predictive abilities into your Amazon QuickSight datasets, see [SageMaker Canvas integration](https://docs.aws.amazon.com/quicksight/latest/userguide/qs-data-sharing-permissions.html) in the *Amazon QuickSight User Guide*.

The following steps explain how you can add a predictive field to your QuickSight dataset using a Canvas model:

1. Open the Canvas application and build a model with your dataset.
2. After building the model in Canvas, send the model to QuickSight. A schema file automatically downloads to your local machine when you send the model to QuickSight. You upload this schema file to QuickSight in the next step.
3. Open QuickSight and choose a dataset with the same schema as the dataset you used to build your model. Add a predictive field to the dataset and do the following:
   a. Specify the model sent from Canvas.
   b. Upload the schema file that was downloaded in Step 2.
4. Save and publish your changes, and then generate predictions for the new dataset. QuickSight uses the model to fill in the target column with predictions.

In order to send a model from Canvas to QuickSight, you must meet the following prerequisites:

- You must have both Canvas and QuickSight set up. Your QuickSight account must be created in the same AWS Region as your Canvas application. If your QuickSight account’s home Region differs from your Canvas application’s Region, you must either close and recreate your QuickSight account, or set up a Canvas application in the same Region as your QuickSight account. Your QuickSight account must also contain the default namespace, which you set up when you first create your QuickSight account. Contact your administrator to help you get access to QuickSight. For more information, see Setting up for Amazon QuickSight in the Amazon QuickSight User Guide.
- Your user must have the necessary AWS Identity and Access Management (IAM) permissions to send your predictions to QuickSight. Your administrator can set up the IAM permissions for your user. For more information, see Grant Your Users Permissions to Send Predictions to Amazon QuickSight.
- QuickSight must have access to the Amazon S3 bucket that you’ve specified for Canvas application storage. For more information, see Configure your Amazon S3 storage (p. 382).

**Time Series Forecasts in Amazon SageMaker Canvas**

**Note**
Time series forecasting models are only supported for tabular datasets.

Amazon SageMaker Canvas gives you the ability to use machine learning time series forecasts. Time series forecasts give you the ability to make predictions that can vary with time.

You can make a time series forecast for the following examples:

- Forecasting your inventory in the coming months.
- The number of items sold in the next four months.
- The effect of reducing the price on sales during the holiday season.
- Item inventory in the next 12 months.
- The number of customers entering a store in the next several hours.
- Forecasting how a 10% reduction in the price of a product affects sales over a time period.

To make a time series forecast, your dataset must have the following:

- A timestamp column with all values having the `datetime` type.
- A target column that has the values that you’re using to forecast future values.

The `datetime` values in the timestamp column must use one of the following formats:

- YYYY-MM-DD HH:MM:SS
- YYYY-MM-DDTHH:MM:SSZ
- YYYY-MM-DD
- MM/DD/YY
- MM/DD/YY HH:MM
You can make forecasts for the following intervals:

- 1 min
- 5 min
- 15 min
- 30 min
- 1 hour
- 1 day
- 1 week
- 1 month
- 1 year

**Future values in your input dataset**

Canvas automatically detects columns in your dataset that might potentially contain future values. If present, these values can enhance the accuracy of predictions. Canvas marks these specific columns with a *Future values* label. Canvas infers the relationship between the data in these columns and the target column that you are trying to predict, and utilizes that relationship to generate more accurate forecasts.

For example, you can forecast the amount of ice cream sold by a grocery store. To make a forecast, you must have a timestamp column and a column that indicates how much ice cream the grocery store sold. For a more accurate forecast, your dataset can also include the price, the ambient temperature, the flavor of the ice cream, or a unique identifier for the ice cream.

Ice cream sales might increase when the weather is warmer. A decrease in the price of the ice cream might result in more units sold. Having a column with ambient temperature data and a column with pricing data can improve your ability to forecast the number of units of ice cream the grocery store sells.

While providing future values is optional, it helps you to perform what-if analyses directly in the Canvas application, showing you how changes in future values could alter your predictions.

**Handling missing values**

You might have missing data for different reasons. The reason for your missing data might inform how you want Canvas to impute it. For example, your organization might use an automatic system that only tracks when a sale happens. If you're using a dataset that comes from this type of automatic system, you have missing values in the target column.

**Important**

If you have missing values in the target column, we recommend using a dataset that doesn't have them. SageMaker Canvas uses the target column to forecast future values. Missing values in the target column can greatly reduce the accuracy of the forecast.

For missing values in the dataset, Canvas automatically imputes the missing values for you by filling the target column with 0 and other numeric columns with the median value of the column.
However, you can select your own filling logic for the target column and other numeric columns in your datasets. Target columns have different filling guidelines and restrictions than the rest of the numeric columns. Target columns are filled up to the end of the historical period, whereas numeric columns are filled across both historical and future periods all the way to the end of the forecast horizon. Canvas only fills future values in a numeric column if your data has at least one record with a future timestamp and a value for that specific column.

You can choose one of the following filling logic options to impute missing values in your data:

- **zero** – Fill with 0.
- **NaN** – Fill with NaN, or not a number. This is only supported for the target column.
- **mean** – Fill with the mean value from the data series.
- **median** – Fill with the median value from the data series.
- **min** – Fill with the minimum value from the data series.
- **max** – Fill with the maximum value from the data series.

When choosing a filling logic, you should consider how your model interprets the logic. For example, in a retail scenario, recording zero sales of an available item is different from recording zero sales of an unavailable item, as the latter scenario doesn't necessarily imply a lack of customer interest in the unavailable item. In this case, filling with 0 in the target column of the dataset might cause the model to be under-biased in its predictions and infer a lack of customer interest in unavailable items. Conversely, filling with NaN might cause the model to ignore true occurrences of zero items being sold of available items.

**Types of forecasts**

You can make one of the following types of forecasts:

- **Single item**
- **All items**

For a forecast on all the items in your dataset, SageMaker Canvas returns a forecast for the future values for each item in your dataset.

For a single item forecast, you specify the item and SageMaker Canvas returns a forecast for the future values. The forecast includes a line graph that plots the predicted values over time.

**Topics**

- [Gain additional insights from your forecast](#)
- [Make a time series forecast](#)

**Gain additional insights from your forecast**

In Amazon SageMaker Canvas, you can use the following optional methods to get more insights from your forecast:

- Group column
- Holiday schedule
- What-if scenario

You can specify a column in your dataset as a **Group column**. Amazon SageMaker Canvas groups the forecast by each value in the column. For example, you can group the forecast on columns containing...
price data or unique item identifiers. Grouping a forecast by a column lets you make more specific forecasts. For example, if you group a forecast on a column containing item identifiers, you can see the forecast for each item.

Overall sales of items might be impacted by the presence of holidays. For example, in the United States, the number of items sold in both November and December might differ greatly from the number of items sold in January. If you use the data from November and December to forecast the sales in January, your results might be inaccurate. Using a holiday schedule prevents you getting inaccurate results. You can use a holiday schedule for 251 countries.

For a forecast on a single item in your dataset, you can use what-if scenarios. A what-if scenario gives you the ability to change values in your data and change the forecast. For example, you can answer the following questions by using a what-if scenario, “What if I lowered prices? How would that affect the number of items sold?”

**Make a time series forecast**

To make a time series forecast, you choose a target column. The target column contains the data that you want to predict. For example, your target column might have data on the number of items sold. After you select the target column, Amazon SageMaker Canvas selects a **Model type**. SageMaker Canvas uses the time-series data to automatically choose a time series model that you can use to make predictions on your data. After you build the model, you can evaluate its performance and use it to make predictions on new data.

Use the following procedure to make a time series forecast.

To make a time-series forecast, do the following.

1. Import the data.
2. Choose a target column in your dataset.
3. SageMaker Canvas automatically chooses **Time series forecasting** as the model type. Choose **Set configuration** to confirm that you're performing a time series forecast.
4. Specify the following fields:
   - **Item ID column** – The column that contains unique identifiers for each item in your dataset. For example, an SKU number uniquely identifies an item.
   - Optional: **Group column** – Groups the time series forecast by values in the column. For example, you can group your forecast for an item by store.
   - **Time stamp column** – The column containing the time stamps in your dataset. For a list of the supported datetime formats for this column, see **Time Series Forecasts in Amazon SageMaker Canvas** (p. 507).
   - **Future timestamp** – A timestamp that indicates a future forecast time. SageMaker Canvas forecasts values up to the point in time specified by the timestamp.
   - Optional: **Holiday schedule** – Activate the holiday schedule to use a country's holiday schedule. Use it to make your forecasts with holiday data more accurate.

You can have one of the following types of missing values:

- Missing future values
- Missing values

Missing future values are missing values in the target column. SageMaker Canvas uses the values in the target column to forecast the values in the future. If you have missing values in the target column, your forecast might be less accurate. We highly recommend updating the dataset.
Missing values are values that are missing in any column other than the target column. With missing values that aren't in the target column, it's helpful to note the following:

- They generally don't reduce the accuracy of your forecast as much as missing future values.
- SageMaker Canvas automatically imputes the missing values.

You can evaluate the model by seeing how close the predictions are within the actual value. You can also use the **Column Impact** metric to determine the direction and magnitude of the column's impact on the model's predictions. For example, in the following image, holidays had the largest positive impact on the forecast for demand. Price had the largest negative impact on demand.

After you've built a model, you can make the following types of forecasts:

- Single item – Make a forecast for a single item in a dataset and a line graph of the values that SageMaker Canvas forecasts. For example, you can see how sales of an item vary over time.
- All items – Make a forecast for all items in a dataset.
- What-if scenario – See how changing values in the dataset can affect the overall forecast for a single item.

The following image shows a single item forecast with a what-if scenario. In a what-if scenario, you have the ability to change values that can vary with time. You can see how changing the values affects the forecast.

The points connected by the solid blue line are the values that the model forecasts. The points connected by the dashed lines show the what-if scenario.
Updating a Model in Amazon SageMaker Canvas

Amazon SageMaker Canvas gives you the ability to update the models that you’ve built using new data. SageMaker Canvas shows you a model history, so that you can compare the models that you’ve built recently to those that you’ve generated in the past.

Each model that you build has a version number. The first model is Version 1, or V1. You can use model versions to see changes in prediction accuracy when you update your data or use advanced transformations.

Note
Text prediction and image prediction models only support one model version.

For new versions of a model, you can only choose datasets that have the same target column as the target column in Version 1. You must build at least one version of a model to add a new version, and you can delete versions that aren’t useful to you anymore.

You can also see Register a model version in the SageMaker model registry (p. 513) to help you track your versions over time and collaborate with Studio users who can approve or reject your model versions.

Use the following procedure to add a new model version or to view all of the versions for you model.

To add a new model version, do the following:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose My models.
3. On the My models page, choose your model. You can Filter by problem type to find your model more easily.
4. After choosing your model, the Versions page opens, listing all of the versions of your model.
5. Choose Add version.

The following image shows the Versions page for a model, on which you can view your model versions and add new versions.
On the **Versions** page, you can view the following information for each of your model versions:

- **Status** – This field tells you whether your model is currently building (In building), done building (Ready), failed to build (Failed), or still being edited (In draft).

- **Model score, F1, Precision, Recall, and AUC** – If you turn on the Show advanced metrics toggle on this page, you can see these model metrics. These metrics indicate the accuracy and performance of your model. For more information, see [Evaluate your model](#).

- **Shared** – This field tells you whether or not you’ve shared the model version with SageMaker Studio users.

- **Model registry** – This field tells you whether or not you’ve registered the version to a model registry. For more information, see [Register a model version in the SageMaker model registry](#).

After you choose a new version, you start the process of building another model. The process for building a new version of a model is almost the same as the process for building a model for the first time. For new versions of a model, you can only choose datasets that have the same target column as the target column in Version 1. For more information about building a model, see [Build a custom model](#).

### Operationalize your models

After building a model in SageMaker Canvas that you feel confident about, you might want to integrate your model with the machine learning operations (MLOps) processes in your organization. MLOps includes common tasks such as deploying a model for use in production or setting up continuous integration and continuous deployment (CI/CD) pipelines.

The following topics describe how you can use features within Canvas to use a Canvas-built model in production.

#### Topics

- [Register a model version in the SageMaker model registry](#)
- [Deploy your models to an endpoint](#)

#### Register a model version in the SageMaker model registry

With SageMaker Canvas, you can build multiple iterations, or versions, of your model to improve it over time. You might want to build a new version of your model if you acquire better training data or if you want to attempt to improve the model’s accuracy. For more information about adding versions to your model, see [Update a model](#).
After you've built a model that you feel confident about, you might want to evaluate its performance and have it reviewed by a data scientist or MLOps engineer in your organization before using it in production. To do this, you can register your model versions to the SageMaker model registry. The SageMaker model registry is a repository that data scientists or engineers can use to catalog machine learning (ML) models and manage model versions and their associated metadata, such as training metrics. They can also manage and log the approval status of a model.

After you register your model versions to the SageMaker model registry, a data scientist or your MLOps team can access the SageMaker model registry through SageMaker Studio, which is a web-based integrated development environment (IDE) for working with machine learning models. In the SageMaker model registry interface in Studio, the data scientist or MLOps team can evaluate your model and update its approval status. If the model doesn't perform to their requirements, the data scientist or MLOps team can update the status to Rejected. If the model does perform to their requirements, then the data scientist or MLOps team can update the status to Approved. Then, they can deploy your model to an endpoint or automate model deployment with CI/CD pipelines. You can use the SageMaker model registry feature to seamlessly integrate models built in Canvas with the MLOps processes in your organization.

The following diagram summarizes an example of registering a model version built in Canvas to the SageMaker model registry for integration into an MLOps workflow.

You can register tabular, image, and text model versions to the SageMaker model registry.

**Note**
Currently, registration of time series forecasting or BYOM model versions built in Canvas to the SageMaker model registry isn't supported.

The following sections show you how to register a model version to the SageMaker model registry from Canvas.

**Permissions management**

By default, you have permissions to register model versions to the SageMaker model registry. SageMaker grants these permissions for all new and existing Canvas user profiles through the AmazonSageMakerCanvasFullAccess policy, which is attached to the AWS IAM execution role for the SageMaker Domain that hosts your Canvas application.

If your Canvas administrator is setting up a new Domain or user profile, when they're setting up the Domain and following the prerequisite instructions in the Getting started guide, SageMaker turns on the model registration permissions through the ML Ops permissions configuration option, which is enabled by default.

The Canvas administrator can manage model registration permissions at the user profile level as well. For example, if the administrator wants to grant model registration permissions to some user profiles but remove permissions for others, they can edit the permissions for a specific user. The following procedure shows how to turn off model registration permissions for a specific user profile:

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the user profile's Domain.
5. On the Domain details page, choose the User profile whose permissions you want to edit.
6. On the User Details page, choose Edit.
7. In the left navigation pane, choose Canvas settings.
8. In the ML Ops permissions configuration section, turn off the Enable Model Registry registration permissions toggle.
9. Choose Submit to save the changes to your Domain settings.

The user profile should no longer have model registration permissions.

Register a model version to the SageMaker model registry

SageMaker model registry tracks all of the model versions that you build to solve a particular problem in a model group. When you build a SageMaker Canvas model and register it to SageMaker model registry, it gets added to a model group as a new model version. For example, if you build and register four versions of your model, then a data scientist or MLOps team working in the SageMaker model registry interface can view the model group and review all four versions of the model in one place.

When registering a Canvas model to the SageMaker model registry, a model group is automatically created and named after your Canvas model. Optionally, you can rename it to a name of your choice, or use an existing model group in the SageMaker model registry. For more information about creating a model group, see Create a Model Group.

Note
Currently, you can only register models built in Canvas to the SageMaker model registry in the same account.

To register a model version to the SageMaker model registry from the Canvas application, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose My models.
3. On the My models page, choose your model. You can Filter by problem type to find your model more easily.
4. After choosing your model, the Versions page opens, listing all of the versions of your model. You can turn on the Show advanced metrics toggle to view the advanced metrics, such as Recall and Precision, to compare your model versions and determine which one you’d like to register.
5. From the list of model versions, for the the version that you want to register, choose the More options icon (⋮). Alternatively, you can double click on the version that you need to register, and then on the version details page, choose the More options icon (⋮).
6. In the dropdown list, choose Add to Model Registry. The Add to Model Registry dialog box opens.
7. In the Add to Model Registry dialog box, do the following:
   a. (Optional) In the SageMaker Studio model group section, for the Model group name field, enter the name of the model group to which you want to register your version. You can specify the name for a new model group that SageMaker creates for you, or you can specify an existing model group. If you don’t specify this field, Canvas registers your version to a default model group with the same name as your model.
   b. Choose Add.

Your model version should now be registered to the model group in the SageMaker model registry. When you register a model version to a model group in the SageMaker model registry, all subsequent versions
of the Canvas model are registered to the same model group (if you choose to register them). If you want to register your versions to a different model group, you need to go to the SageMaker model registry and delete the model group. Then, you can re-register your model versions to the new model group.

To view the status of your models, you can return to the Versions page for your model in the Canvas application. This page shows you the Model Registry status of each version. If the status is Registered, then the model has been successfully registered.

If you want to view the details of your registered model version, for the Model Registry status, you can hover over the Registered field to see the Model registry details pop-up box. These details contain more info, such as the following:

- The Model package group name is the model group that your version is registered to in the SageMaker model registry.
- The Approval status, which can be Pending Approval, Approved, or Rejected. If a Studio user approves or rejects your version in the SageMaker model registry, then this status is updated on your model versions page when you refresh the page.

The following screenshot shows the Model registry details box, along with an Approval status of Approved for this particular model version.

**Model Registry details**

- Model package group name: canvas-test-cv-v1
- Model Registry version: Version 1
- Model Registry account ID
- Approval status: Approved

**Deploy your models to an endpoint**

In Amazon SageMaker Canvas, you can deploy your models to an endpoint to make predictions. SageMaker provides the ML infrastructure for you to host your model on an endpoint with the compute instances that you choose. Then, you can invoke the endpoint (send a prediction request) and get a real-time prediction from your model. With this functionality, you can use your model in production to respond to incoming requests, and you can integrate your model with existing applications and workflows.

To get started, you should have a model version that is ready to deploy. For more information about building a model in Canvas, see **Build a custom model (p. 452)**.

**Important**

You can deploy any model type in SageMaker Canvas except for time series forecasting models.

Review the following Permissions management section, and then begin creating new deployments in the Deploy a model section.

**Permissions management**

By default, you have permissions to deploy model versions to the SageMaker Hosting endpoints. SageMaker grants these permissions for all new and existing Canvas user profiles through the AmazonSageMakerCanvasFullAccess policy, which is attached to the AWS IAM execution role for the SageMaker Domain that hosts your Canvas application.
If your Canvas administrator is setting up a new Domain or user profile, when they're setting up the Domain and following the prerequisite instructions in the Prerequisites for setting up Amazon SageMaker Canvas (p. 370), SageMaker turns on the model deployment permissions through the Enable direct deployment of Canvas models option, which is enabled by default.

The Canvas administrator can manage model deployment permissions at the user profile level as well. For example, if the administrator wants to grant model deployment permissions to some user profiles but remove permissions for others, they can edit the permissions for a specific user.

The following procedure shows how to turn off model deployment permissions for a specific user profile:

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the user profile's Domain.
5. On the Domain details page, choose the User profile whose permissions you want to edit.
6. On the User Details page, choose Edit.
7. In the left navigation pane, choose Canvas settings.
8. In the ML Ops permissions configuration section, turn off the Enable direct deployment of Canvas models toggle.
9. Choose Submit to save the changes to your Domain settings.

The user profile should no longer have model deployment permissions.

Deploy a model

To get started with deploying your model, you create a new deployment in Canvas and specify the model version that you want to deploy along with the ML infrastructure, such as the type and number of compute instances that you would like to use for hosting the model.

Canvas suggests a default type and number of instances based on your model type, or you can learn more about the various SageMaker instance types on the Amazon SageMaker pricing page. You are charged based on the SageMaker instance pricing while your endpoint is active.

After your model is deployed to a SageMaker Hosting real-time inference endpoint, you can begin making predictions by invoking the endpoint.

There are several different ways for you to deploy a model version from the Canvas application. You can access the model deployment option through any of the following methods:

- On the My models page of the Canvas application, you can choose the model that you want to deploy. Then, from the model's Versions page, you can choose the More options icon (⋮) next to a model version and select Deploy.
- When on the details page for a model version, on the Analyze tab, you can choose the Deploy option.
- When on the details page for a model version, on the Predict tab, you can choose the More options icon (⋮) at the top of the page and select Deploy.
- On the Operations page of the Canvas application, you can choose the Deployments tab and then choose Create deployment.

All of these methods open the Deploy model side panel, where you specify the deployment configuration for your model. To deploy the model from this panel, do the following:

1. (Optional) If you're creating a deployment from the Operations page, you'll have the option to Select model and version. Use the dropdown menus to select the model and model version that you want to deploy.
2. Enter a name in the **Deployment name** field.
3. For **Instance type**, SageMaker detects a default instance type and number that is suitable for your model. However, you can change the instance type that you would like to use for hosting your model.

   **Note**
   If you run out of the instance quota for the chosen instance type on your AWS account, you can request a quota increase. For more information about the default quotas and how to request an increase, see *Amazon SageMaker endpoints and quotas* in the AWS General Reference guide.

4. For **Instance count**, you can set the number of active instances that are used for your endpoint. SageMaker detects a default number that is suitable for your model, but you can change this number.
5. When you’re ready to deploy your model, choose **Deploy**.

Your model should now be deployed to an endpoint. For information about how to view your deployment details or perform various actions, see the following sections.

**View your deployments**

You might want to check the status or details of a model deployment in Canvas. For example, if your deployment failed, you might want to check the details to troubleshoot.

You can view your Canvas model deployments from the Canvas application or from the Amazon SageMaker console.

To view deployment details from Canvas, choose one of the following procedures:

To view your deployment details from the **Operations** page, do the following:
1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Operations**.
3. Choose the **Deployments** tab.
4. Choose your deployment by name from the list.

To view your deployment details from a model version’s page, do the following:
1. In the SageMaker Canvas application, go to your model version’s details page.
2. Choose the **Deploy** tab.
3. On the **Deployments** section that lists all of the deployment configurations associated with that model version, find your deployment.
4. Choose the **More options** icon ( ), and then select **View details** to open the details page.

The details page for your deployment opens, and you can view information such as the time of the most recent prediction, the endpoint’s status and configuration, and the model version that is currently deployed to the endpoint.

You can also view your currently active Canvas workspace instances and active endpoints from the **SageMaker dashboard** in the SageMaker console. Your Canvas endpoints are listed alongside any other SageMaker Hosting endpoints that you’ve created, and you can filter them by searching for endpoints with the Canvas tag.

The following screenshot shows the SageMaker dashboard. In the **Canvas** section, you can see that one workspace instance is in service and four endpoints are active.
Use custom models

You can also update your deployment configuration. For example, you can deploy an updated model version to the endpoint, or you can update the instance type or number of instances behind the endpoint based on your capacity needs.

There are several different ways for you to update your deployment from the Canvas application. You can use any of the following methods:

- On the Operations page of the Canvas application, you can choose the Deployments tab and select the deployment that you want to update. Then, choose Update configuration.
- When on the details page for a model version, on the Deploy tab, you can view the deployments for that version. Next to the deployment, choose the More options icon (⋮) and then choose Update configuration.

Both of the preceding methods open the Update configuration side panel, where you can make changes to your deployment configuration. To update the configuration, do the following:

1. For the Select version dropdown menu, you can select a different model version to deploy to the endpoint.
   
   **Note**
   When updating a deployment configuration, you can only choose a different model version to deploy. To deploy a different model, create a new deployment.

2. For Instance type, you can select a different instance type for hosting your model.

3. For Instance count, you can change the number of active instances that are used for your endpoint.
4. Choose **Save**.

Your deployment configuration should now be updated.

**Test your deployment**

You can test your deployment by invoking the endpoint, or making single prediction requests, through the Canvas application. The endpoint returns a response with the prediction along with the probabilities of that prediction being correct. You can use this functionality to confirm that your endpoint responds to requests before invoking your endpoint programmatically in a production environment.

**Note**

Execution length is an estimate of the time taken to invoke and get a response from the endpoint in Canvas. For detailed latency metrics, see [SageMaker Endpoint Invocation Metrics](#).

To test your endpoint through the Canvas application, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation panel, choose **Operations**.
3. Choose the **Deployments** tab.
4. From the list of deployments, choose the one with the endpoint that you want to invoke.
5. On the deployment's details page, choose the **Test deployment** tab.
6. On the deployment testing page, you can modify the **Value** fields to specify a new data point.
7. After modifying the values, choose **Update** to get the prediction result.

The prediction loads, along with the **Invocation result** fields which indicate whether or not the invocation was successful and how long the request took to process.

The following screenshot shows a prediction performed in the Canvas application on the **Test deployment** tab.

For all model types except numeric prediction, the prediction returns the following fields:

- **predicted_label** – the predicted output
- **probability** – the probability that the predicted label is correct
- **labels** – the list of all the possible labels
• **probabilities** – the probabilities corresponding to each label (the order of this list matches the order of the labels)

For numeric prediction models, the prediction only contains the **score** field, which is the predicted output of the model, such as the predicted price of a house.

You can continue making single predictions through the deployment testing page, or you can see the following section [Invoke your endpoint (p. 521)](#) to learn how to invoke your endpoint programmatically from applications.

**Invoke your endpoint**

After testing your deployment, you can use your endpoint in production with your applications by invoking the endpoint programmatically the same way that you can invoke any other [SageMaker real-time endpoint](#). Invoking an endpoint programmatically returns a response object which contains the same fields as mentioned in the preceding section [Test your deployment (p. 520)](#).

For more detailed information about how to programmatically invoke endpoints, see [Invoke real-time endpoints (p. 2491)](#).

The following Python examples show you how to invoke your endpoint based on the model type.

**Numeric and categorical prediction models**

The following example shows you how to invoke numeric or categorical prediction models.

```python
import boto3
import pandas as pd

client = boto3.client("runtime.sagemaker")
body = pd.DataFrame(['feature_column1', 'feature_column2'], ['feature_column1', 'feature_column2']).to_csv(header=False, index=False).encode("utf-8")

response = client.invoke_endpoint(
    EndpointName="endpoint_name",
    ContentType="text/csv",
    Body=body,
    Accept="application/json"
)
```

**Image prediction models**

The following example shows you how to invoke image prediction models.

```python
import boto3

client = boto3.client("runtime.sagemaker")
with open("example_image.jpg", "rb") as file:
    body = file.read()

response = client.invoke_endpoint(
    EndpointName="endpoint_name",
    ContentType="application/x-image",
    Body=body,
    Accept="application/json"
)
```

**Text prediction models**

The following example shows you how to invoke text prediction models.

```python
import boto3
```
import pandas as pd

client = boto3.client("runtime.sagemaker")
body = pd.DataFrame([["Example text 1"], ["Example text 2"]]).to_csv(header=False, index=False).encode("utf-8")

response = client.invoke_endpoint(
    EndpointName="endpoint_name",
    ContentType="text/csv",
    Body=body,
    Accept="application/json"
)

Delete a model deployment

You can delete your model deployment from the Canvas application. This action also deletes the endpoint from the SageMaker console and shuts down any endpoint-related resources.

Note
- Optionally, you can delete your endpoint through the SageMaker console or using the SageMaker DeleteEndpoint API. For more information, see Delete Endpoints and Resources (p. 2395). However, when you delete the endpoint through the SageMaker console or APIs instead of the Canvas application, the list of deployments in Canvas isn't automatically updated. You must also delete the deployment from the Canvas application to remove it from the list.

To delete a deployment in Canvas, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation panel, choose Operations.
3. Choose the Deployments tab.
4. From the list of deployments, choose the one that you want to delete.
5. At the top of the deployment details page, choose the More options icon (↓).
6. Choose Delete deployment.
7. In the Delete deployment dialog box, choose Delete.

Your deployment and SageMaker Hosting endpoint should now be deleted from both Canvas and the SageMaker console.

Manage automations

In SageMaker Canvas, you can create automations that update your dataset or generate predictions from your model on a schedule. For example, you might receive new shipping data on a daily basis. You can set up an automatic update for your dataset and automatic batch predictions that run whenever the dataset is updated. Using these features, you can set up an automated workflow and reduce the amount of time you spend manually updating datasets and making predictions.

Note
- You can only set up a maximum of 20 automatic configurations in your Canvas application.
- Automations are only active while you’re logged in to the Canvas application. If you log out of Canvas, your automatic jobs pause until you log back in.

The following sections describe how to view, edit, and delete configurations for existing automations. To learn how to set up automations, see the following topics:

- To set up automatic dataset updates, see Update a dataset (p. 438).
- To set up automatic batch predictions, see Make batch predictions (p. 500).
View your automations

You can also view all of your auto update jobs by going to the left navigation pane of Canvas and choosing **Automations**. The **Automations** page combines automations for both automatic dataset updates and automatic batch predictions. From the **Automations** page, you can see the following tabs:

- **All jobs** – You can see every instance of a **Dataset update** or **Batch prediction** job that Canvas has done. For each job, you can see fields such as the associated **Input dataset**, the **Configuration name** of the associated auto update configuration, and the **Status** showing whether the job was successful or not. You can filter the jobs by configuration name:
  - For dataset update jobs, you can choose the latest version of the dataset, or the most recent job, to preview the dataset.
  - For batch prediction jobs, you can choose the **More options** icon ( ) to view or download the predictions for that job.

- **Configuration** – You can see all of the **Dataset update** and **Batch prediction** configurations you’ve created. For each configuration, you can see fields such as the associated **Input dataset** and the **Frequency** of the jobs. You can also turn off or turn on the **Auto update** toggle to pause or resume automatic updates. If you choose the **More options** icon ( ) for a specific configuration, you can choose to **View all jobs** for the configuration, **Update configuration**, or **Delete configuration**.

Edit your automatic configurations

After setting up a configuration, you might want to make changes to it. For automatic dataset updates, you can update the Amazon S3 location for Canvas to import data, the frequency of the updates, and the starting time. For automatic batch predictions, you can change the dataset that the configuration tracks for updates. You can also turn off the automation to temporarily pause updates until you choose to resume them.

The following sections show you how to update each type of configuration.

**Note**
You can’t change the frequency for automatic batch predictions because automatic batch predictions run every time the target dataset is updated.

Edit your automatic dataset update configuration

You might want to make changes to your auto update configuration for a dataset, such as changing the frequency of the updates. You might also want to turn off your automatic update configuration to pause the updates to your dataset.

To make changes to your auto update configuration for a dataset, do the following:

1. In the left navigation pane of Canvas, choose **Automations**.
2. Choose the **Configuration** tab.
3. For your auto update configuration, choose the **More options** icon ( ).
4. In the dropdown menu, choose **Update configuration**. You are taken to the **Auto updates** tab of the dataset.
5. Make your changes to the configuration. When you’re done making changes, choose **Save**.

To pause your dataset updates, turn off your automatic configuration. One way to turn off auto updates is by doing the following:

1. In the left navigation pane of Canvas, choose **Automations**.
2. Choose the **Configuration** tab.
3. Find your configuration from the list and turn off the Auto update toggle.

Automatic updates for your dataset are now paused. You can turn this toggle back on at any time to resume the update schedule.

**Edit your automatic batch prediction configuration**

When you edit a batch prediction configuration, you can change the target dataset but not the frequency (since automatic batch predictions occur whenever the dataset is updated).

To make changes to your automatic batch predictions configuration, do the following:

1. In the left navigation pane of Canvas, choose **Automations**.
2. Choose the **Configuration** tab.
3. For your auto update configuration, choose the More options icon ( 
4. In the dropdown menu, choose **Update configuration**. You are taken to the **Auto updates** tab of the dataset.
5. The **Automate batch prediction** dialog box opens. You can select another dataset and choose **Set up** to save your changes.

Your automatic batch predictions configuration is now updated.

To pause your automatic batch predictions, turn off your automatic configuration. Use the following procedure to turn off your configuration:

1. In the left navigation pane of Canvas, choose **Automations**.
2. Choose the **Configuration** tab.
3. Find your configuration from the list and turn off the Auto update toggle.

Automatic batch predictions for your dataset are now paused. You can turn this toggle back on at any time to resume the update schedule.

**Delete an automatic configuration**

You might want to delete a configuration to stop your automated workflow in SageMaker Canvas.

To delete a configuration for automatic dataset updates or automatic batch predictions, do the following:

1. In the left navigation pane of Canvas, choose **Automations**.
2. Choose the **Configuration** tab.
3. Find your auto update configuration, and choose the More options icon ( 
4. Choose **Delete configuration**.
5. In the dialog box that pops up, choose **Delete**.

Your auto update configuration is now deleted.

**Collaborate with data scientists**

**Note**

Collaboration on models with Studio users isn’t supported for single-label image prediction, multi-category text prediction, or time series forecasting model types.
Additionally, SageMaker Canvas doesn’t support sharing your model to the same user profile as the one that created the model. You must have two separate user profiles to share a model.

With Amazon SageMaker Canvas, business analysts using Canvas and data scientists using Amazon SageMaker Studio can share ML models and collaborate with each other while working in their own environments to share domain knowledge and provide expert inputs towards improving models.

Using SageMaker Canvas collaboration, you can share Standard build models from Canvas with data scientists in Studio to review, update, and share back with Canvas users. Users in Canvas can share one version of a model with up to 23 Studio users.

The following sections describe the steps for collaboration:

- In the Canvas application, a business analyst shares their model with a Studio user.
- The Studio user receives the shared model in the Studio application. They can choose to share feedback with the analyst, make updates to the model, or share an alternate model version.
- The business analyst receives the feedback or updated model in Canvas and can generate predictions in view-only mode.

To collaborate, the Canvas user and Studio user must be in the same Amazon SageMaker Domain. For more information about setting up your Domain and users, see the SageMaker Canvas Prerequisites.

Note
Model collaboration is different from Bring your own model to SageMaker Canvas (p. 531), where you can bring a model that you’ve trained anywhere and import it into Canvas for generating predictions.

Prerequisites

Before a Canvas user and Studio user can collaborate on models, the users' IAM role must have AWS Identity and Access Management (IAM) permissions to share models. If you haven't already set up permissions, see Grant Users Permissions to Collaborate with Studio (p. 400).

The Canvas user must also have a Standard build model trained in Canvas and ready to share.

Note
Collaboration does not support Quick build models.

You should also have the user profile name of the Studio user with whom you want to collaborate. The Studio user must be in the same Amazon SageMaker Domain as your Canvas user. You can find a user's profile name by using the following procedure:

2. In the navigation panel, choose Domains.
3. From the list of Domains, choose your Domain. This opens the Domain details page, where you can find all of the User profiles for the Domain.

Keep the user profile name ready for the first step of the following tutorial.

Canvas users: Share a model with Studio users

Within the Canvas application, share your model version with Studio users or request feedback from them. You should use a model version that has been built; you can’t share a model version that is a draft or currently building. You can only share one version per model.

To share your Canvas model with Studio users, use the following procedure.

1. Open the SageMaker Canvas application.
2. From the **Models** page, select the model that you want to share. You can only share Standard build models.

3. In the header, choose **Share**.

4. In the **Share Model** dialog box, do the following:
   a. From the **Choose a model version to share** dropdown list, select the model version for which you want feedback.
   b. From the **SageMaker Studio users** dropdown list, select Studio users by their profile names. You can add up to 23 Studio users.
   c. For the **Add a note** field, you can enter a quick note that accompanies your model when you send it to the Studio users.
   d. Choose **Share**.
   e. In the **Share Model** confirmation box that appears, choose **Share**.

You have now shared your model with the Studio users, and the users receive a notification in Studio that a model has been shared with them.

**Studio users: Receive a model in Studio from Canvas users**

In Studio, if a model has been shared with you, you receive a notification similar to the following when you open the Studio application.

Choose **View shared models** to open the **Shared models and notebooks** page in Studio. If you miss the notification, you can find the **Shared models and notebooks** page by doing the following:

1. Open your Amazon SageMaker Studio application.
2. In the side navigation pane, choose the **Home** icon (🏠).
3. In the side navigation bar that opens, choose **Models**.
4. In the dropdown list, choose **Shared models** to open the **Shared models and notebooks** page.

On the **Shared models and notebooks** page, select the filter **Shared with me**. You should see the Canvas model that has been shared with you in the list of shared models. Choose **View model** on the shared model, which opens the model details page in Autopilot. The opened model should have a banner at the top that looks similar to the following screenshot.

From this page, you can see the model details, as well as any notes about the model shared with you by the Canvas user. In the Canvas banner at the top, you can choose the following actions:

- Share feedback with the Canvas user.
- Make updates to the shared model and share the updates with the Canvas user.
- Share an alternate version of the model with the Canvas user. Canvas uses **Autopilot** to train multiple versions of the model and select the best version. You can select a different version if you decide that it’s better for your use case.

For more information on the preceding actions, see the following sections.
Share feedback

You might want to send a comment or feedback to the Canvas user without making any changes to the model.

To share feedback on the shared model, use the following procedure:

1. On the model details page, choose Share feedback.
2. In the Share feedback dialog box, add a note in the Add feedback field.
3. Choose Share to send the feedback to the Canvas user.

After giving feedback, you can view the feedback you sent in the Canvas banner at the top of the model details page. The Canvas user receives the feedback in the Canvas application and can make changes based on your feedback.

Share an updated model with the Canvas user

You might want to make changes to the model that the Canvas user shared with you. For example, you might want to use advanced data transformations such as one-hot encoding to improve the accuracy of the model. You can update the model with Amazon SageMaker Data Wrangler and Amazon SageMaker Autopilot in Studio, which are features that help you make data transformations and train your model.

**Warning**

If you exit the following workflow at any time, your model updates are not saved, and you must restart the workflow.

To update the model and send the updated model to the Canvas user, use the following procedure:

1. On the model details page, in the Canvas banner, choose Update model.
2. In the banner’s dropdown list, choose Update data transformations.
3. The workflow opens your model in Amazon SageMaker Data Wrangler, where you can choose to edit the data transformations used for the model. Make your data transformations in the Data Wrangler interface. For more information about Data Wrangler and the data transformations you can use, see the Data Wrangler documentation.
4. After you’ve finished your data transformations, choose Retrain model on the Canvas banner to open the Export data and train a model with SageMaker Autopilot page in the Data Wrangler interface.
5. Verify the fields on the Export data and train a model with SageMaker Autopilot page, and then choose Export and train to export your data transformations to Amazon SageMaker Autopilot.
6. The workflow opens the Create an Autopilot experiment page in Autopilot, where you can create an Autopilot experiment and retrain the model with the updated data transformations. Fill out the fields for each of the Create an Autopilot experiment pages.

For more information about Autopilot and Autopilot experiments, see Create an experiment in the Autopilot documentation.
7. After you’ve finished configuring your Autopilot experiment and reviewed the final settings, choose Create experiment in the Autopilot interface to begin training the model. The model trains, during which you can choose Stop training in the Autopilot interface at any time.
8. After the model has trained, the Canvas banner at the top of the page compares the metrics of the old model with the updated model. The **Best model summary** lists the metrics, such as Recall and Precision, and whether the new model improves the metrics or not. Review the metrics and decide whether you would like to share the updated model or not. For more information about Autopilot metrics, see **Metrics and validation**.

9. If you decide that you want to share the updated model with the Canvas user, choose **Share** in the banner.

10. In the **Share** dialog box, do the following:
   a. For the **Select a model to share** dropdown list, the best model from your Autopilot experiment should already be selected and marked with a label **Best Candidate**. If the model version that you want to share is not selected, open the dropdown and select the correct version.
   b. For the **Add feedback** field, you can enter a note for the Canvas user.
   c. Choose **Share** to share the updated model and note with the Canvas user.

After sharing the model, you receive a notification that your model was shared successfully similar to the following screenshot.

![Share model successfully notification](image)

You can choose **View shared models** in the banner to return to the **Shared models and notebooks** page. From this page, you can see the updated model that you shared with the Canvas user under the **Shared by me** label.

**Share an alternate model with the Canvas user**

When SageMaker Canvas builds a model, Amazon SageMaker Autopilot trains multiple versions of the model and selects the best one. You might decide that an alternate version of the model is better according to your needs. You can share an alternate Autopilot version of the model with the Canvas user instead of making changes to the one they sent. For more information about Autopilot, see the **Autopilot documentation**.

To share an alternate model, use the following procedure:

1. On the model details page, in the Canvas banner, choose **Update model**.
2. In the banner’s dropdown list, choose **Recommend an alternate Auto ML candidate**.
3. The page for the Autopilot job opens where you can review all of the trained model versions. When you’re ready to share an alternate version, in the Canvas banner at the top of the page, choose **Share**.
4. In the **Share** dialog box, do the following:
   a. For the **Select a model to share** dropdown list, the best model from the Autopilot experiment is selected and marked with the label **Best Candidate**. Open the dropdown and select the alternate model version that you want to share.
   b. For the **Add feedback** field, you can enter a note for the Canvas user.
   c. Choose **Share** to share the alternate model version and note with the Canvas user.

After sharing the model, you receive a notification that your alternate model was shared successfully similar to the following screenshot.
You can choose View shared models in the banner to return to the Shared models and notebooks page. From this page, you can see the updated model that you shared with the Canvas user under the Shared by me label.

Canvas users: Receive model updates from a Studio user

When a Studio user shares an updated or alternate model with the Canvas user, the Canvas user receives a notification.

In the Canvas app, the notification looks like the following screenshot.

You can choose View update to see the updated model, or you can go to the Models page in the Canvas application and select the shared model to view it.

Note
Canvas users can't edit a model that has been shared with them by a Studio user. Models imported from Studio are view and predict only.

A model on which a Studio user has collaborated looks like the following card on the Models page.
# Customer Churn Model

<table>
<thead>
<tr>
<th>Accuracy</th>
<th>--</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dataset</td>
<td>--</td>
</tr>
<tr>
<td>Target</td>
<td>Plan</td>
</tr>
<tr>
<td>Problem type</td>
<td>Multiclass</td>
</tr>
<tr>
<td>Received</td>
<td>7/3/2021 18:11</td>
</tr>
</tbody>
</table>

The model import from Studio can take up to 20 minutes, during which the model shows as **Importing**.
After importing the model, you can view its metrics and generate predictions with it.

The following screenshot shows the Analyze tab, where you can evaluate the model accuracy and metrics. For more information, see Evaluate Your Model’s Performance in Amazon SageMaker Canvas (p. 489).

![Analyse tab screenshot showing model statistics and accuracy insights.](image)

The model often predicts a value that is within +/- 43052.733 of the actual value for median_house_value.

On both the Analyze and Predict tabs, you can see the Shared History panel, which shows you the model versions and comments shared with you by Studio users.

Bring your own model to SageMaker Canvas

**Note**
You can share models trained with tabular, text, and image data to Canvas. You can’t share time series models. Also, Canvas bring your own model (BYOM) only supports CPU-based models (or models that use CPU instances to make predictions).

Business analysts can benefit from ML models already built by data scientists to solve business problems instead of creating a new model in Amazon SageMaker Canvas. However, it might be difficult to use these models outside the environments in which they are built due to technical requirements, rigidity of tools, and manual processes to import models. This often forces users to rebuild ML models, resulting in the duplication of effort and additional time and resources.
SageMaker Canvas removes these limitations so you can generate predictions in Canvas with models that you've trained anywhere. You can register ML models in SageMaker Model Registry, which is a metadata store for ML models, and import them into SageMaker Canvas. Additionally, you can generate predictions with models that data scientists have trained in Amazon SageMaker Autopilot or SageMaker JumpStart. Canvas users can then analyze and generate predictions from any model that has been shared with them.

After you've satisfied the Prerequisites (p. 532), see the following sections for instructions on how to bring your own models into Canvas and generate predictions. The workflow begins in Studio, where a Studio user shares a model with a Canvas user. Then, the Canvas user signs in to their Canvas app to receive the shared model and generate predictions with it.

**Important**
You can only share models trained with tabular data. Also, you can't share time series models.

**Prerequisites**

To bring your model into SageMaker Canvas, complete the following prerequisites:

- You must have a Amazon SageMaker Studio user who has onboarded to Amazon SageMaker Domain. The Studio user must be in the same Domain as the Canvas user. Model sharing occurs when a Studio user shares a model with a Canvas user from within Studio. If you don't already have a Studio user set up, see the Studio documentation and Onboard to Amazon SageMaker Domain.

- You must have a trained model from SageMaker Autopilot, SageMaker JumpStart, or SageMaker Model Registry. For any model that you've built outside of SageMaker, you must register your model in Model Registry before importing it into Canvas. For more information, see the Model Registry documentation.

- The Canvas user with whom you want to share your model must have permission to access the Amazon S3 bucket in which you store your datasets and model artifacts. For instructions on how admins can give Canvas users the permissions they need, see Grant Users Permissions to Collaborate with Studio (p. 400).

- You should also have the user profile name of the Canvas user with whom you want to collaborate. The Canvas user must be in the same Amazon SageMaker Domain as your Studio user. You can find a user's profile name by using the following procedure:
  2. In the navigation panel, choose Domains.
  3. From the list of Domains, choose your Domain. This opens the Domain details page, where you can find all of the User profiles for the Domain.

Keep the user profile name ready for the first step of the following tutorial.

If your SageMaker Canvas app is running in a private customer VPC, any Autopilot models shared from Studio must use Autopilot HPO mode to support generating predictions in Canvas. For more information about HPO mode, see Training modes and algorithm support in the Autopilot documentation.

**Note**
If you want feedback from data scientists on a model built inside Canvas, see Collaborate with data scientists (p. 524), where a Canvas user shares a model with a Studio user, and the Studio user shares feedback or model updates.

**Studio users: Share a model to SageMaker Canvas**

You should have a model trained with tabular data that you're ready to share with Canvas users. See the following sections for information on how to share your models from features within Studio.
Autopilot

You can share a model to Canvas from Amazon SageMaker Autopilot in Studio. Autopilot is a feature that enables you to train and deploy your models in SageMaker.

You need to have a Studio user and a trained model ready to share from Autopilot. For more information on how to set up Studio, see the Studio documentation. For more information about Autopilot, see the Autopilot documentation.

To share a model from Autopilot to Canvas, use the following procedure.

1. Open your Amazon SageMaker Studio application.
2. In the side navigation pane, choose the Home icon (🏠).
3. In the side navigation bar of Studio, choose AutoML to open Autopilot.
4. On the Autopilot page, select the Autopilot model that you want to share with the Canvas user. You can only share one model at a time.
5. From the Autopilot job details page, in the Models tab, select the model version that you want to share.
6. Choose Share.
7. In the Share model dialog box, do the following:
   a. For the Add Canvas users field, enter the Canvas user’s profile name. You can enter up to 23 Canvas users. If a user profile you specify doesn’t have a Canvas app associated with it, you can't enter the profile name.
   b. For the Add a note field, add a description or note for the Canvas user when they receive the model.
   c. Choose Share to share the model.

You have now shared the model with the Canvas user.

JumpStart

You can share a model to Canvas from SageMaker JumpStart in Studio. With JumpStart, you can access and tune pretrained models before deploying them.

You need to have a Studio user and a successfully completed training job in JumpStart. For more information about how to set up Studio, see the Studio documentation. For more information about JumpStart, see the JumpStart documentation.

To share a model from JumpStart to Canvas, use the following procedure.

1. Open your Amazon SageMaker Studio application.
2. In the side navigation pane, choose the Home icon (🏠).
3. In the side navigation bar that opens, choose SageMaker JumpStart.
4. Choose Launched JumpStart assets to open the page that lists your JumpStart training jobs, models, and endpoints.
5. Choose the Training jobs tab to view the list of your model training jobs.
6. From the Training jobs list, select the training job that you want to share with the Canvas user. You can only share one job at a time. This opens the training job details page.
7. In the header for the training job, choose Share, and select Share to Canvas.
Note
You can only share tabular models to Canvas. Trying to share a model that is not tabular throws an Unsupported data type error.

8. In the Share to Canvas dialog box, do the following:
   a. For the Add Canvas users to share field, enter the Canvas user’s profile name. You can enter up to 23 Canvas users. If a user profile you specify doesn’t have a Canvas app associated with it, you can’t enter the profile name.
   b. For the Add a note field, add a description or note for the Canvas user when they receive the model.
   c. Choose Share to share the model.

You have now shared the model with the Canvas user.

Model Registry
You can share a model to Canvas from SageMaker Model Registry in Studio. With Model Registry, you can register models that you bring from outside of SageMaker and integrate them with your ML pipelines.

You need to have a Studio user and a model version saved in the Model Registry. For more information about how to set up Studio, see the Studio documentation. If you don't have a model version in the Model Registry, create a model group and register a version to it. For more information about Model Registry, see the Model Registry documentation.

To share a model version from Model Registry to Canvas, use the following procedure.

1. Open your Amazon SageMaker Studio application.
2. In the side navigation pane, choose the Home icon (🏠).
3. In the side navigation bar that opens, choose Models.
4. Select Model Registry from the dropdown list to open the Model Registry page and show all of the model groups registered in your account.
5. Choose the model group that has the model version that you want to share.
6. You can share a model version either from the model group page or the model version page.
   - To share a model version from the model group page, complete the following steps:
     1. Choose Versions, and check the box next to the model version you want to share with the Canvas user. You can only share one model version at a time.
     2. In the Actions dropdown menu, choose Share model artifacts.
   - To share a model version from the model version page, complete the following steps:
     1. Choose Versions, and select the name of the model version you want to share with the Canvas user. You can only share one model version at a time.
     2. In the Actions dropdown menu, choose Share model artifacts.
7. In the Share model dialog box, do the following:
   a. For the Add Canvas users to share field, enter the Canvas user’s profile name. You can enter up to 23 Canvas users. If a user profile you specify doesn’t have a Canvas app associated with it, you can’t enter the profile name.
   b. For Add model details, do the following:
      i. For the Training dataset field, enter the Amazon S3 path for your training dataset.
      ii. For the Validation dataset field, enter the Amazon S3 path for your validation dataset.
iii. For **Target column**, either select **Use the first column** if the first column in your dataset is the target, or select **Specify the target column name** to set the target as a different column in your dataset.

iv. For **Column headers**, select one of the following options:
   
   A. Select **Use the first row** if the first row of your dataset contains the column headers.
   
   B. Select **Specify a different dataset in S3 for column headers** if you have a file stored in Amazon S3 containing headers that can be mapped to your dataset. The headers file must have the same number of columns as your dataset.
   
   C. Select **Automatically generate** if you don't already have column headers and would like SageMaker to generate generic column names for your dataset.

v. From the **Problem type** dropdown list, select your model type.

vi. If you selected the **Binary classification** or **Multi-class** problem types, the **Configure model outputs** option appears.

   If you already have a file stored in Amazon S3 that maps default target column class names to your desired class names, then turn on **Model output names** and enter the Amazon S3 path to the mapping file. If you don’t have a mapping file, then turn off **Model output names** and manually enter the **Number of model outputs** (the number of target column classes in your data). Then, enter your desired class names to replace the default class names.

   c. (Optional) For the **Add a note** field, add a description or note for the Canvas user when they receive the model.

d. Choose **Share** to share the model version.

You have now shared the model with the Canvas user.

### Shared models and notebooks

On the **Shared models and notebooks** page in Amazon SageMaker Studio, you can view the models that you’ve shared and that have been shared with you. This page gives you a central place to view and manage all of your models in Studio.

You need to have a Studio user and a model ready to share from Autopilot, JumpStart, or Model Registry. For more information on how to set up Studio, see the Studio documentation. For more information about the **Shared models and notebooks** page, see the Shared models and notebooks documentation.

The following example walks you through sharing an Amazon SageMaker Autopilot model, but you can use the sharing feature on the **Shared models and notebooks** page to share models from any of the other features in the previous sections, such as Jumpstart and Model Registry.

To share an Autopilot model from the **Shared models and notebooks** page, use the following procedure.

1. Open your Amazon SageMaker Studio application.
2. In the side navigation pane, choose the **Home** icon (🏠).
3. In the side navigation bar of Studio, choose **Models**.
4. In the dropdown list, choose **Shared models** to open the **Shared models and notebooks** page.
5. Choose the filter icon, and in the **Shared from** dropdown list, choose **Autopilot**.
6. Select the Autopilot model from the list that you want to share with the Canvas user. You can only share one model at a time. Alternatively, you can select the model to open the model details page.
7. From either the Autopilot jobs page or the model details page, choose **Share**.
8. In the **Share model** dialog box, do the following:
a. For the **Add Canvas users to share** field, enter the Canvas user's profile name. You can enter up to 23 Canvas users. If a user profile you specify doesn't have a Canvas app associated with it, you can't enter the profile name.

b. For the **Add a note** field, add a description or note for the Canvas user when they receive the model.

c. Choose **Share** to share the model.

You have now shared the model with the Canvas user.

After you share the model, you receive a notification popup in Studio similar to the following screenshot.

![Notification Pop-Up]

You can choose **View model** to open the **Shared models and notebooks** page in Studio. You can also view your shared models at any time from the **Shared models and notebooks** page.

From this page, you can see the models that you've shared with the Canvas user under the **Shared by me** label, as shown in the following screenshot.

![Shared Models and Notebooks]

Models that you've shared to Canvas have text on the card similar to the following example: **Shared to: 12 Canvas users.**
Canvas users: Receive a shared model in SageMaker Canvas

When a Studio user shares a model with a Canvas user, you receive a notification within the Canvas application that a Studio user has shared a model with you.

In the Canvas application, the notification is similar to the following screenshot.

![Notification Screenshot](image)

You can choose **View update** to see the shared model, or you can go to the **Models** page in the Canvas application to discover all of the models that have been shared with you.

**Note**

Canvas users can't edit a model that has been shared with them by a Studio user. Models imported from Studio are view and predict only.

A model that has been shared by a Studio user looks like the following card on the **Models** page. This is different from [Collaborate with data scientists](p. 524), where a Canvas user shares a model and a Studio user shares updates or feedback with the Canvas user.
Customer Churn Model

Accuracy  --
Dataset    --
Target     Plan
Problem type Multiclass
Received   7/3/2021 18:11

View
The model import from Studio can take up to 20 minutes, during which the model shows as **Importing**.

After importing the model, you can view its metrics and generate predictions with it. SageMaker Canvas uses [Amazon SageMaker Serverless Inference](https://docs.aws.amazon.com/sagemaker/latest/dg.serverless-inference.html) resources to generate model analysis and predictions for shared models. You might see costs associated with Serverless Inference in your AWS account.

The following screenshot shows the **Analyze** tab in the Canvas application for a shared model, where you can evaluate the model accuracy and metrics. For more information, see [Evaluate Your Model's Performance in Amazon SageMaker Canvas](https://docs.aws.amazon.com/sagemaker/latest/dg/canvas-evaluate-performance.html) (p. 489).

![Analyze tab](image)

The following screenshot shows the **Predict** tab, where you can generate predictions with the model. For more information on generating predictions in Canvas, see [Make predictions for your data](https://docs.aws.amazon.com/sagemaker/latest/dg/canvas-make-predictions.html) (p. 498).

![Predict tab](image)

On both the **Analyze** and **Predict** tabs, you can see the **Shared History** panel, which shows you the model versions and comments shared with you by Studio users.

### Logging out of Amazon SageMaker Canvas

If you’re not using Amazon SageMaker Canvas, you can log out. A **workspace instance** is dedicated for your use as soon as you launch SageMaker Canvas from the console. Logging out ends the workspace instance. You are only billed for the duration you are logged in.
When you log out, your models and datasets aren’t affected, but SageMaker Canvas cancels any Quick build tasks. If you log out of SageMaker Canvas while running a Quick build, your build might be interrupted until you log back in. When you log back in, SageMaker Canvas automatically restarts the build.

To log out, choose the Log out button (⏏) on the left panel of the SageMaker Canvas app.

You can also log out from the SageMaker Canvas app by closing your browser tab and then deleting the app (p. 402) in the console.

After you log out, SageMaker Canvas tells you to relaunch in a different tab. Logging in takes between 3 minutes and 8 minutes. If you have an administrator who set up SageMaker Canvas for you, use the instructions they gave you to log back in. If don’t have an administrator, see the procedure for accessing SageMaker Canvas in Prerequisites for setting up Amazon SageMaker Canvas (p. 370).

Limitations and troubleshooting

The following section outlines troubleshooting help and limitations that apply when using Amazon SageMaker Canvas. You can use this topic to help troubleshoot any issues you encounter.

Troubleshooting issues with granting permissions through the SageMaker console

If you’re having trouble granting Canvas base permissions or Ready-to-use models permissions to your user, your user might have an AWS IAM execution role with more than one trust relationship to other AWS services. A trust relationship is a policy attached to your role that defines which principals (users, roles, accounts, or services) can assume the role. For example, you might encounter an issue granting additional Canvas permissions to your user if their execution role has a trust relationship to both Amazon SageMaker and Amazon Forecast.

You can fix this problem by choosing one of the following options.

1. Remove all but one trusted service from the role.

This solution requires you to edit the trust relationship for your user profile’s IAM role and remove all AWS services except SageMaker.

To edit the trust relationship for your IAM execution role, do the following:

2. In the navigation pane of the IAM console, choose Roles. The console displays the roles for your account.
3. Choose the name of the role that you want to modify, and select the Trust relationships tab on the details page.
4. Choose Edit trust policy.
5. In the Edit trust policy editor, paste the following, and then choose Update Policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "sagemaker.amazonaws.com"
        ],
        "Service": [
          "sagemaker.amazonaws.com"
        ],
        "Action": "sts:AssumeRole"
      }
    }
  ]
}
```
You can also update this policy document using the IAM CLI. For more information, see `update-trust` in the IAM Command Line Reference.

You can now retry granting the Canvas base permissions or the Ready-to-use models permissions to your user.

**2. Use a different role with one or fewer trusted services.**

This solution requires you to specify a different IAM role for your user profile. Use this option if you already have an IAM role that you can substitute.

To specify a different execution role for your user, do the following:

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. From the list of Domains, select the Domain that you want to view a list of user profiles for.
5. On the Domain details page, choose the User profiles tab.
6. Choose the user whose permissions you want to edit. On the User details page, choose Edit.
7. On the General settings page, choose the Execution role dropdown list and select the role that you want to use.
8. Choose Submit to save your changes to the user profile.

Your user should now be using an execution role with only one trusted service (SageMaker).

You can retry granting the Canvas base permissions or the Ready-to-use models permissions to your user.

**3. Manually attach the AWS managed policy to the execution role instead of using the toggle in the SageMaker Domain settings.**

Instead of using the toggle in the Domain or user profile settings, you can manually attach the AWS managed policies that grant a user the correct permissions.

To grant a user Canvas base permissions, attach the `AmazonSageMakerCanvasFullAccess` policy. To grant a user Ready-to-use models permissions, attach the `AmazonSageMakerCanvasAIServicesAccess` policy.

Use the following procedure to attach an AWS managed policy to your role:

2. Choose Roles.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under Permissions, choose Add permissions.
5. From the dropdown menu, choose Attach policies.
6. Search for and select the policy or policies that you want to attach to the user's execution role:

   a. To grant the Canvas base permissions, search for and select the `AmazonSageMakerCanvasFullAccess` policy.
   b. To grant the Ready-to-use models permissions, search for and select the `AmazonSageMakerCanvasAIServicesAccess` policy.
7. Choose Add permissions to attach the policy to the role.

After attaching an AWS managed policy to the user's role through the IAM console, your user should now have the Canvas base permissions or Ready-to-use models permissions.

Limitations for collaboration

The following general limitations apply when you are collaborating with data scientists in Amazon SageMaker Studio.

- You can only share successfully trained models from Canvas to Studio. Similarly, you can only share models that have been successfully trained in Studio back to Canvas.
- You can't share Quick build models from Canvas to Studio. You can only share Standard build models.
- You can only share one version of a Standard build model trained in Canvas. You can train additional versions of your model within Canvas, but you can't share them to Studio.
- From Studio, you can only share feedback or share an updated model with Canvas. You can't perform both actions at the same time.
- The length limitation for comments shared from Studio to Canvas and Canvas to Studio is 1024 characters.
- You can only share your Canvas or Studio models with a different user profile. You can't share models between Canvas and Studio within your own user profile.
- You can't share from a Canvas user to a Canvas user, or from a Studio user to a Studio user.

There are also limitations that apply depending on the type of model you want to share. See the following sections for limitations on time series forecasting models and numeric and categorical prediction models.

Limitations for collaborating on time series forecasting models

The following limitations apply when you are collaborating on time series forecasting models between Canvas and Studio.

- You can't make predictions with time series forecasting models in Studio through an automated Share button. However, you can create a Jupyter notebook and write your own code.
- For time series forecasting models, you can't change the model recipe or data transformations in Studio. You can only make the following updates to time series forecasting models in Studio:
  - You can update the length of the forecast horizon.
  - You can update the item's metadata field, which groups your data by a certain column.
  - You can update other dimension fields, such as specifying a holiday schedule.

Limitations for collaborating on numeric and categorical prediction models

The following limitations apply when you are collaborating on numeric and categorical prediction model types between Canvas and Studio.

- When updating or training models in Studio, if you close the tab with the collaboration banner at the top, it ends the share model workflow and you lose your progress. In that case, you must restart the share model workflow from the Shared With Me section on the Shared Models page. For more information, see Collaborate with data scientists.
- When updating models in Studio, you can't change the target column if you want to share the model updates back to Canvas. If you want to change the target column and re-train the model, train the model and then use the Share button to share to Canvas. For more information about sharing a new model to Canvas, see Bring your own model to SageMaker Canvas.
• When updating models in the Amazon SageMaker Data Wrangler Recipe interface in Studio, there are limits to which changes a Studio user can apply that Canvas supports:
  • You can only share a model to Canvas that has been trained from the last node in a Data Wrangler linear data flow.
  • Only transformation nodes are supported.
  • You can’t perform operations on the Target column.
  • You can’t update the data type of columns.
  • You can’t update the data source or add a new data source.
• When sharing an alternative candidate to Canvas from the Studio Autopilot page, you can’t select the model from the leaderboard. You must choose the shared model from the banner and then select an alternative from the list. For more information, see Share an alternate model with the Canvas user in the Canvas documentation.
• Only models that are compatible with SageMaker Neo can be shared back to Canvas successfully. Compatible models are Autopilot models that use XGBoost or MLP algorithms. Incompatible models include Autopilot models that use the linear learner algorithm.
• For custom formula transforms using Spark SQL, Canvas only supports Unary operations, Aggregate functions, the String concatenation operation and the Power operation. Other operations are not supported.

Limitations for bring your own model (BYOM)

The following general limitations apply when you want to bring your own model to SageMaker Canvas.

• When a model is shared from Studio to Canvas, the Canvas user cannot update or view details on the dataset that was used to build the model.
• When a Canvas user wants to run a single prediction on an imported model, there are no data type restrictions when updating column values. You must manually make sure that when you update values for single predictions, you match the data type of the existing values.
• When a Canvas user wants to run batch predictions on an imported model, Canvas assumes that you (the Canvas user) know what the expected input dataset should look like. You should have a dataset with columns and data types that match the dataset that was used to train the model. If not, consult with the user who shared the model with you and import a dataset that you can use for running batch predictions.
• The Canvas application internally uses a serverless endpoint to run predictions and generate model metrics. The model shared to Canvas must be compatible with serverless endpoints:
  • The maximum memory size is 6144 MB.
  • When configuring the inference input response keys in your container, use the following configuration:

    ```
    INFEERENCE_INPUT_RESPONSE_KEYS = {
        "BINARY": ["predicted_label", "probability"],
        "MULTI_CLASS": ["predicted_label", "probability", "probabilities", "labels"],
    }
    ```
• You can choose either a SageMaker-provided inference container or bring your own image inference container to be used for endpoint. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks. If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see Adapting Your Own Inference Container.
• The Feature exclusions for serverless endpoints also apply.
• To share a model from Studio to Canvas successfully, Canvas accepts model inference outputs in the format below:
Regression: The model inference response should be a byte string where each of the output predictions are separated by 
:

b'\-0.0007884334772825241\n-0.015136942267417908\n0.050063662230968475\n0.02891816757619381\n'

Classification: The model inference response should be a byte string where each of predicted_label, predicted_probability, probabilities, and labels are separated by 
. The following example is for binary classification:

b'no,0.9967488050460815,\n[0.9967488050460815, 0.003251201706007123]\n\nno,0.9999420642852783,\n[0.9999420642852783, 5.793538566560824e-05]\n\nno,0.999846816062927,\n[0.999846816062927, 1.532657188363373e-05]\n\nno,0.9999727606773576,\n[0.9999727606773576, 2.726741877260865e-05]\n'

The following example is for multi-class classification:

b'Iris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n\nIris-setosa,1.0,\n[1.0, 0.0, 0.0]\n'

APPLICATION/JSON

Regression: The model inference response should be a JSON string which contains the prediction key, and its value should be the list of output predictions:

```json
let response = {
   "predictions": [
      // First instance prediction.
      1.75
      // Second instance prediction.
      3.25
   ]
}
```

Classification: The model inference response should be a JSON string which contains the probabilities key, and its value should be the list of probabilities.

The following example is for binary classification:

```json
let response = {
   "probabilities": [
      // First instance prediction.
      [0.9, 0.1]
      // Second instance prediction.
      [0.2, 0.8]
   ]
}
```

The following example is for multi-class classification:

```json
let response = {
   "probabilities": [
      // First instance prediction.
      [0.7, 0.2, 0.1]
   ]
}
```
There are also limitations that apply depending on the type of model you want to bring:

**Bring your own model from SageMaker JumpStart**

Review the following information and limits when sharing a SageMaker JumpStart model with Canvas.

- The following are the supported algorithms for which you can import models into Canvas. For more details, see the [SageMaker JumpStart documentation](#).
  - Tabular classification: LightGBM, CatBoost, XGBoost, AutoGluon-Tabular, TabTransformer, Linear Learner
  - Tabular regression: LightGBM, CatBoost, XGBoost, AutoGluon-Tabular, TabTransformer, Linear Learner

- In SageMaker JumpStart, the **Share** button is only turned on if the model is ready to share to Canvas. If your trained model does not have a **Share** to SageMaker Canvas button, your model is not supported for BYOM.

- You must provide training and validation datasets when training the SageMaker JumpStart model. The datasets should be stored in Amazon S3, and your Studio and Canvas users' execution role must have access to the Amazon S3 location. You can use the same Amazon S3 URIs to share the training and validation datasets with Canvas, or you can share different datasets with the same data schema.

Your training or validation data file should look like the following (in CSV format). You should index your files with the first column as the target.

```
3 1 2 2 1 1 0 4 4
0 0 3 8 0 0 1 3 4
1 0 6 7 0 1 0 1 6
1 0 6 7 0 0 2 2 6
0 0 4 0 0 2 6 6
2 0 5 6 1 0 1 2 6
```

- By default, SageMaker JumpStart uses the first column of the training and validation datasets as the target when training a model. The target column (or by default, the first column) of the datasets is shared to Canvas.

- You must provide the column headers of the training and validation datasets when training the SageMaker JumpStart model. By default, SageMaker JumpStart only accepts datasets without column headers, so you must add the column headers as a file while training your model. The Amazon S3 URI for the column headers file is shared to Canvas as well. Your column headers file should look like the following example (in CSV format). The first column should be the target.

```
Segmentation EverMarried Age Graduated WorkExperience SpendingScore FamilySize Var1
```

- The training job in SageMaker JumpStart must be **Complete** before you can share with Canvas.

- For classification problems (or categorical prediction in Canvas), original class names need to be provided in the **Configure model output** section when sharing to Canvas. The order of the class names must match the indexing used in the model. Your mapping relation file should look like the following example in CSV format, where index 0 (the first index) is mapped to the class name A:

```
A B C D
```

---

545
When the Canvas user views the model metrics in the Canvas application, they can only see the index of each class (0, 1, 2). However, the user can see the class names when viewing the results for a single prediction.

Bring your own model from Autopilot

Review the following information and limits when sharing a model from Autopilot to Canvas.

- You can only share models to Canvas that you've successfully trained from an AutoML job with Ensembling, HPO, or Auto mode (for Auto mode, Autopilot chooses Ensembling or HPO mode based on the training dataset size). The currently supported Autopilot problem types are Regression, Multi-class classification, Binary classification.

- For each Autopilot job, you can choose any model (the Best model or any other candidates) to share to Canvas one at a time. You only need to choose the Share model button and then specify the Canvas users with whom you'd like to share the model and a note.

- AutoGluon-Tabular models that use Data Wrangler transformers for inference cannot be shared to Canvas. This is because Data Wrangler transformers cause the model to use more than one container.

- HPO models that aren't compatible with SageMaker Neo can't be shared to Canvas successfully. Compatible models are Autopilot models that use XGBoost or MLP algorithms. Incompatible models include Autopilot models that use the linear learner algorithm.

Bring your own model from Model Registry

Review the following information and limits when sharing a model from Model Registry to Canvas.

- Unlike the Share button provided by SageMaker JumpStart, Model Registry doesn't provide model validation, so it's possible that a registered model shared successfully from Studio can fail while importing to Canvas due to model incompatibility. Review the following tips before sharing to Canvas from Model Registry:

  - Use a single inference container for your model. You can register models with multiple containers within the AdditionalInferenceSpecifications field, but Canvas is only optimized for one inference container per model. For example, when you use a inference pipeline and register multiple containers in the AdditionalInferenceSpecifications field with multiple data preprocessing containers and an inference container, by default the first container is selected for model inference in Canvas. Evaluate if this works for your use case if you're using machine learning pipelines.

  - Use a SageMaker built-in tabular algorithm with compatible inference formats. Tested sample algorithms with compatible inference outputs are AutoGluon-Tabular, CatBoost, LightGBM, TabTransformer and XGBoost. Algorithms like Factorization Machines don't accept CSV as file input, and the inference output formats for algorithms like Linear Learner and K-NN are not supported by Canvas.

  - You can also bring your own image container and share to Canvas, or modify pre-built SageMaker containers.
    - If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see Adapting Your Own Inference Container.
    - For detailed formatting for your inference output formats, see Limitations for bring your own model (BYOM) (p. 543).

  - When registering your model in a model package group, remember to provide the following attributes with your inference container:
    - Environment:
Manage billing and cost in SageMaker Canvas

To track the costs associated with your SageMaker Canvas application, you can use the AWS Billing and Cost Management service. Billing and Cost Management provides tools to help you gather information related to your cost and usage, analyze your cost drivers and usage trends, and take action to budget your spending. For more information, see What is AWS Billing and Cost Management?

Billing in SageMaker Canvas consists of the following components:

- **Workspace instance charges** – You are charged for the number of hours that you are logged in to or using SageMaker Canvas.
- **AWS service charges** – You are charged for building and making predictions with custom models, or for making predictions with Ready-to-use models:
  - Training charges – You are charged for the resources used to build a custom model.
  - Prediction charges – You are charged for the resources used to generate predictions, depending on the type of custom model that you built or the type of Ready-to-use model you used.

The Ready-to-use models (p. 418) in Canvas leverage other AWS services to generate predictions. When you use a Ready-to-use model, you are charged by the respective service, and their pricing conditions apply:

- For sentiment analysis, entities extraction, language detection, and personal information detection, you're charged with Amazon Comprehend pricing.
- For object detection in images and text detection in images, you're charged with Amazon Rekognition pricing.
For expense analysis, identity document analysis, and document analysis, you’re charged with Amazon Textract pricing.

For more information, see SageMaker Canvas pricing.

To help you track your costs in Billing and Cost Management, you can assign custom tags to your SageMaker Canvas app and users. You can track the costs your apps incur, and by tagging individual user profiles, you can track costs based on the user profile. For more information about tags, see Using Cost Allocation Tags.

You can add tags to your SageMaker Canvas app and users by doing the following:

- If you are setting up your Amazon SageMaker Domain and SageMaker Canvas for the first time, follow the Getting Started instructions and add tags when creating your Domain or users. You can add tags either through the General settings in the Domain console setup, or through the APIs (CreateDomain or CreateUserProfile). SageMaker adds the tags specified in your Domain or UserProfile to any SageMaker Canvas apps or users you create after you create the Domain.
- If you want to add tags to apps in an existing Domain, you must add tags to either the Domain or the UserProfile. You can adds tags through either the console or the AddTags API. If you add tags through the console, then you must delete and relaunch your SageMaker Canvas app in order for the tags to propagate to the app. If you use the API, the tags are added directly to the app. For more information about deleting and relaunching a SageMaker Canvas app, see Manage apps.

After you add tags to your Domain, it might take up to 24 hours for the tags to appear in the AWS Billing and Cost Management console for activation. After they appear in the console, it takes another 24 hours for the tags to activate.

On the Cost explorer page, you can group and filter your costs by tags and usage types to separate your Workspace instance (Session-Hrs) charges from your Training charges. The names of the usage types are as follows:

- Workspace instance (Session-Hrs) charges: REGION-Canvas:Session-Hrs (Hrs)
- Training charges:
  - REGION-Canvas:CreateModelRequest-Tier0 (CreateModelRequest)
  - REGION-Canvas:MillionCells-Tier1 (MillionCells)

Amazon SageMaker geospatial capabilities

Amazon SageMaker geospatial capabilities make it easier for data scientists and machine learning (ML) engineers to build, train, and deploy ML models faster using geospatial data. You have access to open-source and third-party data, processing, and visualization tools to make it more efficient to prepare geospatial data for ML. You can increase your productivity by using purpose-built algorithms and pre-trained ML models to speed up model building and training, and use built-in visualization tools to explore prediction outputs on an interactive map and then collaborate across teams on insights and results.

Note
Currently, SageMaker geospatial capabilities are only supported in the US West (Oregon) Region. If you don’t see the SageMaker geospatial UI available in your current Amazon SageMaker Studio instance check to make sure you are currently in the US West (Oregon) Region.

Why use SageMaker geospatial capabilities?
You can use SageMaker geospatial capabilities to make predictions on geospatial data faster than do-it-yourself solutions. SageMaker geospatial capabilities make it easier to access geospatial data

548
How can I use SageMaker geospatial capabilities?

Note
Currently, SageMaker geospatial capabilities are only supported in the US West (Oregon) Region. If you don't see the SageMaker geospatial capabilities available in your current Amazon SageMaker Studio instance or your SageMaker notebook instance check to make sure you are currently in the US West (Oregon) Region.

You can use SageMaker geospatial capabilities in two ways.

• Through the SageMaker geospatial UI, as a part of Amazon SageMaker Studio UI.
• Through a Studio notebook instance that uses the Geospatial 1.0 image.

SageMaker has the following geospatial capabilities

• Use a purpose built SageMaker geospatial image that supports both CPU and GPU-based notebook instances, and also includes commonly used open-source libraries found in geospatial machine learning workflows.
• Use the Amazon SageMaker Processing and the SageMaker geospatial container to run large-scale workloads with your own datasets, including soil, weather, climate, LiDAR, and commercial aerial and satellite imagery.
• Run an Earth Observation job for raster data processing.
• Run a Vector Enrichment job to convert latitude and longitude into human readable addresses, and match noisy GPS traces to specific roads.
• Use built-in visualization tools right in Studio to interactively view geospatial data or model predictions on a map.

You can also use data from a collection of geospatial data providers. Currently, the data collections available include:

• USGS Landsat
• Sentinel-1
• Sentinel-2
• Copernicus DEM
• National Agriculture Imagery Program

Are you a first-time user of SageMaker geospatial?

If you’re a first-time user of AWS or Amazon SageMaker, we recommend that you do the following:

1. Create an AWS account.

To learn about setting up an AWS account and getting started with SageMaker, see Set Up Amazon SageMaker Prerequisites (p. 8).

2. Create a user role and execution role that work with SageMaker geospatial.
As a managed service, Amazon SageMaker geospatial capabilities perform operations on your behalf on the AWS hardware that SageMaker manages. A SageMaker execution role can perform only the operations that users grant. To work with SageMaker geospatial capabilities, you must set up a user role and an execution role. For more information, see [SageMaker geospatial capabilities roles](p. 3406).

3. **Update your trust policy to include SageMaker geospatial.**

   SageMaker geospatial defines an additional service principal. To learn how to create or update your SageMaker execution role's trust policy, see [Adding the SageMaker geospatial service principal to an existing SageMaker execution role](p. 3407).

4. Set up an Amazon SageMaker Domain to access Amazon SageMaker Studio.

   For more information, see [Onboard to Amazon SageMaker Domain](p. 3407).

5. When you have finished using SageMaker geospatial capabilities, shut down the instance it runs on to avoid incurring additional charges. For more information, see [Shut Down Resources](p. 237).

- Data collections (p. 599)

**Getting Started with Amazon SageMaker geospatial**

SageMaker geospatial provides a purpose built [image](p. 550) and [instance type](p. 560) for Amazon SageMaker Studio notebooks. You can use either CPU or GPU enabled notebooks with the SageMaker geospatial image. You can also visualize your geospatial data using a purpose built visualizer. Furthermore, SageMaker geospatial also provides APIs that allow you to query raster data collections. You can also use pre-trained models to analyze geospatial data, reverse geocoding, and map matching.

To access and get started using Amazon SageMaker geospatial, do the following:

1. Make sure that you have completed each step in the [Are you a first-time user of SageMaker geospatial?](p. 549) section.
2. Follow the procedure in [Create an Amazon SageMaker Studio notebook using the geospatial image](p. 551) to create a notebook.
3. Use the [earth observation jobs (EOJs) API](p. 551) to process Sentinel-2 image data and perform land segmentation on it.
Create an Amazon SageMaker Studio notebook using the geospatial image

Before you start the following procedure, create a domain in Amazon SageMaker Domain by following the steps in Onboard to Amazon SageMaker Domain. After creating a domain, you can access the capabilities that Amazon SageMaker geospatial provides.

**Note**
Currently, SageMaker geospatial is only supported in the US West (Oregon) Region. If you don't see SageMaker geospatial available in your current domain or notebook instance, make sure that you're currently in the US West (Oregon) Region.

To create a SageMaker Studio notebook with a SageMaker geospatial image

1. Choose **Home** in the menu bar.
2. Under **Quick actions**, choose **Open Launcher**.
3. When the **Launcher** dialog box opens, choose **Change environment** under **Notebooks and compute resources**.
4. When the **Change environment** dialog box opens, choose the **Image** dropdown and choose or type **Geospatial 1.0**.
5. Next, choose an **Instance type** from the dropdown.

SageMaker geospatial supports two types of notebook instances: CPU and GPU. The supported CPU instance is called **ml.geospatial.interactive**. Any of the G5-family of GPU instances can be used with the Geospatial 1.0 image.

**Note**
If you receive a ResourceLimitExceeded error when attempting to start a GPU based instance, you need to request a quota increase. To get started on a Service Quotas quota increase request, see Requesting a quota increase in the Service Quotas User Guide.

6. Choose **Select**.
7. Choose **Create notebook**.

After creating a notebook, to learn more about SageMaker geospatial, try the SageMaker geospatial tutorial (p. 551). It shows you how to process Sentinel-2 image data and perform land segmentation on it using the earth observation jobs API.

**Access the Sentinel-2 raster data collection and create an earth observation job to perform land segmentation**

This Python-based tutorial uses the SDK for Python (Boto3) and an Amazon SageMaker Studio notebook. To complete this demo successfully, make sure that you have the required AWS Identity and Access Management (IAM) permissions to use SageMaker geospatial and Studio. SageMaker
geospatial requires that you have a user, group, or role which can access Studio. You must also have a SageMaker execution role that specifies the SageMaker geospatial service principal, sagemaker-geospatial.amazonaws.com in its trust policy.

To learn more about these requirements, see [SageMaker geospatial IAM roles](p. 3406).

This tutorial shows you how to use SageMaker geospatial API to complete the following tasks:

- Find the available raster data collections with `list_raster_data_collections`
- Search a specified raster data collection by using `search_raster_data_collection`
- Create an earth observation job (EOJ) by using `start_earth_observation_job`

## Using `list_raster_data_collections` to find available data collections

SageMaker geospatial supports multiple raster data collections. To learn more about the available data collections, see [Data collections](p. 599).

This demo uses satellite data that's collected from **Sentinel-2 Cloud-Optimized GeoTIFF** satellites. These satellites provide global coverage of Earth's land surface every five days. In addition to collecting surface images of Earth, the Sentinel-2 satellites also collect data across a variety of spectral bands.

To search an area of interest (AOI), you need the ARN that's associated with the Sentinel-2 satellite data. To find the available data collections and their associated ARNs in your AWS Region, use the `list_raster_data_collections` API operation.

Because the response can be paginated, you must use the `get_paginator` operation to return all of the relevant data:

```python
import boto3
import sagemaker
import sagemaker_geospatial_map
import json

## SageMaker Geospatial is currently only available in US-WEST-2
session = boto3.Session(region_name='us-west-2')
execution_role = sagemaker.get_execution_role()

## Creates a SageMaker Geospatial client instance
geospatial_client = session.client(service_name="sagemaker-geospatial")

# Creates a reusable Paginator for the list_raster_data_collections API operation
paginator = geospatial_client.get_paginator("list_raster_data_collections")

# Create a PageIterator from the paginator class
page_iterator = paginator.paginate()

# Use the iterator to iterate through the results of list_raster_data_collections
results = []
for page in page_iterator:
    results.append(page['RasterDataCollectionSummaries'])

print(results)
```

This is a sample JSON response from the `list_raster_data_collections` API operation. It's truncated to include only the data collection (Sentinel-2) that's used in this code example. For more details about a specific raster data collection, use `get_raster_data_collection`:

```json
{
}
```
"Description": "Sentinel-2a and Sentinel-2b imagery, processed to Level 2A (Surface Reflectance) and converted to Cloud-Optimized GeoTIFFs",
"DescriptionPageUrl": "https://registry.opendata.aws/sentinel-2-l2a-cogs",
"Name": "Sentinel 2 L2A COGs",
"SupportedFilters": [
    {
        "Maximum": 100,
        "Minimum": 0,
        "Name": "EoCloudCover",
        "Type": "number"
    },
    {
        "Maximum": 90,
        "Minimum": 0,
        "Name": "ViewOffNadir",
        "Type": "number"
    },
    {
        "Name": "Platform",
        "Type": "string"
    }
],
"Tags": {},
"Type": "PUBLIC"

After running the previous code sample, you get the ARN of the Sentinel-2 raster data collection,

**Searching the Sentinel-2 raster data collection using search_raster_data_collection**

In the preceding section, you used list_raster_data_collections to get the ARN for the Sentinel-2 data collection. Now you can use that ARN to search the data collection over a given area of interest (AOI), time range, properties, and the available UV bands.

To call the search_raster_data_collection API you must pass in a Python dictionary to the RasterDataCollectionQuery parameter. This example uses AreaOfInterest, TimeRangeFilter, PropertyFilters, and BandFilter. For ease, you can specify the Python dictionary using the variable search_rdc_query to hold the search query parameters:

```python
search_rdc_query = {
    "AreaOfInterest": {
        "AreaOfInterestGeometry": {
            "PolygonGeometry": {
                "Coordinates": [
                    # coordinates are input as longitude followed by latitude
                    [-114.529, 36.142],
                    [-114.373, 36.142],
                    [-114.373, 36.411],
                    [-114.529, 36.411],
                    [-114.529, 36.142],
                ]
            }
        }
    },
    "TimeRangeFilter": {
        "StartTime": "2022-01-01T00:00:00Z",
    }
}
```
In this example, you query an AreaOfInterest that includes Lake Mead in Utah. Furthermore, Sentinel-2 supports multiple types of image bands. To measure the change in the surface of the water, you only need the visual band.

After you create the query parameters, you can use the search_raster_data_collection API to make the request.

The following code sample implements a search_raster_data_collection API request. This API does not support pagination using the get_paginator API. To make sure that the full API response has been gathered the code sample uses a while loop to check that NextToken exists. The code sample then uses .extend() to append the satellite image URLs and other response metadata to the items_list.

To learn more about the search_raster_data_collection, see SearchRasterDataCollection in the Amazon SageMaker API Reference.

```python
search_rdc_response = sm_geo_client.search_raster_data_collection(
    RasterDataCollectionQuery=search_rdc_query
)

## items_list is the response from the API request.
items_list = []

## Use the python .get() method to check that the 'NextToken' exists, if null returns None breaking the while loop
while search_rdc_response.get('NextToken'):
    items_list.extend(search_rdc_response['Items'])
    search_rdc_response = sm_geo_client.search_raster_data_collection(
        RasterDataCollectionQuery=search_rdc_query,
        NextToken=search_rdc_response['NextToken']
    )

## Print the number of observation return based on the query
print(len(items_list))
```

The following is a JSON response from your query. It has been truncated for clarity. Only the "BandFilter": ["visual"] specified in the request is returned in the Assets key-value pair:
Now that you have your query results, in the next section you can visualize the results by using matplotlib. This is to verify that results are from the correct geographical region.

**Visualizing your search_raster_data_collection using matplotlib**

Before you start the earth observation job (EOJ), you can visualize a result from our query with matplotlib. The following code sample takes the first item, items_list[0]["Assets"] ["visual"] ["Href"], from the items_list variable created in the previous code sample and prints an image using matplotlib.

```python
# Visualize an example image.
import os
from urllib import request
import tifffile
import matplotlib.pyplot as plt

image_dir = "./images/lake_mead"
os.makedirs(image_dir, exist_ok=True)

image_url = items_list[0]["Assets"] ["visual"] ["Href"]
img_id = image_url.split("/")[-2]
path_to_image = image_dir + "/" + img_id + ".TCI.tif"
response = request.urlretrieve(image_url, path_to_image)
print("Downloaded image: " + img_id)
tci = tifffile.imread(path_to_image)
plt.figure(figsize=(6, 6))
plt.imshow(tci)
plt.show()
```
After checking that the results are in the correct geographical region, you can start the Earth Observation Job (EOJ) in the next step. You use the EOJ to identify the water bodies from the satellite images by using a process called land segmentation.

Starting an earth observation job (EOJ) that performs land segmentation on a series of Satellite images

SageMaker geospatial provides multiple pre-trained models that you can use to process geospatial data from raster data collections. To learn more about the available pre-trained models and custom operations, see Types of Operations (p. 574).

To calculate the change in the water surface area, you need to identify which pixels in the images correspond to water. Land cover segmentation is a semantic segmentation model supported by the start_earth_observation_job API. Semantic segmentation models associate a label with every pixel in each image. In the results, each pixel is assigned a label that's based on the class map for the model. The following is the class map for the land segmentation model:

```python
{
    0: "No_data",
    1: "Saturated_or_defective",
    2: "Dark_area_pixels",
    3: "Cloud_shadows",
    4: "Vegetation",
    5: "Not_vegetated",
    6: "Water",
    7: "Unclassified",
    8: "Cloud_medium_probability",
    9: "Cloud_high_probability",
   10: "Thin_cirrus",
   11: "Snow_ice"
}
```

To start an earth observation job, use the start_earth_observation_job API. When you submit your request, you must specify the following:

- **InputConfig (dict)** – Used to specify the coordinates of the area that you want to search, and other metadata that's associated with your search.
- **JobConfig (dict)** – Used to specify the type of EOJ operation that you performed on the data. This example uses LandCoverSegmentationConfig.
- **ExecutionRoleArn (string)** – The ARN of the SageMaker execution role with the necessary permissions to run the job.
- **Name (string)** – A name for the earth observation job.

The InputConfig is a Python dictionary. Use the following variable `eoj_input_config` to hold the search query parameters. Use this variable when you make the start_earth_observation_job API request.

```python
# Perform land cover segmentation on images returned from the Sentinel-2 dataset.
eoj_input_config = {
   "RasterDataCollectionQuery": {
   "AreaOfInterest": {
       "PolygonGeometry": {
           "Coordinates": [
               [-114.529, 36.142]
           ]
       }
   }
}
```
The JobConfig is a Python dictionary that is used to specify the EOJ operation that you want performed on your data:

eoj_config = {"LandCoverSegmentationConfig": {}}

With the dictionary elements now specified, you can submit your start_earth_observation_job API request using the following code sample:

```python
# Gets the execution role arn associated with current notebook instance
execution_role_arn = sagemaker.get_execution_role()

# Starts an earth observation job
response = sm_geo_client.start_earth_observation_job(
    Name="lake-mead-landcover",
    InputConfig=eoj_input_config,
    JobConfig=eoj_config,
    ExecutionRoleArn=execution_role_arn,
)
print(response)
```

The start an earth observation job returns an ARN along with other metadata.

To get a list of all ongoing and current earth observation jobs use the list_earth_observation_jobs API. To monitor the status of a single earth observation job use the get_earth_observation_job API. To make this request, use the ARN created after submitting your EOJ request. To learn more, see GetEarthObservationJob in the Amazon SageMaker API Reference.

To find the ARNs associated with your EOJs use the list_earth_observation_jobs API operation. To learn more, see ListEarthObservationJobs in the Amazon SageMaker API Reference.

```python
# List all jobs in the account
sg_client.list_earth_observation_jobs()["EarthObservationJobSummaries"]
```

The following is an example JSON response:

```json
{
    "CreationTime": datetime.datetime(2023, 10, 19, 4, 33, 54, 21481, tzinfo = tzlocal()),
    ...
}
```
After the status of your EOJ job changes to **COMPLETED**, proceed to the next section to calculate the change in Lake Mead's surface area.

### Calculating the change in the Lake Mead surface area

To calculate the change in Lake Mead's surface area, first export the results of the EOJ to Amazon S3 by using `export_earth_observation_job`:

```python
sagemaker_session = sagemaker.Session()
s3_bucket_name = sagemaker_session.default_bucket()  # Replace with your own bucket if needed
s3_bucket = session.resource("s3").Bucket(s3_bucket_name)
prefix = "export-lake-mead-eoj"  # Replace with the S3 prefix desired
export_bucket_and_key = f"s3://{s3_bucket_name}/{prefix}/"
eoj_output_config = {"S3Data": {"S3Uri": export_bucket_and_key}}
export_response = sm_geo_client.export_earth_observation_job(
    ExecutionRoleArn=execution_role_arn,
    OutputConfig=eoj_output_config,
    ExportSourceImages=False,
)
```

To see the status of your export job, use `get_earth_observation_job`:

```python
export_job_details = sm_geo_client.get_earth_observation_job(Arn=export_response["Arn"])```

To calculate the changes in Lake Mead's water level, download the land cover masks to the local SageMaker notebook instance and download the source images from our previous query. In the class map for the land segmentation model, the water's class index is 6.

To extract the water mask from a Sentinel-2 image, follow these steps. First, count the number of pixels marked as water (class index 6) in the image. Second, multiply the count by the area that each pixel covers. Bands can differ in their spatial resolution. For the land cover segmentation model all bands are down sampled to a spatial resolution equal to 60 meters.
from botocore.config import Config

# Download land cover masks
mask_dir = "%s/masks/lake_mead"
for s3_object in s3_bucket.objects.filter(Prefix=prefix).all():
    path, filename = os.path.split(s3_object.key)
    if "output" in path:
        mask_name = mask_dir + "" + filename
        s3_bucket.download_file(s3_object.key, mask_name)
        print("Downloaded mask: " + mask_name)

# Download source images for visualization
for tci_url in tci_urls:
    img_id = url_parts.path.split('/')[-2]
    tci_download_path = image_dir + '/' + img_id + '_TCI.tif'
    cogs_bucket.download_file(url_parts.path, tci_download_path)
    print("Downloaded image: " + img_id)

print("Downloads complete.")

# Plot water surface area vs. time.
plt.figure(fignsize=(20,10))
plt.title('Lake Mead surface area for the 2021.02 - 2022.07 period.', fontsize=20)
plt.ylabel('Water surface area [sq km]', fontsize=14)
plt.plot(mask_dates, lake_areas, marker='o')
plt.grid('on')
plt.ylim(240, 320)
for i, v in enumerate(lake_areas):
    plt.text(i, v+2, "%d" %v, ha='center')
plt.show()

Using matplotlib, you can visualize the results with a graph. The graph shows that the surface area of Lake Mead decreased from January 2021–July 2022.

Using a processing jobs for custom geospatial workloads

With Amazon SageMaker Processing (p. 1399), you can use a simplified, managed experience on SageMaker to run your data processing workloads with the purpose-built geospatial container.

The underlying infrastructure for a Amazon SageMaker Processing job is fully managed by SageMaker. During a processing job, cluster resources are provisioned for the duration of your job, and cleaned up when a job completes.

The preceding diagram shows how SageMaker spins up a geospatial processing job. SageMaker takes your geospatial workload script, copies your geospatial data from Amazon Simple Storage Service(Amazon S3), and then pulls the specified geospatial container. The underlying infrastructure for the processing job is fully managed by SageMaker. Cluster resources are provisioned for the duration of your job, and cleaned up when a job completes. The output of the processing job is stored in the bucket you specified.

Path naming constraints
The local paths inside a Processing jobs container must begin with /opt/ml/processing/.
SageMaker geospatial provides a purpose-built container, 081189585635.dkr.ecr.us-west-2.amazonaws.com/sagemaker-geospatial-v1-0:latest that can be specified when running a processing job.

Topics
- Overview: Run processing jobs using ScriptProcessor and a SageMaker geospatial container (p. 561)
- Using ScriptProcessor to calculate the Normalized Difference Vegetation Index (NDVI) using Sentinel-2 satellite data (p. 563)

Overview: Run processing jobs using ScriptProcessor and a SageMaker geospatial container

SageMaker geospatial provides a purpose-built processing container, 081189585635.dkr.ecr.us-west-2.amazonaws.com/sagemaker-geospatial-v1-0:latest. You can use this container when running a job with Amazon SageMaker Processing. When you create an instance of the ScriptProcessor class that is available through the Amazon SageMaker Python SDK for Processing, specify this image_uri.

Note
If you receive a ResourceLimitExceeded error when attempting to start a processing job, you need to request a quota increase. To get started on a Service Quotas quota increase request, see Requesting a quota increase in the Service Quotas User Guide

Prerequisites for using ScriptProcessor

1. You have created a Python script that specifies your geospatial ML workload.
2. You have granted the SageMaker execution role access to any Amazon S3 buckets that are needed.
3. Prepare your data for import into the container. Amazon SageMaker Processing jobs support either setting the s3_data_type equal to "ManifestFile" or to "S3Prefix".

The following procedure shows you how to create an instance of ScriptProcessor and submit a Amazon SageMaker Processing job using the SageMaker geospatial container.

To create a ScriptProcessor instance and submit a Amazon SageMaker Processing job using a SageMaker geospatial container

1. Instantiate an instance of the ScriptProcessor class using the SageMaker geospatial image:

   ```python
   from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput
   sm_session = sagemaker.session.Session()
   execution_role_arn = sagemaker.get_execution_role()

   # purpose-built geospatial container
   image_uri = '081189585635.dkr.ecr.us-west-2.amazonaws.com/sagemaker-geospatial-v1-0:latest'

   script_processor = ScriptProcessor(
       command=['python3'],
       image_uri=image_uri,
       role=execution_role_arn,
       instance_count=4,
       instance_type='ml.m5.4xlarge',
       sagemaker_session=sm_session
   )
   ```
Replace *execution_role_arn* with the ARN of the SageMaker execution role that has access to the input data stored in Amazon S3 and any other AWS services that you want to call in your processing job. You can update the `instance_count` and the `instance_type` to match the requirements of your processing job.

2. To start a processing job, use the `.run()` method:

```python
# Can be replaced with any S3 compliant string for the name of the folder.
s3_folder = geospatial-data-analysis

# Use .default_bucket() to get the name of the S3 bucket associated with your current SageMaker session
s3_bucket = sm_session.default_bucket()

s3_manifest_uri = f's3://{s3_bucket}/{s3_folder}/manifest.json'
s3_prefix_uri = f's3://{s3_bucket}/{s3_folder}/image-prefix

script_processor.run(
    code='preprocessing.py',
    inputs=[
        ProcessingInput(
            source=s3_manifest_uri | s3_prefix_uri,
            destination='/opt/ml/processing/input_data/',
            s3_data_type="ManifestFile" | "S3Prefix",
            s3_data_distribution_type="ShardedByS3Key" | "FullyReplicated"
        ),
    ],
    outputs=[
        ProcessingOutput(
            source='/opt/ml/processing/output_data/',
            destination=s3_output_prefix_url
        )
    ]
)
```

- Replace `preprocessing.py` with the name of your own Python data processing script.

- A processing job supports two methods for formatting your input data. You can either create a manifest file that points to all of the input data for your processing job, or you can use a common prefix on each individual data input. If you created a manifest file set `s3_manifest_uri` equal to "ManifestFile". If you used a file prefix set `s3_manifest_uri` equal to "S3Prefix". You specify the path to your data using `source`.

- You can distribute your processing job data two ways:
  - Distribute your data to all processing instances by setting `s3_data_distribution_type` equal to FullyReplicated.
  - Distribute your data in shards based on the Amazon S3 key by setting `s3_data_distribution_type` equal to ShardedByS3Key. When you use ShardedByS3Key one shard of data is sent to each processing instance.

You can use a script to process SageMaker geospatial data. That script can be found in Step 3: Writing a script that can calculate the NDVI (p. 567). To learn more about the `.run()` API operation, see `run` in the Amazon SageMaker Python SDK for Processing.

To monitor the progress of your processing job, the ProcessingJobs class supports a `describe` method. This method returns a response from the DescribeProcessingJob API call. To learn more, see `DescribeProcessingJob` in the Amazon SageMaker API Reference.
The next topic shows you how to create an instance of the ScriptProcessor class using the SageMaker geospatial container, and then how to use it to calculate the Normalized Difference Vegetation Index (NDVI) with Sentinel-2 images.

Using ScriptProcessor to calculate the Normalized Difference Vegetation Index (NDVI) using Sentinel-2 satellite data

The following code samples show you how to calculate the normalized difference vegetation index of a specific geographical area using the purpose-built geospatial image within a Studio notebook and run a large-scale workload with Amazon SageMaker Processing using ScriptProcessor from the SageMaker Python SDK.

This demo also uses an Amazon SageMaker Studio notebook instance that uses the geospatial kernel and instance type. To learn how to create a Studio geospatial notebook instance, see Create an Amazon SageMaker Studio notebook using the geospatial image (p. 551).

You can follow along with this demo in your own notebook instance by copying and pasting the following code snippets:

1. **Use search_raster_data_collection to query a specific area of interest (AOI) over a given time range using a specific raster data collection, Sentinel-2.** (p. 563)
2. **Create a manifest file that specifies what data will be processed during the processing job.** (p. 565)
3. **Write a data processing Python script calculating the NDVI.** (p. 567)
4. **Create a ScriptProcessor instance and start the Amazon SageMaker Processing job.** (p. 568)
5. **Visualizing the results of your processing job** (p. 569).

Query the Sentinel-2 raster data collection using SearchRasterDataCollection

With search_raster_data_collection you can query supported raster data collections. This example uses data that's pulled from Sentinel-2 satellites. The area of interest (AreaOfInterest) specified is rural northern Iowa, and the time range (TimeRangeFilter) is January 1, 2022 to December 30, 2022. To see the available raster data collections in your AWS Region use list_raster_data_collections. To see a code example using this API, see ListRasterDataCollections (p. 599) in the *Amazon SageMaker Developer Guide*.

A search_raster_data_collection API request requires two parameters:

- You need to specify an Arn parameter that corresponds to the raster data collection that you want to query.
- You also need to specify a RasterDataCollectionQuery parameter, which takes in a Python dictionary.

The following code example contains the necessary key-value pairs needed for the RasterDataCollectionQuery parameter saved to the search_rdc_query variable.

```python
search_rdc_query = {
```
To make the `search_raster_data_collection` request, you must specify the ARN of the Sentinel-2 raster data collection: `arn:aws:sagemaker-geospatial:us-west-2:378778860802:raster-data-collection/public/nmqj48dcu3g7ayw8`. You also must need to pass in the Python dictionary that was defined previously, which specifies query parameters.

```python
## Creates a SageMaker Geospatial client instance
sm_geo_client= session.create_client(service_name="sagemaker-geospatial")

search_rdc_response1 = sm_geo_client.search_raster_data_collection(
    RasterDataCollectionQuery=search_rdc_query
)
```

The results of this API can not be paginated. To collect all the satellite images returned by the `search_raster_data_collection` operation, you can implement a while loop. This checks for `NextToken` in the API response:

```python
## Holds the list of API responses from search_raster_data_collection
items_list = []
while search_rdc_response1.get('NextToken') and search_rdc_response1['NextToken'] != None:
    items_list.extend(search_rdc_response1['Items'])

    search_rdc_response1 = sm_geo_client.search_raster_data_collection(
        RasterDataCollectionQuery=search_rdc_query,
        NextToken=search_rdc_response1['NextToken']
    )
```
The API response returns a list of URLs under the `Assets` key corresponding to specific image bands. The following is a truncated version of the API response. Some of the image bands were removed for clarity.

```json
{
    'Assets': {
        'aot': {
            'Href': 'https://sentinel-cogs.s3.us-west-2.amazonaws.com/sentinel-s2-l2a-cogs/15/T/UH/2022/12/S2A_15TUH_20221230_0_L2A/AOT.tif'
        },
        'blue': {
            'Href': 'https://sentinel-cogs.s3.us-west-2.amazonaws.com/sentinel-s2-l2a-cogs/15/T/UH/2022/12/S2A_15TUH_20221230_0_L2A/B02.tif'
        },
        'swir22-jp2': {
            'Href': 's3://sentinel-s2-l2a/tiles/15/T/UH/2022/12/30/0/B12.jp2'
        },
        'visual-jp2': {
            'Href': 's3://sentinel-s2-l2a/tiles/15/T/UH/2022/12/30/0/TCI.jp2'
        },
        'wvp-jp2': {
            'Href': 's3://sentinel-s2-l2a/tiles/15/T/UH/2022/12/30/0/WVP.jp2'
        }
    },
    'DateTime': datetime.datetime(2022, 12, 30, 17, 21, 52, 469000, tzinfo = tzlocal()),
    'Geometry': {
        'Coordinates': [
            [-95.46676936182894, 43.32623760511659],
            [-94.11293433656887, 43.347431265475954],
            [-94.09532154452742, 42.35884880571144],
            [-95.42776890002203, 42.3383710796791],
            [-95.46676936182894, 43.32623760511659]
        ],
        'Type': 'Polygon'
    },
    'Id': 'S2A_15TUH_20221230_0_L2A',
    'Properties': {
        'EoCloudCover': 62.384969,
        'Platform': 'sentinel-2a'
    }
}
```

In the [next section](p. 565), you create a manifest file using the 'Id' key from the API response.

### Create an input manifest file using the Id key from the search_raster_data_collection API response

When you run a processing job, you must specify a data input from Amazon S3. The input data type can either be a manifest file, which then points to the individual data files. You can also add a prefix to each file that you want processed. The following code example defines the folder where your manifest files will be generated.

Use SDK for Python (Boto3) to get the default bucket and the ARN of the execution role that is associated with your Studio notebook instance:

```python
sm_session = sagemaker.session.Session()
s3 = boto3.resource('s3')
# Gets the default execution role associated with the notebook
execution_role_arn = sagemaker.get_execution_role()
```
# Gets the default bucket associated with the notebook
s3_bucket = sm_session.default_bucket()

# Can be replaced with any name
s3_folder = "script-processor-input-manifest"

Next, you create a manifest file. It will hold the URLs of the satellite images that you wanted processed when you run your processing job later in step 4.

# Format of a manifest file
manifest_prefix = {}
manifest_prefix['prefix'] = 's3://' + s3_bucket + '/' + s3_folder + '/'
manifest = [manifest_prefix]

print(manifest)

The following code sample returns the S3 URI where your manifest files will be created.

[[{'prefix': 's3://sagemaker-us-west-2-111122223333/script-processor-input-manifest/'}]]

All the response elements from the search_raster_data_collection response are not needed to run the processing job.

The following code snippet removes the unnecessary elements 'Properties', 'Geometry', and 'DateTime'. The 'Id' key-value pair, 'Id': 'S2A_15TUH_20221230_0_L2A', contains the year and the month. The following code example parses that data to create new keys in the Python dictionary `dict_month_items`. The values are the assets that are returned from the SearchRasterDataCollection query.

# For each response get the month and year, and then remove the metadata not related to the satellite images.
dict_month_items = {}
for item in items_list:
    # Example ID being split: 'S2A_15TUH_20221230_0_L2A'
    yyyymm = item['Id'].split('_')[2][:6]
    if yyyymm not in dict_month_items:
        dict_month_items[yyyymm] = []

    # Removes unneeded metadata elements for this demo
    item.pop('Properties', None)
    item.pop('Geometry', None)
    item.pop('DateTime', None)

    # Appends the response from search_raster_data_collection to newly created key above
    dict_month_items[yyyymm].append(item)

This code example uploads the `dict_month_items` to Amazon S3 as a JSON object using the `.upload_file()` API operation:

```python
# key_ is the yyyymm timestamp formatted above
# value_ is the reference to all the satellite images collected via our searchRDC query
for key_, value_ in dict_month_items.items():
    filename = f'manifest_{key_}.json'
    with open(filename, 'w') as fp:
        json.dump(value_, fp)
    s3.meta.client.upload_file(filename, s3_bucket, s3_folder + '/' + filename)
    manifest.append(filename)
    os.remove(filename)
```
This code example uploads a parent manifest.json file that points to all the other manifests uploaded to Amazon S3. It also saves the path to a local variable: `s3_manifest_uri`. You'll use that variable again to specify the source of the input data when you run the processing job in step 4.

```python
with open('manifest.json', 'w') as fp:
    json.dump(manifest, fp)
s3.meta.client.upload_file('manifest.json', s3_bucket, s3_folder + '/manifest.json')
os.remove('manifest.json')
s3_manifest_uri = f's3://{s3_bucket}/{s3_folder}/manifest.json'
```

Now that you created the input manifest files and uploaded them, you can write a script that processes your data in the processing job. It processes the data from the satellite images, calculates the NDVI, and then returns the results to a different Amazon S3 location.

**Write a script that calculates the NDVI**

Amazon SageMaker Studio supports the use of the `%writefile` cell magic command. After running a cell with this command, its contents will be saved to your local Studio directory. This is code specific to calculating NDVI. However, the following can be useful when you write your own script for a processing job:

- In your processing job container, the local paths inside the container must begin with `/opt/ml/processing/`. In this example, `input_data_path = '/opt/ml/processing/input_data/'` and `processed_data_path = '/opt/ml/processing/output_data/'` are specified in that way.

- With Amazon SageMaker Processing, a script that a processing job runs can upload your processed data directly to Amazon S3. To do so, make sure that the execution role associated with your ScriptProcessor instance has the necessary requirements to access the S3 bucket. You can also specify an outputs parameter when you run your processing job. To learn more, see the `.run()` API operation in the Amazon SageMaker Python SDK. In this code example, the results of the data processing are uploaded directly to Amazon S3.

- To manage the size of the Amazon EBS container attached to your processing job use the `volume_size_in_gb` parameter. The container's default size is 30 GB. You can also optionally use the Python library `Garbage Collector` to manage storage in your Amazon EBS container.

The following code example loads the arrays into the processing job container. When arrays build up and fill in the memory, the processing job crashes. To prevent this crash, the following example contains commands that remove the arrays from the processing job's container.

```python
%%writefile compute_ndvi.py
import os
import pickle
import sys
import subprocess
import json
import rioxarray
if __name__ == '__main__':
    print("Starting processing")
    input_data_path = '/opt/ml/processing/input_data/
    input_files = []
    for current_path, sub_dirs, files in os.walk(input_data_path):
        for file in files:
            if file.endswith(".json"):
                input_files.append(os.path.join(current_path, file))
```

```
print("Received {} input_files: ".format(len(input_files), input_files))

items = []
for input_file in input_files:
    full_file_path = os.path.join(input_data_path, input_file)
    print(full_file_path)
    with open(full_file_path, 'r') as f:
        items.append(json.load(f))

items = [item for sub_items in items for item in sub_items]
for item in items:
    red_uri = item["Assets"]["red"]["Href"]
    nir_uri = item["Assets"]["nir"]["Href"]

    red = rioxarray.open_rasterio(red_uri, masked=True)
    nir = rioxarray.open_rasterio(nir_uri, masked=True)

    ndvi = (nir - red) / (nir + red)

    file_name = 'ndvi_' + item["Id"] + '.tif'
    output_path = '/opt/ml/processing/output_data'
    output_file_path = f"{output_path}/{file_name}"
    ndvi.rio.to_raster(output_file_path)
    print("Written output:", output_file_path)

You now have a script that can calculate the NDVI. Next, you can create an instance of the ScriptProcessor and run your Processing job.

**Creating an instance of the ScriptProcessor class**

This demo uses the `ScriptProcessor` class that is available via the Amazon SageMaker Python SDK. First, you need to create an instance of the class, and then you can start your Processing job by using the `.run()` method.

```python
from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput

image_uri = '081189585635.dkr.ecr.us-west-2.amazonaws.com/sagemaker-geospatial-v1-0:latest'

processor = ScriptProcessor(
    command=['python3'],
    image_uri=image_uri,
    role=execution_role_arn,
    instance_count=4,
    instance_type='ml.m5.4xlarge',
    sagemaker_session=sm_session
)

print('Starting processing job.')
```

When you start your Processing job, you need to specify a `ProcessingInput` object. In that object, you specify the following:

- The path to the manifest file that you created in step 2, `s3_manifest_uri`. This is the source of the input data to the container.
- The path to where you want the input data to be saved in the container. This must match the path that you specified in your script.
- Use the `s3_data_type` parameter to specify the input as "ManifestFile".
s3_output_prefix_url = f"s3://{s3_bucket}/{s3_folder}/output"

processor.run(
    code='compute_ndvi.py',
    inputs=[
        ProcessingInput(
            source=s3_manifest_uri,
            destination='/opt/ml/processing/input_data/',
            s3_data_type="ManifestFile",
            s3_data_distribution_type="ShardedByS3Key"
        ),
    ],
    outputs=[
        ProcessingOutput(
            source='/opt/ml/processing/output_data/',
            destination=s3_output_prefix_url,
            s3_upload_mode="Continuous"
        )
    ]
)

The following code example uses the `.describe()` method to get details of your Processing job.

```python
preprocessing_job_descriptor = processor.jobs[-1].describe()
s3_output_uri = preprocessing_job_descriptor["ProcessingOutputConfig"]['Outputs'][0]["S3Output"]['S3Uri']
print(s3_output_uri)
```

**Visualizing your results using matplotlib**

With the Matplotlib Python library, you can plot raster data. Before you plot the data, you need to calculate the NDVI using sample images from the Sentinel-2 satellites. The following code example opens the image arrays using the `.open_rasterio()` API operation, and then calculates the NDVI using the nir and red image bands from the Sentinel-2 satellite data.

```python
# Opens the python arrays
import rioxarray
red_uri = items[25]["Assets"]["red"]["Href"]
nir_uri = items[25]["Assets"]["nir"]["Href"]
red = rioxarray.open_rasterio(red_uri, masked=True)
nir = rioxarray.open_rasterio(nir_uri, masked=True)

# Calculates the NDVI
ndvi = (nir - red) / (nir + red)

# Common plotting library in Python
import matplotlib.pyplot as plt
f, ax = plt.subplots(figsize=(18, 18))
ndvi.plot(cmap='viridis', ax=ax)
ax.set_title("NDVI for {}".format(items[25]["Id"]))
ax.set_axis_off()
plt.show()
```

The output of the preceding code example is a satellite image with the NDVI values overlaid on it. An NDVI value near 1 indicates lots of vegetation is present, and values near 0 indicate no vegetation is present.
This completes the demo of using ScriptProcessor.

Earth Observation Jobs

Using an Earth Observation job (EOJ), you can acquire, transform, and visualize geospatial data to make predictions. You can choose an operation based on your use case from a wide range of operations and models. You get the flexibility of choosing your area of interest, selecting the data providers, and setting time-range based and cloud-cover-percentage-based filters. After SageMaker creates an EOJ for you, you can visualize the inputs and outputs of the job using the visualization functionality. An EOJ has various use cases that include comparing deforestation over time and diagnosing plant health. You can create an EOJ by using a SageMaker notebook with a SageMaker geospatial image. You can also access the SageMaker geospatial UI as a part of Amazon SageMaker Studio UI to view the list of all your jobs. You can also use the UI to pause or stop an ongoing job. You can choose a job from the list of available EOJ to view the Job summary, the Job details as well as visualize the Job output.

Topics

- Create an Earth Observation Job Using a Amazon SageMaker Studio Notebook with a SageMaker geospatial Image (p. 571)
- Types of Operations (p. 574)
Create an Earth Observation Job Using a Amazon SageMaker Studio Notebook with a SageMaker geospatial Image

To use a SageMaker Studio notebook with a SageMaker geospatial image:

1. From the Launcher, choose Change environment under Notebooks and compute resources.
2. Next, the Change environment dialog opens.
3. Select the Image dropdown and choose Geospatial 1.0. The Instance type should be ml.geospatial.interactive. Do not change the default values for other settings.
4. Choose Select.
5. Choose Create notebook.

You can initiate an EOJ using a Amazon SageMaker Studio notebook with a SageMaker geospatial image using the code provided below.

```python
import boto3
import sagemaker
import sagemaker_geospatial_map

session = boto3.Session()
execution_role = sagemaker.get_execution_role()
sg_client = session.client(service_name="sagemaker-geospatial")
```

The following is an example showing how to create an EOJ in the in the US West (Oregon) Region.

```python
#Query and Access Data
search_rdc_args = {
    "RasterDataCollectionQuery": {
        "AreaOfInterest": {
            "AreaOfInterestGeometry": {
                "PolygonGeometry": {
                    "Coordinates": [
                        [-114.529, 36.142],
                        [-114.373, 36.142],
                        [-114.373, 36.411],
                        [-114.529, 36.411],
                        [-114.529, 36.142],
                        [-114.529, 36.142]
                    ]
                }
            },
            "TimeRangeFilter": {
                "StartTime": "2021-01-01T00:00:00Z",
                "EndTime": "2022-07-10T23:59:59Z",
            },
            "PropertyFilters": {
                "Properties": [{"Property": {"EoCloudCover": {"LowerBound": 0, "UpperBound": 1}}}],
                "LogicalOperator": "AND",
            },
            "BandFilter": ["visual"]
        }
    }
}
```
tci_urls = []
data_manifests = []
while search_rdc_args.get("NextToken", True):
    search_result = sg_client.search_raster_data_collection(**search_rdc_args)
    if search_result.get("NextToken"):
        data_manifests.append(search_result)
    for item in search_result["Items"]:
        tci_url = item["Assets"]["visual"]["Href"]
        print(tci_url)
        tci_urls.append(tci_url)
    search_rdc_args["NextToken"] = search_result.get("NextToken")

# Perform land cover segmentation on images returned from the sentinel dataset.
eoj_input_config = {
    "RasterDataCollectionQuery": {
        "AreaOfInterest": {
            "AreaOfInterestGeometry": {
                "PolygonGeometry": {
                    "Coordinates": [
                        [-114.529, 36.142],
                        [-114.373, 36.142],
                        [-114.373, 36.411],
                        [-114.529, 36.411],
                        [-114.529, 36.142],
                    ]
                }
            },
            "TimeRangeFilter": {
                "StartTime": "2021-01-01T00:00:00Z",
                "EndTime": "2022-07-10T23:59:59Z",
            },
            "PropertyFilters": {
                "Properties": [{"Property": {"EoCloudCover": {"LowerBound": 0, "UpperBound": 1}}}],
                "LogicalOperator": "AND",
            }
        }
    }
}
eoj_config = {"LandCoverSegmentationConfig": {}}
response = sg_client.start_earth_observation_job(
    Name="lake-mead-landcover",
    InputConfig=eoj_input_config,
    JobConfig=eoj_config,
    ExecutionRoleArn=execution_role,
)

After your EOJ is created, the Arn is returned to you. You use the Arn to identify a job and perform further operations. To get the status of a job, you can run
sg_client.get_earth_observation_job(Arn=response['Arn']).

The following example shows how to query the status of an EOJ until it is completed.

eoj_arn = response['Arn']
job_details = sg_client.get_earth_observation_job(Arn=eoj_arn)
{k: v for k, v in job_details.items() if k in ['Arn', 'Status', 'DurationInSeconds']}
# List all jobs in the account
sg_client.list_earth_observation_jobs()['EarthObservationJobSummaries']
After the EOJ is completed, you can visualize the EOJ outputs directly in the notebook. The following example shows you how an interactive map can be rendered.

```python
map = sagemaker_geospatial_map.create_map(
    'is_raster': True
)
map.set_sagemaker_geospatial_client(sg_client)
# render the map
map.render()
```

The following example shows how the map can be centered on an area of interest and the input and output of the EOJ can be rendered as separate layers within the map.

```python
# visualize the area of interest
config = {'label': 'Lake Mead AOI'}
aoi_layer = map.visualize_eoj_aoi(Arn=eoj_arn, config=config)

# Visualize input.
time_range_filter = {
    "start_date": "2022-07-01T00:00:00Z",
    "end_date": "2022-07-10T23:59:59Z",
}
cfg = {'label': 'Input'}
input_layer = map.visualize_eoj_input(Arn=eoj_arn, config=cfg, time_range_filter=time_range_filter)

# Visualize output, EOJ needs to be in completed status.
time_range_filter = {
    "start_date": "2022-07-01T00:00:00Z",
    "end_date": "2022-07-10T23:59:59Z",
}
cfg = {'preset': 'singleBand', 'band_name': 'mask'}
output_layer = map.visualize_eoj_output(Arn=eoj_arn, config=cfg, time_range_filter=time_range_filter)
```

You can use the `export_earth_observation_job` function to export the EOJ results to your Amazon S3 bucket. The export function makes it convenient to share results across teams. SageMaker also simplifies dataset management. We can simply share the EOJ results using the job ARN, instead of crawling thousands of files in the S3 bucket. Each EOJ becomes an asset in the data catalog, as results can be grouped by the job ARN. The following example shows how you can export the results of an EOJ.

```python
sagemaker_session = sagemaker.Session()
s3_bucket_name = sagemaker_session.default_bucket()  # Replace with your own bucket if needed
s3_bucket = session.resource("s3").Bucket(s3_bucket_name)
prefix = "eoj_lakemead"  # Replace with the S3 prefix desired
export_bucket_and_key = f"s3://{s3_bucket_name}/{prefix}/"
eoj_output_config = {'S3Data': {'S3Uri': export_bucket_and_key}}
export_response = sg_client.export_earth_observation_job(
    Arn=eoj_arn,
    ExecutionRoleArn=execution_role,
    OutputConfig=eoj_output_config,
    ExportSourceImages=False,
)
```

You can monitor the status of your export job using the following snippet.

```python
# Monitor the export job status
```
export_job_details = sg_client.get_earth_observation_job(Arn=export_response["Arn"])
{k: v for k, v in export_job_details.items() if k in ["Arn", "Status", "DurationInSeconds"]}

You are not charged the storage fees after you delete the EOJ.

For an example that showcases how to run an EOJ, see this blog post.

For more example notebooks on SageMaker geospatial capabilities, see this GitHub repository.

**Types of Operations**

When you create an EOJ, you select an operation based on your use case. Amazon SageMaker geospatial capabilities provide a combination of purpose-built operations and pre-trained models. You can use these operations to understand the impact of environmental changes and human activities over time or identify cloud and cloud-free pixels.

**Cloud Masking**

Identify clouds in satellite images is an essential pre-processing step in producing high-quality geospatial data. Ignoring cloud pixels can lead to errors in analysis, and over-detection of cloud pixels can decrease the number of valid observations. Cloud masking has the ability to identify cloudy and cloud-free pixels in satellite images. An accurate cloud mask helps get satellite images for processing and improves data generation. The following is the class map for cloud masking.

```json
{
0: "No_cloud",
1: "cloud"
}
```

**Cloud Removal**

Cloud removal for Sentinel-2 data uses an ML-based semantic segmentation model to identify clouds in the image. Cloudy pixels can be replaced by with pixels from other timestamps. USGS Landsat data contains landsat metadata that is used for cloud removal.

**Temporal Statistics**

Temporal statistics calculate statistics for geospatial data through time. The temporal statistics currently supported include mean, median, and standard deviation. You can calculate these statistics by using GROUPBY and set it to either all or yearly. You can also mention the TargetBands.

**Zonal Statistics**

Zonal statistics performs statistical operations over a specified area on the image.

**Resampling**

Resampling is used to upscale and downscale the resolution of a geospatial image. The value attribute in resampling represents the length of a side of the pixel.

**Geomosaic**

Geomosaic allows you to stitch smaller images into a large image.

**Band Stacking**

Band stacking takes more than one image band as input and stacks them into a single GeoTIFF. The OutputResolution attribute determines the resolution of the output image. Based on the resolutions of the input images, you can set it to lowest, highest or average.

**Band Math**
Band Math, also known as Spectral Index, is a process of transforming the observations from multiple spectral bands to a single band, indicating the relative abundance of features of interests. For instance, Normalized Difference Vegetation Index (NDVI) and Enhanced Vegetation Index (EVI) are helpful for observing the presence of green vegetation features.

**Land Cover Segmentation**

Land Cover segmentation is a semantic segmentation model that has the capability to identify the physical material, such as vegetation, water, and bare ground, at the earth surface. Having an accurate way to map the land cover patterns helps you understand the impact of environmental change and human activities over time. Land Cover segmentation is often used for region planning, disaster response, ecological management, and environmental impact assessment. The following is the class map for Land Cover segmentation.

```plaintext
{
    0: "No_data",
    1: "Saturated_or_defective",
    2: "Dark_area_pixels",
    3: "Cloud_shadows",
    4: "Vegetation",
    5: "Not_vegetated",
    6: "Water",
    7: "Unclassified",
    8: "Cloud_medium_probability",
    9: "Cloud_high_probability",
    10: "Thin_cirrus",
    11: "Snow_ice"
}
```

**Availability of EOJ Operations**

The availability of operations depends on whether you are using the SageMaker geospatial UI or the Amazon SageMaker Studio notebooks with a SageMaker geospatial image. Currently, notebooks support all functionalities. To summarize, the following geospatial operations are supported by SageMaker:

<table>
<thead>
<tr>
<th>Operations</th>
<th>Description</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Masking</td>
<td>Identify cloud and cloud-free pixels to get improved and accurate satellite imagery.</td>
<td>UI, Notebook</td>
</tr>
<tr>
<td>Cloud Removal</td>
<td>Remove pixels containing parts of a cloud from satellite imagery.</td>
<td>Notebook</td>
</tr>
<tr>
<td>Temporal Statistics</td>
<td>Calculate statistics through time for a given GeoTIFF.</td>
<td>Notebook</td>
</tr>
<tr>
<td>Zonal Statistics</td>
<td>Calculate statistics on user-defined regions.</td>
<td>Notebook</td>
</tr>
<tr>
<td>Resampling</td>
<td>Scale images to different resolutions.</td>
<td>Notebook</td>
</tr>
<tr>
<td>Geomosaic</td>
<td>Combine multiple images for greater fidelity.</td>
<td>Notebook</td>
</tr>
<tr>
<td>Band Stacking</td>
<td>Combine multiple spectral bands to create a single image.</td>
<td>Notebook</td>
</tr>
</tbody>
</table>
Vector Enrichment Jobs

A Vector Enrichment Job (VEJ) performs operations on your vector data. Currently, you can use a VEJ to do reverse geocoding or map matching.

Reverse Geocoding

With a reverse geocoding VEJ, you can convert geographic coordinates (latitude, longitude) to human-readable addresses powered by Amazon Location Service. When you upload a CSV file containing the longitude and latitude coordinates, it returns the address number, country, label, municipality, neighborhood, postal code and region of that location. The output file consists of your input data along with columns containing these the values appended at the end. These jobs are optimized to accept tens of thousands of GPS traces.

Map Matching

Map matching allows you to snap GPS coordinates to road segments. The input should be a CSV file containing the trace ID (route), longitude, latitude and the timestamp attributes. There can be multiple GPS co-ordinates per route. The input can contain multiple routes too. The output is a GeoJSON file that contains links of the predicted route. It also has the snap points provided in the input. These jobs are optimized to accept tens of thousands of drives in one request. Map matching is supported by OpenStreetMap. Map matching fails if the names in the input source field don't match the ones in MapMatchingConfig. The error message you receive contains the the field names present in the input file and the expected field name that is not found in MapMatchingConfig.

The input CSV file for a VEJ must contain the following:

- A header row
- Latitude and longitude in separate columns
- The ID and Timestamp columns can be in numeric or string format. All other column data must be in numeric format only
- No missing matching quotes

For the timestamp column, SageMaker geospatial capabilities supports epoch time in seconds and milliseconds (long integer). The string formats supported are as follows:

- "dd.MM.yyyy HH:mm:ss z"
- "yyyy-MM-dd'T'HH:mm:ss.SSS'Z'"
- "yyyy-MM-dd'T'HH:mm:ss"
- "yyyy-MM-dd hh:mm:ss a"
- "yyyy-MM-dd HH:mm:ss"
- "yyyyMMddHHmmss"
While you need to use an Amazon SageMaker Studio notebook to execute a VEJ, you can view all the jobs you create using the UI. To use the visualization in the notebook, you first need to export your output to your S3 bucket. The VEJ actions you can perform are as follows.

- StartVectorEnrichmentJob
- GetVectorEnrichmentJob
- ListVectorEnrichmentJobs
- StopVectorEnrichmentJob
- DeleteVectorEnrichmentJob

Visualization Using SageMaker geospatial capabilities

Using the visualization functionalities provided by Amazon SageMaker geospatial you can visualize geospatial data, the inputs to your EOJ or VEJ jobs as well as the outputs exported from your Amazon S3 bucket. The visualization tool is powered by Foursquare Studio. The following image depicts the visualization tool supported by SageMaker geospatial capabilities.
Geospatial

Overview  Earth Observation jobs  Vector Enrichment jobs  Map Visualization

How to use the map visualization tool

Sagemaker Geospatial

Datasets (0)  + Add Data

Layers  + Add Layer

Layer Blending

normal

Map Overlay Blending

normal
You can use the left navigation panel to add data, layers, filters, and columns. You can also make modifications to how you interact with the map.

**Dataset**

The source of data used for visualization is called a **Dataset**. To add data for visualization, choose **Add Data** in the left navigation panel. You can either upload the data from your Amazon S3 bucket or your local machine. The data formats supported are CSV, JSON and GeoJSON. You can add multiple datasets to your map. After you upload the dataset, you can see it loaded on the map screen.

**Layers**

In the layer panel, a layer is created and populated automatically when you add a dataset. If your map consists of more than one dataset, you can select which dataset belongs to a layer. You can create new layers and group them. SageMaker geospatial capabilities support various layer types, including point, arc, icon, and polygon.

You can choose any data point in a layer to have an **Outline**. You can also further customize the data points. For example, you can choose the layer type as **Point** and then **Fill Color** based on any column of your dataset. You can also change the radius of the points.

The following image shows the layers panel supported by SageMaker geospatial capabilities.
Geospatial

Overview  Earth Observation jobs  Vector Enrichment jobs

How to use the map visualization tool

Sagemaker Geospatial

Layers

+ Add Layer

Point

Basic

Point

Fill Color

Color Based On

Color Scale

Quantile

580
Columns
You can view the columns present in your dataset by using the Columns tab in the left navigation panel.

Filters
You can use filters to limit the data points that display on the map.

Interactions
In the Interactions panel, you can customize how you interact with the map. For example, you can choose what metrics to display when you hover the tooltip over a data point.

Base map
Currently, SageMaker only supports the Amazon Dark base map.

Split Map Modes
You can have a Single Map, Dual Maps or Swipe Maps. With Dual Maps, you can compare the same map side-by-side using different layers. Use Swipe Maps to overlay two maps on each other and use the sliding separator to compare them. You can choose the split map mode by choosing the Split Mode button on the top right corner of your map.

Legends for EOJ in the SageMaker geospatial UI
The output visualization of an EOJ depends on the operation you choose to create it. The legend is based on the default color scale. You can view the legend by choosing the Show legend button on the top right corner of your map.

Spectral Index
When you visualize the output for an EOJ that uses the spectral index operation, you can map the category based on the color from the legend as shown.

Cloud Masking
When you visualize the output for an EOJ that uses the cloud masking operation, you can map the category based on the color from the legend as shown.

Land Cover Segmentation
When you visualize the output for an EOJ that uses the Land Cover Segmentation operation, you can map the category based on the color from the legend as shown.

Amazon SageMaker geospatial Map SDK

You can use Amazon SageMaker geospatial capabilities to visualize maps within the SageMaker geospatial UI as well as SageMaker notebooks with a geospatial image. These visualizations are supported by the map visualization library called Foursquare Studio

You can use the APIs provided by the SageMaker geospatial map SDK to visualize your geospatial data, including the input, output, and AoI for EOJ.

Topics
- add_dataset API (p. 582)
- update_dataset API (p. 583)
- add_layer API (p. 584)
- update_layer API (p. 585)
- visualize_eoj_aoi API (p. 586)
- visualize_eoj_input API (p. 586)
- visualize_eoj_output API (p. 587)

add_dataset API

Adds a raster or vector dataset object to the map.

Request syntax

```python
Request =
    add_dataset(
        self,
        dataset: Union[Dataset, Dict, None] = None,
```
Request parameters

The request accepts the following parameters.

Positional arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset</td>
<td>Union[Dataset, Dict, None]</td>
<td>Data used to create a dataset, in CSV, JSON, or GeoJSON format (for local datasets) or a UUID string.</td>
</tr>
</tbody>
</table>

Keyword arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto_create_layers</td>
<td>Boolean</td>
<td>Whether to attempt to create new layers when adding a dataset. Default value is False.</td>
</tr>
<tr>
<td>center_map</td>
<td>Boolean</td>
<td>Whether to center the map on the created dataset. Default value is True.</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>Unique identifier of the dataset. If you do not provide it, a random ID is generated.</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>Dataset label which is displayed.</td>
</tr>
<tr>
<td>color</td>
<td>Tuple[float, float, float]</td>
<td>Color label of the dataset.</td>
</tr>
<tr>
<td>metadata</td>
<td>Dictionary</td>
<td>Object containing tileset metadata (for tiled datasets).</td>
</tr>
</tbody>
</table>

Response

This API returns the Dataset object that was added to the map.

update_dataset API

Updates an existing dataset's settings.

Request syntax

```python
Request =
update_dataset(
    self,
    dataset_id: str,
```
Request parameters

The request accepts the following parameters.

Positional arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset_id</td>
<td>String</td>
<td>The identifier of the dataset to be updated.</td>
</tr>
<tr>
<td>values</td>
<td>Union[_DatasetUpdateProps, dict, None] = None, **kwargs: Any, ) -&gt; Dataset</td>
<td>The values to update.</td>
</tr>
</tbody>
</table>

Keyword arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>String</td>
<td>Dataset label which is displayed.</td>
</tr>
<tr>
<td>color</td>
<td>RGBColor</td>
<td>Color label of the dataset.</td>
</tr>
</tbody>
</table>

Response

This API returns the updated dataset object for interactive maps, or None for non-interactive HTML environments.

add_layer API

Adds a new layer to the map. This function requires at least one valid layer configuration.

Request syntax

Request = add_layer(
    self,
    layer: Union[LayerCreationProps, dict, None] = None,
    **kwargs: Any
) -> Layer

Request parameters

The request accepts the following parameters.

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layer</td>
<td>Union[LayerCreationProps, dict, None]</td>
<td>A set of properties used to create a layer.</td>
</tr>
</tbody>
</table>
Response

The layer object that was added to the map.

**update_layer API**

Update an existing layer with given values.

**Request syntax**

```python
Request = update_layer(
    self,
    layer_id: str,
    values: Union[LayerUpdateProps, dict, None],
    **kwargs: Any
) -> Layer
```

**Request parameters**

The request accepts the following parameters.

**Arguments**

<table>
<thead>
<tr>
<th>Positional argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layer_id</td>
<td>String</td>
<td>The ID of the layer to be updated.</td>
</tr>
<tr>
<td>values</td>
<td>Union[LayerUpdateProps, dict, None]</td>
<td>The values to update.</td>
</tr>
</tbody>
</table>

**Keyword arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>LayerType</td>
<td>The type of layer.</td>
</tr>
<tr>
<td>data_id</td>
<td>String</td>
<td>Unique identifier of the dataset this layer visualizes.</td>
</tr>
<tr>
<td>fields</td>
<td>Dict [string, Optional[string]]</td>
<td>Dictionary that maps fields that the layer requires for visualization to appropriate dataset fields.</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>Canonical label of this layer.</td>
</tr>
<tr>
<td>is_visible</td>
<td>Boolean</td>
<td>Whether the layer is visible or not.</td>
</tr>
<tr>
<td>config</td>
<td>LayerConfig</td>
<td>Layer configuration specific to its type.</td>
</tr>
</tbody>
</table>

**Response**
Returns the updated layer object.

**visualize_eoj_aoi API**

Visualize the AoI of the given job ARN.

**Request parameters**

The request accepts the following parameters.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arn</td>
<td>String</td>
<td>The ARN of the job.</td>
</tr>
<tr>
<td>config</td>
<td>Dictionary</td>
<td>An option to pass layer properties.</td>
</tr>
</tbody>
</table>

config = { label: <string> custom label of the added AoI layer, default AoI }

**Response**

Reference of the added input layer object.

**visualize_eoj_input API**

Visualize the input of the given EOJ ARN.

**Request parameters**

The request accepts the following parameters.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arn</td>
<td>String</td>
<td>The ARN of the job.</td>
</tr>
<tr>
<td>time_range_filter</td>
<td>Dictionary</td>
<td>An option to provide the start and end time.</td>
</tr>

config = { label: <string> custom label of the added output layer, default Input }

time_range_filter = {
    start_date: <string> date in ISO format
    end_date: <string> date in ISO format
}

586
Response
Reference of the added input layer object.

**visualize_eoj_output API**
Visualize the output of the given EOJ ARN.

**Request parameters**
The request accepts the following parameters.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arn</td>
<td>String</td>
<td>The ARN of the job.</td>
</tr>
<tr>
<td>time_range_filter</td>
<td>Dictionary</td>
<td>An option to provide the start and end time. Defaults to the raster data collection search start and end date.</td>
</tr>
<tr>
<td>config</td>
<td>Dictionary</td>
<td>An option to pass layer properties.</td>
</tr>
</tbody>
</table>

**Response**
Reference of the added output Layer object.

To learn more about visualizing your geospatial data, refer to [Visualization Using Amazon SageMaker geospatial](#).

**SageMaker geospatial capabilities FAQ**
Use the following FAQ items to find answers to commonly asked questions about SageMaker geospatial capabilities.
1. What regions are Amazon SageMaker geospatial capabilities available in?

Currently, SageMaker geospatial capabilities are only supported in the US West (Oregon) Region. To view SageMaker geospatial, choose the name of the currently displayed Region in the navigation bar of the console. Then choose the US West (Oregon) Region.

2. What AWS Identity and Access Management permissions and policies are required to use SageMaker geospatial?

To use SageMaker geospatial you need a user, group, or role that can access SageMaker. You also need to create a SageMaker execution role so that SageMaker geospatial can perform operations on your behalf. To learn more, see SageMaker geospatial capabilities roles.

3. I have an existing SageMaker execution role. Do I need to update it?

Yes. To use SageMaker geospatial you must specify an additional service principal in your IAM trust policy: sagemaker-geospatial.amazonaws.com. To learn about specifying a service principal in a trust relationship, see Adding the SageMaker geospatial service principal to an existing SageMaker execution role (p. 3407) in the Amazon SageMaker Developer Guide.

4. Can I use SageMaker geospatial capabilities through my VPC environment?

Yes, you can use SageMaker geospatial through a VPN. To learn more, see Use Amazon SageMaker geospatial capabilities in Your Amazon Virtual Private Cloud (p. 590).

5. Why can't I see the SageMaker geospatial map visualizer, image or instance type when I navigate to Amazon SageMaker Studio?

Verify that you are launching Amazon SageMaker Studio in the US West (Oregon) Region and that you are not using a shared space.

6. Why can't I see the SageMaker geospatial image or instance type when I try to create a notebook instance in Studio?

Verify that you are launching Amazon SageMaker Studio in the US West (Oregon) Region and that you are not using a shared space. To learn more, see Create an Amazon SageMaker Studio notebook using the geospatial image (p. 551).

7. What bands supported for various raster data collections?

Use the GetRasterDataCollection API response and refer to the ImageSourceBands field to find the bands supported for that particular data collection.

SageMaker geospatial Security and Permissions

Use the topics on this page to learn about SageMaker geospatial capabilities security features. Additionally, learn how to use SageMaker geospatial capabilities in an Amazon Virtual Private Cloud as well as protect your data at rest using encryption.

For more information about IAM users and roles, see Identities (Users, Groups, and Roles) in the IAM User Guide.

To learn more about using IAM with SageMaker, see Identity and Access Management for Amazon SageMaker (p. 3349).

Topics
- Configuration and Vulnerability Analysis in SageMaker geospatial (p. 589)
- Use Amazon SageMaker geospatial capabilities in Your Amazon Virtual Private Cloud (p. 590)
- Use AWS KMS Permissions for Amazon SageMaker geospatial capabilities (p. 591)
Configuration and Vulnerability Analysis in SageMaker geospatial

Configuration and IT controls are a shared responsibility between AWS and you, our customer. AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Shared Responsibility Model.
- Amazon Web Services: Overview of Security Processes.

Amazon SageMaker geospatial capabilities provide a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Apply principle of least privilege

Amazon SageMaker geospatial capabilities provide granular access policy for applications using IAM roles. We recommend that the roles be granted only the minimum set of privileges required by the job. We also recommend auditing the jobs for permissions on a regular basis and upon any change to your application.

Role-based access control (RBAC) permissions

Administrators should strictly control Role-based access control (RBAC) permissions for Amazon SageMaker geospatial capabilities.

Use temporary credentials whenever possible

Where possible, use temporary credentials instead of long-term credentials, such as access keys. For scenarios in which you need IAM users with programmatic access and long-term credentials, we recommend that you rotate access keys. Regularly rotating long-term credentials helps you familiarize yourself with the process. This is useful in case you are ever in a situation where you must rotate credentials, such as when an employee leaves your company. We recommend that you use IAM access last used information to rotate and remove access keys safely. For more information, see Rotating access keys and Security best practices in IAM.

Use AWS CloudTrail to view and log API calls

AWS CloudTrail tracks anyone making API calls in your AWS account. API calls are logged whenever anyone uses the Amazon SageMaker geospatial capabilities API, the Amazon SageMaker geospatial capabilities console or Amazon SageMaker geospatial capabilities AWS CLI commands. Enable logging and specify an Amazon S3 bucket to store the logs.

Your trust, privacy, and the security of your content are our highest priorities. We implement responsible and sophisticated technical and physical controls designed to prevent unauthorized access to, or disclosure of, your content and ensure that our use complies with our commitments to you. For more information, see AWS Data Privacy FAQ.
Use Amazon SageMaker geospatial capabilities in Your Amazon Virtual Private Cloud

The following topic gives information on how to use SageMaker notebooks with a SageMaker geospatial image in a Amazon SageMaker Domain with VPC only mode. For more information on VPCs in Amazon SageMaker Studio see Choose an Amazon VPC.

VPC only communication with the internet

By default, SageMaker Domain uses two Amazon VPC. One of the Amazon VPC is managed by Amazon SageMaker and provides direct internet access. You specify the other Amazon VPC, which provides encrypted traffic between the Domain and your Amazon Elastic File System (Amazon EFS) volume.

You can change this behavior so that SageMaker sends all traffic over your specified Amazon VPC. If VPC only has been chosen as the network access mode during the SageMaker Domain creation, the following requirements need to be considered to still allow usage of SageMaker Studio notebooks within the created SageMaker Domain.

Requirements to use VPC only mode

Note In order to use the visualization components of SageMaker geospatial capabilities, the browser you use to access the SageMaker Studio UI needs to be connected to the internet.

When you choose VpcOnly, follow these steps:

1. You must use private subnets only. You cannot use public subnets in VpcOnly mode.
2. Ensure your subnets have the required number of IP addresses needed. The expected number of IP addresses needed per user can vary based on use case. We recommend between 2 and 4 IP addresses per user. The total IP address capacity for a Studio domain is the sum of available IP addresses for each subnet provided when the domain is created. Ensure that your estimated IP address usage does not exceed the capacity supported by the number of subnets you provide. Additionally, using subnets distributed across many availability zones can aid in IP address availability. For more information, see VPC and subnet sizing for IPv4.

   Note You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

3. Set up one or more security groups with inbound and outbound rules that together allow the following traffic:
   • **NFS traffic over TCP on port 2049** between the domain and the Amazon EFS volume.
   • **TCP traffic within the security group**, This is required for connectivity between the JupyterServer app and the KernelGateway apps. You must allow access to at least ports in the range 8192–65535.
4. If you want to allow internet access, you must use a **NAT gateway** with access to the internet, for example through an internet gateway.
5. If you don't want to allow internet access, **create interface VPC endpoints** (AWS PrivateLink) to allow Studio to access the following services with the corresponding service names. You must also associate the security groups for your VPC with these endpoints.

   Note Currently, SageMaker geospatial capabilities are only supported in the US West (Oregon) Region.

   • SageMaker API: com.amazonaws.us-west-2.sagemaker.api
• SageMaker runtime: com.amazonaws.us-west-2.sagemaker.runtime. This is required to run Studio notebooks with a SageMaker geospatial image.

• Amazon S3: com.amazonaws.us-west-2.s3.

• To use SageMaker Projects: com.amazonaws.us-west-2.servicecatalog.

• SageMaker geospatial capabilities: com.amazonaws.us-west-2.sagemaker-geospatial

If you use the SageMaker Python SDK to run remote training jobs, you must also create the following Amazon VPC endpoints.

• AWS Security Token Service: com.amazonaws.region.sts

• Amazon CloudWatch: com.amazonaws.region.logs. This is required to allow SageMaker Python SDK to get the remote training job status from Amazon CloudWatch.

**Note**

For a customer working within VPC mode, company firewalls can cause connection issues with SageMaker Studio or between JupyterServer and the KernelGateway. Make the following checks if you encounter one of these issues when using SageMaker Studio from behind a firewall.

• Check that the Studio URL is in your networks allowlist.

• Check that the websocket connections are not blocked. Jupyter uses websocket under the hood. If the KernelGateway application is InService, JupyterServer may not be able to connect to the KernelGateway. You should see this problem when opening System Terminal as well.

**Use AWS KMS Permissions for Amazon SageMaker geospatial capabilities**

You can protect your data at rest using encryption for SageMaker geospatial capabilities. By default, it uses server-side encryption with an Amazon SageMaker geospatial owned key. SageMaker geospatial capabilities also supports an option for server-side encryption with a customer managed KMS key.

**Server-Side Encryption with Amazon SageMaker geospatial managed key (Default)**

SageMaker geospatial capabilities encrypts all your data, including computational results from your Earth Observation jobs (EOJ) and Vector Enrichment jobs (VEJ) along with all your service metadata. There is no data that is stored within SageMaker geospatial capabilities unencrypted. It uses a default AWS owned key to encrypt all your data.

**Server-Side Encryption with customer managed KMS key (Optional)**

SageMaker geospatial capabilities supports the use of a symmetric customer managed key that you create, own, and manage to add a second layer of encryption over the existing AWS owned encryption. Because you have full control of this layer of encryption, you can perform such tasks as:

• Establishing and maintaining key policies

• Establishing and maintaining IAM policies and grants

• Enabling and disabling key policies

• Rotating key cryptographic material

• Adding tags

• Creating key aliases
Scheduling keys for deletion

For more information, see [Customer managed keys](https://docs.aws.amazon.com/kms/latest/developerguide/aws-kms-cmk.html) in the *AWS Key Management Service Developer Guide*.

**How SageMaker geospatial capabilities uses grants in AWS KMS**

SageMaker geospatial capabilities requires a grant to use your customer managed key. When you create an EOJ or an VEJ encrypted with a customer managed key, SageMaker geospatial capabilities creates a grant on your behalf by sending a `CreateGrant` request to AWS KMS. Grants in AWS KMS are used to give SageMaker geospatial capabilities access to a KMS key in a customer account. You can revoke access to the grant, or remove the service's access to the customer managed key at any time. If you do, SageMaker geospatial capabilities won't be able to access any of the data encrypted by the customer managed key, which affects operations that are dependent on that data.

**Create a customer managed key**

You can create a symmetric customer managed key by using the AWS Management Console, or the AWS KMS APIs.

**To create a symmetric customer managed key**

Follow the steps for [Creating symmetric encryption KMS keys](https://docs.aws.amazon.com/kms/latest/developerguide/aws-kms-cmk.html) in the *AWS Key Management Service Developer Guide*.

**Key policy**

Key policies control access to your customer managed key. Every customer managed key must have exactly one key policy, which contains statements that determine who can use the key and how they can use it. When you create your customer managed key, you can specify a key policy. For more information, see [Determining access to AWS KMS keys](https://docs.aws.amazon.com/kms/latest/developerguide/aws-kms-cmk.html) in the *AWS Key Management Service Developer Guide*.

To use your customer managed key with your SageMaker geospatial capabilities resources, the following API operations must be permitted in the key policy. The principal for these operations should be the Execution Role you provide in the SageMaker geospatial capabilities request. SageMaker geospatial capabilities assumes the provided Execution Role in the request to perform these KMS operations.

- `kms:CreateGrant`
- `kms:GenerateDataKey`
- `kms:Decrypt`
- `kms:GenerateDataKeyWithoutPlaintext`

The following are policy statement examples you can add for SageMaker geospatial capabilities:

**CreateGrant**

```json
"Statement" : [ 
   
   
   "Sid" : "Allow access to Amazon SageMaker geospatial capabilities",
   "Effect" : "Allow",
   "Principal" : { 
   
   "AWS" : "<Customer provided Execution Role ARN>"
   },
   "Action" : [ 
   "kms:CreateGrant",
   "kms:Decrypt",
   "kms:GenerateDataKey",
   "kms:GenerateDataKeyWithoutPlaintext"
   ]
]```
For more information about specifying permissions in a policy, see AWS KMS permissions in the AWS Key Management Service Developer Guide. For more information about troubleshooting, see Troubleshooting key access in the AWS Key Management Service Developer Guide.

If your key policy does not have your account root as key administrator, you need to add the same KMS permissions on your execution role ARN. Here is a sample policy you can add to the execution role:

```
{
"Version": "2012-10-17",
"Statement": [
{
"Action": [
"kms:CreateGrant",
"kms:Decrypt",
"kms:GenerateDataKey",
"kms:GenerateDataKeyWithoutPlaintext"
],
"Resource": ["<KMS key Arn>"],
"Effect": "Allow"
}
]
}
```

Monitoring your encryption keys for SageMaker geospatial capabilities

When you use an AWS KMS customer managed key with your SageMaker geospatial capabilities resources, you can use AWS CloudTrail or Amazon CloudWatch Logs to track requests that SageMaker geospatial sends to AWS KMS.

Select a tab in the following table to see examples of AWS CloudTrail events to monitor KMS operations called by SageMaker geospatial capabilities to access data encrypted by your customer managed key.

Types of compute instances

SageMaker geospatial capabilities offer three types of compute instances.

- **SageMaker Studio geospatial notebook instances** – SageMaker geospatial supports both CPU and GPU-based notebook instances in Studio. Notebook instances are used to build, train, and deploy ML models. For a list of available notebook instance types that work with the geospatial image, see Supported notebook instance types (p. 597).

- **SageMaker geospatial jobs instances** – Run processing jobs to transform satellite image data.
• **SageMaker geospatial model inference types** – Make predictions by using pre-trained ML models on satellite imagery.

The instance type is determined by the operations that you run.

The following table shows the available SageMaker geospatial specific operations and instance types that you can use.

<table>
<thead>
<tr>
<th>Operations</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temporal Statistics</td>
<td>ml.geospatial.jobs</td>
</tr>
<tr>
<td>Zonal Statistics</td>

**SageMaker geospatial supported notebook instance types**

SageMaker geospatial supports both CPU and GPU-based notebook instances in Studio. If when starting a GPU enabled notebook instance you receive a ResourceLimitExceeded error, you need to request a quota increase. To get started on a Service Quotas quota increase request, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

**Supported Studio notebook instance types**

### Data collections

Amazon SageMaker geospatial supports the following raster data collections. Of the following data collections, you can use the USGS Landsat and the Sentinel-2 Cloud-Optimized GeoTIFF data collections when starting an Earth Observation Job (EOJ). To learn more about the EOJs, see [Earth Observation Jobs](#).

- Copernicus Digital Elevation Model (DEM) – GLO-30
- Copernicus Digital Elevation Model (DEM) – GLO-90
- Sentinel-2 Cloud-Optimized GeoTIFFs
- Sentinel-1
- National Agriculture Imagery Program (NAIP) on AWS
- USGS Landsat 8

To find the list of available raster data collections in your AWS Regions, use `ListRasterDataCollections`. In the `ListRasterDataCollections response`, you get a `RasterDataCollectionMetadata` object that contains details about the available raster data collections.

**Example Example – Calling the ListRasterDataCollections API using the AWS SDK for Python (Boto3)**

When you use the SDK for Python (Boto3) and SageMaker geospatial, you must create a geospatial client, `geospatial_client`. Use the following Python snippet to make a call to the `list_raster_data_collections API`:

```python
import boto3
import sagemaker
import sagemaker_geospatial_map
import json

## SageMaker Geospatial Capabilities is currently only available in US-WEST-2
session = boto3.Session(region_name='us-west-2')
execution_role = sagemaker.get_execution_role()

## Creates a SageMaker Geospatial client instance
geospatial_client = session.client(service_name="sagemaker-geospatial")
```
# Creates a reusable Paginator for the list_raster_data_collections API operation
paginator = geospatial_client.get_paginator("list_raster_data_collections")

# Create a PageIterator from the Paginator
page_iterator = paginator.paginate()

# Use the iterator to iterate through the results of list_raster_data_collections
results = []
for page in page_iterator:
    results.append(page['RasterDataCollectionSummaries'])
print(results)

In the JSON response, you will receive the following, which has been truncated for clarity:

```
{
    "Description": "Copernicus DEM is a Digital Surface Model which represents the surface of the Earth including buildings, infrastructure, and vegetation. GLO-30 is instance of Copernicus DEM that provides limited worldwide coverage at 30 meters."
    "DescriptionPageUrl": "https://registry.opendata.aws/copernicus-dem/",
    "Name": "Copernicus DEM GLO-30",
    "Tags": {},
    "Type": "PUBLIC"
}
```

**Image band information from the USGS Landsat and Sentinel-2 data collections**

Image band information from the USGS Landsat 8 and Sentinel-2 data collections are provided in the following table.

**USGS Landsat**

<table>
<thead>
<tr>
<th>Band name</th>
<th>Wave length range (nm)</th>
<th>Units</th>
<th>Valid range</th>
<th>Fill value</th>

## RStudio on Amazon SageMaker

RStudio is an integrated development environment for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management. Amazon SageMaker supports RStudio as a fully-managed integrated development environment (IDE) integrated with Amazon SageMaker Domain through Posit Workbench. For more information about Posit Workbench, see the [Posit website](https://posit.co/).

RStudio allows customers to create data science insights using an R environment. With RStudio integration, you can launch an RStudio environment in the Domain to run your RStudio workflows on SageMaker resources.

SageMaker integrates RStudio through the creation of a RStudioServerPro app.

The following are supported by RStudio on SageMaker.

- R developers use the RStudio IDE interface with popular developer tools from the R ecosystem. Users can launch new RStudio sessions, write R code, install dependencies from RStudio Package Manager, and publish Shiny apps using RStudio Connect.
- R developers can quickly scale underlying compute resources to run large scale data processing and statistical analysis.
- Platform administrators can set up user identities, authorization, networking, storage, and security for their data science teams through AWS IAM Identity Center and AWS Identity and Access Management integration. This includes connection to private Amazon Virtual Private Cloud (Amazon VPC) resources and internet-free mode with AWS PrivateLink.
- Integration with AWS License Manager.

For information on the onboarding steps to create a Domain with RStudio enabled, see [Onboard to Amazon SageMaker Domain (p. 10)](https://docs.aws.amazon.com/sagemaker/latest/dg/GettingStartedStates.html).

## Region availability

The following table gives information about the AWS Regions that RStudio on SageMaker is supported in.

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
</tr>
</tbody>
</table>
### Region name | Region
---|---
Asia Pacific (Seoul) | ap-northeast-2
Asia Pacific (Singapore) | ap-southeast-1
Asia Pacific (Sydney) | ap-southeast-2
Asia Pacific (Tokyo) | ap-northeast-1
Canada (Central) | ca-central-1
Europe (Frankfurt) | eu-central-1
Europe (Ireland) | eu-west-1
Europe (London) | eu-west-2
Europe (Paris) | eu-west-3
Europe (Stockholm) | eu-north-1
South America (São Paulo) | sa-east-1

## RStudio components

- **RStudioServerPro**: The RStudioServerPro app is a multiuser app that is a shared resource among all user profiles in the Domain. Once an RStudio app is created in a Domain, the admin can give permissions to users in the Domain.
- **RStudio user**: RStudio users are users within the Domain that are authorized to use the RStudio license.
- **RStudio admin**: An RStudio on Amazon SageMaker admin can access the RStudio administrative dashboard. RStudio on Amazon SageMaker admins differ from “stock” Posit Workbench admins because they do not have root access to the instance running the RStudioServerPro app and can't modify the RStudio configuration file.
- **RStudio Server**: The RStudio Server instance is responsible for serving the RStudio UI to all authorized Users. This instance is launched on an Amazon SageMaker instance.
- **RSession**: An RSession is a browser-based interface to the RStudio IDE running on an Amazon SageMaker instance. Users can create and interact with their RStudio projects through the RSession.
- **RSessionGateway**: The RSessionGateway app is used to support an RSession.
- **RStudio administrative dashboard**: This dashboard gives information on the RStudio users in the Amazon SageMaker Domain and their sessions. This dashboard can only be accessed by users that have RStudio admin authorization.

## Differences from Posit Workbench

RStudio on Amazon SageMaker has some significant differences from Posit Workbench.

- When using RStudio on SageMaker, users don't have access to the RStudio configuration files. Amazon SageMaker manages the configuration file and sets defaults. You can modify the RStudio Connect and RStudio Package Manager URLs when creating your RStudio-enabled Amazon SageMaker Domain.
- Project sharing, realtime collaboration, and Job Launcher are not currently supported when using RStudio on Amazon SageMaker.
- When using RStudio on SageMaker, the RStudio IDE runs on Amazon SageMaker instances for on-demand containerized compute resources.
Manage RStudio on Amazon SageMaker

The following topics give information on managing RStudio on Amazon SageMaker. This includes information on your RStudio environment configuration, user sessions, and necessary resources. For information on how to use RStudio on SageMaker, see Use RStudio on Amazon SageMaker (p. 636).

For information about creating a Amazon SageMaker Domain with RStudio enabled, see Onboard to Amazon SageMaker Domain (p. 10).

For information about the AWS Regions that RStudio on SageMaker is supported in, see Supported Regions and Quotas (p. 43).

Topics

- RStudio license (p. 604)
- Upgrade the RStudio Version (p. 605)
- Network and Storage (p. 610)
- RStudioServerPro instance type (p. 610)
- RStudio Connect URL (p. 611)
- RStudio Package Manager (p. 611)
- Create an Amazon SageMaker Domain with RStudio using the AWS CLI (p. 612)
- Add RStudio support to an existing Domain (p. 616)
- Bring your own image to RStudio on SageMaker (p. 619)
- Manage users (p. 632)
- RStudio administrative dashboard (p. 633)
- Shut down and restart RStudio (p. 634)
- Manage billing and cost (p. 635)
- Diagnose issues and get support (p. 635)

RStudio license

RStudio on Amazon SageMaker is a paid product and requires that each user is appropriately licensed. Licenses for RStudio on Amazon SageMaker may be obtained from RStudio PBC directly, or by purchasing a subscription to Posit Workbench on AWS Marketplace. For existing customers of Posit Workbench Enterprise, licenses are issued at no additional cost.

To use an RStudio license with Amazon SageMaker, you must first have a valid RStudio license registered with AWS License Manager. Subscriptions to Posit Workbench on AWS Marketplace automatically trigger license creation with AWS License Manager. For licenses purchased directly through Rstudio PBC, a licenses grant for your AWS Account must be created. Contact RStudio for direct license purchases or to enable existing licenses in AWS License Manager. For more information about registering a license with AWS License Manager, see Seller issued licenses in AWS License Manager.

The following topics show how to acquire and validate a license granted by RStudio PBC.

Get an RStudio license
1. If you don't have an RStudio license, you may purchase one from the AWS Marketplace or from RStudio PBC directly.
   - To purchase a subscription from the AWS Marketplace, complete the steps in Subscribing to an AMI product with contract pricing public offer by searching for Posit Workbench.
   - To purchase from RStudio PBC directly, navigate to RStudio Pricing or contact sales@rstudio.com. When buying or updating an RStudio license, you must provide the AWS Account that will host your Amazon SageMaker Domain.

   If you have an existing RStudio license, contact your RStudio Sales representative or sales@rstudio.com to add RStudio on Amazon SageMaker to your existing Posit Workbench Enterprise license, or to convert your Posit Workbench Standard license. The RStudio Sales representative will send you the appropriate electronic order form.

2. RStudio grants a Posit Workbench license to your AWS Account through AWS License Manager in the US East (N. Virginia) Region. Although the RStudio license is granted in the US East (N. Virginia) Region, your license can be consumed in any AWS Region that RStudio on Amazon SageMaker is supported in. You can expect the license grant process to complete within three business days after you share your AWS account ID with RStudio.

3. When this license is granted, you receive an email from your RStudio Sales representative with instructions to accept your license grant.

**Validate your RStudio license to be used with Amazon SageMaker**

1. Log into the AWS License Manager console in the same region as your Amazon SageMaker Domain. If you are using AWS License Manager for the first time, AWS License Manager prompts you to grant permission to use AWS License Manager.
2. Select Start using AWS License manager.
3. Select I grant AWS License Manager the required permissions and select Grant Permissions.
4. Navigate to Granted Licenses on the left panel.
5. Select the license grant with RSW-SageMaker as the Product name and select View.
6. From the license detail page, select Accept & activate license.

**RStudio administrative dashboard**

You can use the RStudio administrative dashboard to see the number of users on the license following the steps in RStudio administrative dashboard (p. 633).

**Upgrade the RStudio Version**

This guide provides information about the 2023.03.2-454.pro2 version update for RStudio on SageMaker. Starting June 27, 2023, new domains with RStudio support are created with Posit Workbench version 2023.03.2-454.pro2. This applies to the RStudioServerPro applications and default RSessionGateway applications.

During the grace period until August 31, 2023, you can test the latest version in your existing domains. During this period, existing domains continue to use the previous 2022.02.2-485.pro2 version by default. To change this default version, recreate the RStudioServerPro application following the steps in Upgrade to the new version (p. 608). After August 31, 2023, all existing domains automatically launch RStudioServerPro and RSessionGateway applications with version 2023.03.2-454.pro2.

The following sections give information about the 2023.03.2-454.pro2 release and how to test the latest version.
Latest version updates

The latest RStudio version is 2023.03.2-454.pro2. This version includes the following changes:

- Added RTools 4.3 support
- Added support for R 4.3
- Upgraded Quarto to 1.2.335
- Improved session management

For more information about the changes in this release, see https://docs.posit.co/ide/news/.

Versioning

There are currently two versions of Posit Workbench supported by SageMaker.

- Latest version supported: 2023.03.2-454.pro2
- Previous version supported: 2022.02.2-485.pro2

During the grace period, the default Posit Workbench version that's selected by SageMaker depends on the creation date of the domain.

- For domains created after June 27, 2023 (newly created domains), version 2023.03.2-454.pro2 is the default selected version.
- For domains created before June 27, 2023 (existing domains), version 2022.02.2-485.pro2 is the default selected version. You can update your domains to the latest version (2023.03.2-454.pro2) by setting it as the default version for the domain. For more information, see Upgrade to the new version (p. 608).

Note
The default RSessionGateway application version matches the current version of the RStudioServerPro application.

The following table lists the image ARNs for both versions for each AWS Region. These ARNs are passed as part of an update-domain command to set the desired version.

<table>
<thead>
<tr>
<th>Region</th>
<th>2022.02.2-485.pro2 Image ARN</th>
<th>2023.03.2-454.pro2 Image ARN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>ARN for RStudio 2021.08</td>
<td>ARN for RStudio 2023.03</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------</td>
<td>-------------------------</td>
</tr>
</tbody>
</table>
Upgrade to the new version

Existing domains continue using version 2022.02.2-485.pro2 during the grace period. During the grace period, you can use the latest 2023.03.2-454.pro2 version in one of two ways:

- Create a new domain from the AWS CLI with RStudio enabled.
- Update an existing domain to use the 2023.03.2-454.pro2 version.

The following procedure shows how to delete the RStudio application for an existing domain, set the default version to 2023.03.2-454.pro2, and then create an RStudio application. This procedure is only required during the grace period.

1. Delete the RStudioServerPro application and all RSessionGateway applications associated with your existing domain. For information about how to find your domain ID, see View Domains (p. 20). For more information about deleting applications, see Shut down and restart RStudio (p. 634).

   ```bash
   aws sagemaker delete-app \
   --region region \
   --domain-id domainId \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

2. Update the domain to set 2023.03.2-454.pro2 as the default Posit Workbench version. The SageMakerImageArn value in the following update-domain command specifies the RStudio 2023.03.2-454.pro2 version as the default. This ARN must match the Region that your domain is in. For a list of all available ARNs, see Versioning (p. 606).

   Pass an execution role ARN for the domain that provides permissions to update the domain.

   ```bash
   aws sagemaker update-domain \
   --region region \
   --domain-id domainId \
   --domain-settings-for-update "{"\"RStudioServerProDomainSettingsForUpdate\": {\"DefaultResourceSpec\": {\"SageMakerImageArn\": \"arn-for-2023.03.2-454.pro2-version\", \"InstanceType\": \"system\"}, \"DomainExecutionRoleArn\": \"execution-role-arn\"}}"
   ```

3. Create a new RStudioServerPro application in the existing domain.

   ```bash
   aws sagemaker create-app \
   --region region \
   --domain-id domainId \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

Your RStudioServerPro application is now updated to version 2023.03.2-454.pro2. You can now relaunch your RSessionGateway applications.

Downgrade to the existing version

During the grace period, you can manually downgrade the version of your existing RStudio application to the 2022.02.2-485.pro2 version.
To downgrade to the existing version

1. Delete the RStudioServerPro application that's associated with your existing domain. For information about how to find your domain ID, see View Domains (p. 20).

   ```bash
   aws sagemaker delete-app \
   --domain-id domainId \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

2. Pass the corresponding 2022.02.2-485.pro2 ARN for your Region as part of the update-domain command. For a list of all available ARNs, see Versioning (p. 606). You must also pass an execution role ARN for the domain that provides permissions to update the domain.

   ```bash
   aws sagemaker update-domain \
   --region region \
   --domain-id domainId \
   --domain-settings-for-update "{"RStudioServerProDomainSettingsForUpdate": {"DefaultResourceSpec": {"SageMakerImageArn": ", "InstanceType": "system"}, "DomainExecutionRoleArn": ", "ExecutionRoleArn": "}}"
   ```

3. Create a new RStudioServerPro application in the existing domain. The RStudio version defaults to 202.02.2-485.pro2.

   ```bash
   aws sagemaker create-app \
   --domain-id domainId \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

Your RStudioServerPro application is now downgraded to version 2022.02.2-485.pro2.

Changes to BYOI Images

If you use a BYOI image with RStudio and update your RStudioServerPro version to 2023.03.2-454.pro2, you must upgrade your custom images to use the 2023.03.2-454.pro2 release and redeploy your existing RSessions. If you attempt to load a non-compatible image in an RSession of a domain using the 2023.03.2-454.pro2 version, the RSession fails because it cannot parse parameters that it receives. To prevent failure, update all of the deployed custom images in your existing RStudioServerPro application.

The RSW_VERSION in the Dockerfile must be consistent with the Posit Workbench version used in RStudio on SageMaker. You can validate the current version in Posit Workbench. To do so, use the version name that's located in the lower left corner of the Posit Workbench launcher page.

```bash
ARG RSW_VERSION=2023.03.2+454.pro2
ENV RSTUDIO_FORCE_NON_ZERO_EXIT_CODE="1"
ARG RSW_NAME=rstudio-workbench-rhel
ARG RSW_DOWNLOAD_URL=https://s3.amazonaws.com/rstudio-ide-build/server/${OS}/x86_64
RUN RSW_VERSION_URL=`echo -n "$(RSW_VERSION)" | sed 's/+/-/g'` 
   && curl -o rstudio-workbench.rpm ${RSW_DOWNLOAD_URL}/${RSW_NAME}-${RSW_VERSION_URL}-x86_64.rpm 
   && yum install -y rstudio-workbench.rpm
```
Network and Storage

The following topic describes network access and data storage considerations for your RStudio instance. For general information about network access and data storage when using Amazon SageMaker, see Data Protection in Amazon SageMaker (p. 3343).

Amazon EFS volume

RStudio on Amazon SageMaker shares an Amazon EFS volume with the Amazon SageMaker Studio application in the domain. When the RStudio application is added to a domain, SageMaker creates a folder named shared in the Amazon EFS directory. If this shared folder is deleted or changed manually, then the RStudio application may no longer function. For more information about the Amazon EFS volume, see Manage Your Amazon EFS Storage Volume in SageMaker Studio (p. 291).

Installed packages and scripts

Packages that you install from within RStudio are scoped to the user profile level. This means that the installed package persists through RSession shut down, restarts, and across RSessions for each user profile that they are installed in. R Scripts that are saved in RSessions behave the same way. Both packages and R Scripts are saved in the user's Amazon EFS volume.

Encryption

RStudio on Amazon SageMaker supports encryption at rest.

Use RStudio in VPC-only mode

RStudio on Amazon SageMaker supports AWS PrivateLink integration. With this integration, you can use RStudio on SageMaker in VPC-only mode without direct access to the internet. When you use RStudio in VPC-only mode, your security groups are automatically managed by the service. This includes connectivity between your RServer and your RSessions.

The following are required to use RStudio in VPC-only mode. For more information on selecting a VPC, see Choose an Amazon VPC (p. 42).

- A private subnet with either access the internet to make a call to Amazon SageMaker & License Manager, or Amazon Virtual Private Cloud (Amazon VPC) endpoints for both Amazon SageMaker & License Manager.
- The Domain cannot have any more than two associated Security Groups.
- A Security Group ID for use with the Domain in Domain Settings. This must allow all outbound access.
- A Security Group ID for use with the Amazon VPC endpoint. This security group must allow inbound traffic from the Domain Security Group ID.
- Amazon VPC Endpoint for sagemaker.api and AWS License Manager. This must be in the same Amazon VPC as the private subnet.

RStudioServerPro instance type

When deciding which Amazon EC2 instance type to use for your RStudioServerPro app, the main factor to consider is bandwidth. Bandwidth is important because the RStudioServerPro instance is responsible for serving the RStudio UI to all users. This includes UI heavy workflows, such as generating figures, animations, and displaying many data rows. Therefore, there may be some UI performance degradation depending on the workload across all users. The following are the available instance types to use for your RStudioServerPro. For pricing information about these instances, see Amazon SageMaker Pricing.

- ml.t3.medium: This instance type is recommended for Domains with low UI use and is free to use.
- ml.c5.4xlarge: This instance type is recommended for Domains with moderate UI use.
-changing RStudio instance type

To change the instance type of your RStudioServerPro, pass the new instance type as part of a call to the `update-domain` CLI command. You then need to delete the existing RStudioServerPro app using the `delete-app` CLI command and create a new RStudioServerPro app using the `create-app` CLI command.

RStudio Connect URL

RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. RStudio Connect makes it easy to surface machine learning and data science insights by making hosting content simple and scalable. If you have an RStudio Connect server, then you can set the server as the default place where apps are published. For more information about RStudio Connect, see [RStudio Connect](#).

When you onboard to RStudio on Amazon SageMaker Domain, an RStudio Connect server is not created. You can create an RStudio Connect server on an Amazon EC2 instance to use Connect with Amazon SageMaker Domain. For information about how to set up your RStudio Connect server, see [Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker](#).

Add an RStudio Connect URL

If you have an RStudio Connect URL, you can update the default URL so that your RStudio Users can publish to it.

1. Navigate to the Domains page.
2. Select the desired Domain.
3. Choose Domain Settings.
5. From the new page, select RStudio Settings on the left side.
6. Under RStudio Connect URL, enter the RStudio Connect URL to add.
7. Select Submit.

CLI

You can set a default RStudio Connect URL when you create your Domain. The only way to update your RStudio Connect URL from the AWS CLI is to delete your Domain and create a new one with the updated RStudio Connect URL.

RStudio Package Manager

RStudio Package Manager is a repository management server used to organize and centralize packages across your organization. For more information on RStudio Package Manager, see [RStudio Package Manager](#). If you don't supply your own Package Manager URL, Amazon SageMaker Domain uses the default Package Manager repository when you onboard RStudio following the steps in [Onboard to Amazon SageMaker Domain](#). For more information, see [Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker](#).

Update Package Manager URL

You can update the Package Manager URL used for your RStudio-enabled Domain as follows.

1. Navigate to the Domains page.
2. Select the desired Domain.
3. Choose **Domain Settings**.
4. Under **General Settings**, select **Edit**.
5. From the new page, select **RStudio Settings** on the left side.
6. Under **RStudio Package Manager**, enter your RStudio Package Manager URL.
7. Select **Submit**.

**CLI**

The only way to update your Package Manager URL from the AWS CLI is to delete your Domain and create a new one with the updated Package Manager URL.

**Create an Amazon SageMaker Domain with RStudio using the AWS CLI**

The following topic shows how to onboard to Amazon SageMaker Domain with RStudio enabled using the AWS CLI. To onboard using the AWS Management Console, see [Onboard to Amazon SageMaker Domain](p. 10).

**Prerequisites**

- Install and configure [AWS CLI version 2](https://docs.aws.amazon.com/cli/latest/userguide/install-clvm.html)
- Configure the [AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/install-clvm.html) with IAM credentials

**Create DomainExecution role**

To launch the RStudio App, you must provide a DomainExecution role. This role is used to determine whether RStudio needs to be launched as part of Amazon SageMaker Domain creation. This role is also used by Amazon SageMaker to access the RStudio License and push RStudio logs.

**Note**

The DomainExecution role should have at least AWS License Manager permissions to access RStudio License, and CloudWatch permissions to push logs in your account.

The following procedure shows how to create the DomainExecution role with the AWS CLI.

1. Create a file named `assume-role-policy.json` with the following content.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Action": "sts:AssumeRole",
         "Effect": "Allow",
         "Principal": {
           "Service": [
             "sagemaker.amazonaws.com"
           ]
         }
       }
     ]
   }
   ```

2. Create the DomainExecution role. `<REGION>` should be the AWS Region to launch your Domain in.

   ```bash
   aws iam create-role --region <REGION> --role-name DomainExecution --assume-role-policy-document file://assume-role-policy.json
   ```
3. Create a file named `domain-setting-policy.json` with the following content. This policy allows the RStudioServerPro app to access necessary resources and allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "license-manager:ExtendLicenseConsumption",
                "license-manager:ListReceivedLicenses",
                "license-manager:GetLicense",
                "license-manager:CheckoutLicense",
                "license-manager:CheckInLicense",
                "logs:CreateLogDelivery",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DeleteLogDelivery",
                "logs:Describe*",
                "logs:GetLogDelivery",
                "logs:GetLogEvents",
                "logs:ListLogDeliveries",
                "logs:PutLogEvents",
                "logs:PutResourcePolicy",
                "logs:UpdateLogDelivery",
                "sagemaker:CreateApp"
            ],
            "Resource": "*"
        }
    ],
    "Resource": "*"
}
```

4. Create the Domain setting policy that is attached to the DomainExecution role. Be aware of the PolicyArn from the response, you will need to enter that ARN in the following steps.

```bash
aws iam create-policy --region <REGION> --policy-name domain-setting-policy --policy-document file://domain-setting-policy.json
```

5. Attach `domain-setting-policy` to the DomainExecution role. Use the PolicyArn returned in the previous step.

```bash
aws iam attach-role-policy --role-name DomainExecution --policy-arn <POLICY_ARN>
```

### Create Amazon SageMaker Domain with RStudio App

The RStudioServerPro app is launched automatically when you create a Amazon SageMaker Domain using the `create-domain` CLI command with the `RStudioServerProDomainSettings` parameter specified. When launching the RStudioServerPro App, Amazon SageMaker checks for a valid RStudio license in the account and fails Domain creation if the license is not found.

The creation of a Amazon SageMaker Domain differs based on the authentication method and the network type. These options must be used together, with one authentication method and one network connection type selected. For more information about the requirements to create a new Domain, see CreateDomain.

The following authentication methods are supported.
IAM Auth
SSO Auth

The following network connection types are supported:

- PublicInternet
- VPCOnly

Authentication methods

IAM Auth Mode

The following shows how to create an Amazon SageMaker Domain with RStudio enabled and an IAM Auth Network Type. For more information about AWS Identity and Access Management, see What is IAM?

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- app-network-access-type should be either PublicInternetOnly or VPCOnly.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
  --auth-mode IAM \
  --default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
  --domain-settings RStudioServerProDomainSettings={RStudioPackageManagerUrl=<<PACKAGE_MANAGER_URL>,RStudioConnectUrl=<<CONNECT_URL>,DomainExecutionRoleArn=<DOMAINEXECUTION_ROLE_ARN>} \
  --vpc-id <VPC_ID> \
  --subnet-ids <SUBNET_IDS> \
  --app-network-access-type <NETWORK_ACCESS_TYPE>
```

Authentication using IAM Identity Center

The following shows how to create a Amazon SageMaker Domain with RStudio enabled and an SSO Auth Network Type. AWS IAM Identity Center must be enabled for the region that the domain is launched on. For more information about IAM Identity Center, see What is AWS IAM Identity Center?

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- app-network-access-type should be either PublicInternetOnly or VPCOnly.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
  --auth-mode SSO \
  --default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
  --vpc-id <VPC_ID> \
  --subnet-ids <SUBNET_IDS> \
  --app-network-access-type <NETWORK_ACCESS_TYPE>
```
Connection types

PublicInternet/Direct Internet network type

The following shows how to create a Amazon SageMaker Domain with RStudio enabled and a PublicInternet Network Type.

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- auth-mode should be either SSO or IAM.

aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
  --auth-mode <AUTH_MODE> \
  --default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
  --domain-settings RStudioServerProDomainSettings={RStudioPackageManagerUrl=<PACKAGEMANAGEMENT_URL>,RStudioConnectUrl=<CONNECT_URL>,DomainExecutionRoleArn=<DOMAINEXECUTION_ROLE_ARN>} \
  --vpc-id <VPC_ID> \
  --subnet-ids <SUBNET_IDS> \
  --app-network-access-type <NETWORK_ACCESS_TYPE>

VPCOnly mode

The following shows how to launch a Amazon SageMaker Domain with RStudio enabled and a VPCOnly Network Type. For more information about using the VPCOnly network access type, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522).

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. Your private subnet must be able to either access the internet to make a call to Amazon SageMaker, and AWS License Manager or have Amazon VPC endpoints for both Amazon SageMaker and AWS License Manager. For information about Amazon VPC endpoints, see Interface Amazon VPC endpoints. For information about vpc-id and subnet-ids, see VPCs and subnets.
- SecurityGroups must allow outbound access to the Amazon SageMaker and AWS License Manager endpoints.
- auth-mode should be either SSO or IAM.

Note
When using Amazon Virtual Private Cloud endpoints, the security group attached to your Amazon Virtual Private Cloud endpoints must allow inbound traffic from the security group you pass as part of the domain-settings parameter of the create-domain CLI call.
With RStudio, Amazon SageMaker manages security groups for you. This means that Amazon SageMaker manages security group rules to ensure RSessions can access RStudioServerPro Apps. Amazon SageMaker creates one security group rule per user profile.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
  --auth-mode <AUTH_MODE> \
  --default-user-settings SecurityGroups=<USER_SECURITY_GROUP>,ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
  --domain-settings SecurityGroupIds=<DOMAIN_SECURITY_GROUP>,RStudioServerProDomainSettings={DomainExecutionRoleArn=<DOMAINEXECUTION_ROLE_ARN> \
  --vpc-id <VPC_ID> \
  --subnet-ids "<SUBNET_IDS>" \
  --app-network-access-type VPCOnly --app-security-group-management Service
```

Note: The RStudioServerPro app is launched by a special user profile named domain-shared. As a result, this app is not returned as part of list-app API calls by any other user profiles.

You may have to increase the Amazon VPC quota in your account to increase the number of users. For more information, see Amazon VPC quotas.

**Verify Domain creation**

Use the following command to verify that your Domain has been created with a Status of InService. Your domain-id is appended to the Domains ARN. For example, arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:domain/<DOMAIN_ID>.

```
aws sagemaker describe-domain --domain-id <DOMAIN_ID> --region <REGION>
```

**Add RStudio support to an existing Domain**

If you have added an RStudio License through AWS License Manager, you can create a new Amazon SageMaker Domain with support for RStudio on SageMaker. If you have an existing Domain that does not support RStudio, you can add RStudio support to that Domain without having to delete and recreate the Domain.

The following topic outlines how to add this support.

**Prerequisites**

You must complete the following steps before you update your current Domain to add support for RStudio on SageMaker.

- Install and configure AWS CLI version 2
- Configure the AWS CLI with IAM credentials
- Create a Domain execution role following the steps in Create a SageMaker Domain with RStudio using the AWS CLI. This Domain-level IAM role is required by the RStudioServerPro app. The role requires access to AWS License Manager for verifying a valid Posit Workbench license and Amazon CloudWatch Logs for publishing server logs.
- Bring your RStudio license to AWS License Manager following the steps in RStudio license.
- (Optional) If you want to use RStudio in VPCOnly mode, complete the steps in RStudio in VPC-Only.
- Ensure that the security groups you have configured for each UserProfile in your Domain meet the account-level quotas. When configuring the default user profile during Domain creation, you can use the DefaultUserSettings parameter of the CreateDomain API to add SecurityGroups that are inherited by all the user profiles created in the Domain. You can also provide additional security groups
for a specific user as part of the UserSettings parameter of the CreateUserProfile API. If you have added security groups this way, you must ensure that the total number of security groups per user profile doesn't exceed the maximum quota of 2 in VPCOnly mode and 4 in PublicInternetOnly mode. If the resulting total number of security groups for any user profile exceeds the quota, you can combine multiple security groups’ rules into one security group.

Add RStudio support to an existing Domain

After you have completed the prerequisites, you can add RStudio support to your existing Domain. The following steps outline how to update your existing Domain to add support for RStudio.

Step 1: Delete all apps in the Domain

To add support for RStudio in your Domain, SageMaker must update the underlying security groups for all existing user profiles. To complete this, you must delete and recreate all existing apps in the Domain. The following procedure shows how to delete all of the apps.

1. List all of the apps in the Domain.

   ```bash
   aws sagemaker list-apps --domain-id-equals <DOMAIN_ID>
   ```

2. Delete each app for each user profile in the Domain.

   ```bash
   // JupyterServer apps
   aws sagemaker delete-app
       --domain-id <DOMAIN_ID> \
       --user-profile-name <USER_PROFILE> \
       --app-type JupyterServer \
       --app-name <APP_NAME>

   // KernelGateway apps
   aws sagemaker delete-app
       --domain-id <DOMAIN_ID> \
       --user-profile-name <USER_PROFILE> \
       --app-type KernelGateway \
       --app-name <APP_NAME>
   ```

Step 2 - Update all user profiles with the new list of security groups

This is a one-time action that you must complete for all of the existing user profiles in your Domain when you have refactored your existing security groups. This prevents you from hitting the quota for the maximum number of security groups. The UpdateUserProfile API call fails if the user has any apps that are in InService status. Delete all apps, then call UpdateUserProfile API to update the security groups.

   **Note**
   The following requirement for VPCOnly mode outlined in Connect Amazon SageMaker Studio Notebooks in a VPC to External Resources is no longer needed when adding RStudio support because AppSecurityGroupManagement is managed by the SageMaker service: "TCP traffic within the security group. This is required for connectivity between the JupyterServer app and the KernelGateway apps. You must allow access to at least ports in the range 8192-65535.”

   ```bash
   aws sagemaker \
   ```

617
Step 3 - Activate RStudio by calling the UpdateDomain API

1. Call the UpdateDomain API to add support for RStudio on SageMaker. The default usersettings parameter is only needed if you have refactored the default security groups for your user profiles.
   - For VPCOnly mode:
     ```bash
     aws sagemaker \\
     update-domain \\
     --domain-id <DOMAIN_ID> \\
     --app-security-group-management Service \\
     --domain-settings-for-update RStudioServerProDomainSettingsForUpdate={DomainExecutionRoleArn=<DOMAIN_EXECUTION_ROLE_ARN>} \\
     --default-user-settings "{"SecurityGroups": ["<SECURITY_GROUP>", "<SECURITY_GROUP>"],}"
     ```
   - For PublicInternetOnly mode:
     ```bash
     aws sagemaker \\
     update-domain \\
     --domain-id <DOMAIN_ID> \\
     --domain-settings-for-update RStudioServerProDomainSettingsForUpdate={DomainExecutionRoleArn=<DOMAIN_EXECUTION_ROLE_ARN>} \\
     --default-user-settings "{"SecurityGroups": ["<SECURITY_GROUP>", "<SECURITY_GROUP>"],}"
     ```

2. Verify that the Domain status is InService. After the Domain status is InService, support for RStudio on SageMaker is added.
   ```bash
   aws sagemaker \\
   describe-domain \\
   --domain-id <DOMAIN_ID>
   ```

3. Verify that the RStudioServerPro app's status is InService using the following command.
   ```bash
   aws sagemaker list-apps --user-profile-name domain-shared
   ```

Step 4 - Add RStudio access for existing users

As part of the update in Step 3, SageMaker marks the RStudio AccessStatus of all existing user profiles in the Domain as DISABLED by default. This prevents exceeding the number of users allowed by your current license. To add access for existing users, there is a one-time opt-in step. Perform the opt-in by calling the UpdateUserProfile API with the following RStudioServerProAppSettings:

- AccessStatus = ENABLED
- Optional - UserGroup = RUDIO_USER or R_STUDIO_ADMIN

```bash
aws sagemaker \\
update-user-profile \\
--domain-id <DOMAIN_ID> \\
--user-profile-name <USER_PROFILE>
```
Note
By default, the number of users that can have access to RStudio is 60.

Step 5 – Deactivate RStudio access for new users

Unless otherwise specified when calling UpdateDomain, RStudio support is added by default for all new user profiles created after you have added support for RStudio on SageMaker. To deactivate access for a new user profile, you must explicitly set the AccessStatus parameter to DISABLED as part of the CreateUserProfile API call. If the AccessStatus parameter is not specified as part of the CreateUserProfile API, the default access status is ENABLED.

```
aws sagemaker \
  create-user-profile \
  --domain-id <DOMAIN_ID>\n  --user-profile-name <USER_PROFILE> \
  --user-settings "{"RStudioServerProAppSettings": {"AccessStatus": "DISABLED"}}"
```

Bring your own image to RStudio on SageMaker

A SageMaker image is a file that identifies language packages and other dependencies that are required to run RStudio on Amazon SageMaker. SageMaker uses these images to create an environment where you run RStudio. Amazon SageMaker provides a built-in RStudio image for you to use. If you need different functionality, you can bring your own custom images.

The process to bring your own image to use with RStudio on SageMaker takes three steps:

1. Build a custom image from a Dockerfile and push it to a repository in Amazon Elastic Container Registry (Amazon ECR).
2. Create a SageMaker image that points to a container image in Amazon ECR and attach it to your Amazon SageMaker Domain.
3. Launch a new session in RStudio with your custom image.

You can create images and image versions, and attach image versions to your Domain, using the SageMaker control panel, the AWS SDK for Python (Boto3), and the AWS Command Line Interface (AWS CLI). You can also create images and image versions using the SageMaker console, even if you haven’t onboarded to a Domain.

The following topics show how to bring your own image to RStudio on SageMaker by creating, attaching, and launching a custom image.

Key terminology

The following section defines key terms for bringing your own image to use with RStudio on SageMaker.

- **Dockerfile**: A Dockerfile is a file that identifies the language packages and other dependencies for your Docker image.
- **Docker image**: The Docker image is a built Dockerfile. This image is checked into Amazon ECR and serves as the basis of the SageMaker image.
- **SageMaker image**: A SageMaker image is a holder for a set of SageMaker image versions based on Docker images.
- **Image version**: An image version of a SageMaker image represents a Docker image that is compatible with RStudio and stored in an Amazon ECR repository. Each image version is immutable. These image versions can be attached to a domain and used with RStudio on SageMaker.
Prerequisites

You must complete the following prerequisites before bringing your own image to use with RStudio on Amazon SageMaker.

- If you have an existing Domain with RStudio that was created before April 7, 2022, you must delete your RStudioServerPro application and recreate it. For information about how to delete an application, see Shut down and Update SageMaker Studio (p. 292).
- Install the Docker application. For information about setting up Docker, see Orientation and setup.
- Create a local copy of an RStudio-compatible Dockerfile that works with SageMaker. For information about creating a sample RStudio dockerfile, see Use a custom image to bring your own development environment to RStudio on Amazon SageMaker.
- Use an AWS Identity and Access Management execution role that has the AmazonSageMakerFullAccess policy attached. If you have onboarded to Domain, you can get the role from the Domain Summary section of the SageMaker control panel.

Add the following permissions to access the Amazon Elastic Container Registry (Amazon ECR) service to your execution role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "ecr:CreateRepository",
                "ecr:BatchGetImage",
                "ecr:CompleteLayerUpload",
                "ecr:DescribeImages",
                "ecr:DescribeRepositories",
                "ecr:UploadLayerPart",
                "ecr:ListImages",
                "ecr:InitiateLayerUpload",
                "ecr:BatchCheckLayerAvailability",
                "ecr:PutImage"
            ],
            "Resource": "*"
        }
    ]
}
```

- Install and configure AWS CLI with the following (or higher) version. For information about installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

  AWS CLI v1 >= 1.23.6
  AWS CLI v2 >= 2.6.2

Custom RStudio image specifications

In this guide, you'll learn custom RStudio image specifications to use when you bring your own image. There are two sets of requirements that you must satisfy with your custom RStudio image to use it with Amazon SageMaker. These requirements are imposed by RStudio PBC and the Amazon SageMaker Studio platform. If either of these sets of requirements aren't satisfied, then your custom image won't function properly.
RStudio PBC requirements

RStudio PBC requirements are laid out in the Using Docker images with RStudio Workbench / RStudio Server Pro, Launcher, and Kubernetes article. Follow the instructions in this article to create the base of your custom RStudio image.

For instructions about how to install multiple R versions in your custom image, see Installing multiple versions of R on Linux.

Amazon SageMaker Studio requirements

Amazon SageMaker Studio imposes the following set of installation requirements for your RStudio image.

• You must use an RStudio base image of at least 2023.03.2-454.pro2. For more information, see Upgrade the RStudio Version (p. 605).
• You must install the following packages:

```bash
yum install -y sudo \
openjdk-11-jdk \
libpng-dev \
&& yum clean all \
&& /opt/R/$R_VERSION/bin/R -e "install.packages('reticulate', repos='https://packagemanager.rstudio.com/cran/__linux__/centos7/latest')" \
&& /opt/python/$PYTHON_VERSION/bin/pip install --upgrade \
  'boto3>1.0<2.0' \
  'awscli>1.0<2.0' \
  'sagemaker[local]<3'
```

• You must provide default values for the RSTUDIO_CONNECT_URL and RSTUDIO_PACKAGE_MANAGER_URL environment values.

```bash
ENV RSTUDIO_CONNECT_URL "YOUR_CONNECT_URL"
ENV RSTUDIO_PACKAGE_MANAGER_URL "YOUR_PACKAGE_MANAGER_URL"
```

The following general specifications apply to the image that is represented by an RStudio image version.

Running the image

ENTRYPOINT and CMD instructions are overridden so that the image is run as an RSession application.

Stopping the image

The DeleteApp API issues the equivalent of a docker stop command. Other processes in the container won't get the SIGKILL/SIGTERM signals.

File system

The /opt/.sagemakerinternal and /opt/ml directories are reserved. Any data in these directories might not be visible at runtime.

User data

Each user in a SageMaker domain gets a user directory on a shared Amazon Elastic File System volume in the image. The location of the current user's directory on the Amazon Elastic File System volume is /home/sagemaker-user.

Metadata

A metadata file is located at /opt/ml/metadata/resource-metadata.json. No additional environment variables are added to the variables defined in the image. For more information, see Get App Metadata (p. 233).
GPU

On a GPU instance, the image is run with the `--gpus` option. Only the CUDA toolkit should be included in the image, not the NVIDIA drivers. For more information, see NVIDIA User Guide.

Metrics and logging

Logs from the RSession process are sent to Amazon CloudWatch in the customer's account. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/RSession/$appName.

Image size

Image size is limited to 25 GB. To view the size of your image, run `docker image ls`.

Create a custom RStudio image

This topic describes how you can create a custom RStudio image using the SageMaker console and the AWS CLI. If you use the AWS CLI, you must run the steps from your local machine. The following steps do not work from within Amazon SageMaker Studio.

When you create an image, SageMaker also creates an initial image version. The image version represents a container image in Amazon Elastic Container Registry (ECR). The container image must satisfy the requirements to be used in RStudio. For more information, see Custom RStudio image specifications (p. 620).

For information about testing your image locally and resolving common issues, see the SageMaker Studio Custom Image Samples repo.

Topics

- Add a SageMaker-compatible RStudio Docker container image to Amazon ECR (p. 622)
- Create a SageMaker image from the console (p. 623)
- Create an image from the AWS CLI (p. 624)

Add a SageMaker-compatible RStudio Docker container image to Amazon ECR

Use the following steps to add a Docker container image to Amazon ECR:

- Create an Amazon ECR repository.
- Authenticate to Amazon ECR.
- Build a SageMaker-compatible RStudio Docker image.
- Push the image to the Amazon ECR repository.

Note
The Amazon ECR repository must be in the same AWS Region as your domain.

To build and add a Docker image to Amazon ECR

1. Create an Amazon ECR repository using the AWS CLI. To create the repository using the Amazon ECR console, see Creating a repository.

   ```
   aws ecr create-repository --repository-name rstudio-custom --image-scanning-configuration scanOnPush=true
   ```
Manage RStudio on SageMaker

Response:

```json
{
    "repository": {
        "repositoryArn": "arn:aws:ecr:us-east-2:acct-id:repository/rstudio-custom",
        "registryId": "acct-id",
        "repositoryName": "rstudio-custom",
        "repositoryUri": "acct-id.dkr.ecr.us-east-2.amazonaws.com/rstudio-custom",
        ...
    }
}
```

2. Authenticate to Amazon ECR using the repository URI returned as a response from the create-repository command. Make sure that the Docker application is running. For more information, see Registry Authentication.

```bash
aws ecr get-login-password | \
docker login --username AWS --password-stdin <repository-uri>
```

Response:

Login Succeeded

3. Build the Docker image. Run the following command from the directory that includes your Dockerfile.

```bash
docker build .
```

4. Tag your built image with a unique tag.

```bash
docker tag <image-id> "<repository-uri>:<tag>"
```

5. Push the container image to the Amazon ECR repository. For more information, see ImagePush and Pushing an image.

```bash
docker push <repository-uri>:<tag>
```

Response:

```
The push refers to repository [<account-id>.dkr.ecr.us-east-2.amazonaws.com/rstudio-custom]	r: digest: <digest> size: 3066
```

Create a SageMaker image from the console

To create an image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
4. On the Custom images page, choose Create image.
5. For Image source, enter the registry path to the container image in Amazon ECR. The path is in the following format:
6. Choose Next.
7. Under Image properties, enter the following:
   - Image name – The name must be unique to your account in the current AWS Region.
   - (Optional) Image display name – The name displayed in the domain user interface. When not provided, Image name is displayed.
   - (Optional) Description – A description of the image.
   - IAM role – The role must have the AmazonSageMakerFullAccess policy attached. Use the dropdown menu to choose one of the following options:
     - Create a new role – Specify any additional Amazon Simple Storage Service (Amazon S3) buckets that you want your notebooks users to access. If you don’t want to allow access to additional buckets, choose None. SageMaker attaches the AmazonSageMakerFullAccess policy to the role. The role allows your notebook users to access the Amazon S3 buckets listed next to the check marks.
     - Enter a custom IAM role ARN – Enter the Amazon Resource Name (ARN) of your IAM role.
     - Use existing role – Choose one of your existing roles from the list.
   - (Optional) Image tags – Choose Add new tag. You can add up to 50 tags. Tags are searchable using the SageMaker console or the SageMaker Search API.
8. Under Image type, select RStudio image.
9. Choose Submit.

The new image is displayed in the Custom images list and briefly highlighted. After the image has been successfully created, you can choose the image name to view its properties or choose Create version to create another version.

To create another image version

1. Choose Create version on the same row as the image.
2. For Image source, enter the registry path to the Amazon ECR image. The image shouldn’t be the same image as used in a previous version of the SageMaker image.

To use the custom image in RStudio, you must attach it to your domain. For more information, see Attach a custom SageMaker image (p. 626).

Create an image from the AWS CLI

This section shows how to create a custom Amazon SageMaker image using the AWS CLI.

Use the following steps to create a SageMaker image:
   - Create an Image.
   - Create an ImageVersion.
   - Create a configuration file.
   - Create an AppImageConfig.

To create the SageMaker image entities

1. Create a SageMaker image. The role ARN must have at least the AmazonSageMakerFullAccessPolicy policy attached.
aws sagemaker create-image
   --image-name rstudio-custom-image
   --role-arn arn:aws:iam::<acct-id>:role/service-role/<execution-role>

Response:

{
   "ImageArn": "arn:aws:sagemaker:us-east-2:acct-id:image/rstudio-custom-image"
}

2. Create a SageMaker image version from the image. Pass the unique tag value that you chose when you pushed the image to Amazon ECR.

aws sagemaker create-image-version
   --image-name rstudio-custom-image
   --base-image <repository-uri>:<tag>

Response:

{
   "ImageVersionArn": "arn:aws:sagemaker:us-east-2:acct-id:image-version/rstudio-image/1"
}

3. Check that the image version was successfully created.

aws sagemaker describe-image-version
   --image-name rstudio-custom-image
   --version 1

Response:

{
   "ImageVersionStatus": "CREATED"
}

Note
If the response is "ImageVersionStatus": "CREATED_FAILED", the response also includes the failure reason. A permissions issue is a common cause of failure. You also can check your Amazon CloudWatch Logs. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

4. Create a configuration file, named app-image-config-input.json. The app image config is used to configuration for running a SageMaker image as a Kernel Gateway application.

{
   "AppImageConfigName": "rstudio-custom-config"
}

5. Create the AppImageConfig using the file that you created in the previous step.

aws sagemaker create-app-image-config
   --cli-input-json file://app-image-config-input.json
Response:

```
{
}
```

### Attach a custom SageMaker image

This guide shows how to attach a custom RStudio image to your Amazon SageMaker Domain using the SageMaker console or the AWS Command Line Interface (AWS CLI).

To use a custom SageMaker image, you must attach a custom RStudio image to your Domain. When you attach an image version, it appears in the RStudio Launcher and is available in the Select image dropdown list. You use the dropdown to change the image used by RStudio.

There is a limit to the number of image versions that you can attach. After you reach the limit, you must first detach a version so that you can attach a different version of the image.

**Topics**

- [Attach an image version to your Domain using the console (p. 626)](#)
- [Attach an existing image version to your Domain using the AWS CLI (p. 627)](#)

#### Attach an image version to your Domain using the console

You can attach a custom SageMaker image version to your Domain using the SageMaker console's control panel. You can also create a custom SageMaker image, and an image version, and then attach that version to your Domain.

**To attach an existing image**

2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the desired Domain.
5. Choose Environment.
6. Under Custom SageMaker Studio images attached to domain, choose Attach image.
7. For Image source, choose Existing image or New image.

   If you select Existing image, choose an image from the Amazon SageMaker image store.

   If you select New image, provide the Amazon ECR registry path for your Docker image. The path must be in the same AWS Region as the Domain. The Amazon ECR repo must be in the same account as your Domain, or cross-account permissions for SageMaker must be enabled.

8. Choose an existing image from the list.
9. Choose a version of the image from the list.
10. Choose Next.
11. Enter values for Image name, Image display name, and Description.
12. Choose the IAM role. For more information, see [Create a custom RStudio image (p. 622)](#).
13. (Optional) Add tags for the image.
14. (Optional) Choose **Add new tag**, then add a configuration tag.
15. For **Image type**, select **RStudio Image**.
16. Choose **Submit**.

Wait for the image version to be attached to the Domain. After the version is attached, it appears in the **Custom images** list and is briefly highlighted.

**Attach an existing image version to your Domain using the AWS CLI**

Two methods are presented to attach the image version to your Domain using the AWS CLI. In the first method, you create a new Domain with the version attached. This method is simpler but you must specify the Amazon Virtual Private Cloud (Amazon VPC) information and execution role that's required to create the Domain.

If you have already onboarded to the Domain, you can use the second method to attach the image version to your current Domain. In this case, you don't need to specify the Amazon VPC information and execution role. After you attach the version, delete all of the applications in your Domain and relaunch RStudio.

**Attach the SageMaker image to a new Domain**

To use this method, you must specify an execution role that has the **AmazonSageMakerFullAccess** policy attached.

Use the following steps to create the Domain and attach the custom SageMaker image:

- Get your default VPC ID and subnet IDs.
- Create the configuration file for the Domain, which specifies the image.
- Create the Domain with the configuration file.

**To add the custom SageMaker image to your Domain**

1. Get your default VPC ID.

   ```bash
   aws ec2 describe-vpcs \
   --filters Name=isDefault,Values=true \
   --query "Vpcs[0].VpcId" --output text
   
   Response:
   
   vpc-xxxxxxxx
   
   2. Get your default subnet IDs using the VPC ID from the previous step.

   ```bash
   aws ec2 describe-subnets \
   --filters Name=vpc-id,Values=<vpc-id> \
   --query "Subnets[*].SubnetId" --output json
   
   Response:
   
   ```
   ["subnet-b55171dd",
   "subnet-8a5f99c6",
   "subnet-e88d1392"
   ]
   ```
3. Create a configuration file named `create-domain-input.json`. Insert the VPC ID, subnet IDs, ImageName, and AppImageConfigName from the previous steps. Because ImageVersionNumber isn't specified, the latest version of the image is used, which is the only version in this case. Your execution role must satisfy the requirements in Prerequisites (p. 620).

   ```json
   {
     "DomainName": "domain-with-custom-r-image",
     "VpcId": "<vpc-id>",
     "SubnetIds": [
       "<subnet-ids>"
     ],
     "DomainSettings": {
       "RStudioServerProDomainSettings": {
         "DomainExecutionRoleArn": "<execution-role>",
       }
     },
     "DefaultUserSettings": {
       "ExecutionRole": "<execution-role>",
       "RSessionAppSettings": {
         "CustomImages": [
           {
             "AppImageConfigName": "rstudio-custom-config",
             "ImageName": "rstudio-custom-image"
           }
         ]
       },
       "AuthMode": "IAM"
     }
   }
   ```

4. Create the Domain with the attached custom SageMaker image.

   ```bash
   aws sagemaker create-domain \
   --cli-input-json file://create-domain-input.json
   ```

   Response:

   ```json
   {
     "DomainArn": "arn:aws:sagemaker:region:acct-id:domain/domain-id",
     "Url": "https://domain-id.studio.region.sagemaker.aws/..."
   }
   ```

Attach the SageMaker image to an existing Domain

This method assumes that you've already onboarded to Domain. For more information, see Onboard to Amazon SageMaker Domain (p. 10).

**Note**

You must delete all of the applications in your Domain to update the Domain with the new image version. For information about deleting these applications, see Delete an Amazon SageMaker Domain (p. 21).

Use the following steps to add the SageMaker image to your current Domain.

- Get your DomainID from the SageMaker console.
- Use the DomainID to get the DefaultUserSettings for the Domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultUserSettings.
- Update your Domain to include the custom image.
To add the custom SageMaker image to your Domain

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.  
2. On the left navigation pane, choose Admin configurations.  
3. Under Admin configurations, choose Domains.  
4. Select the desired Domain.  
5. Choose Domain settings.  
6. Under General Settings, find the Domain ID. The ID is in the following format: d-xxxxxxxxxxxx.  
7. Use the Domain ID to get the description of the Domain.

```bash
aws sagemaker describe-domain \
  --domain-id <d-xxxxxxxxxxxx>
```

Response:

```json
{
  "DomainId": "d-xxxxxxxxxxxx",
  "DefaultUserSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [
      ],
    },
    ...
  }
}
```

8. Save the DefaultUserSettings section of the response to a file named update-domain-input.json.  
9. Insert the ImageName and AppImageConfigName from the previous steps as a custom image. Because ImageVersionNumber isn’t specified, the latest version of the image is used, which is the only version in this case.

```json
{
  "DefaultUserSettings": {
    "RSessionAppSettings": {
      "CustomImages": [
      {
        "ImageName": "rstudio-custom-image",
        "AppImageConfigName": "rstudio-custom-config"
      }
    ]
  }
}
```

10. Use the Domain ID and default user settings file to update your Domain.

```bash
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://update-domain-input.json
```

Response:

```json
{
  "DomainArn": "arn:aws:sagemaker:region:acct-id:domain/domain-id"
}
```
11. Delete the RStudioServerPro application. You must restart the RStudioServerPro domain-shared application for the RStudio Launcher UI to pick up the latest changes.

```bash
aws sagemaker delete-app \
  --domain-id <d-xxxxxxxxxxxx> --user-profile-name domain-shared \
  --app-type RStudioServerPro --app-name default
```

12. Create a new RStudioServerPro application. You must create this application using the AWS CLI.

```bash
aws sagemaker create-app \
  --domain-id <d-xxxxxxxxxxxx> --user-profile-name domain-shared \
  --app-type RStudioServerPro --app-name default
```

Launch a custom SageMaker image in RStudio

You can use your custom image when launching an RStudio application from the console. After you create your custom SageMaker image and attach it to your domain, the image appears in the image selector dialog box of the RStudio Launcher. To launch a new RStudio app, follow the steps in Open RStudio Launcher and launch RSessions (p. 637) and select your custom image as shown in the following image.

![RStudio Launcher Image Selector](image)

Clean up image resources

This guide shows how to clean up RStudio image resources that you created in the previous sections. To delete an image, complete the following steps using either the SageMaker console or the AWS CLI, as shown in this guide.

- Detach the image and image versions from your Amazon SageMaker Domain.
- Delete the image, image version, and app image config.

After you've completed these steps, you can delete the container image and repository from Amazon ECR. For more information about how to delete the container image and repository, see Deleting a repository.

Clean up resources from the SageMaker console

When you detach an image from a Domain, all versions of the image are detached. When an image is detached, all users of the Domain lose access to the image versions.

To detach an image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. Select the desired Domain.
5. Choose **Environment**.
6. Under **Custom images attached to domain**, choose the image and then choose **Detach**.
7. (Optional) To delete the image and all versions from SageMaker, select **Also delete the selected images** .... This does not delete the associated images from Amazon ECR.
8. Choose **Detach**.

**Clean up resources from the AWS CLI**

**To clean up resources**

1. Detach the image and image versions from your Domain by passing an empty custom image list to the Domain. Open the `update-domain-input.json` file that you created in [Attach the SageMaker image to your current domain](p. 266).
2. Delete the `RSessionAppSettings` custom images and then save the file. Do not modify the `KernelGatewayAppSettings` custom images.

```json
{
    "DomainId": "d-xxxxxxxxxxxx",
    "DefaultUserSettings": {
        "KernelGatewayAppSettings": {
            "CustomImages": [],
            ...
        },
        "RSessionAppSettings": {
            "CustomImages": [],
            "DefaultResourceSpec": {
                ...
            }
        }
    }
}
```

3. Use the Domain ID and default user settings file to update your Domain.

```bash
aws sagemaker update-domain \
    --domain-id <d-xxxxxxxxxxxx> \ 
    --cli-input-json file://update-domain-input.json
```

Response:

```json
{
    "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

4. Delete the app image config.

```bash
aws sagemaker delete-app-image-config \
    --app-image-config-name rstudio-image-config
```

5. Delete the SageMaker image, which also deletes all image versions. The container images in Amazon ECR that are represented by the image versions are not deleted.
Manage users

After your RStudio-enabled Amazon SageMaker Domain is running, you can add user profiles (UserProfiles) to the Domain. The following topics show how to create user profiles that are authorized to use RStudio, as well as update an existing user profile. For information on how to delete an RStudio App, UserProfile, or Domain, follow the steps in Delete an Amazon SageMaker Domain.

**Note**
The limit for the total number of UserProfiles in an Amazon SageMaker Domain is 60.

There are two types of users:

- Unauthorized: This user cannot access the RStudio app.
- Authorized: This user can access the RStudio app and use one of the RStudio license seats. By default, a new user is Authorized if the Domain is enabled for RStudio.

If a user is authorized, they can be given one of the following levels of access to RStudio.

- RStudio User: This is a standard RStudio user and can access RStudio.
- RStudio Admin: The admin of your Amazon SageMaker Domain has the ability to create users, add existing users, and update the permissions of existing users. Admins can also access the RStudio Administrative dashboard. However, this admin is not able to update parameters that are managed by Amazon SageMaker.

**Methods to create a user**

The following topics show how to create a user in your RStudio-enabled Amazon SageMaker Domain.

**Create user console**

To create a user in your RStudio-enabled Amazon SageMaker Domain from the console, complete the steps in Add user profiles (p. 24).

**Create user CLI**

The following command shows how to add users to a Amazon SageMaker Domain with IAM authentication. A User can belong to either the R_STUDIO_USER or R_STUDIO_ADMIN User group.

```bash
aws sagemaker create-user-profile --region <REGION> \
    --domain-id <DOMAIN-ID> \
    --user-profile-name <USER_PROFILE_NAME-ID> \
    --user-settings RStudioServerProAppSettings={UserGroup=<USER-GROUP>}
```

The following command shows how to add users to a Amazon SageMaker Domain with authentication using IAM Identity Center. A user can belong to either the R_STUDIO_USER or R_STUDIO_ADMIN User group.

```bash
aws sagemaker create-user-profile --region <REGION> \
    --domain-id <DOMAIN-ID> \
    --user-profile-name <USER_PROFILE_NAME-ID> \
    --user-settings RStudioServerProAppSettings={UserGroup=<USER-GROUP>}
```
Update existing user

You cannot update the authorization of an existing user. You must delete the existing user and create a new one with the updated authorization.

Log in to RStudio as another user

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Select the domain containing the user profile.
5. Select a user name from the list of users. This opens a new page with details about the user profile and the apps that are running.
7. From the dropdown, select RStudio to launch an RStudio instance.

Terminate sessions for another user

1. From the list of running apps, identify the app you want to delete.
2. Click the respective Delete app button for the app you are deleting.

Delete another user

You cannot delete a user if the user is running any apps. Delete all apps before attempting to delete a user.

1. From the User Profile page, select Edit. This opens a new General settings page.
2. Under Delete user, select Delete user.

RStudio administrative dashboard

This topic shows how to access and use the RStudio administrative dashboard. With the RStudio administrative dashboard, admins can manage users and RSessions, as well as view information about RStudio Server instance utilization and Amazon CloudWatch Logs.

Launch the RStudio administrative dashboard

The R_STUDIO_ADMIN authorization allows the user to access the RStudio administrative dashboard. An R_STUDIO_ADMIN user can access the RStudio administrative dashboard by replacing workspaces with admin in their RStudio URL manually. The following shows how to modify the URL to access the RStudio administrative dashboard.

For example, the following RStudio URL:

https://<DOMAIN-ID>.studio.us-east-2.sagemaker.aws/rstudio/default/s/<SESSION-ID>/workspaces

Can be converted to:
Dashboard tab
This tab gives an overview of your RStudio Server instance utilization, as well as information on the number of active RSessions.

Sessions tab
This tab gives information on the active RSessions, such as the user that launched the RSessions, the time that the RSessions have been running, and their resource utilization.

Users tab
This tab gives information on the RStudio authorized users in the Domain, such as the time that the last RSession was launched and their resource utilization.

Stats tab
This tab gives information on the utilization of your RStudio Server instance.

Logs tab
This tab displays Amazon CloudWatch Logs for the RStudio Server instance. For more information about logging events with Amazon CloudWatch Logs, see What is Amazon CloudWatch Logs?

Shut down and restart RStudio
To shut down and restart your Posit Workbench and the associated RStudioServerPro app, you must first shut down all of your existing RSessions. You can shut down the RSessionGateway apps from within RStudio. You can then shut down the RStudioServerPro app using the AWS CLI. After the RStudioServerPro app is shut down, you must reopen RStudio through the SageMaker console.

Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

Note
If you are using a custom image with RStudio, ensure that your docker image is using an RStudio version that is compatible with the version of Posit Workbench being used by SageMaker after you restart your RStudioServerPro app.

The following topics show how to shut down the RSessionGateway and RStudioServerPro apps and restart them.

Suspend your RSessions
Complete the following procedure to suspend all of your RSessions.

1. From the RStudio Launcher, identify the RSession that you want to suspend.
2. Select Suspend for the session.
3. Repeat this for all RSessions.

Delete your RSessions
Complete the following procedure to shut down all of your RSessions.

1. From the RStudio Launcher, identify the RSession that you want to delete.
2. Select Quit for the session. This opens a new Quit Session window.
3. From the Quit Session window, select Force Quit, to end all child processes in the session.
4. Select Quit Session to confirm deletion of the session.
5. Repeat this for all RSessions.

Delete your RStudioServerPro app

Run the following commands from the AWS CLI to delete and restart your RStudioServerPro app.

1. Delete the RStudioServerPro application by using your current domain id.

   ```
   aws sagemaker delete-app \
   --domain-id <domainId> \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

2. Re-create the RStudioServerPro application.

   ```
   aws sagemaker create-app \
   --domain-id <domainId> \
   --user-profile-name domain-shared \
   --app-type RStudioServerPro \
   --app-name default
   ```

Manage billing and cost

To track the costs associated with your RStudio environment, you can use the AWS Billing and Cost Management service. AWS Billing and Cost Management provides useful tools to help you gather information related to your cost and usage, analyze your cost drivers and usage trends, and take action to budget your spending. For more information, see What is AWS Billing and Cost Management?

The following describes components required to run RStudio on Amazon SageMaker and how each component factors into billing for your RStudio instance.

- **RStudio License** – You must purchase an RStudio license. There is no additional charge for using your RStudio license with Amazon SageMaker. For more information about your RStudio license, see RStudio license (p. 604).
- **RSession** - These are RStudio working sessions launched by end users. You are charged while the RSession is running.
- **RStudio Server** - A multi-tenant server manages all the RSessions. You can choose the instance type to run RStudio Server on, and pay the related costs. The default instance, "system", is free, but you can choose to pay for higher tiers. For more information about the available instance types for your RStudio Server, see RStudioServerPro instance type (p. 610).

Tracking billing at user level

To track billing at the user level using Cost Allocation Tags, see Using Cost Allocation Tags.

Diagnose issues and get support

The following sections describe how to diagnose issues with RStudio on Amazon SageMaker. To get support for RStudio on Amazon SageMaker, contact Amazon SageMaker support. For help with purchasing an RStudio license or modifying the number of license seats, contact sales@rstudio.com.
Upgrade your version

If you receive a warning that there is a version mismatch between your RSession and RStudioServerPro apps, then you must upgrade the version of your RStudioServerPro app. For more information, see Upgrade the RStudio Version (p. 605).

View Metrics and Logs

You can monitor your workflow performance while using RStudio on Amazon SageMaker. View data logs and information about metrics with the RStudio administrative dashboard or Amazon CloudWatch.

View your RStudio logs from the RStudio administrative dashboard

You can view metrics and logs directly from the RStudio administrative dashboard.

1. Log in to your Amazon SageMaker Domain.
2. Navigate to the RStudio administrative dashboard following the steps in RStudio administrative dashboard (p. 633).
3. Select the Logs tab.

View your RStudio logs from Amazon CloudWatch Logs

Amazon CloudWatch monitors your AWS resources and the applications that you run on AWS in real time. You can use Amazon CloudWatch to collect and track metrics, which are variables that you can measure for your resources and applications. To ensure that your RStudio apps have permissions for Amazon CloudWatch, you must include the permissions described in Onboard to Amazon SageMaker Domain (p. 10). You don't need to do any setup to gather Amazon CloudWatch Logs.

The following steps show how to view Amazon CloudWatch Logs for your RSession.

These logs can be found in the /aws/sagemaker/studio log stream from the AWS CloudWatch console.

2. Select Logs from the left side. From the dropdown menu, select Log groups.
3. On the Log groups screen, search for aws/sagemaker/studio. Select the Log group.
4. On the aws/sagemaker/studio Log group screen, navigate to the Log streams tab.
5. To find the logs for your Domain, search Log streams using the following format:

   <DomainId>/domain-shared/rstudioserverpro/default

Use RStudio on Amazon SageMaker

With RStudio support in Amazon SageMaker, you can put your production workflows in place and take advantage of SageMaker features. The following topics show how to launch an RStudio session and complete key workflows. For information about managing RStudio on SageMaker, see Manage RStudio on Amazon SageMaker (p. 604).

For information about the onboarding steps to create an Amazon SageMaker Domain with RStudio enabled, see Onboard to Amazon SageMaker Domain (p. 10).

For information about the AWS Regions that RStudio on SageMaker is supported in, see Supported Regions and Quotas (p. 43).
Collaborate in RStudio

To share your RStudio project, you can connect RStudio to your Git repo. For information on setting this up, see [Version Control with Git and SVN](https://docs.aws.amazon.com/sagemaker/latest/dg/rstudio-git-integrate.html).

**Note**: Project sharing and realtime collaboration are not currently supported when using RStudio on Amazon SageMaker.

Base R image

When launching your RStudio instance, the Base R image serves as the basis of your instance. This image extends the *r-session-complete* Docker image.

This Base R image includes the following:

- R v4.0 or higher
- `awscli`, `sagemaker`, and `boto3` Python packages
- [Reticulate](https://reticulate.r-lib.org/) package for R SDK integration

RSsession application colocation

Users can create multiple RSsession applications on the same instance. Each instance type supports up to four colocated RSsession applications. This applies to each user independently. For example, if two users create applications, then SageMaker allocates different underlying instances to each user. Each of these instances would support 4 RSsession applications.

Customers only pay for the instance type used regardless of how many Rsession applications are running on the instance. If a user creates an RSsession with a different associated instance type, then a new underlying instance is created.

Open RStudio Launcher and launch RSessions

The following topics show how to use the RStudio Launcher to launch RSessions.

Open RStudio Launcher

Open RStudio Launcher from the Amazon SageMaker Console

2. From the left navigation, select **RStudio**.
3. Under **Get Started**, select the domain and user profile to launch.
4. Choose **Launch RStudio**.
Open RStudio Launcher from the AWS CLI

The procedure to open the RStudio Launcher using the AWS CLI differs depending on the method used to manage your users.

IAM Identity Center

1. Use the AWS access portal to open your Amazon SageMaker Domain.
2. Modify the URL path to "/rstudio/default" as follows.

<table>
<thead>
<tr>
<th>Studio URL</th>
<th>Modified URL</th>
</tr>
</thead>
</table>

IAM

To open the RStudio Launcher from the AWS CLI in IAM mode, complete the following procedure.

1. Create a presigned URL using the following command.

   ```bash
   aws sagemaker create-presigned-domain-url --region <REGION> --domain-id <DOMAIN-ID> --user-profile-name <USER-PROFILE-NAME>
   ```

2. Append &redirect=RStudioServerPro to the generated URL.
3. Navigate to the updated URL.

Launch RSessions

After you’ve launched the RStudio Launcher, you can create a new RSession.

1. Select New Session.
2. Enter a Session Name.
3. Select an instance type that your RSession runs on. This defaults to ml.t3.medium.
4. Select an Image that your RSession uses as the kernel.
5. Select Start Session.
6. After your session has been created, you can start it by selecting the name.

   **Note**
   
   If you receive a warning that there is a version mismatch between your RSession and RStudioServerPro apps, then you must upgrade the version of your RStudioServerPro app. For more information, see [Upgrade the RStudio Version](p. 605).

Suspend your RSessions

1. From the RStudio Launcher, identify the RSession that you want to suspend.
2. Select Suspend for the session.

Delete your RSessions

1. From the RStudio Launcher, identify the RSession that you want to delete.
2. Select **Quit** for the session. This opens a new **Quit Session** window.
3. From the **Quit Session** window, select **Force Quit**, to end all child processes in the session.
4. Select **Quit Session** to confirm deletion of the session.

**Publish to RStudio Connect**

RStudio Connect enables data scientists to publish insights, dashboard and web applications from RStudio on Amazon SageMaker. For more information, see [Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker](#).

For more information on RStudio Connect, see the [RStudio Connect User Guide](#).

**Access Amazon SageMaker features with RStudio on Amazon SageMaker**

One of the benefits of using RStudio on Amazon SageMaker is the integration of Amazon SageMaker features. This includes integration with Amazon SageMaker Studio and Reticulate.

**Use Amazon SageMaker Studio JupyterLab and RStudio on Amazon SageMaker**

Your Amazon SageMaker Studio JupyterLab and RStudio instances share the same Amazon EFS file system. This means that files that you import and create using JupyterLab can be accessed using RStudio and vice versa. This allows you to work on the same files using both JupyterLab and RStudio without having to move your files between the two. For more information on this workflow, see the [Announcing Fully Managed RStudio on Amazon SageMaker for Data Scientists](#) blog.

**Use Amazon SageMaker SDK with reticulate**

The **reticulate** package is used as an R interface to [Amazon SageMaker Python SDK](#) to make API calls to Amazon SageMaker. The reticulate package translates between R and Python objects, and Amazon SageMaker provides a serverless data science environment to train and deploy Machine Learning (ML) models at scale. For general information about the reticulate package, see [R Interface to Python](#).

For a blog that outlines how to use the reticulate package with Amazon SageMaker, see [Using R with Amazon SageMaker](#).

The following examples show how to use reticulate for specific use cases.

- For a notebook that describes how to use reticulate to do batch transform to make predictions, see [Batch Transform Using R with Amazon SageMaker](#).
- For a notebook that describes how to use reticulate to conduct hyperparameter tuning and generate predictions, see [Hyperparameter Optimization Using R with Amazon SageMaker](#).
To train a machine learning model, you need a large, high-quality, labeled dataset. You can label your data using Amazon SageMaker Ground Truth. Choose from one of the Ground Truth built-in task types or create your own custom labeling workflow. To improve the accuracy of your data labels and reduce the total cost of labeling your data, use Ground Truth enhanced data labeling features like automated data labeling and annotation consolidation.

Use Amazon SageMaker Ground Truth to Label Data

To train a machine learning model, you need a large, high-quality, labeled dataset. Ground Truth helps you build high-quality training datasets for your machine learning models. With Ground Truth, you can use workers from either Amazon Mechanical Turk, a vendor company that you choose, or an internal, private workforce along with machine learning to enable you to create a labeled dataset. You can use the labeled dataset output from Ground Truth to train your own models. You can also use the output as a training dataset for an Amazon SageMaker model.

Depending on your ML application, you can choose from one of the Ground Truth built-in task types to have workers generate specific types of labels for your data. You can also build a custom labeling workflow to provide your own UI and tools to workers labeling your data. To learn more about the Ground Truth built-in task types, see Built-in Task Types (p. 818). To learn how to create a custom labeling workflow, see Creating Custom Labeling Workflows (p. 785).

In order to automate labeling your training dataset, you can optionally use automated data labeling, a Ground Truth process that uses machine learning to decide which data needs to be labeled by humans. Automated data labeling may reduce the labeling time and manual effort required. For more information, see Automate Data Labeling (p. 921). To create a custom labeling workflow, see Creating Custom Labeling Workflows (p. 785).

Use either pre-built or custom tools to assign the labeling tasks for your training dataset. A labeling UI template is a webpage that Ground Truth uses to present tasks and instructions to your workers. The SageMaker console provides built-in templates for labeling data. You can use these templates to get started, or you can build your own tasks and instructions by using our HTML 2.0 components. For more information, see Creating Custom Labeling Workflows (p. 785).

Use the workforce of your choice to label your dataset. You can choose your workforce from:
Are You a First-time User of Ground Truth?

If you are a first-time user of Ground Truth, we recommend that you do the following:

1. Read Getting started (p. 641)—This section walks you through setting up your first Ground Truth labeling job.
2. Explore other topics—Depending on your needs, do the following:
   - Explore built-in task types—Use built-in task types to streamline the process of creating a labeling job. See Built-in Task Types (p. 818) to learn more about Ground Truth built-in task types.
   - Manage your labeling workforce—Create new work teams and manage your existing workforce. For more information, see Create and Manage Workforces (p. 977).
   - Learn about streaming labeling jobs—Create a streaming labeling job and send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it. To learn more, see Ground Truth Streaming Labeling Jobs (p. 852).
3. See the Reference—This section describes operations to automate Ground Truth operations.

Getting started

This video shows you how to setup and use Amazon SageMaker Ground Truth. (Length: 9:37)

To get started using Amazon SageMaker Ground Truth, follow the instructions in the following sections. The sections here explain how to use the console to create a labeling job, assign a public or private workforce, and send the labeling job to your workforce. You can also learn how to monitor the progress of a labeling job.

If you want to create a custom labeling workflow, see Creating Custom Labeling Workflows (p. 785) for instructions.

Before you create a labeling job, you must upload your dataset to an Amazon S3 bucket. For more information, see Use Input and Output Data (p. 848).

Topics

- Step 1: Before You Begin (p. 642)
- Step 2: Create a Labeling Job (p. 642)
- Step 3: Select Workers (p. 643)
- Step 4: Configure the Bounding Box Tool (p. 645)
Step 1: Before You Begin

Before you begin using the SageMaker console to create a labeling job, you must set up the dataset for use. Do this:

1. Save two images at publicly available HTTP URLs. The images are used when creating instructions for completing a labeling task. The images should have an aspect ratio of around 2:1. For this exercise, the content of the images is not important.
2. Create an Amazon S3 bucket to hold the input and output files. The bucket must be in the same Region where you are running Ground Truth. Make a note of the bucket name because you use it during step 2.

   Ground Truth requires all S3 buckets that contain labeling job input image data have a CORS policy attached. To learn more about this change, see CORS Permission Requirement (p. 930).
3. You can create an IAM role or let SageMaker create a role with the AmazonSageMakerFullAccess IAM policy. Refer to Creating IAM roles and assign the following permissions policy to the user that is creating the labeling job:

   ```
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "sagemakergroundtruth",
         "Effect": "Allow",
         "Action": [
           "cognito-idp:CreateGroup",
           "cognito-idp:CreateUserPool",
           "cognito-idp:CreateUserPoolDomain",
           "cognito-idp:AdminCreateUser",
           "cognito-idp:CreateUserPoolClient",
           "cognito-idp:AdminAddUserToGroup",
           "cognito-idp:DescribeUserPoolClient",
           "cognito-idp:DescribeUserPool",
           "cognito-idp:UpdateUserPool"
         ],
         "Resource": "*"
       }
     ]
   }
   ```

   Next

   Step 2: Create a Labeling Job (p. 642)

Step 2: Create a Labeling Job

In this step you use the console to create a labeling job. You tell Amazon SageMaker Ground Truth the Amazon S3 bucket where the manifest file is stored and configure the parameters for the job. For more information about storing data in an Amazon S3 bucket, see Use Input and Output Data (p. 848).

To create a labeling job

2. From the left navigation, choose Labeling jobs.
3. Choose **Create labeling job** to start the job creation process.
4. In the **Job overview** section, provide the following information:
   - **Job name** – Give the labeling job a name that describes the job. This name is shown in your job list. The name must be unique in your account in an AWS Region.
   - **Label attribute name** – Leave this unchecked as the default value is the best option for this introductory job.
   - **Input data setup** – Select **Automated data setup**. This option allows you to automatically connect to your input data in S3.
   - **S3 location for input datasets** – Enter the S3 location where you added the images in step 1.
   - **S3 location for output datasets** – The location where your output data is written in S3.
   - **Data type** – Use the drop down menu to select **Image**. Ground Truth will use all images found in the S3 location for input datasets as input for your labeling job.
   - **IAM role** – Create or choose an IAM role with the AmazonSageMakerFullAccess IAM policy attached.
5. In the **Task type** section, for the **Task category** field, choose **Image**.
6. In the **Task selection** choose **Bounding box**.
7. Choose **Next** to move on to configuring your labeling job.

**Next**

**Step 3: Select Workers (p. 643)**

**Step 3: Select Workers**

In this step you choose a workforce for labeling your dataset. It is recommended that you create a private workforce to test Amazon SageMaker Ground Truth. Use email addresses to invite the members of your workforce. If you create a private workforce in this step you won't be able to import your Amazon Cognito user pool later. If you want to create a private workforce using an Amazon Cognito user pool, see **Manage a Private Workforce (Amazon Cognito) (p. 985)** and use the Mechanical Turk workforce instead in this tutorial.

**Tip**
To learn about the other workforce options you can use with Ground Truth, see **Create and Manage Workforces (p. 977)**.

**To create a private workforce:**
1. In the **Workers** section, choose **Private**.
2. If this is your first time using a private workforce, in the **Email addresses** field, enter up to 100 email addresses. The addresses must be separated by a comma. You should include your own email address so that you are part of the workforce and can see data object labeling tasks.
3. In the **Organization name** field, enter the name of your organization. This information is used to customize the email sent to invite a person to your private workforce. You can change the organization name after the user pool is created through the console.
4. In the **Contact email** field enter an email address that members of the workforce use to report problems with the task.

If you add yourself to the private workforce, you will receive an email that looks similar to the following. Amazon, Inc. is replaced by the organization you enter in step 3 of the preceding procedure. Select the link in the email to log in using the temporary password provided. If prompted, change your password. When you successfully log in, you see the worker portal where your labeling tasks appear.
Tip
You can find the link to your private workforce's worker portal in the Labeling workforces section of the Ground Truth area of the SageMaker console. To see the link, select the Private tab. The link is under the Labeling portal sign-in URL header in Private workforce summary.

If you choose to use the Amazon Mechanical Turk workforce to label the dataset, you are charged for labeling tasks completed on the dataset.

To use the Amazon Mechanical Turk workforce:

1. In the Workers section, choose Public.
2. Set a Price per task.
3. If applicable, choose The dataset does not contain adult content to acknowledge that the sample dataset has no adult content. This information enables Amazon SageMaker Ground Truth to warn external workers on Mechanical Turk that they might encounter potentially offensive content in your dataset.
4. Choose the check box next to the following statement to acknowledge that the sample dataset does not contain any personally identifiable information (PII). This is a requirement to use Mechanical Turk with Ground Truth. If your input data does contain PII, use the private workforce for this tutorial.

You understand and agree that the Amazon Mechanical Turk workforce consists of independent contractors located worldwide and that you should not share confidential information, personal information or protected health information with this workforce.

Next
Step 4: Configure the Bounding Box Tool (p. 645)
Step 4: Configure the Bounding Box Tool

Finally you configure the bounding box tool to give instructions to your workers. You can configure a task title that describes the task and provides high-level instructions for the workers. You can provide both quick instructions and full instructions. Quick instructions are displayed next to the image to be labeled. Full instructions contain detailed instructions for completing the task. In this example, you only provide quick instructions. You can see an example of full instructions by choosing Full instructions at the bottom of the section.

To configure the bounding box tool

1. In the Task description field type in brief instructions for the task. For example:

   **Draw a box around any objects in the image.**

   Replace objects with the name of an object that appears in your images.

2. In the Labels field, type a category name for the objects that the worker should draw a bounding box around. For example, if you are asking the worker to draw boxes around football players, you could use "Football Player" in this field.

3. The Short instructions section enables you to create instructions that are displayed on the page with the image that your workers are labeling. We suggest that you include an example of a correctly drawn bounding box and an example of an incorrectly drawn box. To create your own instructions, use these steps:

   a. Select the text between GOOD EXAMPLE and the image placeholder. Replace it with the following text:

      **Draw the box around the object with a small border.**

   b. Select the first image placeholder and delete it.

   c. Choose the image button and then enter the HTTPS URL of one of the images that you created in step 1. It is also possible to embed images directly in the short instructions section, however this section has a quota of 100 kilobytes (including text). If your images and text exceed 100 kilobytes, you receive an error.

   d. Select the text between BAD EXAMPLE and the image placeholder. Replace it with the following text:

      **Don't make the bounding box too large or cut into the object.**

   e. Select the second image placeholder and delete it.

   f. Choose the image button and then enter the HTTPS URL of the other image that you created in step 1.

4. Select Preview to preview the worker UI. The preview opens in a new tab, and so if your browser blocks pop ups you may need to manually enable the tab to open. When you add one or more annotations to the preview and then select Submit you can see a preview of the output data your annotation would created.

5. After you have configured and verified your instructions, select Create to create the labeling job.

If you used a private workforce, you can navigate to the worker portal that you logged into in Step 3: Select Workers (p. 643) of this tutorial to see your labeling tasks. The tasks may take a few minutes to appear.

Next

Step 5: Monitoring Your Labeling Job (p. 646)
Step 5: Monitoring Your Labeling Job

After you create your labeling job, you see a list of all the jobs that you have created. You can use this list to monitor that status of your labeling jobs. The list has the following fields:

- **Name** – The name that you assigned the job when you created it.
- **Status** – The completion status of the job. The status can be one of Complete, Failed, In progress, or Stopped.
- **Labeled objects/total** – Shows the total number of objects in the labeling job and how many of them have been labeled.
- **Creation time** – The date and time that you created the job.

You can also clone, chain, or stop a job. Select a job and then select one of the following from the Actions menu:

- **Clone** – Creates a new labeling job with the configuration copied from the selected job. You can clone a job when you want to change to the job and run it again. For example, you can clone a job that was sent to a private workforce so that you can send it to the Amazon Mechanical Turk workforce. Or you can clone a job to rerun it against a new dataset stored in the same location as the original job.
- **Chain** – Creates a new labeling job that can build upon the data and models (if any) of a stopped, failed, or completed job. For more information about the use cases and how to use it, see Chaining Labeling Jobs (p. 927).
- **Stop** – Stops a running job. You cannot restart a stopped job. You can clone a job to start over or chain the job to continue from where it left off. Labels for any already labeled objects are written to the output file location. For more information, see Output Data (p. 890).

Label Images

Use Ground Truth to label images. Select one of the following built in task types to learn more about that task type. Each page includes instructions to help you create a labeling job using that task type.

**Tip**

To learn more about supported file types and input data quotas, see Input Data (p. 848).

**Topics**

- Bounding Box (p. 646)
- Image Semantic Segmentation (p. 652)
- Auto-Segmentation Tool (p. 655)
- Image Classification (Single Label) (p. 659)
- Image Classification (Multi-label) (p. 661)
- Image Label Verification (p. 665)

Bounding Box

The images used to train a machine learning model often contain more than one object. To classify and localize one or more objects within images, use the Amazon SageMaker Ground Truth bounding box labeling job task type. In this context, localization means the pixel-location of the bounding box.

You create a bounding box labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.
Important
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 848).

Creating a Bounding Box Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a bounding box labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Bounding box as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and up to 50 labels that workers can choose from.
**Good example**

Fit each box tightly around the boundaries of the object.

**Bad example**

Boxes should not overlap with the boundaries of objects.
Create a Bounding Box Labeling Job (API)

To create a bounding box labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-BoundingBox`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-BoundingBox`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-bounding-box-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent'],
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-BoundingBox',
        'TaskKeywords': ['Bounding Box'],
        'TaskTitle': 'Bounding Box task',
        'TaskDescription': 'Draw bounding boxes around objects in an image',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-BoundingBox'
        }
    })
```
Provide a Template for Bounding Box Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and header. Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

```html
<crowd-form>
  <crowd-bounding-box
    name="boundingBox"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="please draw box"
    labels="{{ task.input.labels | to_json | escape }}"
  >
    <full-instructions header="Bounding box instructions">
      <ol>
        <li><strong>Inspect</strong> the image</li>
        <li><strong>Determine</strong> if the specified label is/are visible in the picture.</li>
        <li><strong>Outline</strong> each instance of the specified label in the image using the provided “Box” tool.</li>
        <li>Boxes should fit tight around each object</li>
        <li>Do not include parts of the object that are overlapping or that cannot be seen, even though you think you can interpolate the whole shape.</li>
        <li>Avoid including shadows.</li>
        <li>If the target is off screen, draw the box up to the edge of the image.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <h3 style="color: rgb(0, 138, 0);">Good example</h3>
      <p>Enter description of a correct bounding box label and add images</p>
      <h3 style="color: rgb(230, 0, 0);">Bad example</h3>
      <p>Enter description of an incorrect bounding box label and add images</p>
    </short-instructions>
  </crowd-bounding-box>
</crowd-form>
```

Bounding Box Output Data

Once you have created a bounding box labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the `Output dataset location` field of the Job overview section of the console.

For example, the output manifest file of a successfully completed single-class bounding box task will contain the following:

```json
[
  {
    "boundingBox": {
      "boundingBoxes": [
      
    
  }
]```
The `boundingBoxes` parameter identifies the location of the bounding box drawn around an object identified as a "bird" relative to the top-left corner of the image which is taken to be the (0,0) pixel-coordinate. In the previous example, `left` and `top` identify the location of the pixel in the top-left corner of the bounding box relative to the top-left corner of the image. The dimensions of the bounding box are identified with `height` and `width`. The `inputImageProperties` parameter gives the pixel-dimensions of the original input image.

When you use the bounding box task type, you can create single- and multi-class bounding box labeling jobs. The output manifest file of a successfully completed multi-class bounding box will contain the following:

```json
[
  {
    "boundingBox": {
      "boundingBoxes": [
        {
          "height": 938,
          "label": "squirrel",
          "left": 316,
          "top": 218,
          "width": 785
        },
        {
          "height": 825,
          "label": "rabbit",
          "left": 1930,
          "top": 2265,
          "width": 540
        },
        {
          "height": 1174,
          "label": "bird",
          "left": 748,
          "top": 2113,
          "width": 927
        },
        {
          "height": 893,
          "label": "bird",
          "left": 1333,
          "top": 847,
          "width": 736
        }
      ],
      "inputImageProperties": {
        "height": 3726,
        "width": 2662
      }
    }
  }
]
To learn more about the output manifest file that results from a bounding box labeling job, see Bounding Box Job Output (p. 896).

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

**Image Semantic Segmentation**

To identify the contents of an image at the pixel level, use an Amazon SageMaker Ground Truth semantic segmentation labeling task. When assigned a semantic segmentation labeling job, workers classify pixels in the image into a set of predefined labels or classes. Ground Truth supports single and multi-class semantic segmentation labeling jobs.

Images that contain large numbers of objects that need to be segmented require more time. To help workers (from a private or vendor workforce) label these objects in less time and with greater accuracy, Ground Truth provides an AI-assisted auto-segmentation tool. For information, see Auto-Segmentation Tool (p. 655).

You create a semantic segmentation labeling job using the Ground Truth section of the Amazon SageMaker console or the `CreateLabelingJob` operation.

**Important**

For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 848).

**Creating a Semantic Segmentation Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a semantic segmentation labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Semantic segmentation as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Instructions

View full instructions

View tool guide

How to use the Auto-segment tool

Good example

All pixels in the image that are part of an animal have been colors with the appropriate label color.

Bad example

Some animals in the image have not been colored in completely.

The color for a given animal extends beyond the boundaries of the animal.
Create a Semantic Segmentation Labeling Job (API)

To create a semantic segmentation labeling job, use the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-SemanticSegmentation. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Annotation-consolidation Lambda functions for this task type end with ACS-SemanticSegmentation. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-semantic-segmentation-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',

```
Provide a Template for Semantic Segmentation Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in $\text{UiTemplateS3Uri}$. Copy and modify the following template. Only modify the $\text{short-instructions}$, $\text{full-instructions}$, and header.

Upload this template to S3, and provide the S3 URI for this file in $\text{UiTemplateS3Uri}$.

```html
<scrip src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-semantic-segmentation
    name="crowd-semantic-segmentation"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please segment out all pedestrians."
    labels="{{ task.input.labels | to_json | escape }}"
  >
    <full-instructions header="Segmentation instructions">
      <ol>
        <li><strong>Read</strong> the task carefully and inspect the image.</li>
        <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
        <li><strong>Choose</strong> the appropriate label that best suits an object and paint that object using the tools provided.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <h2><span style="color: rgb(0, 138, 0);">Good example</span></h2>
      <p>Enter description to explain a correctly done segmentation</p>
      <h2><span style="color: rgb(230, 0, 0);">Bad example</span></h2>
      <p>Enter description of an incorrectly done segmentation</p>
    </short-instructions>
  </crowd-semantic-segmentation>
</crowd-form>

Semantic Segmentation Output Data

Once you have created a semantic segmentation labeling job, your output data will be located in the Amazon S3 bucket specified in the $\text{S3OutputPath}$ parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of an output manifest file for a semantic segmentation labeling job, see 3D Point Cloud Semantic Segmentation Output (p. 906).

Auto-Segmentation Tool

Image segmentation is the process of dividing an image into multiple segments, or sets of labeled pixels. In Amazon SageMaker Ground Truth, the process of identifying all pixels that fall under a given
label involves applying a colored filler, or "mask", over those pixels. Some labeling job tasks contain images with a large numbers of objects that need to be segmented. To help workers label these objects in less time and with greater accuracy, Ground Truth provides an auto-segmentation tool for segmentation tasks assigned to private and vendor workforces. This tool uses a machine learning model to automatically segment individual objects in the image with minimal worker input. Workers can refine the mask generated by the auto-segmentation tool using other tools found in the worker console. This helps workers complete image segmentation tasks faster and more accurately, resulting in lower cost and higher label quality.

**Note**

The auto-segmentation tool is available for segmentation tasks that are sent to a private workforce or vendor workforce. It isn't available for tasks sent to the public workforce (Amazon Mechanical Turk).

**Tool Preview**

When workers are assigned a labeling job that provides the auto-segmentation tool, they are provided with detailed instructions on how to use the tool. For example, a worker might see the following in the worker console:
Hello, chopt@amazon.com

Instructions  Shortcuts  Use paint brush to paint a mask on each bird in the image.
Workers can use **View full instructions** to learn how to use the tool. Workers will need to place a point on four extreme-points (top-most, bottom-most, left-most, and right-most points) of the object of interest, and the tool will automatically generate a mask for the object. Workers can further-refine the mask using the other tools provided, or by using the auto-segment tool on smaller portions of the object that were missed.

**Tool Availability**

The auto-segmentation tool automatically appears in your workers' consoles if you create a semantic segmentation labeling job using the Amazon SageMaker console. While creating a semantic segmentation job in the SageMaker console, you will be able to preview the tool while creating worker instructions. To learn how to create a semantic segmentation labeling job in the SageMaker console, see [Getting started](#).

If you are creating a custom instance segmentation labeling job in the SageMaker console or creating an instance- or semantic-segmentation labeling job using the Ground Truth API, you need to create a custom task template to design your worker console and instructions. To include the auto-segmentation tool in your worker console, ensure that the following conditions are met in your custom task template:

- For semantic segmentation labeling jobs created using the API, the `<crowd-semantic-segmentation>` is present in the task template. For custom instance segmentation labeling jobs, the `<crowd-instance-segmentation>` tag is present in the task template.
- The task is assigned to a private workforce or vendor workforce.
- The images to be labeled are Amazon Simple Storage Service (Amazon S3) objects that have been pre-signed for the Worker so that they can access it. This is true if the task template includes the `grant_read_access` filter. For information about the `grant_read_access` filter, see [Adding automation with Liquid](#).

The following is an example of a custom task template for a custom instance segmentation labeling job, which includes the `<crowd-instance-segmentation/>` tag and the `grant_read_access` Liquid filter.

```html
<cf-crowd-form>
  <cf-crowd-instance-segmentation name="crowd-instance-segmentation" src="{{ task.input.taskObject | grant_read_access }}" labels="['Car', 'Road']">
    <full-instructions header="Segmentation instructions">
      Segment each instance of each class of objects in the image.
    </full-instructions>
    <short-instructions>
      <p>Segment each instance of each class of objects in the image.</p>
      <h3 style="color: green">GOOD EXAMPLES</h3>
      <img src="path/to/image.jpg" style="width: 100%">
      <p>Good because A, B, C.</p>
      <h3 style="color: red">BAD EXAMPLES</h3>
      <img src="path/to/image.jpg" style="width: 100%">
      <p>Bad because X, Y, Z.</p>
    </short-instructions>
  </cf-crowd-instance-segmentation>
</cf-crowd-form>
```
Image Classification (Single Label)

Use an Amazon SageMaker Ground Truth image classification labeling task when you need workers to classify images using predefined labels that you specify. Workers are shown images and are asked to choose one label for each image.

You can create an image classification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Important
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 848).

Create an Image Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a image classification labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Image Classification (Single Label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create an Image Classification Labeling Job (API)

To create an image classification labeling job, use the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.
Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-ImageMultiClass. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Annotation-consolidation Lambda functions for this task type end with ACS-ImageMultiClass. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent'],
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'TaskKeywords': ['Image classification'],
        'TaskTitle': 'Image classification task',
        'TaskDescription': 'Carefully inspect the image and classify it by selecting one label from the categories provided.',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-ImageMultiClass'
        },
        Tags=[
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
)
Provide a Template for Image Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.

```
<crowd-form
  name="crowd-image-classifier"
  src="{{ task.input.taskObject | grant_read_access }}"
  header="please classify"
  categories="{{ task.input.labels | to_json | escape }}"
>
  <full-instructions header="Image classification instructions">
    <ol>
      <li><strong>Read</strong> the task carefully and inspect the image.</li>
      <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
      <li><strong>Choose</strong> the appropriate label that best suits the image.</li>
    </ol>
  </full-instructions>
  <short-instructions>
    <h3 style="color: rgb(0, 138, 0);">Good example</h3>
    <p>Enter description to explain the correct label to the workers</p>
    <h3 style="color: rgb(230, 0, 0);">Bad example</h3>
    <p>Enter description of an incorrect label</p>
  </short-instructions>
</crowd-image-classifier>
```

Image Classification Output Data

Once you have created an image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of an output manifest file from an image classification labeling job, see Classification Job Output (p. 894).

Image Classification (Multi-label)

Use an Amazon SageMaker Ground Truth multi-label image classification labeling task when you need workers to classify multiple objects in an image. For example, the following image features a dog and a cat. You can use multi-label image classification to associate the labels "dog" and "cat" with this image.
When working on a multi-label image classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label-categories.

When creating a labeling job in the console, Ground Truth doesn't provide a "none" category for when none of the labels applies to an image. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label image classification job.

To restrict workers to choosing a single label for each image, use the Image Classification (Single Label) (p. 659) task type.

**Important**
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 848).

**Create a Multi-Label Image Classification Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a multi-label image classification labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Image Classification (Multi-label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Multi-Label Image Classification Labeling Job (API)

To create a multi-label image classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-ImageMultiClassMultiLabel`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-ImageMultiClassMultiLabel`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',
            ]
        }
    }
)
```
OutputConfig={
'OutputPath': 's3://bucket/path/file-to-store-output-data',
'KmsKeyId': 'string'
},
RoleArn='arn:aws:iam::*:role/*',
LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
StoppingConditions={
'MaxHumanLabeledObjectCount': 123,
'MaxPercentageOfInputDatasetLabeled': 123
},
HumanTaskConfig={
'WorkteamArn': 'arn:aws:sagemaker:region::workteam/private-crowd/*',
'UiConfig': {
'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
},
'TaskKeywords': [
'Image Classification'
],
'TaskTitle': 'Multi-label image classification task',
'TaskDescription': 'Select all labels that apply to the images shown',
'NumberOfHumanWorkersPerDataObject': 123,
'TaskTimeLimitInSeconds': 123,
'TaskAvailabilityLifetimeInSeconds': 123,
'MaxConcurrentTaskCount': 123,
'AnnotationConsolidationConfig': {
'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-ImageMultiClassMultiLabel'
},
'Tags':[
{'Key': 'string',
'Value': 'string'
}],

Provide a Template for Multi-label Image Classification

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.

<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-image-classifier-multi-select
name="crowd-image-classifier-multi-select"
src="{{ task.input.taskObject | grant_read_access }}"
header="Please identify all classes in image"
categories="{{ task.input.labels | to_json | escape }}"
>
<full-instructions header="Multi Label Image classification instructions">
<ol><li><strong>Read</strong> the task carefully and inspect the image.</li>
<li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
<li><strong>Choose</strong> the appropriate labels that best suit the image.</li></ol>
</full-instructions>
<short-instructions>
<h3><span style="color: rgb(0, 138, 0);">Good example</span></h3>
<p>Enter description to explain the correct label to the workers</p>
Multi-label Image Classification Output Data

Once you have created a multi-label image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of output manifest files for multi-label image classification labeling job, see Multi-label Classification Job Output (p. 895).

Image Label Verification

Building a highly accurate training dataset for your machine learning (ML) algorithm is an iterative process. Typically, you review and continuously adjust your labels until you are satisfied that they accurately represent the ground truth, or what is directly observable in the real world.

You can use an Amazon SageMaker Ground Truth image label verification task to direct workers to review a dataset's labels and improve label accuracy. Workers can indicate if the existing labels are correct or rate label quality. They can also add comments to explain their reasoning. Amazon SageMaker Ground Truth supports label verification for Bounding Box (p. 646) and Image Semantic Segmentation (p. 652) labels.

You create an image label verification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Ground Truth provides a worker console similar to the following for labeling tasks. When you create the labeling job with the console, you can modify the images and content that are shown. To learn how to create a labeling job using the Ground Truth console, see Create a Labeling Job (Console) (p. 820).
You can create a label verification labeling job using the SageMaker console or API. To learn how to create a labeling job using the Ground Truth API operation CreateLabelingJob, see Create a Labeling Job (API) (p. 823).

Use Ground Truth to Label Text

Use Ground Truth to label text. Select one of the following built in task types to learn more about that task type. Each page includes instructions to help you create a labeling job using that task type.

**Tip**
To learn more about supported file types and input data quotas, see Input Data (p. 848).

**Topics**
- Named Entity Recognition (p. 666)
- Text Classification (Single Label) (p. 670)
- Text Classification (Multi-label) (p. 673)

**Named Entity Recognition**

To extract information from unstructured text and classify it into predefined categories, use an Amazon SageMaker Ground Truth named entity recognition (NER) labeling task. Traditionally, NER involves sifting through text data to locate noun phrases, called named entities, and categorizing each with a label, such as "person," "organization," or "brand." You can broaden this task to label longer spans of text and categorize those sequences with predefined labels that you specify.

When tasked with a named entity recognition labeling job, workers apply your labels to specific words or phrases within a larger text block. They choose a label, then apply it by using the cursor to highlight the part of the text to which the label applies. The Ground Truth named entity recognition tool supports...
overlapping annotations, in-context label selection, and multi-label selection for a single highlight. Also, workers can use their keyboards to quickly select labels.

You can create a named entity recognition labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

**Important**

If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 848).

**Create a Named Entity Recognition Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a named entity recognition labeling job in the SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Named entity recognition as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

**Create a Named Entity Recognition Labeling Job (API)**

To create a named entity recognition labeling job, using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-NamedEntityRecognition. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
• Annotation-consolidation Lambda functions for this task type end with ACS-NamedEntityRecognition. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

• You must provide the following ARN for HumanTaskUiArn:

```
```

Replace `aws-region` with the AWS Region you use to create the labeling job. For example, use us-west-1 if you create a labeling job in US West (N. California).

• Provide worker instructions in the label category configuration file using the instructions parameter. You can use a string, or HTML markup language in the shortInstruction and fullInstruction fields. For more details, see Provide Worker Instructions in a Label Category Configuration File (p. 669).

```
"instructions": {
  "shortInstruction": "<h1>Add header</h1><p>Add Instructions</p>",
  "fullInstruction": "<p>Add additional instructions.</p>"
}
```

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-ner-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/**',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region::workteam/private-crowd/**',
        'UiConfig': {
            'TaskKeywords': [
                'Named entity Recognition',
            ],
            'TaskTitle': 'Named entity Recognition task',
            'TaskDescription': 'Apply the labels provided to specific words or phrases within the larger text block.'
        }
    }
) 
```
Provide Worker Instructions in a Label Category Configuration File

You must provide worker instructions in the label category configuration file you identify with the LabelCategoryConfigS3Uri parameter in CreateLabelingJob. You can use these instructions to provide details about the task you want workers to perform and help them use the tool efficiently.

You provide short and long instructions using shortInstruction and fullInstruction in the instructions parameter, respectively. To learn more about these instruction types, see Creating Instruction Pages (p. 818).

The following is an example of a label category configuration file with instructions that can be used for a named entity recognition labeling job.

```json
{
  "document-version": "2018-11-28",
  "labels": [
    {
      "label": "label1",
      "shortDisplayName": "L1"
    },
    {
      "label": "label2",
      "shortDisplayName": "L2"
    },
    {
      "label": "label3",
      "shortDisplayName": "L3"
    },
    {
      "label": "label4",
      "shortDisplayName": "L4"
    },
    {
      "label": "label5",
      "shortDisplayName": "L5"
    }
  ],
  "instructions": {
    "shortInstruction": "<p>Enter description of the labels that workers have to choose from</p><br><p>Add examples to help workers understand the label</p>",
    "fullInstruction": "<ol>
    <li><strong>Read</strong> the text carefully.</li>
    <li><strong>Highlight</strong> words, phrases, or sections of the text.</li>
    <li><strong>Choose</strong> the label that best matches what you have highlighted.</li>
  </ol>
  }
}
```
To change a label, choose highlighted text and select a new label.

To remove a label from highlighted text, choose the X next to the abbreviated label name on the highlighted text.

You can select all of a previously highlighted text, but not a portion of it.

Named Entity Recognition Output Data

Once you have created a named entity recognition labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

Text Classification (Single Label)

To categorize articles and text into predefined categories, use text classification. For example, you can use text classification to identify the sentiment conveyed in a review or the emotion underlying a section of text. Use Amazon SageMaker Ground Truth text classification to have workers sort text into categories that you define.

You create a text classification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Important

If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 848).

Create a Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a text classification labeling job in the SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Text Classification (Single Label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Text Classification Labeling Job (API)

To create a text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClass`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClass`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-text-classification-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
        ]
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    }
)```

671
Label Text

Provide a Template for Text Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier name="crowd-classifier"
    categories="{{ task.input.labels | to_json | escape }}"
    header="classify text"
    >
  <classification-target style="white-space: pre-wrap">
    {{ task.input.taskObject }}
  </classification-target>
  <full-instructions header="Classifier instructions">
    <ol>
      <li><strong>Read</strong> the text carefully.</li>
      <li><strong>Read</strong> the examples to understand more about the options.</li>
      <li><strong>Choose</strong> the appropriate labels that best suit the text.</li>
    </ol>
  </full-instructions>
  <short-instructions>
    <p>Enter description of the labels that workers have to choose from</p>
    <p>Add examples to help workers understand the label</p>
  </short-instructions>
</crowd-form>
```
Text Classification Output Data

Once you have created a text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of an output manifest files from a text classification labeling job, see Classification Job Output (p. 894).

Text Classification (Multi-label)

To categorize articles and text into multiple predefined categories, use the multi-label text classification task type. For example, you can use this task type to identify more than one emotion conveyed in text.

When working on a multi-label text classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label categories.

Amazon SageMaker Ground Truth doesn't provide a "none" category for when none of the labels applies. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label text classification job.

To restrict workers to choosing a single label for each document or text selection, use the Text Classification (Single Label) (p. 670) task type.

Important
If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 848).

Create a Multi-Label Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) to learn how to create a multi-label text classification labeling job in the Amazon SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Text Classification (Multi-label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Multi-Label Text Classification Labeling Job (API)

To create a multi-label text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClassMultiLabel`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClassMultiLabel`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-text-classification-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
)```
RoleArn='arn:aws:iam::*:role/*',
LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
StoppingConditions={
  'MaxHumanLabeledObjectCount': 123,
  'MaxPercentageOfInputDatasetLabeled': 123
},
HumanTaskConfig={
  'WorkteamArn': 'arn:aws:sagemaker:region::workteam/private-crowd/*',
  'UiConfig': {
    'UiTemplateS3Uri': 's3://bucket/path/custom-worker-task-template.html'
  },
  'PreHumanTaskLambdaArn': 'arn:aws:lambda::function:PRE-TextMultiClassMultiLabel,

  'TaskDescription': 'Select all labels that apply to the text shown',
  'NumberOfHumanWorkersPerDataObject': 123,
  'TaskTimeLimitInSeconds': 123,
  'TaskAvailabilityLifetimeInSeconds': 123,
  'MaxConcurrentTaskCount': 123,
  'AnnotationConsolidationConfig': {
    'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-TextMultiClassMultiLabel'
  },
  Tags=[
    {
      'Key': 'string',
      'Value': 'string'
    }
  ]
}

Create a Template for Multi-label Text Classification

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.
To learn how to create a custom template, see Creating Custom Labeling Workflows (p. 785).

Multi-label Text Classification Output Data

Once you have created a multi-label text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of output manifest files for multi-label text classification labeling job, see Multi-label Classification Job Output (p. 895).

Label Videos and Video Frames

You can use Ground Truth to classify videos and annotate video frames (still images extracted from videos) using one of the three built-in video task types. These task types streamline the process of creating video and video frame labeling jobs using the Amazon SageMaker console, API, and language-specific SDKs.

- Video clip classification – Enable workers to classify videos into categories you specify. For example, you can use this task type to have workers categorize videos into topics like sports, comedy, music, and education. To learn more, see Video Classification (p. 676).
- Video frame labeling jobs – Enable workers to annotate video frames extracted from a video using bounding boxes, polylines, polygons or keypoint annotation tools. Ground Truth offers two built-in task types to label video frames:
  - Video frame object detection: Enable workers to identify and locate objects in video frames.
  - Video frame object tracking: Enable workers to track the movement of objects across video frames.
- Video frame adjustment jobs: Have workers adjust labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.
- Video frame verification jobs: Have workers verify labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.

If you have video files, you can use the Ground Truth automatic frame extraction tool to extract video frames from your videos. To learn more, see Video Frame Input Data (p. 884).

Tip
To learn more about supported file types and input data quotas, see Input Data (p. 848).

Topics
- Video Classification (p. 676)
- Label Video Frames (p. 681)
- Worker Instructions (p. 693)

Video Classification

Use an Amazon SageMaker Ground Truth video classification labeling task when you need workers to classify videos using predefined labels that you specify. Workers are shown videos and are asked to choose one label for each video.

You create a video classification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.
Your video files must be encoded in a format that is supported by the browser used by the work team that labels your data. It is recommended that you verify that all video file formats in your input manifest file display correctly using the worker UI preview. You can communicate supported browsers to your workers using worker instructions. To see supported file formats, see Supported Data Formats (p. 851).

**Important**

For this task type, if you create your own manifest file, use "source-ref" to identify the location of each video file in Amazon S3 that you want labeled. For more information, see Input Data (p. 848).

**Create a Video Classification Labeling Job (Console)**

You can follow the instructions in Create a Labeling Job (Console) (p. 820) to learn how to create a video classification labeling job in the SageMaker console. In step 10, choose Video from the Task category dropdown list, and choose Video Classification as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels from which workers can choose.
Instructions

View full instructions

View tool guide

Select a single label that best describes this video clip. Select none of the above if none of the other labels apply.

Select Submit when you are done.
Create a Video Classification Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 823) and do the following while you configure your request:

- Use a pre-annotation Lambda function that ends with PRE-VideoClassification. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Use an annotation-consolidation Lambda function that ends with ACS-VideoClassification. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```python
response = client.create_labeling_job(
    LabelingJobName='example-video-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent'],
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region::*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-VideoClassification',
        'TaskKeywords': ['Video Classification'],
        'TaskTitle': 'Video classification task',
        'TaskDescription': 'Select a label to classify this video',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'VideoClassification': [],
            'TaskTitle': 'Video classification task',
            'TaskDescription': 'Select a label to classify this video',
            'NumberOfHumanWorkersPerDataObject': 123,
            'TaskTimeLimitInSeconds': 123,
            'TaskAvailabilityLifetimeInSeconds': 123,
            'MaxConcurrentTaskCount': 123,
            'AnnotationConsolidationConfig': {
```
Provide a Template for Video Classification

If you create a labeling job using the API, you must supply a worker task template in **UiTemplateS3Uri**. Copy and modify the following template by modifying the **short-instructions**, **full-instructions**, and **header**. Upload this template to Amazon S3, and provide the Amazon S3 URI to this file in **UiTemplateS3Uri**.

```html
<crowd-form>
  <crowd-classifier
    name="crowd-classifier"
    categories="{{ task.input.labels | to_json | escape }}"
    header="Please classify video"
  >
    <classification-target type="video/mp4"/>
    <classification-target type="video/webm"/>
    <classification-target type="video/ogg"/>
  </crowd-classifier>
</crowd-form>
```

Your browser does not support the video tag.

```html
<ol>
  <li><strong>Read</strong> the task carefully and inspect the video.</li>
  <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
  <li><strong>Choose</strong> the appropriate label that best suits the video.</li>
</ol>
```

**Good example**

```
<p>Enter description to explain the correct label to the workers</p>
```

```
<img src="https://d7evko5405gb7.cloudfront.net/fe4fed9b-660c-4477-9294-2c66a15d6bbe/src/images/quick-instructions-example-placeholder.png" style="max-width:100%"/>
```

**Bad example**

```
<p>Enter description of an incorrect label</p>
```

```
<img src="https://d7evko5405gb7.cloudfront.net/fe4fed9b-660c-4477-9294-2c66a15d6bbe/src/images/quick-instructions-example-placeholder.png" style="max-width:100%"/>
```
Label Videos and Video Frames

Video Classification Output Data

Once you have created a video classification labeling job, your output data is located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 890).

To see an example of output manifest files for video classification labeling jobs, see Classification Job Output (p. 894).

Label Video Frames

You can use Ground Truth built-in video frame task types to have workers annotate video frames using bounding boxes, polylines, polygons or keypoints. A video frame is a sequence of images that have been extracted from a video.

If you do not have video frames, you can provide video files (MP4 files) and use the Ground Truth automated frame extraction tool to extract video frames. To learn more, see Provide Video Files (p. 886).

You can use the following built-in video task types to create video frame labeling jobs using the Amazon SageMaker console, API, and language-specific SDKs.

- **Video frame object detection** – Use this task type when you want workers to identify and locate objects in sequences of video frames. You provide a list of categories, and workers can select one category at a time and annotate objects which the category applies to in all frames. For example, you can use this task to ask workers to identify and localize various objects in a scene, such as cars, bikes, and pedestrians.

- **Video frame object tracking** – Use this task type when you want workers to track the movement of instances of objects across sequences of video frames. When a worker adds an annotation to a single frame, that annotation is associated with a unique instance ID. The worker adds annotations associated with the same ID in all other frames to identify the same object or person. For example, a worker can track the movement of a vehicle across a sequences of video frames by drawing bounding boxes associated with the same ID around the vehicle in each frame that it appears.

Use the following topics to learn more about these built-in task types and to how to create a labeling job using each task type. See Task Types (p. 690) to learn more about the annotations tools (bounding boxes, polylines, polygons and keypoints) available for these task types.

Before you create a labeling job, we recommend that you review Video Frame Labeling Job Overview (p. 689).

Topics

- Video Frame Object Detection (p. 681)
- Video Frame Object Tracking (p. 685)
- Video Frame Labeling Job Overview (p. 689)

Video Frame Object Detection

You can use the video frame object detection task type to have workers identify and locate objects in a sequence of video frames (images extracted from a video) using bounding boxes, polylines, polygons
or keypoint annotation tools. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object detection task type workers to identify and localize various objects in a series of video frames, such as cars, bikes, and pedestrians.

You can create a video frame object detection labeling job using the Amazon SageMaker Ground Truth console, the SageMaker API, and language-specific AWS SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job (p. 682) and select your preferred method. See Task Types (p. 690) to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI (p. 682).

You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job (p. 685).

Preview the Worker UI

Ground Truth provides workers with a web user interface (UI) to complete your video frame object detection annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object detection tasks:

- For all tasks, workers can use the Copy to next and Copy to all features to copy an annotation to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a Predict next feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same label in all other frames. Workers can then make adjustments to correct predicted box locations.

Create a Video Frame Object Detection Labeling Job

You can create a video frame object detection labeling job using the SageMaker console or the CreateLabelingJob API operation.

This section assumes that you have reviewed the Video Frame Labeling Job Overview (p. 689) and have chosen the type of input data and the input dataset connection you are using.

Create a Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) (p. 820) to learn how to create a video frame object tracking job in the SageMaker console. In step 10, choose Video - Object detection from the Task category dropdown list. Select the task type you want by selecting one of the cards in Task selection.
Task category
Select the type of data being labeled to view available task templates for it or select 'Custom'.

Video - Object detection

Task selection
Select the task that a human worker will perform to label objects in your dataset.

- Bounding box
  Get workers to draw bounding boxes around specified objects in your video.

- Polyline
  Get workers to draw polyline around specified objects in your video.

- Keypoint
  Get workers to track keypoints of objects in your video.
Create a Labeling Job (API)

You create an object detection labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

`Create a Labeling Job (API) (p. 823)` provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use
  arn:aws:sagemaker:<region>:394669845002:human-task-ui/VideoObjectDetection. Replace `<region>` with the AWS Region in which you are creating the labeling job.

  Do not include an entry for the `UiTemplateS3Uri` parameter.

- Your `LabelAttributeName` must end in `-ref`. For example, `video-od-labels-ref`.

- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker console, or create it manually and upload it to Amazon S3. For more information, see `Input Data Setup (p. 886)`.

- You can only use private or vendor work teams to create video frame object detection labeling jobs.

- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using `annotationType` in your label category configuration file. For more information, see `Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833)` to learn how to create this file.

- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `PRE-VideoObjectDetection`.

  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `ACS-VideoObjectDetection`.

- The number of workers specified in `NumberOfHumanWorkersPerDataObject` must be 1.

- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in `LabelingJobAlgorithmsConfig`.

- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

The following is an example of an `AWS Python SDK (Boto3) request` to create a labeling job in the US East (N. Virginia) Region.

```python
response = client.create_labeling_job(
    LabelingJobName='example-video-od-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://DOC-EXAMPLE-BUCKET/path/video-frame-sequence-input-manifest.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [

```
Create Video Frame Object Detection Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how to create one, see Verify and Adjust Labels (p. 778).

Output Data Format

When you create a video frame object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object detection output data format, see Video Frame Object Detection Output (p. 902). If you are a new user of Ground Truth, see Output Data (p. 890) to learn more about the Ground Truth output data format.

Video Frame Object Tracking

You can use the video frame object tracking task type to have workers track the movement of objects in a sequence of video frames (images extracted from a video) using bounding boxes, polylines, polygons...
or keypoint annotation tools. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object tracking task type to ask workers to track the movement of objects, such as cars, bikes, and pedestrians by drawing boxes around them.

You provide a list of categories, and each annotation that a worker adds to a video frame is identified as an instance of that category using an instance ID. For example, if you provide the label category car, the first car that a worker annotates will have the instance ID car:1. The second car the worker annotates will have the instance ID car:2. To track an object's movement, the worker adds annotations associated with the same instance ID around to object in all frames.

You can create a video frame object tracking labeling job using the Amazon SageMaker Ground Truth console, the SageMaker API, and language-specific AWS SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job (p. 682) and select your preferred method. See Task Types (p. 690) to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI (p. 682).

You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job (p. 685).

Preview the Worker UI

Ground Truth provides workers with a web user interface (UI) to complete your video frame object tracking annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object tracking tasks:

- For all tasks, workers can use the Copy to next and Copy to all features to copy an annotation with the same unique ID to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a Predict next feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same unique ID in all other frames. Workers can then make adjustments to correct predicted box locations.

Create a Video Frame Object Tracking Labeling Job

You can create a video frame object tracking labeling job using the SageMaker console or the CreateLabelingJob API operation.

This section assumes that you have reviewed the Video Frame Labeling Job Overview (p. 689) and have chosen the type of input data and the input dataset connection you are using.

Create a Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) (p. 820) to learn how to create a video frame object tracking job in the SageMaker console. In step 10, choose Video - Object tracking from the Task category dropdown list. Select the task type you want by selecting one of the cards in Task selection.
**Task type**  
Info

**Task category**  
Select the type of data being labeled to view available task templates for it or select ‘Custom’ to create your own.

**Video - Object tracking**

**Task selection**  
Select the task that a human worker will perform to label objects in your dataset.

- **Bounding box**  
Get workers to track specific instances of objects in your video across multiple frames in your bounding boxes.  
Info

- **Polyline**  
Get workers to track specific instances of objects in your video across multiple frames in your polylines.  
Info
Create a Labeling Job (API)

You create an object tracking labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 823) provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use
  arn:aws:sagemaker:<region>:394669845002:human-task-ui/VideoObjectTracking. Replace <region> with the AWS Region in which you are creating the labeling job.
  Do not include an entry for the UiTemplateS3Uri parameter.
- Your LabelAttributeName must end in -ref. For example, ot-labels-ref.
- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker console, or create it manually and upload it to Amazon S3. For more information, see Input Data Setup (p. 886). If you create a streaming labeling job, the input manifest file is optional.
- You can only use private or vendor work teams to create video frame object detection labeling jobs.
- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using annotationType in your label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833) to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.
- To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region in which you are creating your labeling job to find the correct ARN that ends with PRE-VideoObjectTracking.
- To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region in which you are creating your labeling job to find the correct ARN that ends with ACS-VideoObjectTracking.
- The number of workers specified in NumberOfHumanWorkersPerDataObject must be 1.
- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in LabelingJobAlgorithmsConfig.
- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604,800 seconds).

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```python
response = client.create_labeling_job(
    LabelingJobName='example-video-ot-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://DOC-EXAMPLE-BUCKET/path/video-frame-sequence-input-manifest.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',
            ]
        }
    }
)
```
Create a Video Frame Object Tracking Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 778).

Output Data Format

When you create a video frame object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object tracking output data format, see Video Frame Object Tracking Output (p. 904). If you are a new user of Ground Truth, see Output Data (p. 890) to learn more about the Ground Truth output data format.

Video Frame Labeling Job Overview

Use this page to learn about the object detection and object tracking video frame labeling jobs. The information on this page applies to both of these built-in task types.

The video frame labeling job is unique because of the following:
You can either provide data objects that are ready to be annotated (video frames), or you can provide video files and have Ground Truth automatically extract video frames.

Workers have the ability to save work as they go.

You cannot use the Amazon Mechanical Turk workforce to complete your labeling tasks.

Ground Truth provides a worker UI, as well as assistive and basic labeling tools, to help workers complete your tasks. You do not need to provide a worker task template.

Use the following topics to learn more.

Topics

- **Input Data (p. 690)**
- **Job Completion Times (p. 690)**
- **Task Types (p. 690)**
- **Workforces (p. 691)**
- **Worker User Interface (UI) (p. 691)**
- **Video Frame Job Permission Requirements (p. 693)**

Input Data

The video frame labeling job uses *sequences* of video frames. A single sequence is a series of images that have been extracted from a single video. You can either provide your own sequences of video frames, or have Ground Truth automatically extract video frame sequences from your video files. To learn more, see **Provide Video Files (p. 886)**.

Ground Truth uses sequence files to identify all images in a single sequence. All of the sequences that you want to include in a single labeling job are identified in an input manifest file. Each sequence is used to create a single worker task. You can automatically create sequence files and an input manifest file using Ground Truth automatic data setup. To learn more, see **Automated Video Frame Input Data Setup (p. 887)**.

To learn how to manually create sequence files and an input manifest file, see **Create a Video Frame Input Manifest File (p. 889)**.

Job Completion Times

Video and video frame labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

We strongly recommend that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth saves their work every 15 minutes.

When using the SageMaker CreateLabelingJob API operation, set the total time a task is available to workers in the TaskTimeLimitInSeconds parameter of HumanTaskConfig.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

Task Types

When you create a video object tracking or video object detection labeling job, you specify the type of annotation that you want workers to create while working on your labeling task. The annotation type determines the type of output data Ground Truth returns and defines the *task type* for your labeling job.
If you are creating a labeling job using the API operation `CreateLabelingJob`, you specify the task type using the label category configuration file parameter `annotationType`. To learn more, see `Create a Labeling Category Configuration File with Label Category and Frame Attributes` (p. 833).

The following task types are available for both video object tracking or video object detection labeling jobs:

- **Bounding box** – Workers are provided with tools to create bounding box annotations. A bounding box is a box that a worker draws around an objects to identify the pixel-location and label of that object in the frame.

- **Polyline** – Workers are provided with tools to create polyline annotations. A polyline is defined by the series of ordered x, y coordinates. Each point added to the polyline is connected to the previous point by a line. The polyline does not have to be closed (the start point and end point do not have to be the same) and there are no restrictions on the angles formed between lines.

- **Polygon** – Workers are provided with tools to create polygon annotations. A polygon is a closed shape defined by a series of ordered x, y coordinates. Each point added to the polygon is connected to the previous point by a line and there are no restrictions on the angles formed between lines. Two lines (sides) of the polygon cannot cross. The start and end point of a polygon must be the same.

- **Keypoint** – Workers are provided with tools to create keypoint annotations. A keypoint is a single point associated with an x, y coordinate in the video frame.

### Workforces

When you create a video frame labeling job, you need to specify a work team to complete your annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the AWS Marketplace. You cannot use the Amazon Mechanical Turk workforce for video frame labeling jobs.

To learn more about vendor workforces, see `Managing Vendor Workforces` (p. 980).

To learn how to create and manage a private workforce, see `Use a Private Workforce` (p. 981).

### Worker User Interface (UI)

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your video labeling tasks. You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation `CreateLabelingJob`, you must provide an ARN provided by Ground Truth in the parameter `HumanTaskUiArn` to specify the worker UI for your task type. You can use `HumanTaskUiArn` with the SageMaker `RenderUiTemplate` API operation to preview the worker UI.

You provide worker instructions, labels, and optionally, attributes that workers can use to provide more information about labels and video frames. These attributes are referred to as label category attributes and frame attributes respectively. They are all displayed in the worker UI.

### Label Category and Frame Attributes

When you create a video object tracking or video object detection labeling job, you can add one or more label category attributes and frame attributes:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to provide metadata about a label.

- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each video frame a worker is sent to annotate. It is used by workers to provide metadata about video frames.
Additionally, you can use label and frame attributes to have workers verify labels in a video frame label verification job.

Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the Create Labeling Job sections on the [task type page](p. 681) of your choice.

**Label Category Attributes**

Add label category attributes to labels to give workers the ability to provide more information about the annotations they create. A label category attribute is added to an individual label, or to all labels. When a label category attribute is applied to all labels it is referred to as a *global label category attribute*.

For example, if you add the label category *car*, you might also want to capture additional data about your labeled cars, such as if they are occluded or the size of the car. You can capture this metadata using label category attributes. In this example, if you added the attribute *occluded* to the car label category, you can assign *partial, completely, no* to the *occluded* attribute and enable workers to select one of these options.

When you create a label verification job, you add labels category attributes to each label you want workers to verify.

**Frame level Attributes**

Add frame attributes to give workers the ability to provide more information about individual video frames. Each frame attribute you add appears on all frames.

For example, you can add a number-frame attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide an answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a video frame.

**Worker Instructions**

You can provide worker instructions to help your workers complete your video frame labeling tasks. You might want to cover the following topics when writing your instructions:

- Best practices and things to avoid when annotating objects.
- The label category attributes provided (for object detection and object tracking tasks) and how to use them.
- How to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker console while creating a labeling job. If you create a labeling job using the API operation CreateLabelingJob, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on [Worker Instructions](p. 693).

**Declining Tasks**

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (NumberOfHumanWorkersPerDataObject) decline the task, the data object is marked as expired and will not be sent to additional workers.
Video Frame Job Permission Requirements

When you create a video frame labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth (p. 931), you must add a CORS policy to your S3 bucket that contains your input manifest file.

Add a CORS Permission Policy to S3 Bucket

When you create a video frame labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "GET",
            "HEAD",
            "PUT"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": [
            "Access-Control-Allow-Origin"
        ],
        "MaxAgeSeconds": 3000
    }
]
```

**XML**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<CORSConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <CORSRule>
        <AllowedOrigin>*</AllowedOrigin>
        <AllowedMethod>GET</AllowedMethod>
        <AllowedMethod>HEAD</AllowedMethod>
        <AllowedMethod>PUT</AllowedMethod>
        <MaxAgeSeconds>3000</MaxAgeSeconds>
        <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
        <AllowedHeader>*</AllowedHeader>
    </CORSRule>
</CORSConfiguration>
```

To learn how to add a CORS policy to an S3 bucket, see How do I add cross-domain resource sharing with CORS? in the Amazon Simple Storage Service User Guide.

**Worker Instructions**

This topic provides an overview of the Ground Truth worker portal and the tools available to complete your video frame labeling task. First, select the type of task you are working on from Topics.

**Important**

It is recommended that you complete your task using a Google Chrome or Firefox web browser.
For adjustment jobs, select the original labeling job task type that produced the labels you are adjusting. Review and adjust the labels in your task as needed.

Topics
- Work on Video Frame Object Tracking Tasks (p. 694)
- Work on Video Frame Object Detection Tasks (p. 701)

Work on Video Frame Object Tracking Tasks

Video frame object tracking tasks require you to track the movement of objects across video frames. A video frame is a still image from a video scene.

You can use the worker UI to navigate between video frames and use the tools provided to identify unique objects and track their movement from one frame to the next. Use this page to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome or Firefox web browser.

Important
If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics
- Your Task (p. 694)
- Navigate the UI (p. 696)
- Bulk Edit Label and Frame Attributes (p. 696)
- Tool Guide (p. 697)
- Icons Guide (p. 699)
- Shortcuts (p. 700)
- Release, Stop and Resume, and Decline Tasks (p. 701)
- Saving Your Work and Submitting (p. 701)

Your Task

When you work on a video frame object tracking task, you need to select a category from the Label category menu on the right side of your worker portal to start annotating. After you've chosen a category, use the tools provided to annotate the objects that the category applies to. This annotation will be associated with a unique label ID that should only be used for that object. Use this same label ID to create additional annotations for the same object in all of the video frames that it appears in. Refer to Tool Guide (p. 697) to learn more about the tools provided.

After you've added a label, you may see a downward pointing arrow next to the label in the Labels menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the Labels menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.
After you've added a label, you can quickly add and edit a label category attribute value by using the downward pointing arrow next to the label in the Labels menu. If you select the pencil icon next to the label in the Labels menu, the Edit instance menu will appear. You can edit the label ID, label category, and label category attributes using this menu.

To edit an annotation, select the label of the annotation that you want to edit in the Labels menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.
After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the Copy to next and Copy to all tools to copy your annotations to the next or all frames respectively.

Navigate the UI

You can navigate between video frames using the navigation bar in the bottom-left corner of your UI.

Use the play button to automatically move through the entire sequence of frames.

Use the next frame and previous frame buttons to move forward or back one frame at a time. You can also input a frame number to navigate to that frame.

You can zoom in to and out of all video frames. Once you have zoomed into a video frame, you can move around in that frame using the move icon. When you set a new view in a single video frame by zooming and moving within that frame, all video frames are set to the same view. You can reset all video frames to their original view using the fit screen icon. For additional view options, see Icons Guide (p. 699).

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task. Additionally, select More instructions and review these instructions.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate video frames and use the tools provided.
- **Help** – Use this option to refer back to this documentation.

Bulk Edit Label and Frame Attributes

You can bulk edit label attributes and frame attributes (attributes).

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify must contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you must specify the desired value for the attribute first. For example, if you want to change an attribute from Yes to No, you must select No, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

**To bulk edit a label or attribute:**

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter 1-10. If you want to apply the edit to frames two to five, eight to ten and twenty enter 2-5, 8-10, 20.
3. Select **Confirm**.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the Duplicate to previous frames and Duplicate to next frames options in the Label menu at the top of your screen.
Tool Guide

Your task will include one or more tools. The tool provided dictates the type of annotations you will create to identify and track objects. Use the following table to learn more about each tool provided.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Icon</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding box</td>
<td><img src="image" alt="Icon" /></td>
<td>Add a bounding box annotation.</td>
<td>Choose this icon to add a bounding box. Each bounding box you add is associated with the category you choose from the Label category drop down menu. Select the bounding box or its associated label to adjust it.</td>
</tr>
<tr>
<td>Bounding box</td>
<td><img src="image" alt="Icon" /></td>
<td>Predict bounding boxes in the next frame.</td>
<td>Select a bounding box, and then choose this icon to predict the location of that box in the next frame. You can select the icon multiple times in a row to automatically detect the location of box in multiple frames. For example, select this icon 5 times to predict the location of a bounding box in the next 5 frames.</td>
</tr>
<tr>
<td>Keypoint</td>
<td><img src="image" alt="Icon" /></td>
<td>Add a keypoint annotation.</td>
<td>Choose this icon to add a keypoint. Click on an object the image to place the keypoint at that location. Each keypoint you add is associated with the category you choose from the Label category drop down menu. Select a keypoint or its associated label to adjust it.</td>
</tr>
<tr>
<td>Polyline</td>
<td><img src="image" alt="Icon" /></td>
<td>Add a polyline annotation.</td>
<td>Choose this icon to add a polyline. To add a polyline, continuously click around the object of interest to add new points. To stop drawing a polyline, select the last point that you placed a second time</td>
</tr>

<td>Choose this icon to zoom out of all of the video frames.</td>
</tr>
<tr>
<td><img src="image" alt="Move Screen" /></td>
<td>move screen</td>
<td>After you've zoomed into a video frame, choose this icon to move around in that video frame. You can move around the video frame using your mouse by clicking and dragging the frame in the direction you want it to move. This will change the view in all view frames.</td>
</tr>
<tr>
<td><img src="image" alt="Fit Screen" /></td>
<td>fit screen</td>
<td>Reset all video frames to their original position.</td>
</tr>
<tr>
<td><img src="image" alt="Undo" /></td>
<td>undo</td>
<td>Undo an action. You can use this icon to remove a bounding box that you just added, or to undo an adjustment you made to a bounding box.</td>
</tr>
<tr>
<td><img src="image" alt="Redo" /></td>
<td>redo</td>
<td>Redo an action that was undone using the undo icon.</td>
</tr>
<tr>
<td><img src="image" alt="Delete Label" /></td>
<td>delete label</td>
<td>Delete a label. This will delete the bounding box associated with the label in a single frame.</td>
</tr>
<tr>
<td><img src="image" alt="Show or Hide Label" /></td>
<td>show or hide label</td>
<td>Select this icon to show a label that has been hidden. If this icon has a slash through it, select it to hide the label.</td>
</tr>
<tr>
<td><img src="image" alt="Edit Label" /></td>
<td>edit label</td>
<td>Select this icon to open the Edit instance menu. Use this menu to edit a label category, ID, and to add or edit label attributes.</td>
</tr>
</tbody>
</table>

**Shortcuts**

The keyboard shortcuts listed in the Shortcuts menu can help you quickly select icons, undo and redo annotations, and use tools to add and edit annotations. For example, once you add a bounding box, you can use P to quickly predict the location of that box in subsequent frames.

Before you start your task, it is recommended that you review the Shortcuts menu and become acquainted with these commands.
Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (Decline task), release it (Release task), and stop and resume it at a later time (Stop and resume later). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as unclear video frame images or an issue with the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you lose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select Confirm, you are returned to the worker portal. If the task is still available, its status will be Available. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the Stop and resume later button to stop working and return to the task at a later time. You should use the Save button to save your work before you select Stop and resume later. When you select this button and then select Confirm, you are returned to the worker portal, and the task status is Stopped. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work using the Save button. Ground Truth will automatically save your work every 15 minutes.

When you open a task, you must complete your work on it before pressing Submit.

Work on Video Frame Object Detection Tasks

Video frame object detection tasks required you to classify and identify the location of objects in video frames using annotations. A video frame is a still image from a video scene.

You can use the worker UI to navigate between video frames and create annotations to identify objects of interest. Use the sections on this page to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome web browser.

**Important**

If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics

- [Your Task](#)
- [Navigate the UI](#)
- [Bulk Edit Label and Frame Attributes](#)
- [Tool Guide](#)
- [UI Icon Guide](#)
- [Shortcuts](#)
- [Release, Stop and Resume, and Decline Tasks](#)
- [Saving Your Work and Submitting](#)
Your Task

When you work on a video frame object detection task, you need to select a category from the **Label category** menu on the right side of your worker portal to start annotating. After you’ve chosen a category, draw annotations around objects that this category applies to. To learn more about the tools you see in your worker UI, refer to the Tool Guide (p. 704).

After you’ve added a label, you may see a downward pointing arrow next to the label in the **Labels** menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the **Labels** menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.
To edit an annotation, select the label of the annotation that you want to edit in the **Labels** menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.

**Note**

The predict next feature will not overwrite manually created annotations. It will only add annotations. If you use predict next and as a result have more than one bounding box around a single object, delete all but one box. Each object should only be identified with a single box.

After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the **Copy to next** and **Copy to all** tools to copy your annotations to the next or all frames respectively.

**Navigate the UI**

You can navigate between video frames using the navigation bar in the bottom-left corner of your UI.

Use the play button to automatically play through multiple frames.

Use the next frame and previous frame buttons to move forward or back one frame at a time. You can also input a frame number to navigate to that frame.

You can zoom in to and out of all video frames. Once you have zoomed into a video frame, you can move around in that frame using the move icon. When you navigate to a new view in a single video frame by zooming and moving within that frame, all video frames are set to the same view. You can reset all video frames to their original view using the fit screen icon. To learn more, see [UI Icon Guide](#).

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task. Additionally, select **More instructions** and review these instructions.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate video frames and use the annotation tools provided.
- **Help** – Use this option to refer back to this documentation.

If you

**Bulk Edit Label and Frame Attributes**

You can bulk edit label attributes and frame attributes (attributes).

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify **must** contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you **must** specify the desired value for the attribute first. For example, if you want to change an attribute from **Yes** to **No**, you must select **No**, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.
To bulk edit a label or attribute:

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter 1-10. If you want to apply the edit to frames two to five, eight to ten and twenty enter 2-5, 8-10, 20.
3. Select Confirm.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the Duplicate to previous frames and Duplicate to next frames options in the Label menu at the top of your screen.

Tool Guide

Your task will include one or more tools. The tool provided dictates the type of annotations you will create to identify and label objects. Use the following table to learn more about the tool or tools you may see in your worker UI.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Icon</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding box</td>
<td><img src="image" alt="Bounding box icon" /></td>
<td>Add a bounding box annotation.</td>
<td>Choose this icon to add a bounding box. Each bounding box you add is associated with the category you choose from the Label category drop down menu. Select the bounding box or its associated label to adjust it.</td>
</tr>
<tr>
<td>Predict next</td>
<td><img src="image" alt="Predict next icon" /></td>
<td>Predict bounding boxes in the next frame.</td>
<td>Select a bounding box, and then choose this icon to predict the location of that box in the next frame. You can select the icon multiple times in a row to automatically detect the location of box in multiple frames. For example, select this icon 5 times to predict the location of a bounding box in the next 5 frames.</td>
</tr>
<tr>
<td>Keypoint</td>
<td><img src="image" alt="Keypoint icon" /></td>
<td>Add a keypoint annotation.</td>
<td>Choose this icon to add a keypoint. Click on an object the image to place the keypoint at that location. Each keypoint you add is associated with the</td>

<td>undo</td>
<td>Undo an action. You can use this icon to remove a bounding box that you just added, or to undo an adjustment you made to a bounding box.</td>
</tr>
<tr>
<td>redo</td>
<td>Redo an action that was undone using the undo icon.</td>
</tr>
<tr>
<td>delete label</td>
<td>Delete a label. This will delete the bounding box associated with the label in a single frame.</td>
</tr>
<tr>
<td>show or hide label</td>
<td>Select this icon to show a label that has been hidden. If this icon has a slash through it, select it to hide the label.</td>
</tr>
</tbody>
</table>

**Shortcuts**

The keyboard shortcuts listed in the **Shortcuts** menu can help you quickly select icons, undo and redo annotations, and use tools to add and edit annotations. For example, once you add a bounding box, you can use P to quickly predict the location of that box in subsequent frames.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as unclear video frame images or an issue with the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you loose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.

- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.
Saving Your Work and Submitting

You should periodically save your work. Ground Truth automatically saves your work every 15 minutes. When you open a task, you must complete your work before pressing **Submit**.

Use Ground Truth to Label 3D Point Clouds

Create a 3D point cloud labeling job to have workers label objects in 3D point clouds generated from 3D sensors like Light Detection and Ranging (LiDAR) sensors and depth cameras, or generated from 3D reconstruction by stitching images captured by an agent like a drone.

3D Point Clouds

Point clouds are made up of three-dimensional (3D) visual data that consists of points. Each point is described using three coordinates, typically x, y, and z. To add color or variations in point intensity to the point cloud, points may be described with additional attributes, such as i for intensity or values for the red (r), green (g), and blue (b) 8-bit color channels. When you create a Ground Truth 3D point cloud labeling job, you can provide point cloud and, optionally, sensor fusion data.

The following image shows a single, 3D point cloud scene rendered by Ground Truth and displayed in the semantic segmentation worker UI.
**LiDAR**

A Light Detection and Ranging (LiDAR) sensor is a common type of sensor used to collect measurements that are used to generate point cloud data. LiDAR is a remote sensing method that uses light in the form of a pulsed laser to measure the distances of objects from the sensor. You can provide 3D point cloud data generated from a LiDAR sensor for a Ground Truth 3D point cloud labeling job using the raw data formats described in [Accepted Raw 3D Data Formats](p. 860).

**Sensor Fusion**

Ground Truth 3D point cloud labeling jobs include a sensor fusion feature that supports video camera sensor fusion for all task types. Some sensors come with multiple LiDAR devices and video cameras that capture images and associate them with a LiDAR frame. To help annotators visually complete your tasks with high confidence, you can use the Ground Truth sensor fusion feature to project annotations (labels) from a 3D point cloud to 2D camera images and vice versa using 3D scanner (such as LiDAR) extrinsic matrix and camera extrinsic and intrinsic matrices. To learn more, see [Sensor Fusion](p. 877).

**Label 3D Point Clouds**

Ground Truth provides a user interface (UI) and tools that workers use to label or annotate 3D point clouds. When you use the object detection or semantic segmentation task types, workers can annotate a single point cloud frame. When you use object tracking, workers annotate a sequence of frames. You can use object tracking to track object movement across all frames in a sequence.

The following demonstrates how a worker would use the Ground Truth worker portal and tools to annotate a 3D point cloud for an object detection task. For similar visual examples of other task types, see [3D Point Cloud Task types](p. 713).
Double click on the point cloud to zoom in.

Double click on the label ID to zoom in the object on point cloud.

**3D Cuboid Controls**

When you are in Edit Cuboid mode:

- **C** Create
- **V** Edit
- **Cmd + Drag** Change dimension
- **Option + Drag** Move cuboid
- **Option + O** Fit label to points
- **Option + G** Set to ground
- **Shift + Drag** Rotate cuboid
- **[** Previous label
- **]** Next label
- **Cmd + ,** Toggle show/hide label
Assistive Labeling Tools for Point Cloud Annotation

Ground Truth offers assistive labeling tools to help workers complete your point cloud annotation tasks faster and with more accuracy. For details about assistive labeling tools that are included in the worker UI for each task type, select a task type (p. 713) and refer to the View the Worker Task Interface section of that page.

Next Steps

You can create six types of tasks when you use Ground Truth 3D point cloud labeling jobs. Use the topics in 3D Point Cloud Task types (p. 713) to learn more about these task types and to learn how to create a labeling job using the task type of your choice.

The 3D point cloud labeling job is different from other Ground Truth labeling modalities. Before creating a labeling job, we recommend that you read 3D Point Cloud Labeling Jobs Overview (p. 744). Additionally, review input data quotas in 3D Point Cloud and Video Frame Labeling Job Quotas (p. 858).

For an end-to-end demo using the SageMaker API and AWS Python SDK (boto 3) to create a 3D point cloud labeling job, see create-3D-pointcloud-labeling-job.ipynb in the SageMaker Examples notebook tab.

Important

If you use a notebook instance created before June 5th, 2020 to run this notebook, you must stop and restart that notebook instance for the notebook to work.

Topics

- 3D Point Cloud Task types (p. 713)
- 3D Point Cloud Labeling Jobs Overview (p. 744)
- Worker Instructions (p. 748)

3D Point Cloud Task types

You can use Ground Truth 3D point cloud labeling modality for a variety of use cases. The following list briefly describes each 3D point cloud task type. For additional details and instructions on how to create a labeling job using a specific task type, select the task type name to see its task type page.

- **3D point cloud object detection** – Use this task type when you want workers to locate and classify objects in a 3D point cloud by adding and fitting 3D cuboids around objects.

- **3D point cloud object tracking** – Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across a sequence of 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.

- **3D point cloud semantic segmentation** – Use this task type when you want workers to create a point-level semantic segmentation mask by painting objects in a 3D point cloud using different colors where each color is assigned to one of the classes you specify.

- **3D point cloud adjustment task types** – Each of the task types above has an associated adjustment task type that you can use to audit and adjust annotations generated from a 3D point cloud labeling job. Refer to the task type page of the associated type to learn how to create an adjustment labeling job for that task.

3D Point Cloud Object Detection

Use this task type when you want workers to classify objects in a 3D point cloud by drawing 3D cuboids around objects. For example, you can use this task type to ask workers to identify different types of objects in a point cloud, such as cars, bikes, and pedestrians.
For this task type, the data object that workers label is a single point cloud frame. Ground Truth renders a 3D point cloud using point cloud data you provide. You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects.

Ground Truth provides workers with tools to annotate objects with 9 degrees of freedom \((x, y, z, r_x, r_y, r_z, l, w, h)\) in three dimensions in both 3D scene and projected side views (top, side, and back). If you provide sensor fusion information (like camera data), when a worker adds a cuboid to identify an object in the 3D point cloud, the cuboid shows up and can be modified in the 2D images. After a cuboid has been added, all edits made to that cuboid in the 2D or 3D scene are projected into the other view.

You can create a job to adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object detection adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D Point Cloud Labeling Jobs Overview (p. 744). This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

### Topics
- [View the Worker Task Interface](#)
- [Create a 3D Point Cloud Object Detection Labeling Job](#)
- [Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job](#)
- [Output Data Format](#)

**View the Worker Task Interface**

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object detection annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth worker UI in the HumanTaskUiArn parameter. When you create a labeling job using this task type in the console, this worker UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object detection worker task interface. If you provide camera data for sensor fusion in the world coordinate system, images are matched up with scenes in the point cloud frame. These images appear in the worker portal as shown in the following GIF.
Double click on the point cloud to zoom in.

Double click on the label ID to zoom in the object on point cloud.

3D Cuboid Controls
When you are in Edit Cuboid mode

- `C` Create
- `V` Edit
- `Cmd + Drag` Change dimension
- `Option + Drag` Move cuboid
- `Option + O` Fit label to points
- `Option + G` Set to ground
- `Shift + Drag` Rotate cuboid
- `[` Previous label
- `]` Next label
- `Cmd + ,` Toggle show/hide label
Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboid in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
Additional view options and features are available in the View menu in the worker UI. See the worker instruction page for a comprehensive overview of the Worker UI.

Assistive Labeling Tools

Ground Truth helps workers annotate 3D point clouds faster and more accurately using machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object.
- **Set to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side panel displays front, side, and top perspectives to help the worker adjust the cuboid tightly around the object. In all of these views, the cuboid includes an arrow that indicates the orientation, or heading of the object. When the worker adjusts the cuboid, the adjustment will appear in real time on all of the views (that is, 3D, top, side, and front).
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time. Additionally, workers will have the option to view the direction the camera is facing and the camera frustum.
- **View options** – Enables workers to easily hide or view cuboids, label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

Create a 3D Point Cloud Object Detection Labeling Job

You can create a 3D point cloud labeling job using the SageMaker console or API operation, CreateLabelingJob. To create a labeling job for this task type you need the following:

- A single-frame input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Frame Input Manifest File (p. 862). If you are a new user of Ground Truth 3D point cloud labeling modalities, you may also want to review Accepted Raw 3D Data Formats (p. 860).
- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk for video frame labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 977).

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 931).

Use one of the following sections to learn how to create a labeling job using the console or an API.

Create a Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) in order to learn how to create a 3D point cloud object detection labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 862).
- Optionally, you can provide label category and frame attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute occluded to have workers identify when an object is partially obstructed.
• Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.

• 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 823), provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

• You must enter an ARN for HumanTaskUiArn. Use
  PointCloudObjectDetection. Replace <region> with the AWS Region you are creating the labeling job in.

  There should not be an entry for the UiTemplateS3Uri parameter.

• Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 862).

• You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. To learn how to create this file, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833).

• You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  • To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudObjectDetection.

  • To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudObjectDetection.

• The number of workers specified in NumberOfHumanWorkersPerDataObject must be 1.

• Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in LabelingJobAlgorithmsConfig.

• 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604,800 seconds).

Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job

You can create an adjustment or verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 778).

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.
Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y'-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x''-axis (roll).

Output Data Format

When you create a 3D point cloud object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is Completed.

If you are a new user of Ground Truth, see Output Data (p. 890) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see 3D Point Cloud Object Detection Output (p. 908).

3D Point Cloud Object Tracking

Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.

For this task type, the data object that workers label is a sequence of point cloud frames. A sequence is defined as a temporal series of point cloud frames. Ground Truth renders a series of 3D point cloud visualizations using a sequence you provide and workers can switch between these 3D point cloud frames in the worker task interface.

Ground Truth providers workers with tools to annotate objects with 9 degrees of freedom: (x,y,z,rx,ry,rz,l,w,h) in three dimensions in both 3D scene and projected side views (top, side, and back). When a worker draws a cuboid around an object, that cuboid is given a unique ID, for example Car:1 for one car in the sequence and Car:2 for another. Workers use that ID to label the same object in multiple frames.

You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects. When a worker adds a 3D cuboid to identify an object in either the 2D image or the 3D point cloud, and the cuboid shows up in the other view.

You can adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object tracking adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D Point Cloud Labeling Jobs Overview (p. 744). This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

Topics

- View the Worker Task Interface (p. 720)
- Create a 3D Point Cloud Object Tracking Labeling Job (p. 728)
- Create a 3D Point Cloud Object Tracking Adjustment or Verification Labeling Job (p. 729)
- Output Data Format (p. 729)

View the Worker Task Interface

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object tracking annotation tasks. When you create the labeling job, you provide the Amazon Resource Name
(ARN) for a pre-built Ground Truth UI in the HumanTaskUiArn parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object tracking worker task interface and demonstrates how the worker can navigate the point cloud frames in the sequence. The annotating tools are a part of the worker task interface. They are not available for the preview interface.
Once workers add a single cuboid, that cuboid is replicated in all frames of the sequence with the same ID. Once workers adjust the cuboid in another frame, Ground Truth will interpolate the movement of that object and adjust all cuboids between the manually adjusted frames. The following GIF demonstrates this interpolation feature. In the navigation bar on the bottom-left, red-areas indicate manually adjusted frames.
If you provide camera data for sensor fusion, images are matched up with scenes in point cloud frames. These images appear in the worker portal as shown in the following GIF.

Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboids in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

**Worker Tools**

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. If workers click on a point in the point cloud, the UI will automatically zoom into that area. Workers can use various tools to draw 3D cuboid around objects. For more information, see Assistive Labeling Tools.

After workers have placed a 3D cuboid in the point cloud, they can adjust these cuboids to fit tightly around cars using a variety of views: directly in the 3D cuboid, in a side-view featuring three zoomed-in perspectives of the point cloud around the box, and if you include images for sensor fusion, directly in the 2D image.

View options that enable workers to easily hide or view label text, a ground mesh, and additional point attributes. Workers can also choose between perspective and orthogonal projections.

**Assistive Labeling Tools**

Ground Truth helps workers annotate 3D point clouds faster and more accurately using UX, machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Label autofill** – When a worker adds a cuboid to a frame, a cuboid with the same dimensions and orientation is automatically added to all frames in the sequence.
- **Label interpolation** – After a worker has labeled a single object in two frames, Ground Truth uses those annotations to interpolate the movement of that object between those two frames. Label interpolation can be turned on and off.
- **Bulk label and attribute management** – Workers can add, delete, and rename annotations, label category attributes, and frame attributes in bulk.
  - Workers can manually delete annotations for a given object before or after a frame. For example, a worker can delete all labels for an object after frame 10 if that object is no longer located in the scene after that frame.
  - If a worker accidentally bulk deletes all annotations for a object, they can add them back. For example, if a worker deletes all annotations for an object before frame 100, they can bulk add them to those frames.
  - Workers can rename a label in one frame and all 3D cuboids assigned that label are updated with the new name across all frames.
  - Workers can use bulk editing to add or edit label category attributes and frame attributes in multiple frames.
- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object's boundaries.
- **Fit to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side panel displays front and two side perspectives to help the worker adjust the cuboid tightly around the object. Workers can annotation the 3D point cloud, the side panel and the adjustments appear in the other views in real time.
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time.
- **Auto-merge cuboids** – Workers can automatically merge two cuboids across all frames if they determine that cuboids with different labels actually represent a single object.
• **View options** – Enables workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

**Create a 3D Point Cloud Object Tracking Labeling Job**

You can create a 3D point cloud labeling job using the SageMaker console or API operation, CreateLabelingJob. To create a labeling job for this task type you need the following:

- A sequence input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Sequence Input Manifest (p. 868). If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats (p. 860).
- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk for 3D point cloud labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 977).

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 931).

To learn how to create a labeling job using the console or an API, see the following sections.

**Create a Labeling Job (API)**

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 823) provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectTracking. Replace <region> with the AWS Region you are creating the labeling job in. There should not be an entry for the UiTemplateS3Uri parameter.
- Your LabelAttributeName must end in -ref. For example, ot-labels-ref.
- Your input manifest file must be a point cloud frame sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest (p. 868).
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833) to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job. To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN that ends with PRE-3DPointCloudObjectTracking.
- To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN that ends with ACS-3DPointCloudObjectTracking.
- The number of workers specified in NumberOfHumanWorkersPerDataObject should be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in LabelingJobAlgorithmsConfig.
3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604,800 seconds).

Create a Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 820) in order to learn how to create a 3D point cloud object tracking labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest (p. 868).
- Optionally, you can provide label category attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute occluded to have workers identify when an object is partially obstructed.
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a 3D Point Cloud Object Tracking Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 778).

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.

Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y’-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x’’-axis (roll).

Output Data Format

When you create a 3D point cloud object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is Completed.

If you are a new user of Ground Truth, see Output Data (p. 890) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object tracking output data format, see 3D Point Cloud Object Tracking Output (p. 910).

3D Point Cloud Semantic Segmentation

Semantic segmentation involves classifying individual points of a 3D point cloud into pre-specified categories. Use this task type when you want workers to create a point-level semantic segmentation mask for 3D point clouds. For example, if you specify the classes car, pedestrian, and bike, workers select one class at a time, and color all of the points that this class applies to the same color in the point cloud.

For this task type, the data object that workers label is a single point cloud frame. Ground Truth generates a 3D point cloud visualization using point cloud data you provide. You can also provide camera
data to give workers more visual information about scenes in the frame, and to help workers paint objects. When a worker paints an object in either the 2D image or the 3D point cloud, the paint shows up in the other view.

You can adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud semantic segmentation adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review [3D Point Cloud Labeling Jobs Overview](p. 744). This labeling modality is different from other Ground Truth task types, and this topic provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

**Topics**

- [View the Worker Task Interface (p. 730)](p. 730)
- [Create a 3D Point Cloud Semantic Segmentation Labeling Job (p. 736)](p. 736)
- [Create a 3D Point Cloud Semantic Segmentation Adjustment or Verification Labeling Job (p. 737)](p. 737)
- [Output Data Format (p. 737)](p. 737)

**View the Worker Task Interface**

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud semantic segmentation annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the `HumanTaskUiArn` parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new use, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud semantic segmentation worker task interface. If you provide camera data for sensor fusion, images are matched with scenes in the point cloud frame. Workers can paint objects in either the 3D point cloud or the 2D image, and the paint appears in the corresponding location in the other medium. These images appear in the worker portal as shown in the following GIF.
Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud. Workers can hide and re-expand all side views and menus. In this GIF, the side-views and menus have been collapsed.
The following GIF demonstrates how a worker can label multiple objects quickly, refine painted objects using the Unpaint option and then view only points that have been painted.
Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

**Worker Tools**

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. When you create a semantic segmentation job, workers have the following tools available to them:

- A paint brush to paint and unpaint objects. Workers paint objects by selecting a label category and then painting in the 3D point cloud. Workers unpaint objects by selecting the Unpaint option from the label category menu and using the paint brush to erase paint.
- A polygon tool that workers can use to select and paint an area in the point cloud.
- A background paint tool, which enables workers to paint behind objects they have already annotated without altering the original annotations. For example, workers might use this tool to paint the road after painting all of the cars on the road.
- View options that enable workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

**Create a 3D Point Cloud Semantic Segmentation Labeling Job**

You can create a 3D point cloud labeling job using the SageMaker console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A single-frame input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Frame Input Manifest File (p. 862). If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats (p. 860).
- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk workers for 3D point cloud labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 977).
- A label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833).

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 931).

Use one of the following sections to learn how to create a labeling job using the console or an API.

**Create a Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 820) in order to learn how to create a 3D point cloud semantic segmentation labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 862).
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).
Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

The page, Create a Labeling Job (API) (p. 823), provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudSemanticSegmentation. Replace <region> with the AWS Region you are creating the labeling job in.

  There should not be an entry for the UiTemplateS3Uri parameter.

- Your LabelAttributeName must end in -ref. For example, ss-labels-ref.

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 862).

- You specify your labels and worker instructions in a label category configuration file. See Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833) to learn how to create this file.

- You need to provide a pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  - To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudSemanticSegmentation.

  - To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudSemanticSegmentation.

- The number of workers specified in NumberOfHumanWorkersPerDataObject should be 1.

- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in LabelingJobAlgorithmsConfig.

- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604800 seconds).

Create a 3D Point Cloud Semantic Segmentation Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 778).

Output Data Format

When you create a 3D point cloud semantic segmentation labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is Completed.

If you are a new user of Ground Truth, see Output Data (p. 890) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see 3D Point Cloud Semantic Segmentation Output (p. 906).
3D-2D Point Cloud Object Tracking

Use this task type when you want workers to link 3D point cloud annotations with 2D images annotations and also link 2D image annotations among various cameras. Currently, Ground Truth supports cuboids for annotation in a 3D point cloud and bounding boxes for annotation in 2D videos. For example, you can use this task type to ask workers to link the movement of a vehicle in 3D point cloud with its 2D video. Using 3D-2D linking, you can easily correlate point cloud data (like the distance of a cuboid) to video data (bounding box) for up to 8 cameras.

Ground Truth provides workers with tools to annotate cuboids in a 3D point cloud and bounding boxes in up to 8 cameras using the same annotation UI. Workers can also link various bounding boxes for the same object across different cameras. For example, a bounding box in camera1 can be linked to a bounding box in camera2. This lets you to correlate an object across multiple cameras using a unique ID.

Note
Currently, SageMaker does not support creating a 3D-2D linking job using the console. To create a 3D-2D linking job using the SageMaker API, see Create a Labeling Job (API) (p. 743).

Topics

- View the Worker Task Interface (p. 738)
- Input Data Format (p. 742)
- Create a 3D-2D Point Cloud Object Tracking Labeling Job (p. 743)
- Output Data (p. 744)

View the Worker Task Interface

Ground Truth provides workers with a web portal and tools to complete your 3D-2D object tracking annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the HumanTaskUiArn parameter. To use the UI when you create a labeling job for this task type using the API, you need to provide the HumanTaskUiArn. You can preview and interact with the worker UI when you create a labeling job through the API. The annotating tools are a part of the worker task interface. They are not available for the preview interface. The following image demonstrates the worker task interface used for the 3D-2D point cloud object tracking annotation task.
When interpolation is enabled by default. After a worker adds a single cuboid, that cuboid is replicated in all frames of the sequence with the same ID. If the worker adjusts the cuboid in another frame, Ground Truth interpolates the movement of that object and adjust all cuboids between the manually adjusted frames. Additionally, using the camera view section, a cuboid can be shown with a projection (using to B button for “toggle labels” in the camera view) that provides the worker with a reference from the camera images. The accuracy of the cuboid to image projection is based on accuracy of calibrations captured in the extrinsic and intrinsic data.

If you provide camera data for sensor fusion, images are matched up with scenes in point cloud frames. Note that the camera data should be time synchronized with the point cloud data to ensure an accurate depiction of point cloud to imagery over each frame in the sequence as shown in the following image.

The manifest file holds the extrinsic and intrinsic data and the pose to allow the cuboid projection on the camera image to be shown by using the P button.

Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboids in the 3D scene, a side-view appears with the three projected side views: top, side, and front. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The worker should first select the cuboid to draw a corresponding bounding box on any of the camera views. This links the cuboid and the bounding box with a common name and unique ID.

The worker can also first draw a bounding box, select it and draw the corresponding cuboid to link them.

Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

**Worker Tools**

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. If workers click on a point in the point cloud, the UI automatically zooms into that area. Workers can use various tools to draw 3D cuboid around objects. For more information, see Assistive Labeling Tools in the following discussion.
After workers have placed a 3D cuboid in the point cloud, they can adjust these cuboids to fit tightly around cars using a variety of views: directly in the 3D point cloud, in a side-view featuring three zoomed-in perspectives of the point cloud around the box, and if you include images for sensor fusion, directly in the 2D image.

Additional view options enable workers to easily hide or view label text, a ground mesh, and additional point attributes. Workers can also choose between perspective and orthogonal projections.

**Assistive Labeling Tools**

Ground Truth helps workers annotate 3D point clouds faster and more accurately using UX, machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Label autofill** – When a worker adds a cuboid to a frame, a cuboid with the same dimensions, orientation and xyz position is automatically added to all frames in the sequence.

- **Label interpolation** – After a worker has labeled a single object in two frames, Ground Truth uses those annotations to interpolate the movement of that object between all the frames. Label interpolation can be turned on and off. It is on by default. For example, if a worker working with 5 frames adds a cuboid in frame 2, it is copied to all the 5 frames. If the worker then makes adjustments in frame 4, frame 2 and 4 now act as two points, through which a line is fit. The cuboid is then interpolated in frames 1, 3 and 5.

- **Bulk label and attribute management** – Workers can add, delete, and rename annotations, label category attributes, and frame attributes in bulk.
  
  - Workers can manually delete annotations for a given object before and after a frame, or in all frames. For example, a worker can delete all labels for an object after frame 10 if that object is no longer located in the scene after that frame.
  
  - If a worker accidentally bulk deletes all annotations for an object, they can add them back. For example, if a worker deletes all annotations for an object before frame 100, they can bulk add them to those frames.
  
  - Workers can rename a label in one frame and all 3D cuboids assigned that label are updated with the new name across all frames.
  
  - Workers can use bulk editing to add or edit label category attributes and frame attributes in multiple frames.

- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth’s autofit tool snap the cuboid tightly around the object’s boundaries.

- **Fit to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.

- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side-panel displays front and two side perspectives to help the worker adjust the cuboid tightly around the object. Workers can annotation the 3D point cloud, the side panel and the adjustments appear in the other views in real time.

- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations are projected into the other view in real time. To learn more about the data for sensor fusion, see [*Understand Coordinate Systems and Sensor Fusion*](#).

- **Auto-merge cuboids** – Workers can automatically merge two cuboids across all frames if they determine that cuboids with different labels actually represent a single object.

- **View options** – Enables workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.
Input Data Format

You can create a 3D-2D object tracking job using the SageMaker API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A sequence input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Sequence Input Manifest (p. 868). If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats (p. 860).
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes to learn how to create this file. The following is an example showing a label category configuration file for creating a 3D-2D object tracking job.

```json
{
    "document-version": "2020-03-01",
    "categoryGlobalAttributes": [
        {
            "name": "Occlusion",
            "description": "global attribute that applies to all label categories",
            "type": "string",
            "enum": [
                "Partial",
                "Full"
            ]
        }
    ],
    "labels": [

```
Note
You need to provide BoundingBox and Cuboid as annotationType in the label category configuration file to create a 3D-2D object tracking job.

Create a 3D-2D Point Cloud Object Tracking Labeling Job

You can create a 3D-2D point cloud labeling job using the SageMaker API operation, CreateLabelingJob. To create a labeling job for this task type you need the following:

- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk for 3D point cloud labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 977).
- Add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in CORS Permission Requirement.
- Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 931).

To learn how to create a labeling job using the API, see the following sections.

Create a Labeling Job (API)

This section covers details you need to know when you create a 3D-2D object tracking labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 823) provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectTracking. Replace <region> with the AWS Region you are creating the labeling job in. There should not be an entry for the UiTemplateS3Uri parameter.
- Your LabelAttributeName must end in -ref. For example, ot-labels-ref.
- Your input manifest file must be a point cloud frame sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest (p. 868). You also need to provide a label category configuration file as mentioned above.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.
- To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN that ends with PRE-3DPointCloudObjectTracking.
- To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN that ends with ACS-3DPointCloudObjectTracking.
• The number of workers specified in `NumberOfHumanWorkersPerDataObject` should be 1.
• Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
• 3D-2D object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

**Note**
After you have successfully created a 3D-2D object tracking job, it shows up on the console under labeling jobs. The task type for the job is displayed as **Point Cloud Object Tracking**.

### Output Data
When you create a 3D-2D object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (`LabelingJobStatus`) is `Completed`.

If you are a new user of Ground Truth, see **Output Data** (p. 890) to learn more about the Ground Truth output data format. To learn about the 3D-2D point cloud object tracking output data format, see 3D-2D Object Tracking Point Cloud Object Tracking Output (p. 913).

### 3D Point Cloud Labeling Jobs Overview
This topic provides an overview of the unique features of a Ground Truth 3D point cloud labeling job. You can use the 3D point cloud labeling jobs to have workers label objects in a 3D point cloud generated from a 3D sensors like LiDAR and depth cameras or generated from 3D reconstruction by stitching images captured by an agent like a drone.

#### Job Pre-processing Time
When you create a 3D point cloud labeling job, you need to provide an input manifest file (p. 860). The input manifest file can be:

• A **frame input manifest file** that has a single point cloud frame on each line.
• A **sequence input manifest file** that has a single sequence on each line. A sequence is defined as a temporal series of point cloud frames.

For both types of manifest files, **job pre-processing time** (that is, the time before Ground Truth starts sending tasks to your workers) depends on the total number and size of point cloud frames you provide in your input manifest file. For frame input manifest files, this is the number of lines in your manifest file. For sequence manifest files, this is the number of frames in each sequence multiplied by the total number of sequences, or lines, in your manifest file.

Additionally, the number of points per point cloud and the number of fused sensor data objects (like images) factor into job pre-processing times. On average, Ground Truth can pre-process 200 point cloud frames in approximately 5 minutes. If you create a 3D point cloud labeling job with a large number of point cloud frames, you might experience longer job pre-processing times. For example, if you create a sequence input manifest file with 4 point cloud sequences, and each sequence contains 200 point clouds, Ground Truth pre-processes 800 point clouds and so your job pre-processing time might be around 20 minutes. During this time, your labeling job status is `InProgress`.

While your 3D point cloud labeling job is pre-processing, you receive CloudWatch messages notifying you of the status of your job. To identify these messages, search for `3D_POINT_CLOUD_PROCESSING_STATUS` in your labeling job logs.

For **frame input manifest files**, your CloudWatch logs will have a message similar to the following:
The event log message, `datasetObjectId from: 0 to 10, status: IN_PROGRESS`, identifies the number of frames from your input manifest that have been processed. You receive a new message every time a frame has been processed. For example, after a single frame has processed, you receive another message that says `datasetObjectId from: 1 to 10, status: IN_PROGRESS`.

For **sequence input manifest files**, your CloudWatch logs will have a message similar to the following:

```json
{
  "labeling-job-name": "example-point-cloud-labeling-job",
  "event-name": "3D_POINT_CLOUD_PROCESSING_STATUS",
  "event-log-message": "datasetObjectId: 0, status: IN_PROGRESS"
}
```

The event log message, `datasetObjectId from: 0, status: IN_PROGRESS`, identifies the number of sequences from your input manifest that have been processed. You receive a new message every time a sequence has been processed. For example, after a single sequence has processed, you receive a message that says `datasetObjectId from: 1, status: IN_PROGRESS` as the next sequence begins processing.

### Job Completion Times

3D point cloud labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

It is strongly recommended that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth will save their work every 15 minutes.

When using the SageMaker `CreateLabelingJob` API operation, set the total time a task is available to workers in the `TaskTimeLimitInSeconds` parameter of `HumanTaskConfig`.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

### Workforces

When you create a 3D point cloud labeling job, you need to specify a work team that will complete your point cloud annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the AWS Marketplace. You cannot use the Amazon Mechanical Turk workforce for 3D point cloud labeling jobs.

To learn more about vendor workforce, see [Managing Vendor Workforces](#). To learn how to create and manage a private workforce, see [Use a Private Workforce](#).

### Worker User Interface (UI)

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your 3D point cloud labeling tasks.

You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation `CreateLabelingJob`, you must provide an ARN provided by Ground Truth in the parameter `HumanTaskUiArn` to specify the worker UI for your task.
Label 3D Point Clouds

You provide worker instructions, labels, and optionally, label category attributes that are displayed in the worker UI.

**Label Category Attributes**

When you create a 3D point cloud object tracking or object detection labeling job, you can add one or more **label category attributes**. You can add **frame attributes** to all 3D point cloud task types:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to provide metadata about a label.
- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each point cloud frame a worker is sent to annotate. It is used by workers to provide metadata about frames.

Additionally, you can use label and frame attributes to have workers verify labels in a 3D point cloud label verification job.

Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the Create Labeling Job section on the task type page of your choice.

**Label Category Attributes**

Add label category attributes to labels to give workers the ability to provide more information about the annotations they create. A label category attribute is added to an individual label, or to all labels. When a label category attribute is applied to all labels it is referred to as a **global label category attribute**.

For example, if you add the label category **car**, you might also want to capture additional data about your labeled cars, such as if they are occluded or the size of the car. You can capture this metadata using label category attributes. In this example, if you added the attribute **occluded** to the car label category, you can assign **partial, completely, no** to the **occluded** attribute and enable workers to select one of these options.

When you create a label verification job, you add labels category attributes to each label you want workers to verify.

**Frame Attributes**

Add frame attributes to give workers the ability to provide more information about individual point cloud frames. You can specify up to 10 frame attributes, and these attributes will appear on all frames.

For example, you can add a frame attribute that allows workers to enter a number. You may want to use this attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide a free form answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a point cloud frame.

**Worker Instructions**

You can provide worker instructions to help your workers complete your point cloud labeling tasks. You might want to use these instructions to do the following:

- Best practices and things to avoid when annotating objects.
- Explanation of the label category attributes provided (for object detection and object tracking tasks), and how to use them.
• Advice on how to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker console while creating a labeling job. If you create a labeling job using the API operation `CreateLabelingJob`, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on Worker Instructions (p. 748).

**Declining Tasks**

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (`NumberOfHumanWorkersPerDataObject`) decline the task, the data object is marked as expired and will not be sent to additional workers.

**3D Point Cloud Labeling Job Permission Requirements**

When you create a 3D point cloud labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth (p. 931), you must add a CORS policy to your S3 bucket that contains your input manifest file.

**Add a CORS Permission Policy to S3 Bucket**

When you create a 3D point cloud labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
[
    {
        "AllowedHeaders": [ "*" ],
        "AllowedMethods": [ "GET", "HEAD", "PUT" ],
        "AllowedOrigins": [ "*" ],
        "ExposeHeaders": [ "Access-Control-Allow-Origin" ],
        "MaxAgeSeconds": 3000
    }
]
```

**XML**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<CORSConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <CORSRule>
        <AllowedOrigin>*</AllowedOrigin>
        <AllowedMethod>GET</AllowedMethod>
        <AllowedMethod>HEAD</AllowedMethod>
        <AllowedMethod>PUT</AllowedMethod>
    </CORSRule>
</CORSConfiguration>
```
To learn how to add a CORS policy to an S3 bucket, see How do I add cross-domain resource sharing with CORS? in the Amazon Simple Storage Service User Guide.

Worker Instructions

This topic provides an overview of the Ground Truth worker portal and the tools available to complete your 3D Point Cloud labeling task. First, select the type of task you are working on from Topics.

For adjustment jobs, select the original labeling job task type that produced the labels you are adjusting. Review and adjust the labels in your task as needed.

Important
It is recommended that you complete your task using a Google Chrome or Firefox web browser.

Topics

• 3D Point Cloud Semantic Segmentation (p. 748)
• 3D Point Cloud Object Detection (p. 757)
• 3D Point Cloud Object Tracking (p. 767)

3D Point Cloud Semantic Segmentation

Use this page to become familiarize with the user interface and tools available to complete your 3D point cloud semantic segmentation task.

Topics

• Your Task (p. 748)
• Navigate the UI (p. 753)
• Icon Guide (p. 755)
• Shortcuts (p. 756)
• Release, Stop and Resume, and Decline Tasks (p. 756)
• Saving Your Work and Submitting (p. 757)

Your Task

When you work on a 3D point cloud semantic segmentation task, you need to select a category from the Annotations menu on the right side of your worker portal using the drop down menu Label Categories. After you've selected a category, use the paint brush and polygon tools to paint each object in the 3D point cloud that this category applies to. For example, if you select the category Car, you would use these tools to paint all of the cars in the point cloud. The following video demonstrates how to use the paint brush tool to paint an object.

If you see one or more images in your worker portal, you can paint in the images or paint in the 3D point cloud and the paint will show up in the other medium.

You may see frame attributes under the Labels menu. Use these attribute prompts to enter additional information about the point cloud.
Important
If you see that objects have already been painted when you open the task, adjust those annotations.

The following video includes an image that can be annotated. You may not see an image in your task.
After you've painted one or more objects using a label category, you can select that category from the Label Category menu on the right to only view points painted for that category.
**Navigate the UI**

You can navigate in the 3D scene using their keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud and in the side-view. You can hide and re-expand all side views using the full screen icon. In this GIF, the side-views and menus have been collapsed.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that some or all of these options may not be available.
- **Paint** – Use this menu to modify the functionality of the paint brush.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the paint icon, you can add paint to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full screen, select the full screen icon.

For the camera images and side-panels, you have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.

**Icon Guide**

Use this table to learn about the icons available in your worker task portal.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="brush" /></td>
<td>brush</td>
<td>Choose this icon to turn on the brush tool. To use with this tool, choose and move over the objects that you want to paint with your mouse. After you choose it, everything you paint will be associated with the category you chose.</td>
</tr>
<tr>
<td><img src="image2.png" alt="polygon" /></td>
<td>polygon</td>
<td>Choose this icon to use the polygon paint tool. Use this tool to draw polygons around objects that you want to paint. After you choose it, everything you draw a polygon around will be associated with the category you have chosen.</td>
</tr>
<tr>
<td><img src="image3.png" alt="reset scene" /></td>
<td>reset scene</td>
<td>Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.</td>
</tr>
<tr>
<td><img src="image4.png" alt="move scene" /></td>
<td>move scene</td>
<td>Choose this icon to move the scene. By default, this icon will be selected when you first start a task.</td>
</tr>
</tbody>
</table>
### Icon | Name | Description
---|---|---
full screen | full screen | Choose this icon to make the 3D point cloud visualization full screen, and to collapse all side panels.
ruler | ruler | Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data.

When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement.

After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set.

After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.

### Shortcuts

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use the paint tool.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

### Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task:** You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.
- **Release Task:** If you release a task, you lose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later:** You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and
resume later. When you select this button and then select Confirm, you are returned to the worker portal, and the task status is Stopped. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work every 15 minutes. When you open a task, you must complete your work on it before pressing Submit.

3D Point Cloud Object Detection

Use this page to become familiarize with the user interface and tools available to complete your 3D point cloud object detection task.

Topics

- Your Task (p. 757)
- Navigate the UI (p. 759)
- Icon Guide (p. 765)
- Shortcuts (p. 766)
- Release, Stop and Resume, and Decline Tasks (p. 766)
- Saving Your Work and Submitting (p. 767)

Your Task

When you work on a 3D point cloud object detection task, you need to select a category from the Annotations menu on the right side of your worker portal using the Label Categories menu. After you've chosen a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its dimensions, location, and orientation directly in the point cloud, and the three panels shown on the right.

If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

If you see cuboids have already been added to the 3D point cloud when you open your task, adjust those cuboids and add additional cuboids as needed.

To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the Shortcuts menu in your UI. The following are important key-combinations that you should become familiar with before starting your labeling task.

<table>
<thead>
<tr>
<th>Mac Command</th>
<th>Windows Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmd + Drag</td>
<td>Ctrl + Drag</td>
<td>Modify the dimensions of the cuboid.</td>
</tr>
<tr>
<td>Option + Drag</td>
<td>Alt + Drag</td>
<td>Move the cuboid.</td>
</tr>
<tr>
<td>Shift + Drag</td>
<td>Shift + Drag</td>
<td>Rotate the cuboid.</td>
</tr>
<tr>
<td>Option + O</td>
<td>Alt + O</td>
<td>Fit the cuboid tightly around the points it has been drawn around. Before using the option, make</td>
</tr>
<tr>
<td>Mac Command</td>
<td>Windows Command</td>
<td>Action</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
<td>--------</td>
</tr>
<tr>
<td>Option + G</td>
<td>Alt + G</td>
<td>Set the cuboid to the ground.</td>
</tr>
</tbody>
</table>

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the Label Id menu. Fill in required values for all label attributes.

You may see frame attributes under the Labels menu. Use these attribute prompts to enter additional information about each frame.
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [ and ] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [ or ], the UI will zoom into the first label in the Label Id list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object’s boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon. Resetting the view will not modify your annotations.

After you select the add cuboid icon, you can add cuboids to the 3D point cloud visualization. Once you've added a cuboid, you can adjust it in the three views (top, side, and front) and in the images (if included).
Double click on the point cloud to zoom in

Double click on the label ID to zoom in the object on point cloud.

3D Cuboid Controls
When you are in Edit Cuboid mode

C  Create

V  Edit

Cmd + Drag  Change dimension

Option + Drag  Move cuboid

Option + O  Fit label to points

Option + G  Set to ground

Shift + Drag  Rotate cuboid

[  Previous label

]  Next label

Cmd + ,  Toggle show/hide label
You must choose the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.
Icon Guide

Use this table to learn about the icons you see in your worker task portal.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add cuboid</td>
<td>Choose this icon to add a cuboid. Each cuboid you add is associated with the category you chose.</td>
</tr>
<tr>
<td>edit cuboid</td>
<td>Choose this icon to edit a cuboid. After you have added a cuboid, you can edit its dimensions, location, and orientation. After a cuboid is added, it automatically switches to edit cuboid mode.</td>
</tr>
<tr>
<td>ruler</td>
<td>Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data. When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement. After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set. After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.</td>
</tr>
<tr>
<td>reset scene</td>
<td>Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.</td>
</tr>
<tr>
<td>move scene</td>
<td>Choose this icon to move the scene. By default, this icon is chosen when you first start a task.</td>
</tr>

</table>

**Shortcuts**

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: If you release a task, you loose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.

- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.
Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work every 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

3D Point Cloud Object Tracking

Use this page to become familiar with the user interface and tools available to complete your 3D point cloud object detection task.

**Topics**
- Your Task (p. 767)
- Navigate the UI (p. 771)
- Bulk Edit Label Category and Frame Attributes (p. 775)
- Icon Guide (p. 776)
- Shortcuts (p. 777)
- Release, Stop and Resume, and Decline Tasks (p. 777)
- Saving Your Work and Submitting (p. 778)

Your Task

When you work on a 3D point cloud object tracking task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the **Label Categories** menu. After you've selected a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its location, dimensions, and orientation directly in the point cloud, and the three panels shown on the right. If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

**Important**

If you see cuboids have already been added to the 3D point cloud frames when you open your task, adjust those cuboids and add additional cuboids as needed.

To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the **Shortcuts** menu in your UI. The following are important key-combinations that you should become familiar with before starting your labeling task.

<table>
<thead>
<tr>
<th>Mac Command</th>
<th>Windows Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmd + Drag</td>
<td>Ctrl + Drag</td>
<td>Modify the dimensions of the cuboid.</td>
</tr>
<tr>
<td>Option + Drag</td>
<td>Alt + Drag</td>
<td>Move the cuboid.</td>
</tr>
<tr>
<td>Shift + Drag</td>
<td>Shift + Drag</td>
<td>Rotate the cuboid.</td>
</tr>
<tr>
<td>Option + O</td>
<td>Alt + O</td>
<td>Fit the cuboid tightly around the points it has been drawn around.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Before using the option, make sure the cuboid fully-surrounds the object of interest.</td>
</tr>
<tr>
<td>Option + G</td>
<td>Alt + G</td>
<td>Set the cuboid to the ground.</td>
</tr>
</tbody>
</table>
When you open your task, two frames will be loaded. If your task includes more than two frames, you need to use the navigation bar in the lower-left corner, or the load frames icon to load additional frames. You should annotate and adjust labels in all frames before submitting.

After you fit a cuboid tightly around the boundaries of an object, navigate to another frame using the navigation bar in the lower-left corner of the UI. If that same object has moved to a new location, add another cuboid and fit it tightly around the boundaries of the object. Each time you manually add a cuboid, you see the frame sequence bar in the lower-left corner of the screen turn red where that frame is located temporally in the sequence.

Your UI automatically infers the location of that object in all other frames after you've placed a cuboid. This is called interpolation. You can see the movement of that object, and the inferred and manually created cuboids using the arrows. Adjust inferred cuboids as needed. The following video demonstrates how to navigate between frames. The following video shows how, if you add a cuboid in one frame, and then adjust it in another, your UI will automatically infer the location of the cuboid in all of the frames in-between.
Point cloud View x
**Tip**
You can turn off the automatic cuboid interpolation across frames using the 3D Point Cloud menu item. Select **3D Point Cloud** from the top-menu, and then select **Interpolate Cuboids Across Frames**. This will uncheck this option and stop cuboid interpolation. You can reselect this item to turn cuboid interpolation back on.

Turning cuboid interpolation off will not impact cuboids that have already been interpolated across frames.

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the **Label Id** menu. Fill in required values for all label attributes.

You may see frame attributes under the **Label Id** menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [ and ] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [ or ], the UI will zoom into the first label in the Label Id list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object's boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the add cuboid icon, you can add cuboids to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.
Delete Cuboids

You can select a cuboid or label ID and:

- Delete an individual cuboid in the current frame you are viewing.
- Delete all cuboids with that label ID before or after the frame you are viewing.
- Delete all cuboids with that label ID in all frames.

A common use-case for cuboid deletion is if the object leaves the scene.

You can use one or more of these options to delete both manually placed and interpolated cuboids with the same label ID.

- To delete all cuboids before or after the frame you are currently on, select the cuboid, select the Label menu item at the top of the UI and then select one of Delete in previous frames or Delete in next frames. Use the Shortcuts menu to see the shortcut keys you can use for these options.
- To delete a label in all frames, select Delete in all frames from the Labels menu, or use the shortcut Shift + Delete on your keyboard.
- To delete an individual cuboid from a single frame, select the cuboid and either select the trashcan icon next to that label ID in the Label ID sidebar on the right or use the Delete key on your keyboard to delete that cuboid.

If you have manually placed more than one cuboid with the same label in different frames, when you delete one of the manually placed cuboids, all interpolated cuboids adjust. This adjustment happens because the UI uses manually placed cuboids as anchor points when calculating the location of interpolated cuboid. When you remove one of these anchor points, the UI must recalculate the position of interpolated cuboids.

If you delete a cuboid from a frame, but later decide that you want to get it back, you can use the Duplicate to previous frames or Duplicate to next frames options in the Label menu to copy the cuboid into all the previous or all of the following frames, respectively.

Bulk Edit Label Category and Frame Attributes

You can bulk edit label attributes and frame attributes.

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify must contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you must specify the desired value for the attribute first. For example, if you want to change an attribute from Yes to No, you must select No, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

**To bulk edit a label or attribute:**

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter 1-10. If you want to apply the edit to frames two to five, eight to ten and twenty enter 2-5, 8-10, 20.
3. Select Confirm.
If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the **Duplicate to previous frames** and **Duplicate to next frames** options in the **Label** menu at the top of your screen.

**Icon Guide**

Use this table to learn about the icons you see in your worker task portal.

<table>
<thead>
<tr>
<th>Icon</th>

</tbody>
</table>

**Shortcuts**

The shortcuts listed in the *Shortcuts* menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the *Shortcuts* menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (*Decline task*), release it (*Release task*), and stop and resume it at a later time (*Stop and resume later*). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point clouds, images or the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you loose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select *Confirm*, you are returned to the worker portal. If the task is still available, its status will be *Available*. If other workers pick it up, it will disappear from your portal.

- **Stop and resume later**: You can use the *Stop and resume later* button to stop working and return to the task at a later time. You should use the *Save* button to save your work before you select *Stop and resume later*. When you select this button and then select *Confirm*, you are returned to the worker portal, and the task status is *Stopped*. You can select the same task to resume work on it.
Verify and Adjust Labels

When the labels on a dataset need to be validated, Amazon SageMaker Ground Truth provides functionality to have workers verify that labels are correct or to adjust previous labels.

These types of jobs fall into two distinct categories:

- **Label verification** — Workers indicate if the existing labels are correct, or rate their quality, and can add comments to explain their reasoning. Workers will not be able to modify or adjust labels.

  If you create a 3D point cloud or video frame label adjustment or verification job, you can choose to make label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes editable by workers.

- **Label adjustment** — Workers adjust prior annotations and, if applicable, label category and frame attributes to correct them.

The following Ground Truth built-in task types support adjustment and verification labeling jobs:

- Bounding box
- Semantic segmentation
- 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation
- All video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint

**Tip**

For 3D point cloud and video frame labeling verification jobs, it is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame. To learn more about label category and frame attributes, see [Worker User Interface (UI) (p. 745)](p.745) for 3D point cloud and [Worker User Interface (UI) (p. 691)](p.691) for video frame.

You can start a label verification and adjustment jobs using the SageMaker console or the API.

Topics

- [Requirements to Create Verification and Adjustment Labeling Jobs (p. 779)](p.779)
- [Create a Label Verification Job (Console) (p. 779)](p.779)
- [Create a Label Adjustment Job (Console) (p. 781)](p.781)
- [Start a Label Verification or Adjustment Job (API) (p. 782)](p.782)
- [Label Verification and Adjustment Data in the Output Manifest (p. 784)](p.784)
- [Cautions and Considerations (p. 785)](p.785)
Requirements to Create Verification and Adjustment Labeling Jobs

To create a label verification or adjustment job, the following criteria must be satisfied.

- For non streaming labeling jobs: The input manifest file you use must contain the label attribute name (LabelAttributeName) of the labels that you want adjusted. When you chain a successfully completed labeling job, the output manifest file is used as the input manifest file for the new, chained job. To learn more about the format of the output manifest file Ground Truth produces for each task type, see Output Data (p. 890).

- For streaming labeling jobs: The Amazon SNS message you sent to the Amazon SNS input topic of the adjustment or verification labeling job must contain the label attribute name of the labels you want adjusted or verified. To see an example of how you can create an adjustment or verification labeling job with streaming labeling jobs, see this Jupyter Notebook example in GitHub.

- The task type of the verification or adjustment labeling job must be the same as the task type of the original job unless you are using the Image Label Verification (p. 665) task type to verify bounding box or semantic segmentation image labels. See the next bullet point for more details about the video frame task type requirements.

- For video frame annotation verification and adjustment jobs, you must use the same annotation task type used to create the annotations from the previous labeling job. For example, if you create a video frame object detection job to have workers draw bounding boxes around objects, and then you create a video object detection adjustment job, you must specify bounding boxes as the annotation task type. To learn more video frame annotation task types, see Task Types (p. 690).

- The task type you select for the adjustment or verification labeling job must support an audit workflow. The following Ground Truth built-in task types support adjustment and verification labeling jobs: bounding box, semantic segmentation, 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation, and all video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint.

Create a Label Verification Job (Console)

Bounding box and semantic segmentation labeling jobs are created by choosing the Label verification task type in the console. To create a verification job for 3D point cloud and video frame task types, you must choose the same task type as the original labeling job and choose to display existing labels. Use one of the following sections to create a label verification job for your task type.

Topics
- Create an Image Label Verification Job (Console) (p. 779)
- Create a Point Cloud or Video Frame Label Verification Job (Console) (p. 780)

Create an Image Label Verification Job (Console)

Use the following procedure to create a bounding box or semantic segmentation verification job using the console. This procedure assumes that you have already created a bounding box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want verified.

To create an image label verification job:

2. Start a new labeling job by chaining (p. 927) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. In the **Task type** pane, select **Label verification**.

4. Choose **Next**.

5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see [Create and Manage Workforces](p. 977).

6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.

7. In the **Existing-labels display options** pane, the system shows the available label attribute names in your manifest. Choose the label attribute name that identifies the labels that you want workers to verify. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

8. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

   You can add new labels that workers choose from to verify labels. For example, you can ask workers to verify the image quality, and provide the labels **Clear** and **Blurry**. Workers will also have the option to add a comment to explain their selection.

9. Choose **See preview** to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.

10. Select **Create**. This will create and start your labeling job.

### Create a Point Cloud or Video Frame Label Verification Job (Console)

Use the following procedure to create a 3D point cloud or video frame verification job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

**To create an image label verification job:**

2. Start a new labeling job by **chaining** (p. 927) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.

3. In the **Task type** pane, select the same task type as the labeling job that you chained. For example, if the original labeling job was a video frame object detection keypoint labeling job, select that task type.

4. Choose **Next**.

5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see [Create and Manage Workforces](p. 977).

6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.

7. Toggle on the switch next to **Display existing labels**.

8. Select **Verification**.

9. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for verification. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

10. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

   You cannot modify or add new labels. You can remove, modify and add new label category attributes or frame attributes. It is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame.
By default, preexisting label category attributes and frame attributes will not be editable by workers. If you want to make a label category or frame attribute editable, select the **Allow workers to edit this attribute** check box for that attribute.

To learn more about label category and frame attributes, see [Worker User Interface (UI) (p. 745)](p. 745) for 3D point cloud and [Worker User Interface (UI) (p. 691)](p. 691) for video frame.

11. Choose **See preview** to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.

12. Select **Create**. This will create and start your labeling job.

### Create a Label Adjustment Job (Console)

Use one of the following sections to create a label verification job for your task type.

**Topics**

- [Create an Image Label Adjustment Job (Console) (p. 781)](p. 781)
- [Create a Point Cloud or Video Frame Label Adjustment Job (Console) (p. 782)](p. 782)

### Create an Image Label Adjustment Job (Console)

Use the following procedure to create a bounding box or semantic segmentation adjustment labeling job using the console. This procedure assumes that you have already created a bounding box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want adjusted.

**To create an image label adjustment job (console)**

2. Start a new labeling job by [chaining (p. 927)](p. 927) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.

3. Choose the same task type as the original labeling job.

4. Choose **Next**.

5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see [Create and Manage Workforces (p. 977)](p. 977).

6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.

7. Expand **Existing-labels display options** by selecting the arrow next to the title.

8. Check the box next to **I want to display existing labels from the dataset for this job**.

9. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

10. Use the instructions areas of the tool designer to provide context about what the previous labelers were tasked with doing and what the current verifiers need to check and adjust.

11. Choose **See preview** to check that the tool shows the prior labels correctly and presents the task clearly.

12. Select **Create**. This will create and start your labeling job.
Create a Point Cloud or Video Frame Label Adjustment Job (Console)

Use the following procedure to create a 3D point cloud or video frame adjustment job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

To create a 3D point cloud or video frame label adjustment job (console)

2. Start a new labeling job by chaining (p. 927) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. Choose the same task type as the original labeling job.
4. Toggle on the switch next to Display existing labels.
5. Select Adjustment.
6. For Label attribute name, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.
7. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current adjusters need to check.
   You cannot remove or modify existing labels but you can add new labels. You can remove, modify and add new label category attributes or frame attributes.
   Be default, preexisting label category attributes and frame attributes will be editable by workers. If you want to make a label category or frame attribute uneditable, deselect the Allow workers to edit this attribute check box for that attribute.
   To learn more about label category and frame attributes, see Worker User Interface (UI) (p. 745) for 3D point cloud and Worker User Interface (UI) (p. 691) for video frame.
8. Choose See preview to check that the tool shows the prior labels correctly and presents the task clearly.
9. Select Create. This will create and start your labeling job.

Start a Label Verification or Adjustment Job (API)

Start a label verification or adjustment job by chaining a successfully completed job or starting a new job from scratch using the CreateLabelingJob operation. The procedure is almost the same as setting up a new labeling job with CreateLabelingJob, with a few modifications. Use the following sections to learn what modifications are required to chain a labeling job to create an adjustment or verification labeling job.

When you create an adjustment or verification labeling job using the Ground Truth API, you must use a different LabelAttributeName than the original labeling job. The original labeling job is the job used to create the labels you want adjusted or verified.

Important
The label category configuration file you identify for an adjustment or verification job in LabelCategoryConfigS3Uri of CreateLabelingJob must contain the same labels used in the original labeling job. You can add new labels. For 3D point cloud and video frame jobs, you can add new label category and frame attributes to the label category configuration file.
Bounding Box and Semantic Segmentation

To create a bounding box or semantic segmentation label verification or adjustment job, use the following guidelines to specify API attributes for the CreateLabelingJob operation.

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- If you are chaining the job, the labels from the previous labeling job to be adjusted or verified will be specified in the custom UI template. To learn how to create a custom template, see Create Custom Worker Task Templates (p. 1139).

Identify the location of the UI template in the `UiTemplateS3Uri` parameter. SageMaker provides widgets that you can use in your custom template to display old labels. Use the initial-value attribute in one of the following crowd elements to extract the labels that need verification or adjustment and include them in your task template:

- `crowd-semantic-segmentation` (p. 1062)—Use this crowd element in your custom UI task template to specify semantic segmentation labels that need to be verified or adjusted.
- `crowd-bounding-box` (p. 1008)—Use this crowd element in your custom UI task template to specify bounding box labels that need to be verified or adjusted.

- The `LabelCategoryConfigS3Uri` parameter must contain the same label categories as the previous labeling job.
- Use the bounding box or semantic segmentation adjustment or verification lambda ARNs for `PreHumanTaskLambdaArn` and `AnnotationConsolidationLambdaArn`:
  - For bounding box, the adjustment labeling job lambda function ARNs end with `AdjustmentBoundingBox` and the verification lambda function ARNs end with `VerificationBoundingBox`.
  - For semantic segmentation, the adjustment labeling job lambda function ARNs end with `AdjustmentSemanticSegmentation` and the verification lambda function ARNs end with `VerificationSemanticSegmentation`.

3D Point Cloud and Video Frame

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- You must use the human task UI Amazon Resource Name (ARN) (`HumanTaskUiArn`) used for the original labeling job. To see supported ARNs, see `HumanTaskUiArn`.
- In the label category configuration file, you must specify the label attribute name (`LabelAttributeName`) of the previous labeling job that you use to create the adjustment or verification labeling job in the `auditLabelAttributeName` parameter.
- You specify whether your labeling job is a verification or adjustment labeling job using the `editsAllowed` parameter in your label category configuration file identified by the `LabelCategoryConfigS3Uri` parameter.
  - For verification labeling jobs, you must use the `editsAllowed` parameter to specify that all labels cannot be modified. `editsAllowed` must be set to "none" in each entry in `labels`. Optionally, you can specify whether or not label categories attributes and frame attributes can be adjusted by workers.
  - Optionally, for adjustment labeling jobs, you can use the `editsAllowed` parameter to specify labels, label category attributes, and frame attributes that can or cannot be modified by workers. If you do not use this parameter, all labels, label category attributes, and frame attributes will be adjustable.
To learn more about the editsAllowed parameter and configuring your label category configuration file, see Label Category Configuration File Schema (p. 833).

- Use the 3D point cloud or video frame adjustment lambda ARNs for PreHumanTaskLambdaArn and AnnotationConsolidationLambdaArn for both adjustment and verification labeling jobs:
  - For 3D point clouds, the adjustment and verification labeling job lambda function ARNs end with Adjustment3DPointCloudSemanticSegmentation, Adjustment3DPointCloudObjectTracking, and Adjustment3DPointCloudObjectDetection for 3D point cloud semantic segmentation, object detection, and object tracking respectively.
  - For video frames, the adjustment and verification labeling job lambda function ARNs end with AdjustmentVideoObjectDetection and AdjustmentVideoObjectTracking for video frame object detection and object tracking respectively.

Ground Truth stores the output data from a label verification or adjustment job in the S3 bucket that you specified in the S3OutputPath parameter of the CreateLabelingJob operation. For more information about the output data from a label verification or adjustment labeling job, see Label Verification and Adjustment Data in the Output Manifest (p. 784).

**Label Verification and Adjustment Data in the Output Manifest**

Amazon SageMaker Ground Truth writes label verification data to the output manifest within the metadata for the label. It adds two properties to the metadata:

- A type property, with a value of "groundtruth/label-verification.
- A worker-feedback property, with an array of comment values. This property is added when the worker enters comments. If there are no comments, the field doesn't appear.

The following example output manifest shows how label verification data appears:

```json
{
  "source-ref": "S3 bucket location",
  "verify-bounding-box": "1",
  "verify-bounding-box-metadata": {
    "class-name": "bad",
    "confidence": 0.93,
    "type": "groundtruth/label-verification",
    "job-name": "verify-bounding-boxes",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256",
    "worker-feedback": [
      {"comment": "The bounding box on the bird is too wide on the right side."},
      {"comment": "The bird on the upper right is not labeled."}
    ]
  }
}
```

The worker output of adjustment tasks resembles the worker output of the original task, except that it contains the adjusted values and an adjustment-status property with the value of adjusted or unadjusted to indicate whether an adjustment was made.

For more examples of the output of different tasks, see Output Data (p. 890).
Cautions and Considerations

To get expected behavior when creating a label verification or adjustment job, carefully verify your input data.

- If you are using image data, verify that your manifest file contains hexadecimal RGB color information.
- To save money on processing costs, filter your data to ensure you are not including unwanted objects in your labeling job input manifest.
- Add required Amazon S3 permissions to ensure your input data is processed correctly.

When you create an adjustment or verification labeling job using the Ground Truth API, you must use a different LabelAttributeName than the original labeling job.

Color Information Requirements for Semantic Segmentation Jobs

To properly reproduce color information in verification or adjustment tasks, the tool requires hexadecimal RGB color information in the manifest (for example, #FFFFFF for white). When you set up a Semantic Segmentation verification or adjustment job, the tool examines the manifest to determine if this information is present. If it can't find it, Amazon SageMaker Ground Truth displays an error message and the ends job setup.

In prior iterations of the Semantic Segmentation tool, category color information wasn't output in hexadecimal RGB format to the output manifest. That feature was introduced to the output manifest at the same time the verification and adjustment workflows were introduced. Therefore, older output manifests aren't compatible with this new workflow.

Filter Your Data Before Starting the Job

Amazon SageMaker Ground Truth processes all objects in your input manifest. If you have a partially labeled data set, you might want to create a custom manifest using an Amazon S3 Select query on your input manifest. Unlabeled objects individually fail, but they don't cause the job to fail, and they might incur processing costs. Filtering out objects you don't want verified reduces your costs.

If you create a verification job using the console, you can use the filtering tools provided there. If you create jobs using the API, make filtering your data part of your workflow where needed.

Creating Custom Labeling Workflows

This document guides you through the process of setting up a workflow with a custom labeling template. To learn more about starting a labeling job, see Getting started (p. 641). In that section, when you choose the Task type, select Custom labeling task, and then follow this section's instructions to configure it.

Topics

- Step 1: Setting up your workforce (p. 786)
- Step 2: Creating your custom worker task template (p. 786)
- Step 3: Processing with AWS Lambda (p. 792)
- Demo Template: Annotation of Images with crowd-bounding-box (p. 806)
- Demo Template: Labeling Intents with crowd-classifier (p. 810)
- Custom Workflows via the API (p. 817)

For more information about creating custom labeling workflows, see Build a custom data labeling workflow with Amazon SageMaker Ground Truth.
Step 1: Setting up your workforce

In this step you use the console to establish which worker type to use and make the necessary sub-selections for the worker type. It assumes you have already completed the steps up to this point in the Getting started (p. 641) section and have chosen the Custom labeling task as the Task type.

To configure your workforce.

1. First choose an option from the Worker types. There are three types currently available:
   - Public uses an on-demand workforce of independent contractors, powered by Amazon Mechanical Turk. They are paid on a per-task basis.
   - Private uses your employees or contractors for handling data that needs to stay within your organization.
   - Vendor uses third party vendors that specialize in providing data labeling services, available via the AWS Marketplace.

2. If you choose the Public option, you are asked to set the number of workers per dataset object. Having more than one worker perform the same task on the same object can help increase the accuracy of your results. The default is three. You can raise or lower that depending on the accuracy you need.

   You are also asked to set a price per task by using a drop-down menu. The menu recommends price points based on how long it will take to complete the task.

   The recommended method to determine this is to first run a short test of your task with a private workforce. The test provides a realistic estimate of how long the task takes to complete. You can then select the range your estimate falls within on the Price per task menu. If your average time is more than 5 minutes, consider breaking your task into smaller units.

Next

Step 2: Creating your custom worker task template (p. 786)

Step 2: Creating your custom worker task template

A worker task template is a file used by Ground Truth to customize the worker user interface (UI), or human task UI. You can create a worker task template using HTML, CSS, JavaScript, Liquid template language, and Crowd HTML Elements. Liquid is used to automate the template, and Crowd HTML Elements can be used to include common annotation tools and provide the logic to submit to Ground Truth.

• Starting with a base template (p. 787)
• Developing templates locally (p. 787)
• Using External Assets (p. 787)
• Track your variables (p. 787)
• A simple sample (p. 788)
• Adding automation with Liquid (p. 789)
• End-to-end demos (p. 791)
• Next (p. 792)

Use the following topics to learn how you can create a worker task template. You can see a repository of example Ground Truth worker task templates on GitHub.
Starting with a base template

You can use a template editor in the Ground Truth console to start creating a template. This editor includes a number of pre-designed base templates and an HTML and Crowd HTML Element autofill feature.

To access the Ground Truth custom template editor:

1. Following the instructions in Create a Labeling Job (Console) (p. 820) and select Custom for the labeling job Task type.
2. When you select Next, you will be able to access the template editor and base templates in the Custom labeling task setup section.
3. (Optional) Select a base template from the drop-down menu under Templates. If you prefer to create a template from scratch, choose Custom from the drop down-menu for a minimal template skeleton.

Developing templates locally

While you need to be in the console to test how your template will process incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding this code to the top of your HTML file.

Example

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

This loads the necessary code to render the custom HTML elements. Use this if you want to develop your template's look and feel in your preferred editor rather than in the console.

Remember, though, this will not parse your variables. You may want to replace them with sample content while developing locally.

Using External Assets

Amazon SageMaker Ground Truth custom templates allow external scripts and style sheets to be embedded. For example, the following code block demonstrates how you would add a style sheet located at https://www.example.com/my-enhancement-styles.css to your template.

Example

```html
<script src="https://www.example.com/my-enhancement-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css"

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding types for remote scripts are: application/javascript;CHARSET=UTF-8.

The MIME and encoding type for remote stylesheets are: text/css;CHARSET=UTF-8.

Track your variables

In the process of building the sample below, there will be a step that adds variables to it to represent the pieces of data that may change from task to task, worker to worker. If you're starting with one of the
sample templates, you will need to make sure you're aware of the variables it already uses. When you create your pre-annotation AWS Lambda script, its output will need to contain values for any of those variables you choose to keep.

The values you use for the variables can come from your manifest file. All the key-value pairs in your data object are provided to your pre-annotation Lambda. If it's a simple pass-through script, matching keys for values in your data object to variable names in your template is the easiest way to pass those values through to the tasks forms your workers see.

A simple sample

All tasks begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between them.

For a simple tweet-analysis task, use the `<crowd-classifier>` element. It requires the following attributes:

- `name` - the variable name to use for the result in the form output.
- `categories` - a JSON formatted array of the possible answers.
- `header` - a title for the annotation tool

As children of the `<crowd-classifier>` element, you must have three regions.

- `<classification-target>` - the text the worker will classify based on the options specified in the categories attribute above.
- `<full-instructions>` - instructions that are available from the "View full instructions" link in the tool. This can be left blank, but it is recommended that you give good instructions to get better results.
- `<short-instructions>` - a more brief description of the task that appears in the tool's sidebar. This can be left blank, but it is recommended that you give good instructions to get better results.

A simple version of this tool would look like this.

Example of using `crowd-classifier`

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="['positive','negative','neutral', 'unclear']"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      My favorite football team won today!
      Bring on the division finals!
    </classification-target>

    <full-instructions header="Sentiment Analysis Instructions">
      Try to determine the sentiment the author of the tweet is trying to express.
      If none seem to match, choose "cannot determine."
    </full-instructions>

    <short-instructions>
      Pick the term best describing the sentiment of the tweet.
    </short-instructions>

  </crowd-classifier>
</crowd-form>
```
You can copy and paste the code into the editor in the Ground Truth labeling job creation workflow to preview the tool, or try out a demo of this code on CodePen.

Adding automation with Liquid

Our custom template system uses Liquid for automation. It is an open source inline markup language. In Liquid, the text between single curly braces and percent symbols is an instruction or tag that performs an operation like control flow or iteration. Text between double curly braces is a variable or object that outputs its value.

The most common use of Liquid will be to parse the data coming from your pre-annotation Lambda and pull out the relevant variables to create the task. The taskInput object returned by your Pre-annotation Lambda (p. 793) will be available as the task.input object in your templates.

The properties in your manifest's data objects are passed into your Pre-annotation Lambda (p. 793) as the event.dataObject. A simple pass-through script simply returns that object as the taskInput object. You would represent values from your manifest as variables as follows.

Example Manifest data object

```
{
  "source": "This is a sample text for classification",
  "labels": ["angry", "sad", "happy", "inconclusive"],
  "header": "What emotion is the speaker feeling?"
}
```

Example Sample HTML using variables

```
<crowd-classifier
  name='tweetFeeling' 
  categories='{{ task.input.labels | to_json }}'
  header='{{ task.input.header }}'>
<classification-target>
```
Note the addition of " | to_json" to the labels property above. That's a filter to turn the array into a JSON representation of the array. Variable filters are explained in the next section.

The following list includes two types of Liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you will be redirected to the Liquid documentation.

- **Control flow**: Includes programming logic operators like if/else, unless, and case/when.
- **Iteration**: Enables you to run blocks of code repeatedly using statements like for loops.

For an example of an HTML template that uses Liquid elements to create a for loop, see translation-review-and-correction.liquid.html in GitHub.

For more information and documentation, visit the [Liquid homepage](http://liquid.tanukisoft.net).

### Variable filters

In addition to the standard Liquid filters and actions, Ground Truth offers a few additional filters. Filters are applied by placing a pipe (|) character after the variable name, then specifying a filter name. Filters can be chained in the form of:

```liquid
{{ <content> | <filter> | <filter> }}
```

### Autoescape and explicit escape

By default, inputs will be HTML escaped to prevent confusion between your variable text and HTML. You can explicitly add the escape filter to make it more obvious to someone reading the source of your template that the escaping is being done.

**escape_once**

escape_once ensures that if you've already escaped your code, it doesn't get re-escaped on top of that. For example, so that & doesn't become &amp;.

**skip_autoescape**

skip_autoescape is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

**Use skip_autoescape sparingly**

The best practice in templates is to avoid passing in functional code or markup with skip_autoescape unless you are absolutely sure you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a Cross Site Scripting attack.

**to_json**

to_json will encode what you feed it to JSON (JavaScript Object Notation). If you feed it an object, it will serialize it.

**grant_read_access**

grant_read_access takes an S3 URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display to workers photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible.
Example of the filters

Input

| auto-escape: {{ "Have you read 'James & the Giant Peach'" }} |
| explicit escape: {{ "Have you read 'James & the Giant Peach'" | escape }} |
| explicit escape_once: {{ "Have you read 'James & the Giant Peach'" | escape_once }} |
| skip_autoescape: {{ "Have you read 'James & the Giant Peach'" | skip_autoescape }} |
| to_json: {{ jsObject | to_json }} |
| grant_read_access: {{ "s3://mybucket/myphoto.png" | grant_read_access }} |

Example

Output

| auto-escape: Have you read 'James & the Giant Peach'? |
| explicit escape: Have you read 'James & the Giant Peach'? |
| explicit escape_once: Have you read 'James & the Giant Peach'? |
| skip_autoescape: Have you read 'James & the Giant Peach'? |
| to_json: { "point_number": 8, "coords": [ 59, 76 ] } |
| grant_read_access: https://s3.amazonaws.com/mybucket/myphoto.png?access token and other params |

Example of an automated classification template.

To automate the simple text classification sample, replace the tweet text with a variable.

The text classification template is below with automation added. The changes/additions are highlighted in bold.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="['positive', 'negative', 'neutral', 'cannot determine']"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      {{ task.input.source }}
    </classification-target>

    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author of the tweet is trying to express. If none seem to match, choose "other."
    </full-instructions>

    <short-instructions>
      Pick the term best describing the sentiment of the tweet.
    </short-instructions>

  </crowd-classifier>
</crowd-form>
```

The tweet text that was in the prior sample is now replaced with an object. The entry.taskInput object uses source (or another name you specify in your pre-annotation Lambda) as the property name for the text and it is inserted directly in the HTML by virtue of being between double curly braces.

End-to-end demos

You can view the following end-to-end demos which include sample Lambda function:
• Demo Template: Annotation of Images with crowd-bounding-box (p. 806)
• Demo Template: Labeling Intents with crowd-classifier (p. 810)

Next

Step 3: Processing with AWS Lambda (p. 792)

Step 3: Processing with AWS Lambda

In this step, you learn how to create and specify the two types of AWS Lambda functions that are required to create a custom labeling workflow:

• **Pre-annotation Lambda**: This function initiates for and pre-processes each data object sent to your labeling job prior to sending it to workers.
• **Post-annotation Lambda**: This function processes the results once workers submit a task. If you specify multiple workers per data object, this function may include logic to consolidate annotations.

If you are a new user of Lambda and Ground Truth, we recommend that you use the pages in this section as follows:

1. First, review Pre-annotation and Post-annotation Lambda Function Requirements (p. 792).
2. Then, use the page Required Permissions To Use AWS Lambda With Ground Truth (p. 799) to learn about security and permission requirements to use your pre-annotation and post-annotation Lambda functions in a Ground Truth custom labeling job.
3. Next, you need to visit the Lambda console or use Lambda's APIs to create your functions. Use the section Create Lambda Functions for a Custom Labeling Workflow (p. 803) to learn how to create Lambda functions.
4. To learn how to test your Lambda functions, see Test Pre-Annotation and Post-Annotation Lambda Functions (p. 803).
5. After you create pre-processing and post-processing Lambda functions, select them from the Lambda functions section that comes after the code editor for your custom HTML in the Ground Truth console. To learn how to use these functions in a CreateLabelingJob API request, see Create a Labeling Job (API) (p. 823).

For a custom labeling workflow tutorial that includes example pre-annotation and post-annotation Lambda functions, in the "Demo Template: Annotation of Images with crowd-bounding-box (p. 806)" document.

Topics
• Pre-annotation and Post-annotation Lambda Function Requirements (p. 792)
• Required Permissions To Use AWS Lambda With Ground Truth (p. 799)
• Create Lambda Functions for a Custom Labeling Workflow (p. 803)
• Test Pre-Annotation and Post-Annotation Lambda Functions (p. 803)

Pre-annotation and Post-annotation Lambda Function Requirements

Use this section to learn about the syntax of the requests sent to pre-annotation and post-annotation Lambda functions, and the response syntax that Ground Truth requires to run a custom labeling workflow.

Topics
Pre-annotation Lambda

Before a labeling task is sent to the worker, your pre-annotation Lambda function is invoked.

Ground Truth sends your Lambda function a JSON-formatted request to provide details about the labeling job and the data object. The following table contains the pre-annotation request schemas. Each parameter is described below.

Data object identified with "source-ref"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "<labelingJobArn>
    "dataObject" : {
        "source-ref": "<s3Uri>
    }
}
```

Data object identified with "source"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "<labelingJobArn>
    "dataObject" : {
        "source": "<string>
    }
}
```

- **version (string):** This is a version number used internally by Ground Truth.
- **labelingJobArn (string):** This is the Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as DescribeLabelingJob.
- **dataObject (JSON object):** The key contains a single JSON line, either from your input manifest file or sent from Amazon SNS. The JSON line objects in your manifest can be up to 100 kilobytes in size and contain a variety of data. For a very basic image annotation job, the dataObject JSON may just contain a source-ref key, identifying the image to be annotated. If the data object (for example, a line of text) is included directly in the input manifest file, the data object is identified with source. If you create a verification or adjustment job, this line may contain label data and metadata from the previous labeling job.

The following table includes code block examples of a pre-annotation request. Each parameter in these example requests is explained below the tabbed table.

Data object identified with "source-ref"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "arn:aws:sagemaker:<aws_region>:<aws_account_number>:labeling-job/<labeling_job_name>
    "dataObject" : {
        "source-ref": "s3://<input-data-bucket>/<data-object-file-name>
    }
}
```
Data object identified with "source"

```
{
  "version": "2018-10-16",
  "labelingJobArn": "arn:aws:sagemaker:<aws_region>:<aws_account_number>:labeling-job/<labeling_job_name>"
  "dataObject": {
    "source": "Sue purchased 10 shares of the stock on April 10th, 2020"
  }
}
```

In return, Ground Truth requires a response formatted like the following:

**Example of expected return data**

```
{
  "taskInput": <json object>,
  "isHumanAnnotationRequired": <boolean> # Optional
}
```

In the previous example, the `<json object>` needs to contain all the data your custom worker task template needs. If you’re doing a bounding box task where the instructions stay the same all the time, it may just be the HTTP(S) or Amazon S3 resource for your image file. If it’s a sentiment analysis task and different objects may have different choices, it is the object reference as a string and the choices as an array of strings.

**Implications of isHumanAnnotationRequired**

This value is optional because it defaults to `true`. The primary use case for explicitly setting it is when you want to exclude this data object from being labeled by human workers.

If you have a mix of objects in your manifest, with some requiring human annotation and some not needing it, you can include a `isHumanAnnotationRequired` value in each data object. You can add logic to your pre-annotation Lambda to dynamically determine if an object requires annotation, and set this boolean value accordingly.

**Examples of Pre-annotation Lambda Functions**

The following, basic pre-annotation Lambda function accesses the JSON object in `dataObject` from the initial request, and returns it in the `taskInput` parameter.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

Assuming the input manifest file uses "source-ref" to identify data objects, the worker task template used in the same labeling job as this pre-annotation Lambda must include a Liquid element like the following to ingest `dataObject`:

```
{{ task.input.source-ref | grant_read_access }}
```

If the input manifest file used `source` to identify the data object, the work task template can ingest `dataObject` with the following:
The following pre-annotation Lambda example includes logic to identify the key used in dataObject, and to point to that data object using taskObject in the Lambda's return statement.

```python
import json
def lambda_handler(event, context):
    # Event received
    print("Received event: " + json.dumps(event, indent=2))

    # Get source if specified
    source = event['dataObject']['source'] if "source" in event['dataObject'] else None

    # Get source-ref if specified
    source_ref = event['dataObject']['source-ref'] if "source-ref" in event['dataObject'] else None

    # if source field present, take that otherwise take source-ref
    task_object = source if source is not None else source_ref

    # Build response object
    output = {
        "taskInput": {
            "taskObject": task_object
        },
        "humanAnnotationRequired": "true"
    }

    print(output)
    # If neither source nor source-ref specified, mark the annotation failed
    if task_object is None:
        print("Failed to pre-process {} !".format(event["labelingJobArn"]))
        output["humanAnnotationRequired"] = "false"

    return output
```

**Post-annotation Lambda**

When all workers have annotated the data object or when TaskAvailabilityLifetimeInSeconds has been reached, whichever comes first, Ground Truth sends those annotations to your post-annotation Lambda. This Lambda is generally used for Consolidate Annotations (p. 920).

**Tip**

To see an example of a post-consolidation Lambda function, see annotation_consolidation_lambda.py in the aws-sagemaker-ground-truth-recipe GitHub repository.

The following code block contains the post-annotation request schema. Each parameter is described in the following bulleted list.

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "<string>",
    "labelCategories": [<string>],
    "labelAttributeName": <string>,
    "roleArn": <string>,
    "payload": {
        "s3Uri": <string>}
}
```
• `version` (string): A version number used internally by Ground Truth.
• `labelingJobArn` (string): The Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as DescribeLabelingJob.
• `labelCategories` (list of strings): Includes the label categories and other attributes you either specified in the console, or that you include in the label category configuration file.
• `labelAttributeName` (string): Either the name of your labeling job, or the label attribute name you specify when you create the labeling job.
• `roleArn` (string): The Amazon Resource Name (ARN) of the IAM execution role you specify when you create the labeling job.
• `payload` (JSON object): A JSON that includes an `s3Uri` key, which identifies the location of the annotation data for that data object in Amazon S3. The second code block below shows an example of this annotation file.

The following code block contains an example of a post-annotation request. Each parameter in this example request is explained below the code block.

**Example of an post-annotation Lambda request**

```json
{
    "version": "2018-10-16",
    "labelCategories": ["Ex Category1", "Ex Category2", "Ex Category3"],
    "labelAttributeName": "labeling-job-attribute-name",
    "roleArn" : "arn:aws:iam::111122223333:role/role-name",
    "payload": {
        "s3Uri": "s3://DOC-EXAMPLE-BUCKET/annotations.json"
    }
}
```

**Note**

If no worker works on the data object and `TaskAvailabilityLifetimeInSeconds` has been reached, the data object is marked as failed and not included as part of post-annotation Lambda invocation.

The following code block contains the payload schema. This is the file that is indicated by the `s3Uri` parameter in the post-annotation Lambda request `payload` JSON object. For example, if the previous code block is the post-annotation Lambda request, the following annotation file is located at `s3://DOC-EXAMPLE-BUCKET/annotations.json`.

Each parameter is described in the following bulleted list.

**Example of an annotation file**

```json
[
    {
        "datasetObjectId": "<string>",
        "dataObject": {
            "s3Uri": "<string>",
            "content": "<string>",
            "annotations": [{
                "workerId": "<string>",
                "annotationData": {
                    "content": "<string>",
                }
            }
        }
    }
]```
• **datasetObjectId** (string): Identifies a unique ID that Ground Truth assigns to each data object you send to the labeling job.

• **dataObject** (JSON object): The data object that was labeled. If the data object is included in the input manifest file and identified using the source key (for example, a string), dataObject includes a content key, which identifies the data object. Otherwise, the location of the data object (for example, a link or S3 URI) is identified with s3Uri.

• **annotations** (list of JSON objects): This list contains a single JSON object for each annotation submitted by workers for that dataObject. A single JSON object contains a unique workerId that can be used to identify the worker that submitted that annotation. The annotationData key contains one of the following:
  - **content** (string): Contains the annotation data.
  - **s3Uri** (string): Contains an S3 URI that identifies the location of the annotation data.

The following table contains examples of the content that you may find in payload for different types of annotation.

**Named Entity Recognition Payload**

```json
[
  {
    "datasetObjectId": "1",
    "dataObject": {
      "content": "Sift 3 cups of flour into the bowl."
    },
    "annotations": [
      {
        "workerId": "private.us-west-2.ef7294f850a3d9d1",
        "annotationData": {
          "content": "{"crowd-entity-annotation":{"entities":[{"endOffset":4,"label":"verb","startOffset":0},{"endOffset":6,"label":"number","startOffset":5},{"endOffset":20,"label":"object","startOffset":15},
            {"endOffset":34,"label":"object","startOffset":30}]}}"
        }
      }
    ]
  }
]
```

**Semantic Segmentation Payload**

```json
[
  {
    "datasetObjectId": "2",
    "dataObject": {
      "s3Uri": "s3://DOC-EXAMPLE-BUCKET/gt-input-data/images/bird3.jpg"
    },
    "annotations": [
      {
        "workerId": "private.us-west-2.ab1234c5678a919d0",
        "annotationData": {
          "content": "{"crowd-semantic-segmentation":{"inputImageProperties":{"height":2000,"width":3020},"labelMappings":{"Bird":{"color":"#2ca02c"}},"labeledImage":{"pngImageData":"iVBOR..."}}"
        }
      }
    ]
  }
]
```
Bounding Box Payload

```
[
  {
    "datasetObjectId": "0",
    "dataObject": {
      "s3Uri": "s3://DOC-EXAMPLE-BUCKET/gt-input-data/images/bird1.jpg"
    },
    "annotations": [
      {
        "workerId": "private.us-west-2.ab1234c5678a919d0",
        "annotationData": {
          "content": "{"boundingBox": ["boundingBoxes": [{"height": 2052, "label": "Bird", "left": 583, "top": 302, "width": 1375}], "inputImageProperties": {"height": 2497, "width": 3745}}"]
        }
      }
    ]
  }
]
```

Your post-annotation Lambda function may contain logic similar to the following to loop through and access all annotations contained in the request. For a full example, see `annotation_consolidation_lambda.py` in the `aws-sagemaker-ground-truth-recipe` GitHub repository. In this GitHub example, you must add your own annotation consolidation logic.

```python
for i in range(len(annotations)):
    worker_id = annotations[i]['workerId']
    annotation_content = annotations[i]['annotationData'].get('content')
    annotation_s3_uri = annotations[i]['annotationData'].get('s3uri')
    annotation = annotation_content if annotation_s3_uri is None else
    s3_client.get_object_from_s3(
        annotation_s3_uri)
    annotation_from_single_worker = json.loads(annotation)
    print("{} Received Annotations from worker [{}] is [{]"
          .format(log_prefix, worker_id, annotation_from_single_worker))
```

**Tip**

When you run consolidation algorithms on the data, you can use an AWS database service to store results, or you can pass the processed results back to Ground Truth. The data you return to Ground Truth is stored in consolidated annotation manifests in the S3 bucket specified for output during the configuration of the labeling job.

In return, Ground Truth requires a response formatted like the following:

**Example of expected return data**

```
[
  {
    "datasetObjectId": <string>,
    "consolidatedAnnotation": {
      "content": {
        "<labelattributename>": {
```
At this point, all the data you're sending to your S3 bucket, other than the `datasetObjectId`, is in the `content` object.

When you return annotations in `content`, this results in an entry in your job's output manifest like the following:

**Example of label format in output manifest**

```json
{
  "source-ref":"source": "<s3uri or content>",
  "<labelAttributeName>": {
    # ... label content from you
  },
  "<labelAttributeName>-metadata": {
    # This will be added by Ground Truth
    "job_name": "<labelingJobName>",
    "type": "groundTruth/custom",
    "human-annotated": "yes",
    "creation_date": <date> # Timestamp of when received from Post-labeling Lambda
  }
}
```

Because of the potentially complex nature of a custom template and the data it collects, Ground Truth does not offer further processing of the data.

**Required Permissions To Use AWS Lambda With Ground Truth**

You may need to configure some or all the following to create and use AWS Lambda with Ground Truth.

- You need to grant an IAM role or user (collectively, an IAM entity) permission to create the pre-annotation and post-annotation Lambda functions using AWS Lambda, and to choose them when creating the labeling job.
- The IAM execution role specified when the labeling job is configured needs permission to invoke the pre-annotation and post-annotation Lambda functions.
- The post-annotation Lambda functions may need permission to access Amazon S3.

Use the following sections to learn how to create the IAM entities and grant permissions described above.

**Topics**

- [Grant Permission to Create and Select an AWS Lambda Function](p. 800)
Grant Permission to Create and Select an AWS Lambda Function

If you do not require granular permissions to develop pre-annotation and post-annotation Lambda functions, you can attach the AWS managed policy `AWSLambda_FullAccess` to a user or role. This policy grants broad permissions to use all Lambda features, as well as permission to perform actions in other AWS services with which Lambda interacts.

To create a more granular policy for security-sensitive use cases, refer to the documentation Identity-based IAM policies for Lambda in the to AWS Lambda Developer Guide to learn how to create an IAM policy that fits your use case.

Policies to Use the Lambda Console

If you want to grant an IAM entity permission to use the Lambda console, see Using the Lambda console in the AWS Lambda Developer Guide.

Additionally, if you want the user to be able to access and deploy the Ground Truth starter pre-annotation and post-annotation functions using the AWS Serverless Application Repository in the Lambda console, you must specify the `<aws-region>` where you want to deploy the functions (this should be the same AWS Region used to create the labeling job), and add the following policy to the IAM role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "VisualEditor0",
        "Effect": "Allow",
        "Action": [
          "serverlessrepo:ListApplicationVersions",
          "serverlessrepo:GetApplication",
          "serverlessrepo:CreateCloudFormationTemplate"
        ],
      },
      {
        "Sid": "VisualEditor1",
        "Effect": "Allow",
        "Action": "serverlessrepo:SearchApplications",
        "Resource": "*"
      }
    ]
}
```

Policies to See Lambda Functions in the Ground Truth Console

To grant an IAM entity permission to view Lambda functions in the Ground Truth console when the user is creating a custom labeling job, the entity must have the permissions described in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console (p. 932), including the permissions described in the section Custom Labeling Workflow Permissions (p. 935).

Grant IAM Execution Role Permission to Invoke AWS Lambda Functions

If you add the IAM managed policy `AmazonSageMakerGroundTruthExecution` to the IAM execution role used to create the labeling job, this role has permission to list and invoke Lambda functions with one
of the following strings in the function name: GtRecipe, SageMaker, Sagemaker, sagemaker, or LabelingFunction.

If the pre-annotation or post-annotation Lambda function names do not include one of the terms in the preceding paragraph, or if you require more granular permission than those in the AmazonSageMakerGroundTruthExecution managed policy, you can add a policy similar to the following to give the execution role permission to invoke pre-annotation and post-annotation functions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": [
        "arn:aws:lambda:<region>:<account-id>:function:<post-annotation-lambda-name>"
      ]
    }
  ]
}
```

Grant Post-Annotation Lambda Permissions to Access Annotation

As described in Post-annotation Lambda (p. 795), the post-annotation Lambda request includes the location of the annotation data in Amazon S3. This location is identified by the s3Uri string in the payload object. To process the annotations as they come in, even for a simple pass through function, you need to assign the necessary permissions to the post-annotation Lambda execution role to read files from the Amazon S3.

There are many ways that you can configure your Lambda to access annotation data in Amazon S3. Two common ways are:

- Allow the Lambda execution role to assume the SageMaker execution role identified in roleArn in the post-annotation Lambda request. This SageMaker execution role is the one used to create the labeling job, and has access to the Amazon S3 output bucket where the annotation data is stored.
- Grant the Lambda execution role permission to access the Amazon S3 output bucket directly.

Use the following sections to learn how to configure these options.

Grant Lambda Permission to Assume SageMaker Execution Role

To allow a Lambda function to assume a SageMaker execution role, you must attach a policy to the Lambda function's execution role, and modify the trust relationship of the SageMaker execution role to allow Lambda to assume it.

1. Attach the following IAM policy to your Lambda function's execution role to assume the SageMaker execution role identified in Resource. Replace 222222222222 with an AWS account ID. Replace sm-execution-role with the name of the assumed role.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::<account-id>:role/sm-execution-role"
  }
}
```
"Resource": "arn:aws:iam::222222222222:role/sm-execution-role"

2. Modify the trust policy of the SageMaker execution role to include the following Statement. Replace 222222222222 with an AWS account ID. Replace my-lambda-execution-role with the name of the assumed role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::222222222222:role/my-lambda-execution-role"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

**Grant Lambda Execution Role Permission to Access S3**

You can add a policy similar to the following to the post-annotation Lambda function execution role to give it S3 read permissions. Replace DOC-EXAMPLE-BUCKET with the name of the output bucket you specify when you create a labeling job.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject"],
            "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
        }
    ]
}
```

To add S3 read permissions to a Lambda execution role in the Lambda console, use the following procedure.

**Add S3 read permissions to post-annotation Lambda:**

1. Open the Functions page in the Lambda console.
2. Choose the name of the post-annotation function.
3. Choose Configuration and then choose Permissions.
4. Select the Role name and the summary page for that role opens in the IAM console in a new tab.
5. Select Attach policies.
6. Do one of the following:
   - Search for and select AmazonS3ReadOnlyAccess to give the function permission to read all buckets and objects in the account.
   - If you require more granular permissions, select Create policy and use the policy example in the preceding section to create a policy. Note that you must navigate back to the execution role summary page after you create the policy.
7. If you used the AmazonS3ReadOnlyAccess managed policy, select **Attach policy**.

   If you created a new policy, navigate back to the Lambda execution role summary page and attach the policy you just created.

**Create Lambda Functions for a Custom Labeling Workflow**

You can create a Lambda function using the Lambda console, the AWS CLI, or an AWS SDK in a supported programming language of your choice. Use the AWS Lambda Developer Guide to learn more about each of these options:

- To learn how to create a Lambda function using the console, see [Create a Lambda function with the console](#).
- To learn how to create a Lambda function using the AWS CLI, see [Using AWS Lambda with the AWS Command Line Interface](#).
- Select the relevant section in the table of contents to learn more about working with Lambda in the language of your choice. For example, select [Working with Python](#) to learn more about using Lambda with the AWS SDK for Python (Boto3).

Ground Truth provides pre-annotation and post-annotation templates through an AWS Serverless Application Repository (SAR) **recipe**. Use the following procedure to select the Ground Truth recipe in the Lambda console.

**Use the Ground Truth SAR recipe to create pre-annotation and post-annotation Lambda functions:**

1. Open the **Functions page** on the Lambda console.
2. Select **Create function**.
3. Select **Browse serverless app repository**.
4. In the search text box, enter **aws-sagemaker-ground-truth-recipe** and select that app.
5. Select **Deploy**. The app may take a couple of minutes to deploy.
   
   Once the app deploys, two functions appear in the **Functions** section of the Lambda console: `serverlessrepo-aws-sagema-GtRecipePreHumanTaskFunc-<id>` and `serverlessrepo-aws-sagema-GtRecipeAnnotationConsole-<id>`.
6. Select one of these functions and add your custom logic in the **Code** section.
7. When you are finished making changes, select **Deploy** to deploy them.

**Test Pre-Annotation and Post-Annotation Lambda Functions**

You can test your pre-annotation and post annotation Lambda functions in the Lambda console. If you are a new user of Lambda, you can learn how to test, or **invoke**, your Lambda functions in the console using the [Create a Lambda function](#) tutorial with the console in the AWS Lambda Developer Guide.

You can use the sections on this page to learn how to test the Ground Truth pre-annotation and post-annotation templates provided through an AWS Serverless Application Repository (SAR).

**Topics**

- [Prerequisites](#)
- [Test the Pre-annotation Lambda Function](#)
- [Test the Post-Annotation Lambda Function](#)
Prerequisites

You must do the following to use the tests described on this page.

- You need access to the Lambda console, and you need permission to create and invoke Lambda functions. To learn how to set up these permissions, see Grant Permission to Create and Select an AWS Lambda Function (p. 800).
- If you have not deployed the Ground Truth SAR recipe, use the procedure in Create Lambda Functions for a Custom Labeling Workflow (p. 803) to do so.
- To test the post-annotation Lambda function, you must have a data file in Amazon S3 with sample annotation data. For a simple test, you can copy and paste the following code into a file and save it as sample-annotations.json and upload this file to Amazon S3. Note the S3 URI of this file—you need this information to configure the post-annotation Lambda test.

```json
[{
"datasetObjectId": "0",
"dataObject": {
"content": "To train a machine learning model, you need a large, high-quality, labeled dataset. Ground Truth helps you build high-quality training datasets for your machine learning models."},
"annotations": [{
"workerId": "private.us-west-2.0123456789",
"annotationData": {
"content": "\{\"crowd-entity-annotation\":\{\"entities\":\{\"endOffset\":8,\"label\":\"verb\",\"startOffset\":3,\"endOffset\":27,\"label\":\"adjective\",\"startOffset\":11,\"endOffset\":33,\"label\":\"object\",\"startOffset\":28,\"endOffset\":51,\"label\":\"adjective\",\"startOffset\":46,\"endOffset\":65,\"label\":\"adjective\",\"startOffset\":53,\"endOffset\":74,\"label\":\"adjective\",\"startOffset\":62,\"endOffset\":82,\"label\":\"adjective\",\"startOffset\":75,\"endOffset\":102,\"label\":\"verb\",\"startOffset\":97,\"endOffset\":112,\"label\":\"verb\",\"startOffset\":107,\"endOffset\":125,\"label\":\"adjective\",\"startOffset\":113,\"endOffset\":134,\"label\":\"adjective\",\"startOffset\":126,\"endOffset\":143,\"label\":\"object\",\"startOffset\":135,\"endOffset\":169,\"label\":\"adjective\",\"startOffset\":153,\"endOffset\":176,\"label\":\"object\",\"startOffset\":170]\}\}]]
},
"datasetObjectId": "1",
"dataObject": {
"content": "Sift 3 cups of flour into the bowl."
},
"annotations": [{
"workerId": "private.us-west-2.0123456789",
"annotationData": {
"content": "\{\"crowd-entity-annotation\":\{\"entities\":\{\"endOffset\":4,\"label\":\"verb\",\"startOffset\":0,\"endOffset\":6,\"label\":\"number\",\"startOffset\":5,\"endOffset\":20,\"label\":\"object\",\"startOffset\":15,\"endOffset\":34,\"label\":\"object\",\"startOffset\":30]\}\}\}]]
},
"datasetObjectId": "2",
"dataObject": {
"content": "Jen purchased 10 shares of the stock on January 1st, 2020."
},
"annotations": [{
"workerId": "private.us-west-2.0123456789",
"annotationData": {
"content": "\{\"crowd-entity-annotation\":\{\"entities\":\{\"endOffset\":3,\"label\":\"person\",\"startOffset\":0,\"endOffset\":13,\"label\":\"verb\",\"startOffset\":4,\"endOffset\":16,\"label\":\"number\",\"startOffset\":14,\"endOffset\":58,\"label\":\"date\",\"startOffset\":60]\}\}\}]]
},
"datasetObjectId": "3",
"dataObject": {
"content": "The narrative was interesting, however the character development was weak."
},
"annotations": [{
"workerId": "private.us-west-2.0123456789",
"annotationData": {
"content": "\{\"crowd-entity-annotation\":\{\"entities\":\{\"endOffset\":29,\"label\":\"adjective\",\"startOffset\":18,\"endOffset\":73,\"label\":\"adjective\",\"startOffset\":69]\}\}\}]
}]
}
```

- You must use the directions in Grant Post-Annotation Lambda Permissions to Access Annotation (p. 801) to give your post-annotation Lambda function's execution role permission to assume the SageMaker execution role you use to create the labeling job. The post-annotation Lambda function uses the SageMaker execution role to access the annotation data file, sample-annotations.json, in S3.

Test the Pre-annotation Lambda Function

Use the following procedure to test the pre-annotation Lambda function created when you deployed the Ground Truth AWS Serverless Application Repository (SAR) recipe.

**Test the Ground Truth SAR recipe pre-annotation Lambda function**

1. Open the **Functions page** in the Lambda console.
2. Select the pre-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to serverlessrepo-aws-sagemaker-GtRecipePreHumanTaskFunc-<id>.

3. In the **Code source** section, select the arrow next to **Test**.

4. Select **Configure test event**.

5. Keep the **Create new test event** option selected.

6. Under **Event template**, select **SageMaker Ground Truth PreHumanTask**.

7. Give your test an **Event name**.

8. Select **Create**.

9. Select the arrow next to **Test** again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.

10. Select **Test** to run the test.

After you run the test, you can see the **Execution results**. In the **Function logs**, you should see a response similar to the following:

```
START RequestId: cd117d38-8365-4e1a-bff9-0dcd631a878f Version: $LATEST
Received event: {
  "version": "2018-10-16",
  "dataObject": {
    "source-ref": "s3://sagemakerexample/object_to_annotate.jpg"
  }
}
{'taskInput': {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'}, 'isHumanAnnotationRequired': 'true'}
END RequestId: cd117d38-8365-4e1a-bff9-0dcd631a878f
REPORT RequestId: cd117d38-8365-4e1a-bff9-0dcd631a878f Duration: 0.42 ms Billed Duration: 1 ms Memory Size: 128 MB Max Memory Used: 43 MB
```

In this response, we can see the Lambda function's output matches the required pre-annotation response syntax:

```
{"taskInput": {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'}, 'isHumanAnnotationRequired': 'true'}
```

**Test the Post-Annotation Lambda Function**

Use the following procedure to test the post-annotation Lambda function created when you deployed the Ground Truth AWS Serverless Application Repository (SAR) recipe.

**Test the Ground Truth SAR recipe post-annotation Lambda**

1. Open the **Functions page** in the Lambda console.

2. Select the post-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to serverlessrepo-aws-sagemaker-GtRecipeAnnotationConsol-<id>.

3. In the **Code source** section, select the arrow next to **Test**.

4. Select **Configure test event**.

5. Keep the **Create new test event** option selected.

6. Under **Event template**, select **SageMaker Ground Truth AnnotationConsolidation**.

7. Give your test an **Event name**.

8. Modify the template code provided as follows:
• Replace the Amazon Resource Name (ARN) in `roleArn` with the ARN of the SageMaker execution role you used to create the labeling job.
• Replace the S3 URI in `s3Uri` with the URI of the `sample-annotations.json` file you added to Amazon S3.

After you make these modifications, your test should look similar to the following:

```json
{
   "version": "2018-10-16",
   "labelAttributeName": "example-attribute",
   "roleArn": "arn:aws:iam::222222222222:role/sm-execution-role",
   "payload": {
      "s3Uri": "s3://your-bucket/sample-annotations.json"
   }
}
```

9. Select Create.
10. Select the arrow next to Test again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.
11. Select the Test to run the test.

After you run the test, you should see a -- Consolidated Output -- section in the Function Logs, which contains a list of all annotations included in `sample-annotations.json`.

**Demo Template: Annotation of Images with crowd-bounding-box**

When you chose to use a custom template as your task type in the Amazon SageMaker Ground Truth console, you reach the Custom labeling task panel. There you can choose from multiple base templates. The templates represent some of the most common tasks and provide a sample to work from as you create your customized labeling task's template. If you are not using the console, or as an additional recourse, see Amazon SageMaker Ground Truth Sample Task UIs for a repository of demo templates for a variety of labeling job task types.

This demonstration works with the BoundingBox template. The demonstration also works with the AWS Lambda functions needed for processing your data before and after the task. In the Github repository above, to find templates that work with AWS Lambda functions, look for `{{ task.input.<property name> }}` in the template.

**Topics**
- Starter Bounding Box custom template (p. 806)
- Your own Bounding Box custom template (p. 807)
- Your manifest file (p. 808)
- Your pre-annotation Lambda function (p. 809)
- Your post-annotation Lambda function (p. 809)
- The output of your labeling job (p. 810)

**Starter Bounding Box custom template**

This is the starter bounding box template that is provided.
The custom templates use the Liquid template language, and each of the items between double curly braces is a variable. The pre-annotation AWS Lambda function should provide an object named taskInput and that object's properties can be accessed as {{ task.input.<property name> }} in your template.

**Your own Bounding Box custom template**

As an example, assume you have a large collection of animal photos in which you know the kind of animal in an image from a prior image-classification job. Now you want to have a bounding box drawn around it.

In the starter sample, there are three variables: taskObject, header, and labels.

Each of these would be represented in different parts of the bounding box.

- **taskObject** is an HTTP(S) URL or S3 URI for the photo to be annotated. The added | grant_read_access is a filter that will convert an S3 URI to an HTTPS URL with short-lived access to that resource. If you're using an HTTP(S) URL, it's not needed.
- **header** is the text above the photo to be labeled, something like "Draw a box around the bird in the photo."
• labels is an array, represented as ['item1', 'item2', ...]. These are labels that can be assigned by the worker to the different boxes they draw. You can have one or many.

Each of the variable names come from the JSON object in the response from your pre-annotation Lambda. The names above are merely suggested. Use whatever variable names make sense to you and will promote code readability among your team.

Only use variables when necessary
If a field will not change, you can remove that variable from the template and replace it with that text, otherwise you have to repeat that text as a value in each object in your manifest or code it into your pre-annotation Lambda function.

Example: Final Customized Bounding Box Template
To keep things simple, this template will have one variable, one label, and very basic instructions. Assuming your manifest has an “animal” property in each data object, that value can be re-used in two parts of the template.

Note the re-use of {{ task.input.animal }} throughout the template. If your manifest had all of the animal names beginning with a capital letter, you could use {{ task.input.animal | downcase }}, incorporating one of Liquid’s built-in filters in sentences where it needed to be presented lowercase.

Your manifest file
Your manifest file should provide the variable values you’re using in your template. You can do some transformation of your manifest data in your pre-annotation Lambda, but if you don't need to, you maintain a lower risk of errors and your Lambda will run faster. Here’s a sample manifest file for the template.
Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda function that can be called to process your manifest entries and pass them to the template engine.

**Naming your Lambda function**

The best practice in naming your function is to use one of the following four strings as part of the function name: SageMaker, Sagemaker, sagemaker, or LabelingFunction. This applies to both your pre-annotation and post-annotation functions.

When you're using the console, if you have AWS Lambda functions that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic example, you're just passing through the information from the manifest without doing any additional processing on it. This sample pre-annotation function is written for Python 3.7.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

The JSON object from your manifest will be provided as a child of the event object. The properties inside the taskInput object will be available as variables to your template, so simply setting the value of taskInput to event['dataObject'] will pass all the values from your manifest object to your template without having to copy them individually. If you wish to send more values to the template, you can add them to the taskInput object.

Your post-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer consolidation and scoring as it comes in, you can apply the scoring and/or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

**Provide permissions to your post-annotation Lambda**

The annotation data will be in a file designated by the s3Uri string in the payload object. To process the annotations as they come in, even for a simple pass through function, you need to assign S3ReadOnly access to your Lambda so it can read the annotation files.

In the Console page for creating your Lambda, scroll to the Execution role panel. Select Create a new role from one or more templates. Give the role a name. From the Policy templates drop-down, choose Amazon S3 object read-only permissions. Save the Lambda and the role will be saved and selected.

The following sample is in Python 2.7.

```python
import json
import boto3
from urlparse import urlparse

def lambda_handler(event, context):
    consolidated_labels = []
    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);
    for dataset in annotations:
        for annotation in dataset['annotations']:
```
new_annotation = json.loads(annotation['annotationData']['content'])
label = {
    'datasetObjectId': dataset['datasetObjectId'],
    'consolidatedAnnotation': {
        'content': {
            event['labelAttributeName']: {
                'workerId': annotation['workerId'],
                'boxesInfo': new_annotation,
                'imageSource': dataset['dataObject']
            }
        }
    }
}
consolidated_labels.append(label)
return consolidated_labels

The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the payload object the Lambda should iterate through. What you send back will be an object meeting the API contract (p. 792).

The output of your labeling job

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a subfolder named manifests.

For a bounding box task, the output you find in the output manifest will look a bit like the demo below. The example has been cleaned up for printing. The actual output will be a single line per record.

Example: JSON in your output manifest

```json
{
  "source-ref": "<URL>",
  "<label attribute name>": {
    "workerId": "<URL>",
    "imageSource": "<image URL>",
    "boxesInfo": "{"boundingBox": [{"height": 878, "label": "bird", "left": 208, "top": 6, "width": 809}], "inputImageProperties": {"height": 924, "width": 1280}}"},
  "<label attribute name>-metadata": {
    "type": "groundTruth/custom",
    "job_name": "<Labeling job name>",
    "human-annotated": "yes"
  },
  "animal": "bird"
}
```

Note how the additional animal attribute from your original manifest is passed to the output manifest on the same level as the source-ref and labeling data. Any properties from your input manifest, whether they were used in your template or not, will be passed to the output manifest.

Demo Template: Labeling Intents with crowd-classifier

If you choose a custom template, you'll reach the Custom labeling task panel. There you can select from multiple starter templates that represent some of the more common tasks. The templates provide a starting point to work from in building your customized labeling task's template.

In this demonstration, you work with the Intent Detection template, which uses the crowd-classifier (p. 1016) element, and the AWS Lambda functions needed for processing your data before and after the task.
Topics

- Starter Intent Detection custom template (p. 811)
- Your Intent Detection custom template (p. 811)
- Your pre-annotation Lambda function (p. 815)
- Your post-annotation Lambda function (p. 815)
- Your labeling job output (p. 816)

Starter Intent Detection custom template

This is the intent detection template that is provided as a starting point.

```
<crowd-form>
  <crowd-classifier
    name="intent"
    categories="{{ task.input.labels | to_json | escape }}"
    header="Pick the most relevant intention expressed by the below text"
  >
    <classification-target>
      {{ task.input.utterance }}
    </classification-target>

    <full-instructions header="Intent Detection Instructions">
      <p>Select the most relevant intention expressed by the text.</p>
      <p><strong>Example:</strong> I would like to return a pair of shoes</p>
      <p><strong>Intent: </strong>Return</p>
    </full-instructions>

    <short-instructions>
      Pick the most relevant intention expressed by the text
    </short-instructions>
  </crowd-classifier>
</crowd-form>
```

The custom templates use the Liquid template language, and each of the items between double curly braces is a variable. The pre-annotation AWS Lambda function should provide an object named taskInput and that object's properties can be accessed as `{{ task.input.<property name> }}` in your template.

Your Intent Detection custom template

In the starter template, there are two variables: the `task.input.labels` property in the `crowd-classifier` element opening tag and the `task.input.utterance` in the `classification-target` region's content.

Unless you need to offer different sets of labels with different utterances, avoiding a variable and just using text will save processing time and creates less possibility of error. The template used in this demonstration will remove that variable, but variables and filters like `to_json` are explained in more detail in the crowd-bounding-box demonstration article.

Styling Your Elements

Two parts of these custom elements that sometimes get overlooked are the `<full-instructions>` and `<short-instructions>` regions. Good instructions generate good results.
In the elements that include these regions, the `<short-instructions>` appear automatically in the "Instructions" pane on the left of the worker's screen. The `<full-instructions>` are linked from the "View full instructions" link near the top of that pane. Clicking the link opens a modal pane with more detailed instructions.

You can not only use HTML, CSS, and JavaScript in these sections, you are encouraged to if you believe you can provide a strong set of instructions and examples that will help workers complete your tasks with better speed and accuracy.

**Example Try out a sample with JSFiddle**

Try out an example `<crowd-classifier>` task. The example is rendered by JSFiddle, therefore all the template variables are replaced with hard-coded values. Click the "View full instructions" link to see a set of examples with extended CSS styling. You can fork the project to experiment with your own changes to the CSS, adding sample images, or adding extended JavaScript functionality.

**Example : Final Customized Intent Detection Template**

This uses the example `<crowd-classifier>` task, but with a variable for the `<classification-target>`. If you are trying to keep a consistent CSS design among a series of different labeling jobs, you can include an external stylesheet using a `<link rel...>` element the same way you'd do in any other HTML document.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="intent"
    categories="['buy', 'eat', 'watch', 'browse', 'leave']"
    header="Pick the most relevant intent expressed by the text below"
  >
    <classification-target>
```
In the statements and questions provided in this exercise, what category of action is the speaker interested in doing?

<table>
<thead>
<tr>
<th>Example Utterance</th>
<th>Good Choice</th>
</tr>
</thead>
<tbody>
<tr>
<td>When is the Seahawks game on?</td>
<td>watch, browse</td>
</tr>
<tr>
<td></td>
<td>eat</td>
</tr>
<tr>
<td>When is the Seahawks game on?</td>
<td>watch, browse</td>
</tr>
<tr>
<td></td>
<td>buy</td>
</tr>
<tr>
<td></td>
<td>eat</td>
</tr>
</tbody>
</table>

What is the speaker expressing they would like to do next?
Example: Your manifest file

If you are preparing your manifest file manually for a text-classification task like this, have your data formatted in the following manner.

```json
[{
"source": "Roses are red"
}, {
"source": "Violets are Blue"
}, {
"source": "Ground Truth is the best"
}, {
"source": "And so are you"
]```

This differs from the manifest file used for the "Demo Template: Annotation of Images with crowdbounding-box (p. 806)" demonstration in that source-ref was used as the property name instead of source. The use of source-ref designates S3 URIs for images or other files that must be converted to HTTP. Otherwise, source should be used like it is with the text strings above.
Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda that can be called to process your manifest entries and pass them to the template engine.

This Lambda function is required to have one of the following four strings as part of the function name: SageMaker, Sagemaker, sagemaker, or LabelingFunction.

This applies to both your pre-annotation and post-annotation Lambdas.

When you're using the console, if you have Lambdas that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic sample, where you have only one variable, it's primarily a pass-through function. Here's a sample pre-labeling Lambda using Python 3.7.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

The `dataObject` property of the event contains the properties from a data object in your manifest.

In this demonstration, which is a simple pass through, you just pass that straight through as the `taskInput` value. If you add properties with those values to the `event['dataObject']` object, they will be available to your HTML template as Liquid variables with the format `{{ task.input.<property name> }}`.

Your post-annotation Lambda function

As part of the job set up, provide the ARN of an Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer-consolidation and scoring as data comes in, you can apply the scoring or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

**Set permissions for your post-annotation Lambda function**

The annotation data will be in a file designated by the `s3Uri` string in the `payload` object. To process the annotations as they come in, even for a simple pass through function, you need to assign S3ReadOnly access to your Lambda so it can read the annotation files.

In the Console page for creating your Lambda, scroll to the **Execution role** panel. Select **Create a new role from one or more templates**. Give the role a name. From the **Policy templates** drop-down, choose **Amazon S3 object read-only permissions**. Save the Lambda and the role will be saved and selected.

The following sample is for Python 3.7.

```python
import json
import boto3
from urllib.parse import urlparse

def lambda_handler(event, context):
    consolidated_labels = []

    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);

    for dataset in annotations:
        consolidated_labels.append(dataset['dataset'])
```

815
for annotation in dataset['annotations']:
    new_annotation = json.loads(annotation['annotationData']['content'])
    label = {
        'datasetObjectId': dataset['datasetObjectId'],
        'consolidatedAnnotation': {
            'content': {
                event['labelAttributeName']: {
                    'workerId': annotation['workerId'],
                    'result': new_annotation,
                    'labeledContent': dataset['dataObject']
                }
            }
        }
    }
    consolidated_labels.append(label)
return consolidated_labels

Your labeling job output

The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the payload object the Lambda should iterate through.

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a subfolder named manifests.

For an intent detection task, the output in the output manifest will look a bit like the demo below. The example has been cleaned up and spaced out to be easier for humans to read. The actual output will be more compressed for machine reading.

Example: JSON in your output manifest

```json
[
    {
        "datasetObjectId": "<Number representing item's place in the manifest>",
        "consolidatedAnnotation": {
            "content": {
                "<name of labeling job>": {
                    "workerId": "private.us-east-1.XXXXXXXXXXXXXXXXXXXXX",
                    "result": {
                        "intent": {
                            "label": "<label chosen by worker>",
                        },
                        "labeledContent": {
                            "content": "<text content that was labeled>"
                        }
                    }
                }
            }
        }
    },
    {
        "datasetObjectId": "<Number representing item's place in the manifest>",
        "consolidatedAnnotation": {
            "content": {
                "<name of labeling job>": {
                    "workerId": "private.us-east-1.XXXXXXXXXXXXXXXXXXXXX",
                    "result": {
                        "intent": {
                            "label": "<label chosen by worker>",
                        },
                        "labeledContent": {
                            "content": "<text content that was labeled>"
                        }
                    }
                }
            }
        }
    }
]```
Create a Labeling Job

You can create a labeling job in the Amazon SageMaker console and by using an AWS SDK in your preferred language to run CreateLabelingJob. After a labeling job has been created, you can track worker metrics (for private workforces) and your labeling job status using CloudWatch.

Before you create a labeling job it is recommended that you review the following pages, as applicable:

- You can specify your input data using an automatic data setup in the console, or an input manifest file in either the console or when using CreateLabelingJob API. For automated data setup, see Automated Data Setup (p. 850). To learn how to create an input manifest file, see Use an Input Manifest File (p. 849).
- Review labeling job input data quotas: Input Data Quotas (p. 856).

After you have chosen your task type, use the topics on this page to learn how to create a labeling job.

If you are a new Ground Truth user, we recommend that you start by walking through the demo in Getting started (p. 641).

Important

Ground Truth requires all S3 buckets that contain labeling job input image data to have a CORS policy attached. To learn more, see CORS Permission Requirement (p. 930).

This should help you create and use your own custom template.

Custom Workflows via the API

When you have created your custom UI template (Step 2) and processing Lambda functions (Step 3), you should place the template in an Amazon S3 bucket with a file name format of: `<FileName>.liquid.html`.

Use the CreateLabelingJob action to configure your task. You'll use the location of a custom template (Step 2: Creating your custom worker task template (p. 786)) stored in a `<filename>.liquid.html` file on S3 as the value for the UiTemplateS3Uri field in the UiConfig object within the HumanTaskConfig object.

For the AWS Lambda tasks described in Step 3: Processing with AWS Lambda (p. 792), the post-annotation task’s ARN will be used as the value for the AnnotationConsolidationLambdaArn field, and the pre-annotation task will be used as the value for the PreHumanTaskLambdaArn field.
Topics
• Built-in Task Types (p. 818)
• Creating Instruction Pages (p. 818)
• Create a Labeling Job (Console) (p. 820)
• Create a Labeling Job (API) (p. 823)
• Create a Streaming Labeling Job (p. 828)
• Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833)

Built-in Task Types
Amazon SageMaker Ground Truth has several built-in task types. Ground Truth provides a worker task template for built-in task types. Additionally, some built in task types support Automate Data Labeling (p. 921). The following topics describe each built-in task type and demo the worker task templates that are provided by Ground Truth in the console. To learn how to create a labeling job in the console using one of these task types, select the task type page.

<table>
<thead>
<tr>
<th>Label Images</th>
<th>Label Text</th>
<th>Label Videos and Video Frames</th>
<th>Label 3D Point Clouds</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Bounding Box (p. 646)</td>
<td>• Named Entity Recognition (p. 666)</td>
<td>• Video Classification (p. 676)</td>
<td>• 3D Point Cloud Object Detection (p. 713)</td>
</tr>
<tr>
<td>• Image Classification (Single Label) (p. 659)</td>
<td>• Text Classification (Single Label) (p. 670)</td>
<td>• Video Frame Object Detection (p. 681)</td>
<td>• 3D Point Cloud Object Tracking (p. 720)</td>
</tr>
<tr>
<td>• Image Classification (Multi-label) (p. 661)</td>
<td>• Text Classification (Multi-label) (p. 673)</td>
<td>• Video Frame Object Tracking (p. 685)</td>
<td>• 3D Point Cloud Semantic Segmentation (p. 729)</td>
</tr>
<tr>
<td>• Image Semantic Segmentation (p. 652)</td>
<td>• Verify and Adjust Labels (p. 778)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note
Each of the video frame and 3D point cloud task types has an adjustment task type that you use to verify and adjust labels from a previous labeling job. Select a video frame or 3D point cloud task type page above to learn how to adjust labels created using that task type.

Creating Instruction Pages
Create custom instructions for labeling jobs to improve your worker's accuracy in completing their task. You can modify the default instructions that are provided in the console or you can create your own. The instructions are shown to the worker on the page where they complete their labeling task.

There are two kinds of instructions:
• Short instructions—instructions that are shown on the same webpage where the worker completes their task. These instructions should provide an easy reference to show the worker the correct way to label an object.
• Full instructions—instructions that are shown on a dialog box that overlays the page where the worker completes their task. We recommend that you provide detailed instructions for completing the task with multiple examples showing edge cases and other difficult situations for labeling objects.
Create instructions in the console when you are creating your labeling job. Start with the existing instructions for the task and use the editor to modify them to suit your labeling job.

**Note**

Once you create your labeling job, it will automatically start and you will not be able to modify your worker instructions. If you need to change your worker instructions, stop the labeling job that you created, clone it, and modify your worker instructions before creating a new job. You can clone a labeling job in the console by selecting the labeling job and then selecting **Clone** in the **Actions** menu.

To clone a labeling job using the Amazon SageMaker API or your preferred Amazon SageMaker SDK, make a new request to the `CreateLabelingJob` operation with the same specifications as your original job after modifying your worker instructions.

**Short Instructions**

Short instructions appear on the same web page that workers use to label your data object. For example, the following is the editing page for a bounding box task. The short instructions panel is on the left.

Keep in mind that a worker will only spend seconds looking at the short instructions. Workers must be able to scan and understand your information quickly. In all cases it should take less time to understand the instructions than it takes to complete the task. Keep these points in mind:

- Your instructions should be clear and simple.
• Pictures are better than words. Create a simple illustration of your task that your workers can immediately understand.
• If you must use words, use short, concise examples.
• Your short instructions are more important than your full instructions.

The Amazon SageMaker Ground Truth console provides an editor so that you can create your short instructions. Replace the placeholder text and images with instructions for your task. Preview the worker's task page by choosing Preview. The preview will open in a new window, be sure to turn off pop-up blocking so that the window will show.

**Full Instructions**

You can provide additional instructions for your workers in a dialog box that overlays the page where workers label your data objects. Use full instructions to explain more complex tasks and to show workers the proper way to label edge cases or other difficult objects.

You can create full instructions using an editor in the Ground Truth console. As with quick instructions, keep the following in mind:

• Workers will want detailed instruction the first few times that they complete your task. Any information that they must have should be in the quick instructions.
• Pictures are more important than words.
• Text should be concise.
• Full instructions should supplement the short instructions. Don't repeat information that appears in the short instructions.

The Ground Truth console provides an editor so that you can create your full instructions. Replace the placeholder text and images with instructions for your task. Preview the full instruction page by choosing Preview. The preview will open in a new window, be sure to turn off pop-up blocking so that the window will show.

**Add example images to your instructions**

Images provide useful examples for your workers. To add a publicly accessible image to your instructions:

• Place the cursor where the image should go in the instructions editor.
• Click the image icon in the editor toolbar.
• Enter the URL of your image.

If your instruction image in Amazon S3 is not publicly accessible:

• As the image URL, enter: {{ 'https://s3.amazonaws.com/your-bucket-name/image-file-name' | grant_read_access }}.
• This renders the image URL with a short-lived, one-time access code appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview.

**Create a Labeling Job (Console)**

You can use the Amazon SageMaker console to create a labeling job for all of the Ground Truth built-in task types and custom labeling workflows. For built-in task types, we recommend that you use this page alongside the page for your task type. Each task type page includes specific details on creating a labeling job using that task type.
You need to provide the following to create a labeling job in the SageMaker console:

- An input manifest file in Amazon S3. You can place your input dataset in Amazon S3 and automatically generate a manifest file using the Ground Truth console (not supported for 3D point cloud labeling jobs).
  Alternatively, you can manually create an input manifest file. To learn how, see Input Data (p. 848).
- An Amazon S3 bucket to store your output data.
- An IAM role with permission to access your resources in Amazon S3 and with a SageMaker execution policy attached. For a general solution, you can attach the managed policy, AmazonSageMakerFullAccess, to an IAM role and include sagemaker in your bucket name.
  For more granular policies, see the section called “IAM Permissions” (p. 931).
- A work team. You create a work team from a workforce made up of Amazon Mechanical Turk workers, vendors, or your own private workers. To lean more, see Create and Manage Workforces (p. 977).
  You cannot use the Mechanical Turk workforce for 3D point cloud or video frame labeling jobs.
- If you are using a custom labeling workflow, you must save a worker task template in Amazon S3 and provide an Amazon S3 URI for that template. For more information, see Step 2: Creating your custom worker task template (p. 786).
- (Optional) An AWS KMS key ARN if you want SageMaker to encrypt the output of your labeling job using your own AWS KMS encryption key instead of the default Amazon S3 service key.
- (Optional) Existing labels for the dataset you use for your labeling job. Use this option if you want workers to adjust, or approve and reject labels.
- If you want to create an adjustment or verification labeling job, you must have an output manifest file in Amazon S3 that contains the labels you want adjusted or verified. This option is only supported for bounding box and semantic segmentation image labeling jobs and 3D point cloud and video frame labeling jobs. It is recommended that you use the instructions on Verify and Adjust Labels (p. 778) to create a verification or adjustment labeling job.

Important
Your work team, input manifest file, output bucket, and other resources in Amazon S3 must be in the same AWS Region you use to create your labeling job.

When you create a labeling job using the SageMaker console, you add worker instructions and labels to the worker UI that Ground Truth provides. You can preview and interact with the worker UI while creating your labeling job in the console. You can also see a preview of the worker UI on your built-in task type page.

To create a labeling job (console)

2. In the left navigation pane, choose Labeling jobs.
4. For Job name, enter a name for your labeling job.
5. (Optional) If you want to identify your labels with a key, select I want to specify a label attribute name different from the labeling job name. If you do not select this option, the labeling job name you specified in the previous step will be used to identify your labels in your output manifest file.
6. Choose a data setup to create a connection between your input dataset and Ground Truth.
   - For Automated data setup:
     - Follow the instructions in Automated Data Setup (p. 850) for image, text, and video clip labeling jobs.
• Follow the instructions in Automated Video Frame Input Data Setup (p. 887) for video frame labeling jobs.

• For Manual data setup:
  • For Input dataset location, provide the location in Amazon S3 in which your input manifest file is located. For example, if your input manifest file, manifest.json, is located in example-bucket, enter s3://example-bucket/manifest.json.
  • For Output dataset location, provide the location in Amazon S3 where you want Ground Truth to store the output data from your labeling job.

7. For IAM Role, choose an existing IAM role or create an IAM role with permission to access your resources in Amazon S3, to write to the output Amazon S3 bucket specified above, and with a SageMaker execution policy attached.

8. (Optional) For Additional configuration, you can specify how much of your dataset you want workers to label, and if you want SageMaker to encrypt the output data for your labeling job using an AWS KMS encryption key. To encrypt your output data, you must have the required AWS KMS permissions attached to the IAM role you provided in the previous step. For more details, see the section called "IAM Permissions" (p. 931).

9. In the Task type section, under Task category, use the dropdown list to select your task category.

10. In Task selection, choose your task type.

11. (Optional) Provide tags for your labeling job to make it easier to find in the console later.

12. Choose Next.

13. In the Workers section, choose the type of workforce you would like to use. For more details about your workforce options see Create and Manage Workforces (p. 977).

14. (Optional) After you’ve selected your workforce, specify the Task timeout. This is the maximum amount of time a worker has to work on a task.

   For 3D point cloud annotation tasks, the default task timeout is 3 days. The default timeout for text and image classification and label verification labeling jobs is 5 minutes. The default timeout for all other labeling jobs is 60 minutes.

15. (Optional) For bounding box, semantic segmentation, video frame, and 3D point cloud task types, you can select Display existing labels if you want to display labels for your input data set for workers to verify or adjust.

   For bounding box and semantic segmentation labeling jobs, this will create an adjustment labeling job.

   For 3D point cloud and video frame labeling jobs:

   • Select Adjustment to create an adjustment labeling job. When you select this option, you can add new labels but you cannot remove or edit existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box Allow workers to edit this attribute for that attribute.

   Optionally, you can add new label category and frame attributes.

   • Select Verification to create an adjustment labeling job. When you select this option, you cannot add, modify, or remove existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box Allow workers to edit this attribute for that attribute.

   We recommend that you can add new label category attributes to the labels that you want workers to verify, or add one or more frame attributes to have workers provide information about the entire frame.

For more information, see Verify and Adjust Labels (p. 778).
16. Configure your workers' UI:
   
   - If you are using a built-in task type, specify workers instructions and labels.
   - For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other built-in task types, you must specify at least one label category.
   - (Optional) If you are creating a 3D point cloud or video frame labeling job, you can specify label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes. Label category attributes can be assigned to one or more labels. Frame attributes will appear on each point cloud or video frame workers label. To learn more, see Worker User Interface (UI) (p. 745) for 3D point cloud and Worker User Interface (UI) (p. 691) for video frame.
   - (Optional) Add Additional instructions to help your worker complete your task.
   - If you are creating a custom labeling workflow you must:
     - Enter a custom template in the code box. Custom templates can be created using a combination of HTML, the Liquid templating language and our pre-built web components. Optionally, you can choose a base-template from the drop-down menu to get started.
     - Specify pre-annotation and post-annotation lambda functions. To learn how to create these functions, see Step 3: Processing with AWS Lambda (p. 792).
   17. (Optional) You can select See preview to preview your worker instructions, labels, and interact with the worker UI. Make sure the pop-up blocker of the browser is disabled before generating the preview.
   18. Choose Create.

After you've successfully created your labeling job, you are redirected to the Labeling jobs page. The status of the labeling job you just created is In progress. This status progressively updates as workers complete your tasks. When all tasks are successfully completed, the status changes to Completed. If an issue occurs while creating the labeling job, its status changes to Failed.

To view more details about the job, choose the labeling job name.

Next Steps

After your labeling job status changes to Completed, you can view your output data in the Amazon S3 bucket that you specified while creating that labeling job. For details about the format of your output data, see Output Data (p. 890).

Create a Labeling Job (API)

To create a labeling job using the Amazon SageMaker API, you use the CreateLabelingJob operation. For specific instructions on creating a labeling job for a built-in task type, see that task type page. To learn how to create a streaming labeling job, which is a labeling job that runs perpetually, see Create a Streaming Labeling Job (p. 828).

To use the CreateLabelingJob operation, you need the following:

- A worker task template (UiTemplateS3Uri) or human task UI ARN (HumanTaskUiArn) in Amazon S3.
- For 3D point cloud jobs, video object detection and tracking jobs, and NER jobs, use the ARN listed in HumanTaskUiArn for your task type.
- If you are using a built-in task type other than 3D point cloud tasks, you can add your worker instructions to one of the pre-built templates and save the template (using a .html or .liquid extension) in your S3 bucket. Find the pre-build templates on your task type page.
Create a Labeling Job

• If you are using a custom labeling workflow, you can create a custom template and save the template in your S3 bucket. To learn how to build a custom worker template, see Step 2: Creating your custom worker task template (p. 786). For custom HTML elements that you can use to customize your template, see Crowd HTML Elements Reference (p. 1002). For a repository of demo templates for a variety of labeling tasks, see Amazon SageMaker Ground Truth Sample Task UIs.

• An input manifest file that specifies your input data in Amazon S3. Specify the location of your input manifest file in ManifestS3Uri. For information about creating an input manifest, see Input Data (p. 848). If you create a streaming labeling job, this is optional. To learn how to create a streaming labeling job, see Create a Streaming Labeling Job (p. 828).

• An Amazon S3 bucket to store your output data. You specify this bucket, and optionally, a prefix in S3OutputPath.

• A label category configuration file. Each label category name must be unique. Specify the location of this file in Amazon S3 using the LabelCategoryConfigS3Uri parameter. The format and label categories for this file depend on the task type you use:
  - For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other task types, the minimum number of label categories required is one.
  - For named entity recognition tasks, you must provide worker instructions in this file. See Provide Worker Instructions in a Label Category Configuration File (p. 669) for details and an example.
  - For 3D point cloud and video frame task type, use the format in Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 833).
  - For all other built-in task types and custom tasks, your label category configuration file must be a JSON file in the following format. Identify the labels you want to use by replacing label_1, label_2,...,label_n with your label categories.

```json
{
    "document-version": "2018-11-28",
    "labels": [
        {
            "label": "label_1"
        },
        {
            "label": "label_2"
        },
        ...
    ],
    "label": "label_n"
}
```

• An AWS Identity and Access Management (IAM) role with the AmazonSageMakerGroundTruthExecution managed IAM policy attached and with permissions to access your S3 buckets. Specify this role in RoleArn. To learn more about this policy, see Use IAM Managed Policies with Ground Truth (p. 931). If you require more granular permissions, see the section called "IAM Permissions" (p. 931).

If your input or output bucket name does not contain sagemaker, you can attach a policy similar to the following to the role that is passed to the CreateLabelingJob operation.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject"],
            "Resource": ["arn:aws:s3:::my_input_bucket/*"]
        },
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject"],
            "Resource": ["arn:aws:s3:::my_output_bucket/*"]
        }
    ]
}
```
A pre-annotation and post-annotation (or annotation-consolidation) AWS Lambda function Amazon Resource Name (ARN) to process your input and output data.

- Lambda functions are predefined in each AWS Region for built-in task types. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

- For custom labeling workflows, you must provide a custom pre- and post-annotation Lambda ARN. To learn how to create these Lambda functions, see Step 3: Processing with AWS Lambda (p. 792).

- A work team ARN that you specify in WorkteamArn. You receive a work team ARN when you subscribe to a vendor workforce or create a private workteam. If you are creating a labeling job for a video frame or point cloud task type, you cannot use the Amazon Mechanical Turk workforce. For all other task types, to use the Mechanical Turk workforce, use the following ARN. Replace region with the AWS Region you are using to create the labeling job.

  arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default

If you use the Amazon Mechanical Turk workforce, use the ContentClassifiers parameter in DataAttributes of InputConfig to declare that your content is free of personally identifiable information and adult content.

Ground Truth requires that your input data is free of personally identifiable information (PII) if you use the Mechanical Turk workforce. If you use Mechanical Turk and do not specify that your input data is free of PII using the FreeOfPersonallyIdentifiableInformation flag, your labeling job will fail. Use the FreeOfAdultContent flag to declare that your input data is free of adult content. SageMaker may restrict the Amazon Mechanical Turk workers that can view your task if it contains adult content.

To learn more about work teams and workforces, see Create and Manage Workforces (p. 977).

- If you use the Mechanical Turk workforce, you must specify the price you'll pay workers for performing a single task in PublicWorkforceTaskPrice.

- To configure the task, you must provide a task description and title using TaskDescription and TaskTitle respectively. Optionally, you can provide time limits that control how long the workers have to work on an individual task (TaskTimeLimitInSeconds) and how long tasks remain in the worker portal, available to workers (TaskAvailabilityLifetimeInSeconds).

- (Optional) For some task types, you can have multiple workers label a single data object by inputting a number greater than one for the NumberOfHumanWorkersPerDataObject parameter. For more information about annotation consolidation, see Consolidate Annotations (p. 920).

- (Optional) To create an automated data labeling job, specify one of the ARNs listed in LabelingJobAlgorithmSpecificationArn in LabelingJobAlgorithmsConfig. This ARN identifies the algorithm used in the automated data labeling job. The task type associated with this ARN must match the task type of the PreHumanTaskLambdaArn and AnnotationConsolidationLambdaArn you specify. Automated data labeling is supported for the following task types: image classification, bounding box, semantic segmentation, and text classification. The minimum number of objects allowed for automated data labeling is 1,250, and we strongly suggest providing a minimum of 5,000 objects. To learn more about automated data labeling jobs, see Automate Data Labeling (p. 921).

- (Optional) You can provide StoppingConditions that cause the labeling job to stop if one the conditions is met. You can use stopping conditions to control the cost of the labeling job.
Examples

The following code examples demonstrate how to create a labeling job using CreateLabelingJob. For additional examples, we recommend you use one of the Ground Truth Labeling Jobs Jupyter notebooks in the SageMaker Examples section of a SageMaker notebook instance. To learn how to use a notebook example from the SageMaker Examples, see Example Notebooks (p. 330). You can also see these example notebooks on GitHub in the SageMaker Examples repository.

AWS SDK for Python (Boto3)

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job for a built-in task type in the US East (N. Virginia) Region using a private workforce. Replace all red-italicized text with your labeling job resources and specifications.

```python
response = client.create_labeling_job(
    LabelingJobName="example-labeling-job",
    LabelAttributeName="label",
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': "s3://bucket/path/manifest-with-input-data.json"
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                "FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent",
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': "s3://bucket/path/file-to-store-output-data",
        'KmsKeyId': "string"
    },
    RoleArn="arn:aws:iam::*:role/*",
    LabelCategoryConfigS3Uri="s3://bucket/path/label-categories.json",
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': "arn:aws:sagemaker:region:::workteam/private-crowd/*",
        'UiConfig': {
            'UiTemplateS3Uri': "s3://bucket/path/custom-worker-task-template.html"
        },
        'TaskKeywords': [
            "Images",
            "Classification",
            "Multi-label"
        ],
        'TaskTitle': "Multi-label image classification task",
        'TaskDescription': "Select all labels that apply to the images shown",
        'NumberOfHumanWorkersPerDataObject': 1,
        'TaskTimeLimitInSeconds': 3600,
        'TaskAvailabilityLifetimeInSeconds': 21600,
        'MaxConcurrentTaskCount': 1000,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': "arn:aws:lambda:us-east-1:432418664414:function:ACS-"
        },
    },
    Tags=[
        {'Key': "string",
```
AWS CLI

The following is an example of an AWS CLI request to create a labeling job for a built-in task type in the US East (N. Virginia) Region using the Amazon Mechanical Turk workforce. For more information, see start-human-loop in the AWS CLI Command Reference. Replace all red-italicized text with your labeling job resources and specifications.

```bash
$ aws --region us-east-1 sagemaker create-labeling-job \
--labeling-job-name "example-labeling-job" \
--label-attribute-name "label" \
--role-arn "arn:aws:iam::account-id:role/role-name" \
--input-config '{
    "DataAttributes": {
        "ContentClassifiers": [
            "FreeOfPersonallyIdentifiableInformation",
            "FreeOfAdultContent"
        ],
        "DataSource":{
            "S3DataSource": {
                "ManifestS3Uri": "s3://bucket/path/manifest-with-input-data.json"
            }
        }
    }
} \
--output-config '{
    "KmsKeyId": "",
    "S3OutputPath": "s3://bucket/path/file-to-store-output-data"
} \
--human-task-config '{
    "AnnotationConsolidationLambdaArn": "arn:aws:lambda:us-east-1:432418664414:function:ACS-",
    "TaskAvailabilityLifetimeInSeconds": 21600,
    "TaskTimeLimitInSeconds": 3600,
    "NumberOfHumanWorkersPerDataObject": 1,
    "WorkteamArn": "arn:aws:sagemaker:us-east-1:394669845002:workteam/public-crowd/default",
    "PublicWorkforceTaskPrice": {
        "AmountInUsd": {
            "Dollars": 0,
            "TenthFractionsOfACent": 6,
            "Cents": 3
        }
    },
    "TaskDescription": "Select all labels that apply to the images shown",
    "MaxConcurrentTaskCount": 1000,
    "TaskTitle": "Multi-label image classification task",
    "TaskKeywords": [
        "Images",
        "Classification",
        "Multi-label"
    ],
    "UiConfig": {
        "UiTemplateS3Uri": "s3://bucket/path/custom-worker-task-template.html"
    }
}'
```
For more information about this operation, see CreateLabelingJob. For information about how to use other language-specific SDKs, see See Also in the CreateLabelingJobs topic.

Create a Streaming Labeling Job

Streaming labeling jobs enable you to send individual data objects in real time to a perpetually running, streaming labeling job. To create a streaming labeling job, you must create an Amazon SNS input topic and specify this topic in CreateLabelingJob parameters InputConfig of SnsDataSource. Optionally, you can also create an Amazon SNS output topic and specify it in OutputConfig if you want to receive label data in real time.

Important
If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review Ground Truth Streaming Labeling Jobs (p. 852) before creating a streaming labeling job.

Use the following sections to create the resources that you need and can use to create a streaming labeling job:

- Learn how to create SNS topics with the permissions required for Ground Truth streaming labeling jobs by following the steps in Create Amazon SNS Input and Output Topics (p. 828). Your SNS topics must be created in the same AWS Region as your labeling job.
- See Subscribe an Endpoint to Your Amazon SNS Output Topic (p. 830) to learn how to set up an endpoint to receive labeling task output data at a specified endpoint each time a labeling task is completed.
- To learn how to configure your Amazon S3 bucket to send notifications to your Amazon SNS input topic, see Set up Amazon S3 Bucket Event Notifications (p. 831).
- Optionally, add data objects that you want to have labeled as soon as the labeling job starts to your input manifest. For more information, see Create a Manifest File (Optional) (p. 831).
- There are other resources required to create a labeling job, such as an IAM role, Amazon S3 bucket, a worker task template and label categories. These are described in the Ground Truth documentation on creating a labeling job. For more information, see Create a Labeling Job (p. 817).

Important
When you create a labeling job you must provide an IAM execution role. Attach the AWS managed policy AmazonSageMakerGroundTruthExecution to this role to ensure it has required permissions to execute your labeling job.

When you submit a request to create a streaming labeling job, the state of your labeling job is Initializing. Once the labeling job is active, the state changes to InProgress. Do not send new data objects to your labeling job or attempt to stop your labeling job while it is in the Initializing state. Once the state changes to InProgress, you can start sending new data objects using Amazon SNS and the Amazon S3 configuration.

Topics
- Create Amazon SNS Input and Output Topics (p. 828)
- Set up Amazon S3 Bucket Event Notifications (p. 831)
- Create a Manifest File (Optional) (p. 831)
- Example: Use SageMaker API To Create Streaming Labeling Job (p. 831)
- Stop a Streaming Labeling Job (p. 832)

Create Amazon SNS Input and Output Topics

You need to create an Amazon SNS input to create a streaming labeling job. Optionally, you may provide an Amazon SNS output topic.
When you create an Amazon SNS topic to use in your streaming labeling job, note down the topic Amazon Resource Name (ARN). The ARN will be the input values for the parameter SnsTopicArn in InputConfig and OutputConfig when you create a labeling job.

**Create an Input Topic**

Your input topic is used to send new data objects to Ground Truth. To create an input topic, follow the instructions in [Creating an Amazon SNS topic](https://docs.aws.amazon.com/AmazonSNS/latest/dg/sns-topic-create.html) in the Amazon Simple Notification Service Developer Guide.

Note down your input topic ARN and use it as input for the CreateLabelingJob parameter SnsTopicArn in InputConfig.

**Create an Output Topic**

If you provide an output topic, it is used to send notifications when a data object is labeled. When you create a topic, you have the option to add an encryption key. Use this option to add a AWS Key Management Service customer managed key to your topic to encrypt the output data of your labeling job before it is published to your output topic.

To create an output topic, follow the instructions in [Creating an Amazon SNS topic](https://docs.aws.amazon.com/AmazonSNS/latest/dg/sns-topic-create.html) in the Amazon Simple Notification Service Developer Guide.

If you add encryption, you must attach additional permission to the topic. See [Add Encryption to Your Output Topic (Optional) (p. 829)] for more information.

**Important**

To add a customer managed key to your output topic while creating a topic in the console, do not use the (Default) alias/aws/sns option. Select a customer managed key that you created.

Note down your input topic ARN and use it in your CreateLabelingJob request in the parameter SnsTopicArn in OutputConfig.

**Add Encryption to Your Output Topic (Optional)**

To encrypt messages published to your output topic, you need to provide an AWS KMS customer managed key to your topic. Modify the following policy and add it to your customer managed key to give Ground Truth permission to encrypt output data before publishing it to your output topic.

Replace `<account_id>` with the ID of the account that you are using to create your topic. To learn how to find your AWS account ID, see [Finding Your AWS Account ID](https://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html).

```json
{
  "Id": "key-console-policy",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<account_id>:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<account_id>:role/Admin"
      }
    }
  ]
}
```

829
Additionally, you must modify and add the following policy to the execution role that you use to create your labeling job (the input value for RoleArn).

Replace `<account_id>` with the ID of the account that you are using to create your topic. Replace `<region>` with the AWS Region you are using to create your labeling job. Replace `<key_id>` with your customer managed key ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "sid1",
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": "arn:aws:kms:<region>:<account_id>:key/<key_id>"
    }
  ]
}
```

For more information on creating and securing keys, see Creating Keys and Using Key Policies in the AWS Key Management Service Developer Guide.

**Subscribe an Endpoint to Your Amazon SNS Output Topic**

When a worker completes a labeling job task from a Ground Truth streaming labeling job, Ground Truth uses your output topic to publish output data to one or more endpoints that you specify. To receive notifications when a worker finishes a labeling task, you must subscribe an endpoint to your Amazon SNS output topic.

To learn how to add endpoints to your output topic, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

To learn more about the output data format that is published to these endpoints, see Output Data (p. 890).

**Important**

If you do not subscribe an endpoint to your Amazon SNS output topic, you will not receive notifications when new data objects are labeled.
Set up Amazon S3 Bucket Event Notifications

You can add an event notification to your Amazon S3 bucket using the Amazon S3 console, API, and language specific AWS SDKs, or the AWS Command Line Interface. Set up this event to send notifications to the same Amazon SNS input topic that you specify using SnsTopicArn in InputConfig when you create a labeling job. Do not set up event notifications using the same Amazon S3 location that you specified for S3OutputPath in OutputConfig – doing so may result in unwanted data objects being processed by Ground Truth for labeling.

You decide the types of events that you want to send to your Amazon SNS topic. Ground Truth creates a labeling job when you send object creation events.

The event structure sent to your Amazon SNS input topic must be a JSON message formatted using the same structure found in Event message structure.

To see examples of how you can set up an event notification for your Amazon S3 bucket using the Amazon S3 console, AWS SDK for .NET, and AWS SDK for Java, follow this walkthrough, Walkthrough: Configure a bucket for notifications (SNS topic or SQS queue) in the Amazon Simple Storage Service User Guide.

Create a Manifest File (Optional)

When you create a streaming labeling job, you have the one time option to add objects (such as images or text) to an input manifest file that you specify in ManifestS3Uri of CreateLabelingJob. When the streaming labeling job starts, these objects are sent to workers or added to the Amazon SQS queue if the total number of objects exceed MaxConcurrentTaskCount. The results are added to the Amazon S3 path that you specify when creating the labeling job periodically as workers complete labeling tasks. Output data is sent to any endpoint that you subscribe to your output topic.

If you want to provide initial objects to be labeled, create a manifest file that identifies these objects and place it in Amazon S3. Specify the S3 URI of this manifest file in ManifestS3Uri within InputConfig.

To learn how to format your manifest file, see Input Data (p. 848). To use the SageMaker console to automatically generate a manifest file (not supported for 3D point cloud task types), see Automated Data Setup (p. 850).

Example: Use SageMaker API To Create Streaming Labeling Job

The following is an example of an AWS Python SDK (Boto3) request that you can use to start a streaming labeling job for a built-in task type in the US East (N. Virginia) Region. For more details about each parameter below see CreateLabelingJob. To learn how you can create a labeling job using this API and associated language specific SDKs, see Create a Labeling Job (API).

In this example, note the following parameters:

- SnsDataSource – This parameter appears in InputConfig and OutputConfig and is used to identify your input and output Amazon SNS topics respectively. To create a streaming labeling job, you are required to provide an Amazon SNS input topic. Optionally, you can also provide an Amazon SNS output topic.
- S3DataSource – This parameter is optional. Use this parameter if you want to include an input manifest file of data objects that you want labeled as soon as the labeling job starts.
- StoppingConditions – This parameter is ignored when you create a streaming labeling job. To learn more about stopping a streaming labeling job, see Stop a Streaming Labeling Job (p. 832).
- Streaming labeling jobs do not support automated data labeling. Do not include the LabelingJobAlgorithmsConfig parameter.

```python
response = client.create_labeling_job(
```
Create a Labeling Job

```python
LabelingJobName='example-labeling-job',
LabelAttributeName='label',
InputConfig={
    'DataSource': {
        'S3DataSource': {
            'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
        },
        'SnsDataSource': {
            'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-input-topic'
        }
    },
    'DataAttributes': {
        'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']
    }
},
OutputConfig={
    'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
    'KmsKeyId': 'string',
    'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-output-topic'
},
RoleArn='arn:aws:iam::*:role/*',

        'Value': 'string'
    }
]
```

Stop a Streaming Labeling Job

You can manually stop your streaming labeling job using the operation StopLabelingJob.

If your labeling job remains idle for over 10 days, it is automatically stopped by Ground Truth. In this context, a labeling job is considered idle if no objects are sent to the Amazon SNS input topic and no objects remain in your Amazon SQS queue, waiting to be labeled. For example, if no data objects are fed to the Amazon SNS input topic and all the objects fed to the labeling job are already labeled, Ground Truth starts a timer. After the timer starts, if no items are received within a 10 day period, the labeling job is stopped.
When a labeling job is stopped, its status is STOPPING while Ground Truth cleans up labeling job resources and unsubscribes your Amazon SNS topic from your Amazon SQS queue. The Amazon SQS is not deleted by Ground Truth because this queue may contain unprocessed data objects. You should manually delete the queue if you want to avoid incurring additional charges from Amazon SQS. To learn more, see Amazon SQS pricing.

Create a Labeling Category Configuration File with Label Category and Frame Attributes

When you create a 3D point cloud or video frame labeling job using the Amazon SageMaker API operation CreateLabelingJob, you use a label category configuration file to specify your labels and worker instructions. Optionally, you can also provide the following in your label category attribute file:

- You can provide label category attributes for video frame and 3D point cloud object tracking and object detection task types. Workers can use one or more attributes to give more information about an object. For example, you may want to use the attribute occluded to have workers identify when an object is partially obstructed. You can either specify a label category attribute for a single label using the categoryAttributes parameter, or for all labels using the categoryGlobalAttributes parameter.

- You can provide frame attributes for video frame and 3D point cloud object tracking and object detection task types using frameAttributes. When you create a frame attribute, it appears on each frame or point cloud in the worker task. In video frame labeling jobs, these are attributes that workers assign to an entire video frame. For 3D point cloud labeling jobs, these attributes are applied to a single point cloud. Use frame attributes to have workers provide more information about the scene in a specific frame or point cloud.

- For video frame labeling jobs, you use the label category configuration file to specify the task type (bounding box, polyline, polygon, or keypoint) sent to workers.

For workers, specifying values for label category attributes and frame attributes will be optional.

**Important**
You should only provide a label attribute name in auditLabelAttributeName if you are running an audit job to verify or adjust labels. Use this parameter to input the LabelAttributeName used in the labeling job that generated the annotations you want your worker to adjust. When you create a labeling job in the console, if you did not specify a label attribute name, the Name of your job is used as the LabelAttributeName.

**Topics**
- Label Category Configuration File Schema (p. 833)
- Example: Label Category Configuration Files for 3D Point Cloud Labeling Jobs (p. 840)

Create a Labeling Job

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>annotationType (only supported for video frame labeling jobs)</td>
<td>No</td>
<td>String</td>
<td>Use this to specify the task type for your video frame labeling jobs. For example, for a polygon video frame object detection task, choose Polygon. If you do not specify an annotationType when you create a video frame labeling job, Ground Truth will use BoundingBox by default.</td>
</tr>
<tr>
<td>instructions</td>
<td>No</td>
<td>A JSON object</td>
<td>Use this parameter to add worker instructions to help your workers complete their tasks. For more information about worker instructions, see Worker Instructions (p. 746). Short instructions must be under 255 characters and long instruction must be under 2,048 characters. For more information, see Creating Worker Instructions (p. 847).</td>
</tr>
<tr>
<td>auditLabelAttributeName</td>
<td>Required for adjustment and verification task types</td>
<td>String</td>
<td>Enter the LabelAttributeName used in the labeling job you want to adjust annotations of. Only use this parameter if you are creating an adjustment job for video frame and 3D point cloud object detection, object tracking, or 3D point cloud semantic segmentation.</td>
</tr>
</tbody>
</table>

The following table describes the parameters that you can and must use to create a list of Labels. Each parameter should be included in a JSON object.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>Yes</td>
<td>String</td>
<td>The name of the label category that is displayed to workers. Each label category name must be unique.</td>
</tr>
<tr>
<td>categoryAttributes</td>
<td>No</td>
<td>A list of JSON objects. Use this parameter to add label category attributes to specific labels you specify in labels. To add one or more label category attributes to a label, include the categoryAttributes JSON object in the same labels JSON object as that label. See the following table for more information.</td>
<td></td>
</tr>
<tr>
<td>editsAllowed</td>
<td>No</td>
<td>String</td>
<td>Specifies whether or not a label can be edited by workers. For video frame or 3D point cloud adjustment labeling jobs, add this parameter to one or more JSON objects in the labels list to specify whether or not a worker can edit a label. For 3D point cloud and video frame verification labeling jobs, add this parameter with the value &quot;none&quot; to each JSON object in the labels list. This will make all labels uneditable.</td>
</tr>
</tbody>
</table>

The following table describes the parameters that you can and must use to create a frame attributes using `frameAttributes` and label category attribute using the `categoryGlobalAttributes` and `categoryAttributes` parameters.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Yes</td>
<td>String</td>
<td>Use this parameter to assign a name to your label category or frame attribute. This is the attribute name that workers see. Each label category attribute name in your label category configuration file must be unique. Global label category attributes and label specific label category attributes cannot have the same name.</td>
</tr>
</tbody>
</table>
| type      | Yes      | String          | Use this parameter to define the label category or frame attribute type. Required Values: "string" or "number"  
If you specify "string" for type and provide an enum value for this attribute, workers will be able to choose from one of the choices you provide.  
If you specify "string" for type and do not provide an enum value, workers can enter free form text.  
If you specify number for type, worker can enter a number between the minimum and maximum numbers you specify. |
<p>| enum      | No       | List of strings | Use this parameter to define options that workers can choose from for this label category or frame attribute. Workers can choose one value specified in enum. For example, if you specify [&quot;foo&quot;, &quot;buzz&quot;, |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>&quot;bar&quot; for enum, workers can choose one of foo, buzz, or bar. You must specify &quot;string&quot; for type to use an enum list.</td>
<td></td>
</tr>
<tr>
<td>description</td>
<td>frameAttributes: Yes, categoryAttributes or categoryGlobalAttributes: No</td>
<td>String</td>
<td>Use this parameter to add a description of the label category or frame attribute. You can use this field to give workers more information about the attribute. This field is only required for frame attributes.</td>
</tr>
<tr>
<td>minimum and maximum</td>
<td>Required if attribute type is &quot;number&quot;</td>
<td>Integers</td>
<td>Use these parameters to specify minimum and maximum (inclusive) values workers can enter for numeric label category or frame attributes. You must specify &quot;number&quot; for type to use minimum and maximum.</td>
</tr>
<tr>
<td>editsAllowed</td>
<td>No</td>
<td>String</td>
<td>Specifies whether or not a label category or frame attribute can be edited by workers. For video frame or 3D point cloud adjustment and verification labeling jobs, add this parameter to label category and frame attribute JSON objects to specify whether or not a worker can edit an attribute.</td>
</tr>
</tbody>
</table>

**Required Values:**
- "none": no modifications are not allowed.
- or
- "any" (Default): all modifications are allowed.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isRequired</td>
<td>No</td>
<td>Boolean</td>
<td>Specifies whether workers are required to annotate an attribute. Workers cannot submit the job until all required attributes are annotated.</td>
</tr>
</tbody>
</table>

**Label and label category attribute quotas**

You can specify up to 10 label category attributes per class. This 10-attribute quotas includes global label category attributes. For example, if you create four global label category attributes, and then assign three label category attributes to label X, that label will have $4+3=7$ label category attributes in total. For all label category and label category attribute limits, refer to the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labels (Labels)</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>Label name character quota</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Label category attributes per label (sum of categoryAttributes and categoryGlobalAttributes)</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>Free form text entry label category attributes per label (sum of categoryAttributes and categoryGlobalAttributes)</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>Frame attributes</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>Free form text entry attributes in frameAttributes</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>Attribute name character quota (name)</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Attribute description character quota (description)</td>
<td>0</td>
<td>128</td>
</tr>
<tr>
<td>Attribute type characters quota (type)</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Allowed values in the enum list for a string attribute</td>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>Character quota for a value in enum list</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Maximum characters in free form text response for free form text frameAttributes</td>
<td>0</td>
<td>1000</td>
</tr>
</tbody>
</table>
Create a Labeling Job

<table>
<thead>
<tr>
<th>Type</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum characters in free form text response for free form text categoryAttributes and categoryGlobalAttributes</td>
<td>0</td>
<td>80</td>
</tr>
</tbody>
</table>

**Example: Label Category Configuration Files for 3D Point Cloud Labeling Jobs**

Select a tab in the following tables to see examples of 3D point cloud label category configuration files for object detection, object tracking, semantic segmentation, adjustment, and verification labeling jobs.

**3D Point Cloud Object Tracking and Object Detection**

The following is an example of a label category configuration file that includes label category attributes for a 3D point cloud object detection or object tracking labeling job. This example includes a two frame attributes, which will be added to all point clouds submitted to the labeling job. The Car label will include four label category attributes—X, Y, Z, and the global attribute, W.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players to you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"],
      "isRequired": true
    }
  ],
  "categoryGlobalAttributes": [
    {
      "name": "W",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buzz", "biz"]
    }
  ],
  "labels": [
    {
      "label": "Car",
      "categoryAttributes": [
        {
          "name": "X",
          "description": "enter a number",
          "type": "number",
        },
        {
          "name": "Y",
          "description": "select an option",
          "type": "string",
          "enum": ["y1", "y2"]
        },
        {
          "name": "Z",
          "description": "submit a free-form response",
          "type": "string",
        }
      ]
    }
  ]
}
```
3D Point Cloud Semantic Segmentation

The following is an example of a label category configuration file for a 3D point cloud semantic segmentation labeling job.

Label category attributes are not supported for 3D point cloud semantic segmentation task types. Frame attributes are supported. If you provide label category attributes for a semantic segmentation labeling job, they will be ignored.

```
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players to you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "labels": [
    {
      "label": "Car",
      "categoryAttributes": [...]
    },
    {
      "label": "Pedestrian",
      "categoryAttributes": [...]  
    },
    {
      "label": "Cyclist",
    }
  ],
  "instructions": {
    "shortInstruction": "Draw a tight Cuboid",
    "fullInstruction": "<html markup>"
  }
}
```

Select a tab in the following table to see an example of a label category configuration file for 3D point cloud verification or adjustment labeling jobs.

### 3D Point Cloud Adjustment

The following is an example of a label category configuration file for a 3D point cloud object detection or object tracking adjustment labeling job. For 3D point cloud semantic segmentation adjustment labeling jobs, categoryGlobalAttributes and categoryAttributes are not supported.
You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the adjustment labeling job. Optionally, you can use the `editsAllowed` parameter to specify whether or not a label or frame attribute can be edited.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players do you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "editsAllowed": "none",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "categoryGlobalAttributes": [
    {
      "name": "W",
      "editsAllowed": "any",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buzz", "biz"]
    }
  ],
  "labels": [
    {
      "label": "Car",
      "editsAllowed": "any",
      "categoryAttributes": [
        {
          "name": "X",
          "description": "enter a number",
          "type": "number"
        },
        {
          "name": "Y",
          "description": "select an option",
          "type": "string",
          "enum": ["y1", "y2"],
          "editsAllowed": "any"
        },
        {
          "name": "Z",
          "description": "submit a free-form response",
          "type": "string",
          "editsAllowed": "none"
        }
      ]
    },
    {
      "label": "Pedestrian",
      "categoryAttributes": [
        ...
      ]
    }
  ],
  "instructions": {
    "shortInstruction": "Draw a tight Cuboid",
    "fullInstruction": "<html
markup>"},
// include auditLabelAttributeName for label adjustment jobs
"auditLabelAttributeName": "myPrevJobLabelAttributeName"
}
```
3D Point Cloud Verification

The following is an example of a label category configuration file you may use for a 3D point cloud object detection or object tracking verification labeling job. For a 3D point cloud semantic segmentation verification labeling job, categoryGlobalAttributes and categoryAttributes are not supported.

You must include auditLabelAttributeName to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Additionally, you must use the editsAllowed parameter to specify that no labels can be edited.

```
{
   "documentVersion": "2020-03-01",
   "frameAttributes": [
   {
      "name": "count players",
      "editsAllowed": "any",
      "description": "How many players to you see in the scene?",
      "type": "number"
   },
   {
      "name": "select one",
      "editsAllowed": "any",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
   }
   ],
   "categoryGlobalAttributes": [
   {
      "name": "W",
      "editsAllowed": "none",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buzz", "biz"]
   }
   ],
   "labels": [
   {
      "label": "Car",
      "editsAllowed": "none",
      "categoryAttributes": [
      {
         "name": "X",
         "description": "enter a number",
         "type": "number",
         "editsAllowed": "none"
      },
      {
         "name": "Y",
         "description": "select an option",
         "type": "string",
         "enum": ["y1", "y2"],
         "editsAllowed": "any"
      },
      {
         "name": "Z",
         "description": "submit a free-form response",
         "type": "string",
         "edits Allowed": "none"
      }
      ]
   }
   ]
}
```
Example: Label Category Configuration Files for Video Frame Labeling Jobs

The annotation tools available to your worker and task type used depends on the value you specify for annotationType. For example, if you want workers to use key points to track changes in the pose of specific objects across multiple frames, you would specify Keypoint for the annotationType. If you do not specify an annotation type, BoundingBox will be used by default.

The following is an example of a video frame keypoint label category configuration file with label category attributes. This example includes two frame attributes, which will be added to all frames submitted to the labeling job. The Car label will include four label category attributes—X, Y, Z, and the global attribute, W.

```json
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name": "count players",
            "description": "How many players to you see in the scene?",
            "type": "number"
        },
        {
            "name": "select one",
            "description": "describe the scene",
            "type": "string",
            "enum": ["clear", "blurry"]
        }
    ],
    "categoryGlobalAttributes": [
        {
            "name": "W",
            "description": "label-attributes-for-all-labels",
            "type": "string",
            "enum": ["foo", "buz", "buz2"]
        }
    ],
    "labels": [
        {
            "label": "Car",
            "categoryAttributes": [
                {
                    "name": "X",
                    "description": "enter a number",
                    "type": "number"
                },
                {
                    "name": "Y",
                    "description": "select an option",
                    "type": "string",
                    "enum": ["y1", "y2"]
                }
            ]
        }
    ]
}
```
Select a tab from the following table to see examples of label category configuration files for video frame adjustment and verification labeling jobs.

Video Frame Adjustment

The following is an example of a label category configuration file you may use for a video frame adjustment labeling job.

You must include auditLabelAttributeName to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Optionally, you can use the editsAllowed parameter to specify whether or not labels, label category attributes, or frame attributes can be edited.
Video Frame Verification

The following is an example of a label category configuration file for a video frame labeling job.

You must include auditLabelAttributeName to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Additionally, you must use the editsAllowed parameter to specify that no labels can be edited.

```json
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name": "count players",
            "editsAllowed": "none",
            "description": "How many players do you see in the scene?",
            "type": "number"
        },
        {
            "name": "select one",
            "editsAllowed": "any",
            "description": "Describe the scene",
            "type": "string",
            "enum": ["clear", "blurry"]
        }
    ],
    "categoryGlobalAttributes": [
        {
            "name": "W",
            "editsAllowed": "none",
            "description": "label-attributes-for-all-labels",
            "type": "string",
            "enum": ["foo", "buz", "buz2"]
        }
    ],
    "labels": [
        
    ]
}
```
Creating Worker Instructions

Create custom instructions for labeling jobs to improve your worker's accuracy in completing their task. Your instructions are accessible when workers select the Instructions menu option in the worker UI. Short instructions must be under 255 characters and long instruction must be under 2,048 characters.

There are two kinds of instructions:

- **Short instructions** – These instructions are shown to workers when they select Instructions in the worker UI menu. They should provide an easy reference to show the worker the correct way to label an object.

- **Full instructions** – These instructions are shown when workers select More Instructions in instructions the pop-up window. We recommend that you provide detailed instructions for completing the task with multiple examples showing edge cases and other difficult situations for labeling objects.

For 3D point cloud and video frame labeling jobs, you can add worker instructions to your label category configuration file. You can use a single string to create instructions or you can add HTML mark up to customize the appearance of your instructions and add images. Make sure that any images you include in your instructions are publicly available, or if your instructions are in Amazon S3, that your workers have read-access so that they can view them.
Use Input and Output Data

The input data that you provide to Amazon SageMaker Ground Truth is sent to your workers for labeling. You choose the data to send to your workers by creating a single manifest file that defines all of the data that requires labeling or by sending input data objects to an ongoing, streaming labeling job to be labeled in real time.

The output data is the result of your labeling job. The output data file, or augmented manifest file, contains label data for each object you send to the labeling job and metadata about the label assigned to data objects.

When you use image classification (single and multi-label), text classification (single and multi-label), object detection, and semantic segmentation built in task types to create a labeling job, you can use the resulting augmented manifest file to launch a SageMaker training job. For a demonstration of how to use an augmented manifest to train an object detection machine learning model with Amazon SageMaker, see object_detection_augmented_manifest_training.ipynb. For more information, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2327).

Topics
- Input Data (p. 848)
- 3D Point Cloud Input Data (p. 860)
- Video Frame Input Data (p. 884)
- Output Data (p. 890)

Input Data

The input data are the data objects that you send to your workforce to be labeled. There are two ways to send data objects to Ground Truth for labeling:

- Send a list of data objects that require labeling using an input manifest file.
- Send individual data objects in real time to a perpetually running, streaming labeling job.

If you have a dataset that needs to be labeled one time, and you do not require an ongoing labeling job, create a standard labeling job using an input manifest file.

If you want to regularly send new data objects to your labeling job after it has started, create a streaming labeling job. When you create a streaming labeling job, you can optionally use an input manifest file to specify a group of data that you want labeled immediately when the job starts. You can continuously send new data objects to a streaming labeling job as long as it is active.

Note
Streaming labeling jobs are only supported through the SageMaker API. You cannot create a streaming labeling job using the SageMaker console.

The following task types have special input data requirements and options:

- For 3D point cloud labeling job input data requirements, see 3D Point Cloud Input Data (p. 860).
- For video frame labeling job input data requirements, see Video Frame Input Data (p. 884).

Topics
- Use an Input Manifest File (p. 849)
- Automated Data Setup (p. 850)
- Supported Data Formats (p. 851)
- Ground Truth Streaming Labeling Jobs (p. 852)
Use an Input Manifest File

Each line in an input manifest file is an entry containing an object, or a reference to an object, to label. An entry can also contain labels from previous jobs and for some task types, additional information.

Input data and the manifest file must be stored in Amazon Simple Storage Service (Amazon S3). Each has specific storage and access requirements, as follows:

- The Amazon S3 bucket that contains the input data must be in the same AWS Region in which you are running Amazon SageMaker Ground Truth. You must give Amazon SageMaker access to the data stored in the Amazon S3 bucket so that it can read it. For more information about Amazon S3 buckets, see Working with Amazon S3 buckets.
- The manifest file must be in the same AWS Region as the data files, but it doesn't need to be in the same location as the data files. It can be stored in any Amazon S3 bucket that is accessible to the AWS Identity and Access Management (IAM) role that you assigned to Ground Truth when you created the labeling job.

**Note**

3D point cloud and video frame task types have different input manifest requirements and attributes. For **3D point cloud task types**, refer to Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 862). For **video frame task types**, refer to Create a Video Frame Input Manifest File (p. 889).

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \n. Because each line must be a valid JSON object, you can't have unescaped line break characters. For more information about data format, see JSON Lines.

Each JSON object in the manifest file can be no larger than 100,000 characters. No single attribute within an object can be larger than 20,000 characters. Attribute names can't begin with $(dollar sign).

Each JSON object in the manifest file must contain one of the following keys: source-ref or source. The value of the keys are interpreted as follows:

- **source-ref** – The source of the object is the Amazon S3 object specified in the value. Use this value when the object is a binary object, such as an image.
- **source** – The source of the object is the value. Use this value when the object is a text value.

The following is an example of a manifest file for files stored in an Amazon S3 bucket:

```json
{"source-ref": "S3 bucket location 1"}
{"source-ref": "S3 bucket location 2"}
..."source-ref": "S3 bucket location n"
```

Use the source-ref key for image files for bounding box, image classification (single and multi-label), semantic segmentation, and video clips for video classification labeling jobs. 3D point cloud and video frame labeling jobs also use the source-ref key but these labeling jobs require additional information in the input manifest file. For more information see 3D Point Cloud Input Data (p. 860) and Video Frame Input Data (p. 884).

The following is an example of a manifest file with the input data stored in the manifest:
Use the `source` key for single and multi-label text classification and named entity recognition labeling jobs.

You can include other key-value pairs in the manifest file. These pairs are passed to the output file unchanged. This is useful when you want to pass information between your applications. For more information, see Output Data (p. 890).

**Automated Data Setup**

You can use the automated data setup to create manifest files for your labeling jobs in the Ground Truth console using images, videos, video frames, text (.txt) files, and comma-separated value (.csv) files stored in Amazon S3. When you use automated data setup, you specify an Amazon S3 location where your input data is stored and the input data type, and Ground Truth looks for the files that match that type in the location you specify.

**Note**

Ground Truth does not use an AWS KMS key to access your input data or write the input manifest file in the Amazon S3 location that you specify. The user or role that creates the labeling job must have permissions to access your input data objects in Amazon S3.

Before using the following procedure, ensure that your input images or files are correctly formatted:

- **Image files** – Image files must comply with the size and resolution limits listed in the tables found in Input File Size Quota (p. 856).
- **Text files** – Text data can be stored in one or more .txt files. Each item that you want labeled must be separated by a standard line break.
- **CSV files** – Text data can be stored in one or more .csv files. Each item that you want labeled must be in a separate row.
- **Videos** – Video files can be any of the following formats: .mp4, .ogg, and .webm. If you want to extract video frames from your video files for object detection or object tracking, see Provide Video Files (p. 886).
- **Video frames** – Video frames are images extracted from a video. All images extracted from a single video are referred to as a sequence of video frames. Each sequence of video frames must have unique prefix keys in Amazon S3. See Provide Video Frames (p. 885). For this data type, see Automated Video Frame Input Data Setup (p. 887).

**Important**

For video frame object detection and video frame object tracking labeling jobs, see Automated Video Frame Input Data Setup (p. 887) to learn how to use the automated data setup.

Use these instructions to automatically set up your input dataset connection with Ground Truth.

**Automatically connect your data in Amazon S3 with Ground Truth**

1. Navigate to the Create labeling job page in the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.

   This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the navigation bar, choose the name of the currently displayed Region.

2. Select Create labeling job.

3. Enter a Job name.
4. In the section **Input data setup**, select **Automated data setup**.
5. Enter an Amazon S3 URI for **S3 location for input datasets**.
6. Specify your **S3 location for output datasets**. This is where your output data is stored.
7. Choose your **Data type** using the dropdown list.
8. Use the drop down menu under **IAM Role** to select an execution role. If you select **Create a new role**, specify the Amazon S3 buckets that you want grant this role permission to access. This role must have permission to access the S3 buckets you specified in Steps 5 and 6.
9. Select **Complete data setup**.

The following GIF demonstrates how to use the automated data setup for image data. This example will create a file, dataset-{YMMDDTHHMMSS}.manifest in the Amazon S3 bucket example-groundtruth-images where YMMDDTHHMMSS indicates the year (YY), month (MM), day (DD) and time in hours (HH), minutes (mm) and seconds (ss), that the input manifest file was created.

### Supported Data Formats

When you create an input manifest file for a **built-in task types** manually, your input data must be in one of the following support file formats for the respective input data type. To learn about automated data setup, see [Automated Data Setup](p. 850).

**Tip**

When you use the automated data setup, additional data formats can be used to generate an input manifest file for video frame and text based task types.

<table>

</tbody>
</table>
Ground Truth Streaming Labeling Jobs

If you want to perpetually send new data objects to Amazon SageMaker Ground Truth to be labeled, use a streaming labeling job. Streaming labeling jobs allow you to:

- Send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it.
- Gain visibility into the number of objects that have been queued and are waiting to be labeled. Use this information to control the flow of data objects sent to your labeling job.
- Receive label data for individual data objects in real time as workers finish labeling them.

Ground Truth streaming labeling jobs remain active until they are manually stopped or have been idle for more than 10 days. You can intermittently send new data objects to workers while the labeling job is active.

If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review How It Works (p. 852).

Use Create a Streaming Labeling Job (p. 828) to learn how to create a streaming labeling job.

Note

Ground Truth streaming labeling jobs are only supported through the SageMaker API.

Topics

- How It Works (p. 852)
- Send Data to a Streaming Labeling Job (p. 852)
- Manage Labeling Requests with an Amazon SQS Queue (p. 854)
- Receive Output Data from a Streaming Labeling Job (p. 854)
- Duplicate Message Handling (p. 854)

How It Works

When you create a Ground Truth streaming labeling job, the job remains active until it is manually stopped, remains idle for more than 10 days, or is unable to access input data sources. You can intermittently send new data objects to workers while it is active. A worker can continue to receive new data objects in real time as long as the total number of tasks currently available to the worker is less than the value in MaxConcurrentTaskCount. Otherwise, the data object is sent to a queue that Ground Truth creates on your behalf in Amazon Simple Queue Service (Amazon SQS) for later processing. These tasks are sent to workers as soon as the total number of tasks currently available to a worker falls below MaxConcurrentTaskCount. If a data object is not sent to a worker after 14 days, it expires. You can view the number of tasks pending in the queue and adjust the number of objects you send to the labeling job. For example, you may decrease the speed at which you send objects to the labeling job if the backlog of pending objects moves above a threshold.

Send Data to a Streaming Labeling Job

You can optionally submit input data to a streaming labeling job one time when you create the labeling job using an input manifest file. Once the labeling job has started and the state is InProgress, you

<table>
<thead>
<tr>
<th>Task Types</th>
<th>Input Data Type</th>
<th>Support Formats</th>
<th>Example Input Manifest Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>3D Point Cloud Object Tracking</td>
<td></td>
<td>Sequence files:</td>
<td>json</td>
</tr>
</tbody>
</table>

Duplicate Message Handling (p. 854)
can submit new data objects to your labeling job in real time using your Amazon SNS input topic and Amazon S3 event notifications.

**Submit Data Objects When you Start the Labeling Job (One Time):**

- **Use an Input Manifest File** – You can optionally specify an input manifest file Amazon S3 URI in `ManifestS3Uri` when you create the streaming labeling job. Ground Truth sends each data object in the manifest file to workers for labeling as soon as the labeling job starts. To learn more, see [Create a Manifest File (Optional)](p. 831).

After you submit a request to create the streaming labeling job, its status will be **Initializing**. Once the labeling job is active, the state changes to **InProgress** and you can start using the real-time options to submit additional data objects for labeling.

**Submit Data Objects in Real Time:**

- **Send data objects using Amazon SNS messages** – You can send Ground Truth new data objects to label by sending an Amazon SNS message. You will send this message to an Amazon SNS input topic that you create and specify when you create your streaming labeling job. For more information, see [Send Data Objects Using Amazon SNS](p. 853).

- **Send data objects by placing them in an Amazon S3 bucket** – Each time you add a new data object to an Amazon S3 bucket, you can prompt Ground Truth to process that object for labeling. To do this, you add an event notification to the bucket so that it notifies your Amazon SNS input topic each time a new object is added to (or created in) that bucket. For more information, see [Send Data Objects using Amazon S3](p. 854). This option is not available for text-based labeling jobs such as text classification and named entity recognition.

**Important**

If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.

**Send Data Objects Using Amazon SNS**

You can send data objects to your streaming labeling job using Amazon Simple Notification Service (Amazon SNS). Amazon SNS is a web service that coordinates and manages the delivery of messages to and from endpoints (for example, an email address or AWS Lambda function). An Amazon SNS topic acts as a communication channel between two or more endpoints. You use Amazon SNS to send, or publish, new data objects to the topic specified in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`. The format of these messages is the same as a single line from an input manifest file.

For example, you may send a piece of text to an active text classification labeling job by publishing it to your input topic. The message that you publish may look similar to the following:

```json
{"source": "Lorem ipsum dolor sit amet"}
```

To send a new image object to an image classification labeling job, your message may look similar to the following:

```json
{"source-ref": "s3://awsexamplebucket/example-image.jpg"}
```

**Note**

You can also include custom deduplication IDs and deduplication keys in your Amazon SNS messages. To learn more, see [Duplicate Message Handling](p. 854).

When Ground Truth creates your streaming labeling job, it subscribes to your Amazon SNS input topic.
Send Data Objects using Amazon S3

You can send one or more new data objects to a streaming labeling job by placing them in an Amazon S3 bucket that is configured with an Amazon SNS event notification. You can set up an event to notify your Amazon SNS input topic anytime a new object is created in your bucket. You must specify this same Amazon SNS input topic in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`.

Anytime you configure an Amazon S3 bucket to send notifications to Amazon SNS, Ground Truth will publish a test event, "s3:TestEvent", to ensure that the topic exists and that the owner of the Amazon S3 bucket specified has permission to publish to the specified topic. It is recommended that you set up your Amazon S3 connection with Amazon SNS before starting a streaming labeling job. If you do not, this test event may register as a data object and be sent to Ground Truth for labeling.

**Important**
- If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.
- For image-based labeling jobs, Ground Truth requires all S3 buckets to have a CORS policy attached. To learn more, see CORS Permission Requirement (p. 930).

Once you have configured your Amazon S3 bucket and created your labeling job, you can add objects to your bucket and Ground Truth either sends that object to workers or places it on your Amazon SQS queue.

To learn more, see Set up Amazon S3 Bucket Event Notifications (p. 831).

**Important**
- This option is not available for text-based labeling jobs such as text classification and named entity recognition.

Manage Labeling Requests with an Amazon SQS Queue

When Ground Truth creates your streaming labeling job, it creates an Amazon SQS queue in the AWS account used to create the labeling job. The queue name is `GroundTruth-labeling_job_name` where `labeling_job_name` is the name of your labeling job, in lowercase letters. When you send data objects to your labeling job, Ground Truth either sends the data objects directly to workers or places the task in your queue to be processed at a later time. If a data object is not sent to a worker after 14 days, it expires and is removed from the queue. You can setup an alarm in Amazon SQS to detect when objects expire and use this mechanism to control the volume of objects you send to your labeling job.

**Important**
- Modifying, deleting, or sending objects directly to the Amazon SQS queue associated with your streaming labeling job may lead to job failures.

Receive Output Data from a Streaming Labeling Job

Your Amazon S3 output bucket is periodically updated with new output data from your streaming labeling job.

Optionally, you can specify an Amazon SNS output topic. Each time a worker submits a labeled object, a notification with the output data is sent to that topic. You can subscribe an endpoint to your SNS output topic to receive notifications or trigger events when you receive output data from a labeling task. Use an Amazon SNS output topic if you want to do real time chaining to another streaming job and receive an Amazon SNS notifications each time a data object is submitted by a worker.

To learn more, see Subscribe an Endpoint to Your Amazon SNS Output Topic (p. 830).

Duplicate Message Handling

For data objects sent in real time, Ground Truth guarantees idempotency by ensuring each unique object is only sent for labeling once, even if the input message referring to that object is received multiple
times (duplicate messages). To do this, each data object sent to a streaming labeling job is assigned a deduplication ID, which is identified with a deduplication key.

If you send your requests to label data objects directly through your Amazon SNS input topic using Amazon SNS messages, you can optionally choose a custom deduplication key and deduplication IDs for your objects. For more information, see Specify A Deduplication Key and ID in an Amazon SNS Message (p. 855).

If you do not provide your own deduplication key, or if you use the Amazon S3 configuration to send data objects to your labeling job, Ground Truth uses one of the following for the deduplication ID:

- For messages sent directly to your Amazon SNS input topic, Ground Truth uses the SNS message ID.
- For messages that come from an Amazon S3 configuration, Ground Truth creates a deduplication ID by combining the Amazon S3 URI of the object with the sequencer token in the message.

### Specify A Deduplication Key and ID in an Amazon SNS Message

When you send a data object to your streaming labeling job using an Amazon SNS message, you have the option to specify your deduplication key and deduplication ID in one of the following ways. In all of these scenarios, identify your deduplication key with dataset-objectid-attribute-name.

### Bring Your Own Deduplication Key and ID

Create your own deduplication key and deduplication ID by configuring your Amazon SNS message as follows. Replace byo-key with your key and UniqueId with the deduplication ID for that data object.

```json
{
  "source-ref": "s3://bucket/prefix/object1",
  "dataset-objectid-attribute-name": "byo-key",
  "byo-key": "UniqueId"
}
```

Your deduplication key can be up to 140 characters. Supported patterns include: \^\[^{[a-zA-Z0-9]-*[a-zA-Z0-9]}\]*\.

Your deduplication ID can be up to 1,024 characters. Supported patterns include: \^(https|s3)://\([^/]+\)/?([^\*]+)$.

### Use an Existing Key for your Deduplication Key

You can use an existing key in your message as the deduplication key. When you do this, the value associated with that key is used for the deduplication ID.

For example, you can specify use the source-ref key as your deduplication key by formatting your message as follows:

```json
{
  "source-ref": "s3://bucket/prefix/object1",
  "dataset-objectid-attribute-name": "source-ref"
}
```

In this example, Ground Truth uses "s3://bucket/prefix/object1" for the deduplication id.

### Find Deduplication Key and ID in Your Output Data

You can see the deduplication key and ID in your output data. The deduplication key is identified by dataset-objectid-attribute-name.
When you use your own custom deduplication key, your output contains something similar to the following:

```
"dataset-objectid-attribute-name": "byo-key",
"byo-key": "UniqueId",
```

When you do not specify a key, you can find the deduplication ID that Ground Truth assigned to your data object as follows. The $label-attribute-name-object-id parameter identifies your deduplication ID.

```
{
"source-ref":"s3://bucket/prefix/object1",
"dataset-objectid-attribute-name":"$label-attribute-name-object-id"
"label-attribute-name":0,
"label-attribute-name-metadata": {...},
"$label-attribute-name-object-id":"<service-generated-key>"
}
```

For `<service-generated-key>`, if the data object came through an Amazon S3 configuration, Ground Truth adds a unique value used by the service and emits a new field keyed by $sequencer which shows the Amazon S3 sequencer used. If object was fed to SNS directly, Ground Truth use the SNS message ID.

**Note**
Do not use the $ character in your label attribute name.

## Input Data Quotas

Input datasets used in semantic segmentation labeling jobs have a quota of 20,000 items. For all other labeling job types, the dataset size quota is 100,000 items. To request an increase to the quota for labeling jobs other than semantic segmentation jobs, review the procedures in [AWS Service Quotas](https://aws.amazon.com/service-quotas) to request a quota increase.

Input image data for active and non-active learning labeling jobs must not exceed size and resolution quotas. **Active learning** refers to labeling job that use automated data labeling. **Non-active learning** refers to labeling jobs that don't use automated data labeling.

Additional quotas apply for label categories for all task types, and for input data and labeling category attributes for 3D point cloud and video frame task types.

### Input File Size Quota

Input files can't exceed the following size- quotas for both active and non-active learning labeling jobs. There is no input file size quota for videos used in **video classification** labeling jobs.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Input File Size Quota</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
Input Image Resolution Quotas

Image file resolution refers to the number of pixels in an image, and determines the amount of detail an image holds. Image resolution quotas differ depending on the labeling job type and the SageMaker built-in algorithm used. The following table lists the resolution quotas for images used in active and non-active learning labeling jobs.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Resolution Quota - Non Active Learning</th>

</table>

Label Category Quotas

Each labeling job task type has a quota for the number of label categories you can specify. Workers select label categories to create annotations. For example, you may specify label categories car, pedestrian, and biker when creating a bounding box labeling job and workers will select the car category before drawing bounding boxes around cars.

**Important**

Label category names cannot exceed 256 characters. All label categories must be unique. You cannot specify duplicate label categories.

The following label category limits apply to labeling jobs. Quotas for label categories depend on whether you use the SageMaker API operation CreateLabelingJob or the console to create a labeling job.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Label Category Quota - API</th>
<th>Label Category Quota - Console</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image classification (Multi-label)</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>Image classification (Single label)</td>
<td>Unlimited</td>
<td>30</td>
</tr>
<tr>
<td>Bounding box (Object detection)</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>Label verification</td>
<td>Unlimited</td>
<td>30</td>
</tr>
<tr>
<td>Semantic segmentation (with active learning)</td>
<td>20</td>
<td>10</td>
</tr>
<tr>
<td>Semantic segmentation (without active learning)</td>
<td>Unlimited</td>
<td>10</td>
</tr>
</tbody>
</table>
Labeling Job Task Type | Label Category Quota - API | Label Category Quota - Console
--- | --- | ---
Named entity recognition | Unlimited | 30
Text classification (Multi-label) | 50 | 50
Text classification (Single label) | Unlimited | 30
Video classification | 30 | 30
Video frame object detection | 30 | 30
Video frame object tracking | 30 | 30
3D point cloud object detection | 30 | 30
3D point cloud object tracking | 30 | 30
3D point cloud semantic segmentation | 30 | 30

### 3D Point Cloud and Video Frame Labeling Job Quotas

The following quotas apply for 3D point cloud and video frame labeling job input data.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Input Data Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Video frame object detection</td>
<td>2,000 video frames (images) per sequence</td>
</tr>
<tr>
<td>Video frame object detection</td>
<td>10 video frame sequences per manifest file</td>
</tr>
<tr>
<td>Video frame object tracking</td>
<td>2,000 video frames (images) per sequence</td>
</tr>
<tr>
<td>Video frame object tracking</td>
<td>10 video frame sequences per manifest file</td>
</tr>
<tr>
<td>3D point cloud object detection</td>
<td>100,000 point cloud frames per labeling job</td>
</tr>
<tr>
<td>3D point cloud object tracking</td>
<td>100,000 point cloud frame sequences per labeling job</td>
</tr>
<tr>
<td>3D point cloud object tracking</td>
<td>500 point cloud frames in each sequence file</td>
</tr>
</tbody>
</table>

When you create a video frame or 3D point cloud labeling job, you can add one or more label category attributes to each label category that you specify to have workers provide more information about an annotation.

Each label category attribute has a single label category attribute name, and a list of one or more options (values) to choose from. To learn more, see Worker User Interface (UI) (p. 745) for 3D point cloud labeling jobs and Worker User Interface (UI) (p. 691) for video frame labeling jobs.

The following quotas apply to the number of label category attributes names and values you can specify for labeling jobs.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Label Category Attribute (name) Quota</th>
<th>Label Category Attribute Values Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Video frame object detection</td>
<td>10</td>
<td>10</td>
</tr>
</tbody>
</table>
Filter and Select Data for Labeling

You can use the Amazon SageMaker console to select a portion of your dataset for labeling. The data must be stored in an Amazon S3 bucket. You have three options:

- Use the full dataset.
- Choose a randomly selected sample of the dataset.
- Specify a subset of the dataset using a query.

The following options are available in the Labeling jobs section of the SageMaker console after selecting Create labeling job. To learn how to create a labeling job in the console, see Getting started (p. 641).

To configure the dataset that you use for labeling, in the Job overview section, choose Additional configuration.

Use the Full Dataset

When you choose to use the Full dataset, you must provide a manifest file for your data objects. You can provide the path of the Amazon S3 bucket that contains the manifest file or use the SageMaker console to create the file. To learn how to create a manifest file using the console, see Automated Data Setup (p. 850).

Choose a Random Sample

When you want to label a random subset of your data, select Random sample. The dataset is stored in the Amazon S3 bucket specified in the Input dataset location field.

After you have specified the percentage of data objects that you want to include in the sample, choose Create subset. SageMaker randomly picks the data objects for your labeling job. After the objects are selected, choose Use this subset.

SageMaker creates a manifest file for the selected data objects. It also modifies the value in the Input dataset location field to point to the new manifest file.

Specify a Subset

You can specify a subset of your data objects using an Amazon S3 SELECT query on the object file names.

The SELECT statement of the SQL query is defined for you. You provide the WHERE clause to specify which data objects should be returned.

For more information about the Amazon S3 SELECT statement, see Selecting Content from Objects.

Choose Create subset to start the selection, and then choose Use this subset to use the selected data.

SageMaker creates a manifest file for the selected data objects. It also updates the value in the Input dataset location field to point to the new manifest file.

3D Point Cloud Input Data

To create a 3D point cloud labeling job, you must create an input manifest file. Use this topic to learn the formatting requirements of the input manifest file for each task type. To learn about the raw input data formats Ground Truth accepts for 3D point cloud labeling jobs, see the section Accepted Raw 3D Data Formats (p. 860).

Use your labeling job task type to choose a topics on Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 862) to learn about the formatting requirements for each line of your input manifest file.

Topics

- Accepted Raw 3D Data Formats (p. 860)
- Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 862)
- Understand Coordinate Systems and Sensor Fusion (p. 875)

Accepted Raw 3D Data Formats

Ground Truth uses your 3D point cloud data to render a 3D scenes that workers annotate. This section describes the raw data formats that are accepted for point cloud data and sensor fusion data for a point cloud frame. To learn how to create an input manifest file to connect your raw input data files with Ground Truth, see Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 862).

For each frame, Ground Truth supports Compact Binary Pack Format (.bin) and ASCII (.txt) files. These files contain information about the location (x, y, and z coordinates) of all points that make up that frame, and, optionally, information about the pixel color of each point for colored point clouds. When you create a 3D point cloud labeling job input manifest file, you can specify the format of your raw data in the format parameter.

The following table lists elements that Ground Truth supports in point cloud frame files to describe individual points.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>The x coordinate of the point.</td>
</tr>
<tr>
<td>y</td>
<td>The y coordinate of the point.</td>
</tr>
<tr>
<td>z</td>
<td>The z coordinate of the point.</td>
</tr>
<tr>
<td>i</td>
<td>The intensity of the point.</td>
</tr>
<tr>
<td>r</td>
<td>The red color channel component. An 8-bit value (0-255).</td>
</tr>
<tr>
<td>g</td>
<td>The green color channel component. An 8-bit value (0-255)</td>
</tr>
<tr>
<td>b</td>
<td>The blue color channel component. An 8-bit value (0-255)</td>
</tr>
</tbody>
</table>

Ground Truth assumes the following about your input data:

- All of the positional coordinates (x, y, z) are in meters.
- All the pose headings (qx, qy, qz, qw) are measured in Spatial Quaternions.
Compact Binary Pack Format

The Compact Binary Pack Format represents a point cloud as an ordered set of a stream of points. Each point in the stream is an ordered binary pack of 4-byte float values in some variant of the form \texttt{xyzirgb}. The \texttt{x}, \texttt{y}, and \texttt{z} elements are required and additional information about that pixel can be included in a variety of ways using \texttt{i}, \texttt{r}, \texttt{g}, and \texttt{b}.

To use a binary file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter \texttt{binary/} in the \texttt{format} parameter for your input manifest file and replace with the order of elements in each binary pack. For example, you may enter one of the following for the \texttt{format} parameter.

- \texttt{binary/xyzi} – When you use this format, your point element stream would be in the following order: \texttt{x1y1z1i1x2y2z2i2}...
- \texttt{binary/xyzrgb} – When you use this format, your point element stream would be in the following order: \texttt{x1y1z1r1g1b1x2y2z2r2g2b2}...
- \texttt{binary/xyzirgb} – When you use this format, your point element stream would be in the following order: \texttt{x1y1z1i1r1g1b1x2y2z2i2r2g2b2}...

When you use a binary file for your point cloud frame data, if you do not enter a value for \texttt{format}, the default pack format \texttt{binary/xyzi} is used.

ASCII Format

The ASCII format uses a text file to represent a point cloud, where each line in the ASCII point cloud file represents a single point. Each point is a line the text file and contains white space separated values, each of which is a 4-byte float ASCII values. The \texttt{x}, \texttt{y}, and \texttt{z} elements are required for each point and additional information about that point can be included in a variety of ways using \texttt{i}, \texttt{r}, \texttt{g}, and \texttt{b}.

To use a text file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter \texttt{text/} in the \texttt{format} parameter for your input manifest file and replace with the order of point elements on each line.

For example, if you enter \texttt{text/xyzi} for \texttt{format}, your text file for each point cloud frame should look similar to the following:

```
x1 y1 z1 i1
x2 y2 z2 i2
...
```

If you enter \texttt{text/xyzrgb}, your text file should look similar to the following:

```
x1 y1 z1 r1 g1 b1
x2 y2 z2 r2 g2 b1
...
```

When you use a text file for your point cloud frame data, if you do not enter a value for \texttt{format}, the default format \texttt{text/xyzi} will be used.

Point Cloud Resolution Limits

Ground Truth does not have a resolution limit for 3D point cloud frames. However, we recommend that you limit each point cloud frame to 500K points for optimal performance. When Ground Truth renders the 3D point cloud visualization, it must be viewable on your workers' computers, which depends on workers' computer hardware. Point cloud frames that are larger than 1 million points may not render on standard machines, or may take too long to load.
Create an Input Manifest File for a 3D Point Cloud Labeling Job

When you create a labeling job, you provide an input manifest file where each line of the manifest describes a unit of task to be completed by annotators. The format of your input manifest file depends on your task type.

- If you are creating a 3D point cloud **object detection** or **semantic segmentation** labeling job, each line in your input manifest file contains information about a single 3D point cloud frame. This is called a **point cloud frame input manifest**. To learn more, see Create a Point Cloud Frame Input Manifest File (p. 862).

- If you are creating a 3D point cloud **object tracking** labeling job, each line of your input manifest file contains a sequence of 3D point cloud frames and associated data. This is called a **point cloud sequence input manifest**. To learn more, see Create a Point Cloud Sequence Input Manifest (p. 868).

Create a Point Cloud Frame Input Manifest File

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, `\n` or `\n\n`. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the single-frame input manifest file, each line in the manifest contains data for a single point cloud frame. The point cloud frame data can either be stored in binary or ASCII format (see Accepted Raw 3D Data Formats (p. 860)). This is the manifest file formatting required for 3D point cloud object detection and semantic segmentation. Optionally, you can also provide camera sensor fusion data for each point cloud frame.

Ground Truth supports point cloud and video camera sensor fusion in the world coordinate system (p. 875) for all modalities. If you can obtain your 3D sensor extrinsic (like a LiDAR extrinsic), we recommend that you transform 3D point cloud frames into the world coordinate system using the extrinsic. For more information, see Sensor Fusion (p. 877).

However, if you cannot obtain a point cloud in world coordinate system, you can provide coordinates in the original coordinate system that the data was captured in. If you are providing camera data for sensor fusion, it is recommended that you provide LiDAR sensor and camera pose in the world coordinate system.

To create a single-frame input manifest file, you will identify the location of each point cloud frame that you want workers to label using the `source-ref` key. Additionally, you must use the `source-ref-metadata` key to identify the format of your dataset, a timestamp for that frame, and, optionally, sensor fusion data and video camera images.

The following example demonstrates the syntax used for an input manifest file for a single-frame point cloud labeling job. The example includes two point cloud frames. For details about each parameter, see the table following this example.

**Important**
Each line in your input manifest file must be in JSON Lines format. The following code block shows an input manifest file with two JSON objects. Each JSON object is used to point to and provide details about a single point cloud frame. The JSON objects have been expanded for readability, but you must minimize each JSON object to fit on a single line when creating an input manifest file. An example is provided under this code block.

```json
{

When you create an input manifest file, you must collapse your JSON objects to fit on a single line. For example, the code block above would appear as follows in an input manifest file:

```
{"source-ref":"s3://awsexamplebucket/examplefolder/frame1.bin","source-ref-metadata":
{"format":"binary/xyz","unix-timestamp":1566861644.759115,"ego-vehicle-pose":{"position":
{"x":-2.7161461413869947,"y":116.25822288149078,"z":1.8348751887989483},
"heading":
{"qx":0.02111296123795955,"qy":-0.006495469416730261,"qz":-0.00802456904865688,"qw":0.9997181192298086},
"camera-model":"pinhole"}},
{"source-ref":"s3://awsexamplebucket/examplefolder/frame2.bin","source-ref-metadata":
{"format":"binary/xyz","unix-timestamp":1566861632.759133,"ego-vehicle-pose":{"position":
{"x":-2.7161461413869947,"y":116.25822288149078,"z":1.8348751887989483},
"heading":
{"qx":0.02111296123795955,"qy":-0.006495469416730261,"qz":-0.00802456904865688,"qw":0.9997181192298086},
"camera-model":"pinhole"}}
```

The following table shows the parameters you can include in your input manifest file:

Use Input and Output Data

### Parameter Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>No</td>
<td>String</td>
<td>The location in Amazon S3 where your metadata, such as camera images, is stored for this frame. The prefix must end with a forward slash: <code>/</code>.</td>
</tr>
<tr>
<td>images</td>
<td>No</td>
<td>List</td>
<td>A list of parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest (p. 867).</td>
</tr>
</tbody>
</table>

### Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the location of the vehicle used to capture point cloud data. Ground Truth use this information to compute LiDAR extrinsic matrix.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion (p. 877).

The following table provides more information about the position and orientation (heading) parameters that are required when you provide ego-vehicle information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td>Yes</td>
<td>JSON object</td>
<td>The translation vector of the ego vehicle in the world coordinate system.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Required Parameters:</strong></td>
<td>x, y, and z. Enter numbers for these parameters.</td>
</tr>
<tr>
<td>heading</td>
<td>Yes</td>
<td>JSON Object</td>
<td>The orientation of the frame of reference of the device or sensor mounted on the vehicle sensing the surrounding, measured in quaternions, (qx, qy, qz, qw) in the a coordinate system.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Required Parameters:</strong></td>
<td>qx, qy, qz, and qw. Enter numbers for these parameters.</td>
</tr>
</tbody>
</table>
Include Camera Data in Your Input Manifest

If you want to include video camera data with a frame, use the following parameters to provide information about each image. The **Required** column below applies when the `images` parameter is included in the input manifest file under `source-ref-metadata`. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the camera position and heading used to capture the images in the world coordinate system.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients (k1, k2, k3, k4, p1, p1), the camera model and the camera intrinsic matrix. The intrinsic matrix is made up of focal length (fx, fy), and the principal point (cx, cy). See [Intrinsic Matrix (p. 879)] to learn how Ground Truth uses the camera intrinsic. If distortion coefficients are not included, Ground Truth will not undistort an image.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-path</td>
<td>Yes</td>
<td>String</td>
<td>The relative location, in Amazon S3 of your image file. This relative path will be appended to the path you specify in prefix.</td>
</tr>
<tr>
<td>unix-timestamp</td>

<td>No</td>
<td>Number</td>
<td>Tangential distortion coefficients. Supported</td>
</tr>
</tbody>
</table>
### Point Cloud Frame Limits

You can include up to 100,000 point cloud frames in your input manifest file. 3D point cloud labeling job have longer pre-processing times than other Ground Truth task types. For more information, see [Job Pre-processing Time](p. 744).

### Create a Point Cloud Sequence Input Manifest

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \n\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the point cloud sequence input manifest file, each line in the manifest contains a sequence of point cloud frames. The point cloud data for each frame in the sequence can either be stored in binary or ASCII format. For more information, see [Accepted Raw 3D Data Formats](p. 860). This is the manifest file formatting required for 3D point cloud object tracking. Optionally, you can also provide point attribute and camera sensor fusion data for each point cloud frame. When you create a sequence input manifest file, you must provide LiDAR and video camera sensor fusion data in a [world coordinate system](p. 875).

The following example demonstrates the syntax used for an input manifest file when each line in the manifest is a sequence file. Each line in your input manifest file must be in [JSON Lines](p. 868) format.

```json
["source-ref": "s3://awsexamplebucket/example-folder/seq1.json"]
["source-ref": "s3://awsexamplebucket/example-folder/seq2.json"]
```

The data for each sequence of point cloud frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the frames list. This is an example of a sequence file with two point cloud frame files, frame300.bin and frame303.bin. The ... is used to indicated where you should include information for additional frames. Add a JSON object for each frame in the sequence.

The following code block includes a JSON object for a single sequence file. The JSON object has been expanded for readability.

The following table provides details about the top-level parameters of a sequence file. For detailed information about the parameters required for individual frames in the sequence file, see Parameters for Individual Point Cloud Frames (p. 870).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seq-no</td>
<td>Yes</td>
<td>Integer</td>
<td>The ordered number of the sequence.</td>
</tr>
</tbody>
</table>
| prefix        | Yes      | String          | The Amazon S3 location where the sequence files are located. The prefix must end with a forward slash: /.
| number-of-frames | Yes      | Integer         | The total number of frames included in the sequence file. This number must match the total number of frames listed in the frames parameter in the next row. |
| frames        | Yes      | List of JSON objects | A list of frame data. The length of the list must equal number-of-frames. In the worker UI, frames in a sequence will be the same as the order of frames in this array. For details about the format of each frame, see Parameters for Individual Point Cloud Frames (p. 870). |

Parameters for Individual Point Cloud Frames

The following table shows the parameters you can include in your input manifest file.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame-no</td>
<td>No</td>
<td>Integer</td>
<td>A frame number. This is an optional identifier specified by the customer to identify the frame within a sequence. It is not used by Ground Truth.</td>
</tr>
<tr>

|                        |          | **Accepted string value format:** s3://<bucket-name>/<folder-name>/ |                                                                                                                                              |
| images                 | No       | List                     | A list parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest (p. 873). |
Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the pose of the vehicle used to capture point cloud data. Ground Truth uses this information to compute LiDAR extrinsic matrices.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion (p. 877).

The following table provides more information about the position and orientation (heading) parameters that are required when you provide ego-vehicle information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td>Yes</td>
<td>JSON object</td>
<td>The translation vector of the ego vehicle in the world coordinate system. Required Parameters: x, y, and z. Enter numbers for these parameters.</td>
</tr>
<tr>
<td>heading</td>
<td>Yes</td>
<td>JSON Object</td>
<td>The orientation of the frame of reference of the device or sensor mounted on the vehicle sensing the surrounding, measured in quaternions, (qx, qy, qz, qw) in the a coordinate system. Required Parameters: qx, qy, qz, and qw. Enter numbers for these parameters.</td>
</tr>
</tbody>
</table>

Include Camera Data in Your Input Manifest

If you want to include color camera data with a frame, use the following parameters to provide information about each image. The Required column in the following table applies when the images parameter is included in the input manifest file. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the position and orientation (heading) of the camera used to capture the images.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients (k1, k2, k3, k4, p1, p1), camera model and focal length (fx, fy), and the principal point (cx, cy). To learn more about these coefficients and undistorting images, see Camera calibration With OpenCV. If distortion coefficients are not included, Ground Truth will not undistort an image.

<table>
<thead>
<tr>

</tbody>
</table>

**Sequence File and Point Cloud Frame Limits**

You can include up to 100,000 point cloud frame sequences in your input manifest file. You can include up to 500 point cloud frames in each sequence file.
Keep in mind that 3D point cloud labeling jobs have longer pre-processing times than other Ground Truth task types. For more information, see Job Pre-processing Time (p. 744).

Understand Coordinate Systems and Sensor Fusion

Point cloud data is always located in a coordinate system. This coordinate system may be local to the vehicle or the device sensing the surroundings, or it may be a world coordinate system. When you use Ground Truth 3D point cloud labeling jobs, all the annotations are generated using the coordinate system of your input data. For some labeling job task types and features, you must provide data in a world coordinate system.

In this topic, you'll learn the following:

- When you are required to provide input data in a world coordinate system or global frame of reference.
- What a world coordinate is and how you can convert point cloud data to a world coordinate system.
- How you can use your sensor and camera extrinsic matrices to provide pose data when using sensor fusion.

Coordinate System Requirements for Labeling Jobs

If your point cloud data was collected in a local coordinate system, you can use an extrinsic matrix of the sensor used to collect the data to convert it to a world coordinate system or a global frame of reference. If you cannot obtain an extrinsic for your point cloud data and, as a result, cannot obtain point clouds in a world coordinate system, you can provide point cloud data in a local coordinate system for 3D point cloud object detection and semantic segmentation task types.

For object tracking, you must provide point cloud data in a world coordinate system. This is because when you are tracking objects across multiple frames, the ego vehicle itself is moving in the world and so all of the frames need a point of reference.

If you include camera data for sensor fusion, it is recommended that you provide camera poses in the same world coordinate system as the 3D sensor (such as a LiDAR sensor).

Using Point Cloud Data in a World Coordinate System

This section explains what a world coordinate system (WCS), also referred to as a global frame of reference, is and explains how you can provide point cloud data in a world coordinate system.

What is a World Coordinate System?

A WCS or global frame of reference is a fixed universal coordinate system in which vehicle and sensor coordinate systems are placed. For example, if multiple point cloud frames are located in different coordinate systems because they were collected from two sensors, a WCS can be used to translate all of the coordinates in these point cloud frames into a single coordinate system, where all frames have the same origin, (0,0,0). This transformation is done by translating the origin of each frame to the origin of the WCS using a translation vector, and rotating the three axes (typically x, y, and z) to the right orientation using a rotation matrix. This rigid body transformation is called a homogeneous transformation.

A world coordinate system is important in global path planning, localization, mapping, and driving scenario simulations. Ground Truth uses the right-handed Cartesian world coordinate system such as the one defined in ISO 8855, where the x axis is forward toward the car's movement, y axis is left, and the z axis points up from the ground.

The global frame of reference depends on the data. Some datasets use the LiDAR position in the first frame as the origin. In this scenario, all the frames use the first frame as a reference and device heading and position will be near the origin in the first frame. For example, KITTI datasets have the first frame as a reference for world coordinates. Other datasets use a device position that is different from the origin.
Note that this is not the GPS/IMU coordinate system, which is typically rotated by 90 degrees along the z-axis. If your point cloud data is in a GPS/IMU coordinate system (such as OxTS in the open source AV KITTI dataset), then you need to transform the origin to a world coordinate system (typically the vehicle's reference coordinate system). You apply this transformation by multiplying your data with transformation metrics (the rotation matrix and translation vector). This will transform the data from its original coordinate system to a global reference coordinate system. Learn more about this transformation in the next section.

Convert 3D Point Cloud Data to a WCS

Ground Truth assumes that your point cloud data has already been transformed into a reference coordinate system of your choice. For example, you can choose the reference coordinate system of the sensor (such as LiDAR) as your global reference coordinate system. You can also take point clouds from various sensors and transform them from the sensor's view to the vehicle's reference coordinate system view. You use the a sensor's extrinsic matrix, made up of a rotation matrix and translation vector, to convert your point cloud data to a WCS or global frame of reference.

Collectively, the translation vector and rotation matrix can be used to make up an extrinsic matrix, which can be used to convert data from a local coordinate system to a WCS. For example, your LiDAR extrinsic matrix may be composed as follows, where \( R \) is the rotation matrix and \( T \) is the translation vector:

\[
\text{LiDAR}_{\text{extrinsic}} = \begin{bmatrix} R & T \\ 0 & 0 & 0 & 1 \end{bmatrix}
\]

For example, the autonomous driving KITTI dataset includes a rotation matrix and translation vector for the LiDAR extrinsic transformation matrix for each frame. The pykitti python module can be used for loading the KITTI data, and in the dataset dataset.oxts[i].T_w_imu gives the LiDAR extrinsic transform for the \( i \)th frame with can be multiplied with points in that frame to convert them to a world frame - np.matmul(lidar_transform_matrix, points). Multiplying a point in LiDAR frame with a LiDAR extrinsic matrix transforms it into world coordinates. Multiplying a point in the world frame with the camera extrinsic matrix gives the point coordinates in the camera's frame of reference.

The following code example demonstrates how you can convert point cloud frames from the KITTI dataset into a WCS.

```python
import pykitti
import numpy as np

basedir = '/Users/nameofuser/kitti-data'
date = '2011_09_26'
drive = '0079'

# The 'frames' argument is optional - default: None, which loads the whole dataset.
# Calibration, timestamps, and IMU data are read automatically.
# Camera and velodyne data are available via properties that create generators
# when accessed, or through getter methods that provide random access.
data = pykitti.raw(basedir, date, drive, frames=range(0, 50, 5))

# i is frame number
i = 0

# lidar extrinsic for the ith frame
lidar_extrinsic_matrix = data.oxts[i].T_w_imu

# velodyne raw point cloud in lidar scanners own coordinate system
points = data.get_velo(i)

# transform points from lidar to global frame using lidar_extrinsic_matrix
def generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix):
    tps = []
    for point in points:
        # Transform point from lidar to global frame
        transformed_point = np.dot(lidar_extrinsic_matrix, point)
        tps.append(transformed_point)
    return np.array(tps)
```

876
transformed_points = np.matmul(lidar_extrinsic_matrix, np.array([point[0],
point[1], point[2], 1], dtype=np.float32).reshape(4,1)).tolist()
if len(point) > 3 and point[3] is not None:
    tps.append([transformed_points[0][0], transformed_points[1][0],
    transformed_points[2][0], point[3]])
return tps

# customer transforms points from lidar to global frame using lidar_extrinsic_matrix
transformed_pcl = generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix)

Sensor Fusion

Ground Truth supports sensor fusion of point cloud data with up to 8 video camera inputs. This feature allows human labellers to view the 3D point cloud frame side-by-side with the synchronized video frame. In addition to providing more visual context for labeling, sensor fusion allows workers to adjust annotations in the 3D scene and in 2D images and the adjustment are projected into the other view. The following video demonstrates a 3D point cloud labeling job with LiDAR and camera sensor fusion.
For best results, when using sensor fusion, your point cloud should be in a WCS. Ground Truth uses your sensor (such as LiDAR), camera, and ego vehicle pose information to compute extrinsic and intrinsic matrices for sensor fusion.

**Extrinsic Matrix**

Ground Truth uses sensor (such as LiDAR) extrinsic and camera extrinsic and intrinsic matrices to project objects to and from the point cloud data's frame of reference to the camera's frame of reference.

For example, in order to project a label from the 3D point cloud to camera image plane, Ground Truth transforms 3D points from LiDAR's own coordinate system to the camera's coordinate system. This is typically done by first transforming 3D points from LiDAR's own coordinate system to a world coordinate system (or a global reference frame) using the LiDAR extrinsic matrix. Ground Truth then uses the camera inverse extrinsic (which converts points from a global frame of reference to the camera's frame of reference) to transform the 3D points from world coordinate system obtained in previous step into the camera image plane. The LiDAR extrinsic matrix can also be used to transform 3D data into a world coordinate system. If your 3D data is already transformed into world coordinate system then the first transformation doesn't have any impact on label translation, and label translation only depends on the camera inverse extrinsic. A view matrix is used to visualize projected labels. To learn more about these transformations and the view matrix, see Ground Truth Sensor Fusion Transformations (p. 883).

Ground Truth computes these extrinsic matrices by using LiDAR and camera pose data that you provide: heading (in quaternions: qx, qy, qz, and qw) and position (x, y, z). For the vehicle, typically the heading and position are described in vehicle's reference frame in a world coordinate system and are called a ego vehicle pose. For each camera extrinsic, you can add pose information for that camera. For more information, see Pose (p. 880).

**Intrinsic Matrix**

Ground Truth use the camera extrinsic and intrinsic matrices to compute view metrics to transform labels to and from the 3D scene to camera images. Ground Truth computes the camera intrinsic matrix using camera focal length (fx, fy) and optical center coordinates (cx, cy) that you provide. For more information, see Intrinsic and Distortion (p. 883).

**Image Distortion**

Image distortion can occur for a variety of reasons. For example, images may be distorted due to barrel or fish-eye effects. Ground Truth uses intrinsic parameters along with distortion co-efficient to undistort images you provide when creating 3D point cloud labeling jobs. If a camera image is already been undistorted, all distortion coefficients should be set to 0.

For more information about the transformations Ground Truth performs to undistort images, see Camera Calibrations: Extrinsic, Intrinsic and Distortion (p. 883).

**Ego Vehicle**

To collect data for autonomous driving applications, the measurements used to generate point cloud data and are taken from sensors mounted on a vehicle, or the ego vehicle. To project label adjustments to and from the 3D scene and 2D images, Ground Truth needs your ego vehicle pose in a world coordinate system. The ego vehicle pose is comprised of position coordinates and orientation quaternion.

Ground Truth uses your ego vehicle pose to compute rotation and transformations matrices. Rotations in 3 dimensions can be represented by a sequence of 3 rotations around a sequence of axes. In theory, any three axes spanning the 3D Euclidean space are enough. In practice, the axes of rotation are chosen to be the basis vectors. The three rotations are expected to be in a global frame of reference (extrinsic). Ground Truth does not a support body centered frame of reference (intrinsic) which is attached to, and moves with, the object under rotation. To track objects, Ground Truth needs to measure from a global reference where all vehicles are moving. When using Ground Truth 3D point cloud labeling jobs, z specifies the axis of rotation (extrinsic rotation) and yaw Euler angles are in radians (rotation angle).
Pose

Ground Truth uses pose information for 3D visualizations and sensor fusion. Pose information you input through your manifest file is used to compute extrinsic matrices. If you already have an extrinsic matrix, you can use it to extract sensor and camera pose data.

For example in the autonomous driving KITTI dataset, the `pykitti` python module can be used for loading the KITTI data. In the dataset `dataset.oxts[i].T_w_imu` gives the LiDAR extrinsic transform for the i\textsuperscript{th} frame and it can be multiplied with the points to get them in a world frame - \( \text{matmul(liidar\_transform\_matrix, points)} \). This transform can be converted into position (translation vector) and heading (in quaternion) of LiDAR for the input manifest file JSON format. Camera extrinsic transform for `cam0` in i\textsuperscript{th} frame can be calculated by \( \text{inv(matmul(dataset.calib.T_cam0_velo, inv(dataset.oxts[i].T_w_imu)))} \) and this can be converted into heading and position for `cam0`.

```python
import numpy
rotation = [[ 9.96714314e-01, -8.09967396e-02, 1.16333982e-03],
            [ 8.09967396e-02, 9.96661051e-01, -1.03090934e-02],
            [-3.24531964e-04, 1.03694477e-02, 9.99946183e-01]]
origin= [1.71104606e+00,
         5.80000039e-01,
         9.43144935e-01]

from scipy.spatial.transform import Rotation as R

# position is the origin
position = origin
r = R.from_matrix(np.asarray(rotation))

# heading in WCS using scipy
heading = r.as_quat()
print(f"pose:{position}\nheading: {heading}")
```

Position

In the input manifest file, position refers to the position of the sensor with respect to a world frame. If you are unable to put the device position in a world coordinate system, you can use LiDAR data with local coordinates. Similarly, for mounted video cameras you can specify the position and heading in a world coordinate system. For camera, if you do not have position information, please use (0, 0, 0).

The following are the fields in the position object:

1. x (float) – x coordinate of ego vehicle, sensor, or camera position in meters.
2. y (float) – y coordinate of ego vehicle, sensor, or camera position in meters.
3. z (float) – z coordinate of ego vehicle, sensor, or camera position in meters.

The following is an example of a position JSON object:

```json
{
    "position": {
        "y": -152.77584902657554,
        "x": 311.21505956090624,
        "z": -10.854137529636024
    }
}
```
Heading

In the input manifest file, `heading` is an object that represents the orientation of a device with respect to world frame. Heading values should be in quaternion. A quaternion is a representation of the orientation consistent with geodesic spherical properties. If you are unable to put the sensor heading in world coordinates, please use the identity quaternion \((q_x = 0, q_y = 0, q_z = 0, q_w = 1)\). Similarly, for cameras, specify the heading in quaternions. If you are unable to obtain extrinsic camera calibration parameters, please also use the identity quaternion.

Fields in `heading` object are as follows:

1. \(q_x\) (float) - x component of ego vehicle, sensor, or camera orientation.
2. \(q_y\) (float) - y component of ego vehicle, sensor, or camera orientation.
3. \(q_z\) (float) - z component of ego vehicle, sensor, or camera orientation.
4. \(q_w\) (float) - w component of ego vehicle, sensor, or camera orientation.

The following is an example of a `heading` JSON object:

```json
{
  "heading": {
    "qy": -0.7046155108831117,
    "qx": 0.034278837280808494,
    "qz": 0.7070617895701465,
    "qw": -0.04904659893885366
  }
}
```

To learn more, see [Compute Orientation Quaternions and Position](p. 881).

Compute Orientation Quaternions and Position

Ground Truth requires that all orientation, or heading, data be given in quaternions. A quaternion is a representation of the orientation consistent with geodesic spherical properties that can be used to approximate rotation. Compared to Euler angles they are simpler to compose and avoid the problem of gimbal lock. Compared to rotation matrices they are more compact, more numerically stable, and more efficient.

You can compute quaternions from a rotation matrix or a transformation matrix.

If you have a rotation matrix (made up of the axis rotations) and translation vector (or origin) in world coordinate system instead of a single 4x4 rigid transformation matrix, then you can directly use the rotation matrix and translation vector to compute quaternions. Libraries like [scipy](https://scipy.org/) and [pyqaternion](https://github.com/baals/pyqaternion) can help. The following code-block shows an example using these libraries to compute quaternion from a rotation matrix.

```python
import numpy

rotation = [[9.96714314e-01, -8.09890350e-02, 1.16333982e-03],
            [8.09967596e-02, 9.96661051e-01, -1.03090934e-02],
            [-3.24531964e-04, 1.03694477e-02, 9.99946183e-01]]

origin = [1.71104606e+00,
          5.80000039e-01,
          9.43144955e-01]

from scipy.spatial.transform import Rotation as R

# position is the origin
position = origin
```

881
r = R.from_matrix(np.asarray(rotation))
# heading in WCS using scipy
heading = r.as_quat()
print(f"position:{position}\nheading: {heading}"

A UI tool like 3D Rotation Converter can also be useful.

If you have a 4x4 extrinsic transformation matrix, note that the transformation matrix is in the form \([R \ T; 0 \ 0 \ 0 \ 1]\) where \(R\) is the rotation matrix and \(T\) is the origin translation vector. That means you can extract rotation matrix and translation vector from the transformation matrix as follows.

```python
import numpy as np
transformation
= [[ 9.96714314e-01, -8.09890350e-02,  1.16333982e-03, 1.71104606e+00],
  [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02, 5.80000039e-01],
  [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01, 9.43144935e-01],
  [              0,               0,               0,              1]]
transformation  = np.array(transformation )
rotation = transformation[0:3][0:3]
translation= transformation[0:3][3]
from scipy.spatial.transform import Rotation as R
# position is the origin translation
position = translation
r = R.from_matrix(np.asarray(rotation))
# heading in WCS using scipy
heading = r.as_quat()
print(f"position:{position}\nheading: {heading}"

With your own setup, you can compute an extrinsic transformation matrix using the GPS/IMU position and orientation (latitude, longitude, altitude and roll, pitch, yaw) with respect to the LiDAR sensor on the ego vehicle. For example, you can compute pose from KITTI raw data using pose = convertOxtsToPose(oxts) to transform the oxts data into a local euclidean poses, specified by 4x4 rigid transformation matrices. You can then transform this pose transformation matrix to a global reference frame using the reference frames transformation matrix in the world coordinate system.

```

struct Quaternion
{
    double w, x, y, z;
};

Quaternion ToQuaternion(double yaw, double pitch, double roll) // yaw (Z), pitch (Y), roll (X)
{
    // Abbreviations for the various angular functions
    double cy = cos(yaw * 0.5);
    double sy = sin(yaw * 0.5);
    double cp = cos(pitch * 0.5);
    double sp = sin(pitch * 0.5);
    double cr = cos(roll * 0.5);
    double sr = sin(roll * 0.5);
    Quaternion q;
    q.w = cr * cp * cy + sr * sp * sy;
    q.x = sr * cp * cy - cr * sp * sy;
    q.y = cr * sp * cy + sr * cp * sy;
    q.z = cr * cp * sy - sr * sp * cy;
    return q;
}
Ground Truth Sensor Fusion Transformations

The following sections go into greater detail about the Ground Truth sensor fusion transformations that are performed using the pose data you provide.

LiDAR Extrinsic

In order to project to and from a 3D LiDAR scene to a 2D camera image, Ground Truth computes the rigid transformation projection metrics using the ego vehicle pose and heading. Ground Truth computes rotation and translation of a world coordinates into the 3D plane by doing a simple sequence of rotations and translation.

Ground Truth computes rotation metrics using the heading quaternions as follows:

\[
M = \begin{pmatrix}
1 - 2y^2 - 2z^2 & 2xy + 2zw & 2xz - 2yw \\
2xy - 2zw & 1 - 2x^2 - 2z^2 & 2yz + 2xw \\
2xz + 2yw & 2yz - 2xw & 1 - 2x^2 - 2y^2
\end{pmatrix}
\]

Here, \([x, y, z, w]\) corresponds to parameters in the heading JSON object, \([qx, qy, qz, qw]\). Ground Truth computes the translation column vector as \(T = [\text{poseX}, \text{poseY}, \text{poseZ}]\). Then the extrinsic metrics is simply as follows:

\[
\text{LiDAR_extrinsic} = [R \, T; 0 \, 0 \, 0 \, 1]
\]

Camera Calibrations: Extrinsic, Intrinsic and Distortion

Geometric camera calibration, also referred to as camera resectioning, estimates the parameters of a lens and image sensor of an image or video camera. You can use these parameters to correct for lens distortion, measure the size of an object in world units, or determine the location of the camera in the scene. Camera parameters include intrinsics and distortion coefficients.

Camera Extrinsic

If the camera pose is given, then Ground Truth computes the camera extrinsic based on a rigid transformation from the 3D plane into the camera plane. The calculation is the same as the one used for the LiDAR Extrinsic (p. 883), except that Ground Truth uses camera pose (position and heading) and computes the inverse extrinsic.

\[
\text{camera_inverse_extrinsic} = \operatorname{inv}([Rc \, Tc; 0 \, 0 \, 0 \, 1]) \quad \text{#where Rc and Tc are camera pose components}
\]

Intrinsic and Distortion

Some cameras, such as pinhole or fisheye cameras, may introduce significant distortion in photos. This distortion can be corrected using distortion coefficients and the camera focal length. To learn more, see Camera calibration With OpenCV in the OpenCV documentation.

There are two types of distortion Ground Truth can correct for: radial distortion and tangential distortion.

Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion. The presence of the radial distortion manifests in form of the barrel or fish-eye effect and Ground Truth uses Formula 1 to undistort it.

**Formula 1:**

\[
x_{\text{corrected}} = x(1 + k_1r^2 + k_2r^4 + k_3r^6)
\]
\[
y_{\text{corrected}} = y(1 + k_1r^2 + k_2r^4 + k_3r^6)
\]
**Tangential distortion** occurs because the lenses used to take the images are not perfectly parallel to the imaging plane. This can be corrected with Formula 2.

**Formula 2:**

\[
\begin{align*}
x_{\text{corrected}} &= x + [2p_1 xy + p_2 (r^2 + 2x^2)] \\
y_{\text{corrected}} &= y + [p_1 (r^2 + 2y^2) + 2p_2 xy]
\end{align*}
\]

In the input manifest file, you can provide distortion coefficients and Ground Truth will undistort your images. All distortion coefficients are floats.

- \(k_1, k_2, k_3, k_4\) – Radial distortion coefficients. Supported for both fisheye and pinhole camera models.
- \(p_1, p_2\) – Tangential distortion coefficients. Supported for pinhole camera models.

If images are already undistorted, all distortion coefficients should be 0 in your input manifest.

In order to correctly reconstruct the corrected image, Ground Truth does a unit conversion of the images based on focal lengths. If a common focal length is used with a given aspect ratio for both axes, such as 1, in the upper formula we will have a single focal length. The matrix containing these four parameters is referred to as the **in camera intrinsic calibration matrix**.

\[
\begin{pmatrix}
x \\
y \\
w
\end{pmatrix} = \begin{pmatrix}
f_x & 0 & c_x \\
0 & f_y & c_y \\
0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
X \\
Y \\
Z
\end{pmatrix}
\]

While the distortion coefficients are the same regardless of the camera resolutions used, these should be scaled with the current resolution from the calibrated resolution.

The following are float values.

- \(f_x\) - focal length in x direction.
- \(f_y\) - focal length in y direction.
- \(c_x\) - x coordinate of principal point.
- \(c_y\) - y coordinate of principal point.

Ground Truth uses the camera extrinsic and camera intrinsic to compute view metrics as shown in the following code block to transform labels between the 3D scene and 2D images.

```python
def generate_view_matrix(intrinsic_matrix, extrinsic_matrix):
    intrinsic_matrix = np.c_[intrinsic_matrix, np.zeros(3)]
    view_matrix = np.matmul(intrinsic_matrix, extrinsic_matrix)
    view_matrix = np.insert(view_matrix, 2, np.array((0, 0, 0, 1)), 0)
    return view_matrix
```

**Video Frame Input Data**

When you create a video frame object detection or object tracking labeling job, you can choose video files (MP4 files) or video frames for input data. All worker tasks are created using video frames, so if you choose video files, use the Ground Truth frame extraction tool to extract video frames (images) from your video files.
For both of these options, you can use the **Automated data setup** option in the Ground Truth section of the Amazon SageMaker console to set up a connection between Ground Truth and your input data in Amazon S3 so that Ground Truth knows where to look for your input data when creating your labeling tasks. This creates and stores an input manifest file in your Amazon S3 input dataset location. To learn more, see [Automated Video Frame Input Data Setup](p. 887).

Alternatively, you can manually create sequence files for each sequence of video frames that you want labeled and provide the Amazon S3 location of an input manifest file that references each of these sequences files using the `source-ref` key. To learn more, see [Create a Video Frame Input Manifest File](p. 889).

**Topics**

- [Choose Video Files or Video Frames for Input Data](p. 885)
- [Input Data Setup](p. 886)

### Choose Video Files or Video Frames for Input Data

When you create a video frame object detection or object tracking labeling job, you can provide a sequence of video frames (images) or you can use the Amazon SageMaker console to have Ground Truth automatically extract video frames from your video files. Use the following sections to learn more about these options.

**Provide Video Frames**

Video frames are sequences of images extracted from a video file. You can create a Ground Truth labeling job to have workers label multiple sequences of video frames. Each sequence is made up of images extracted from a single video.

To create a labeling job using video frame sequences, you must store each sequence using a unique key name prefix in Amazon S3. In the Amazon S3 console, key name prefixes are folders. So in the Amazon S3 console, each sequence of video frames must be located in its own folder in Amazon S3.

For example, if you have two sequences of video frames, you might use the key name prefixes `sequence1/` and `sequence2/` to identify your sequences. In this example, your sequences may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence1/` and `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence2/`.

If you are using the Ground Truth console to create an input manifest file, all of the sequence key name prefixes should be in the same location in Amazon S3. For example, in the Amazon S3 console, each sequence could be in a folder in `s3://DOC-EXAMPLE-BUCKET/video-frames/`. In this example, your first sequence of video frames (images) may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence1/` and your second sequence may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence2/`.

**Important**

Even if you only have a single sequence of video frames that you want workers to label, that sequence must have a key name prefix in Amazon S3. If you are using the Amazon S3 console, this means that your sequence is located in a folder. It cannot be located in the root of your S3 bucket.

When creating worker tasks using sequences of video frames, Ground Truth uses one sequence per task. In each task, Ground Truth orders your video frames using **UTF-8** binary order.

For example, video frames might be in the following order in Amazon S3:

```
[0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg]
```
They are arranged in the same order in the worker's task: 0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg.

Frames might also be ordered using a naming convention like the following:

[frame1.jpg, frame2.jpg, ..., frame11.jpg]

In this case, frame10.jpg and frame11.jpg come before frame2.jpg in the worker task. Your worker sees your video frames in the following order: frame1.jpg, frame10.jpg, frame11.jpg, frame2.jpg, ..., frame9.jpg.

Provide Video Files

You can use the Ground Truth frame splitting feature when creating a new labeling job in the console to extract video frames from video files (MP4 files). A series of video frames extracted from a single video file is referred to as a sequence of video frames.

You can either have Ground Truth automatically extract all frames, up to 2,000, from the video, or you can specify a frequency for frame extraction. For example, you can have Ground Truth extract every 10th frame from your videos.

You can provide up to 50 videos when you use automated data setup to extract frames, however your input manifest file cannot reference more than 10 video frame sequence files when you create a video frame object tracking and video frame object detection labeling job. If you use the automated data setup console tool to extract video frames from more than 10 video files, you will need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more about these quotas, see 3D Point Cloud and Video Frame Labeling Job Quotas (p. 858).

To use the video frame extraction tool, see Automated Video Frame Input Data Setup (p. 887).

When all of your video frames have been successfully extracted from your videos, you will see the following in your S3 input dataset location:

- A key name prefix (a folder in the Amazon S3 console) named after each video. Each of these prefixes leads to:
  - A sequence of video frames extracted from the video used to name that prefix.
  - A sequence file used to identify all of the images that make up that sequence.
  - An input manifest file with a .manifest extension. This identifies all of the sequence files that will be used to create your labeling job.

All of the frames extracted from a single video file are used for a labeling task. If you extract video frames from multiple video files, multiple tasks are created for your labeling job, one for each sequence of video frames.

Ground Truth stores each sequence of video frames that it extracts in your Amazon S3 location for input datasets using a unique key name prefix. In the Amazon S3 console, key name prefixes are folders.

Input Data Setup

When you create a video frame labeling job, you need to let Ground Truth know where to look for your input data. You can do this in one of two ways:

- You can store your input data in Amazon S3 and have Ground Truth automatically detect the input dataset used for your labeling job. See Automated Video Frame Input Data Setup (p. 887) to learn more about this option.
- You can create an input manifest file and sequence files and upload them to Amazon S3. See Manual Input Data Setup (p. 889) to learn more about this option.
Automated Video Frame Input Data Setup

You can use the Ground Truth automated data setup to automatically detect video files in your Amazon S3 bucket and extract video frames from those files. To learn how, see "Provide Video Files" (p. 886).

If you already have video frames in Amazon S3, you can use the automated data setup to use these video frames in your labeling job. For this option, all video frames from a single video must be stored using a unique prefix. To learn about the requirements to use this option, see "Provide Video Frames" (p. 885).

Select one of the following sections to learn how to set up your automatic input dataset connection with Ground Truth.

Provide Video Files and Extract Frames

Use the following procedure to connect your video files with Ground Truth and automatically extract video frames from those files for video frame object detection and object tracking labeling jobs.

**Note**

If you use the automated data setup console tool to extract video frames from more than 10 video files, you will need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more, see "Provide Video Files" (p. 886).

Make sure your video files are stored in an Amazon S3 bucket in the same AWS Region that you perform the automated data setup in.

Automatically connect your video files in Amazon S3 with Ground Truth and extract video frames:

   Your input and output S3 buckets must be located in the same AWS Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the navigation bar, choose the name of the currently displayed Region.

2. Select Create labeling job.

3. Enter a Job name.

4. In the section Input data setup, select Automated data setup.

5. Enter an Amazon S3 URI for S3 location for input datasets. An S3 URI looks like the following: s3://DOC-EXAMPLE-BUCKET/path-to-files/. This URI should point to the Amazon S3 location where your video files are stored.

6. Specify your S3 location for output datasets. This is where your output data is stored. You can choose to store your output data in the Same location as input dataset or Specify a new location and entering the S3 URI of the location that you want to store your output data.

7. Choose Video Files for your Data type using the dropdown list.

8. Choose Yes, extract frames for object tracking and detection tasks.

   - When you choose Use all frames extracted from the video to create a labeling task, Ground Truth extracts all frames from each video in your S3 location for input datasets, up to 2,000
frames. If a video in your input dataset contains more than 2,000 frames, the first 2,000 are extracted and used for that labeling task.

- When you choose **Use every x frame from a video to create a labeling task**, Ground Truth extracts every \(x\)th frame from each video in your S3 location for input datasets.

  For example, if your video is 2 seconds long, and has a frame rate of 30 frames per second, there are 60 frames in your video. If you specify 10 here, Ground Truth extracts every 10\(^{th}\) frame from your video. This means the 1\(^{st}\), 10\(^{th}\), 20\(^{th}\), 30\(^{th}\), 40\(^{th}\), 50\(^{th}\), and 60\(^{th}\) frames are extracted.

10. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.

11. Select **Complete data setup**.

### Provide Video Frames

Use the following procedure to connect your sequences of video frames with Ground Truth for video frame object detection and object tracking labeling jobs.

Make sure your video frames are stored in an Amazon S3 bucket in the same AWS Region that you perform the automated data setup in. Each sequence of video frames should have a unique prefix. For example, if you have two sequences stored in s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/, each should have a unique prefix like sequence1 and sequence2 and should both be located directly under the /sequences/ prefix. In the example above, the locations of these two sequences is: s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence1/ and s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence2/.

#### Automatically connect your video frame in Amazon S3 with Ground Truth:

1. Navigate to the **Create labeling job** page in the Amazon SageMaker console: https://console.aws.amazon.com/sagemaker/groundtruth.

   Your input and output S3 buckets must be located in the same AWS Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the navigation bar, choose the name of the currently displayed Region.

2. Select **Create labeling job**.

3. Enter a **Job name**.

4. In the section **Input data setup**, select **Automated data setup**.

5. Enter an Amazon S3 URI for **S3 location for input datasets**.

   This should be the Amazon S3 location where your sequences are stored. For example, if you have two sequences stored in s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence1/, s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence2/, enter s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/ here.

6. Specify your **S3 location for output datasets**. This is where your output data is stored. You can choose to store your output data in the **Same location as input dataset** or **Specify a new location** and entering the S3 URI of the location that you want to store your output data.

7. Choose **Video frames** for your **Data type** using the dropdown list.

8. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.

9. Select **Complete data setup**.

These procedures will create an input manifest in the Amazon S3 location for input datasets that you specified in step 5. If you are creating a labeling job using the SageMaker API or, AWS CLI, or an AWS SDK, use the Amazon S3 URI for this input manifest file as input to the parameter ManifestS3Uri.
Manual Input Data Setup

Choose the manual data setup option if you have created sequence files for each of your video frame sequences, and a manifest file listing references to those sequences files.

Create a Video Frame Input Manifest File

Ground Truth uses the input manifest file to identify the location of your input dataset when creating labeling tasks. For video frame object detection and object tracking labeling jobs, each line in the input manifest file identifies the location of a video frame sequence file. Each sequence file identifies the images included in a single sequence of video frames.

Use this page to learn how to create a video frame sequence file and an input manifest file for video frame object tracking and object detection labeling jobs.

If you want Ground Truth to automatically generate your sequence files and input manifest file, see Automated Video Frame Input Data Setup (p. 887).

Create a Video Frame Sequence Input Manifest

In the video frame sequence input manifest file, each line in the manifest is a JSON object, with a "source-ref" key that references a sequence file. Each sequence file identifies the location of a sequence of video frames. This is the manifest file formatting required for all video frame labeling jobs.

The following example demonstrates the syntax used for an input manifest file:

```
{"source-ref": "s3://DOC-EXAMPLE-BUCKET/example-folder/seq1.json"}
{"source-ref": "s3://DOC-EXAMPLE-BUCKET/example-folder/seq2.json"}
```

Create a Video Frame Sequence File

The data for each sequence of video frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the frames list. The following JSON has been expanded for readability.

```
{
  "seq-no": 1,
  "prefix": "s3://mybucket/prefix/video1/",
  "number-of-frames": 3,
  "frames": [
    {"frame-no": 1, "unix-timestamp": 1566861644, "frame": "frame0001.jpg" },
    {"frame-no": 2, "unix-timestamp": 1566861644, "frame": "frame0002.jpg" },
    {"frame-no": 3, "unix-timestamp": 1566861644, "frame": "frame0003.jpg" }
  ]
}
```

The following table provides details about the parameters shown in the this code example.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seq-no</td>
<td>Yes</td>
<td>Integer</td>
<td>The ordered number of the sequence.</td>
</tr>
<tr>
<td>prefix</td>
<td>Yes</td>
<td>String</td>
<td>The Amazon S3 location where the sequence files are located.</td>
</tr>
</tbody>
</table>

<p>| Accepted Values: | s3://&lt;bucket-name&gt;/&lt;prefix&gt;/ |</p>
<table>
<thead>

<th>Yes</th>
<th>Integer</th>
<th>The total number of frames included in the sequence file. This number must match the total number of frames listed in the frames parameter in the next row.</th>
</tr>
</thead>
<tbody>
<tr>
<td>frames</td>
<td>Yes</td>
<td>List of JSON objects</td>
<td>A list of frame data. The length of the list must equal number-of-frames. In the worker UI, frames in a sequence are ordered in UTF-8 binary order. To learn more about this ordering, see Provide Video Frames (p. 885).</td>
</tr>
</tbody>
</table>
|                    |          |                 | Required:
| frame-no           | Yes      | Integer         | The frame order number. This will determine the order of a frame in the sequence.                                                        |
|                    |          |                 | Optional:
| unix-timestamp     | No       | Integer         | The unix timestamp of a frame. The number of seconds since January 1st, 1970 until the UTC time when the frame was captured.                |
| frame              | Yes      | String          | The name of a video frame image file.                                                                                                        |

**Output Data**

The output from a labeling job is placed in the Amazon S3 location that you specified in the console or in the call to the CreateLabelingJob operation. Output data appears in this location when the workers have submitted one or more tasks, or when tasks expire. Note that it may take a few minutes for output data to appear in Amazon S3 after the worker submits the task or the task expires.

Each line in the output data file is identical to the manifest file with the addition of an attribute and value for the label assigned to the input object. The attribute name for the value is defined in the console or in the call to the CreateLabelingJob operation. You can't use -metadata in the label attribute name. If you are running an image semantic segmentation, 3D point cloud semantic segmentation, or 3D point cloud object tracking job, the label attribute must end with -ref. For any other type of job, the attribute name can't end with -ref.

The output of the labeling job is the value of the key-value pair with the label. The label and the value overwrites any existing JSON data in the input file with the new value.
For example, the following is the output from an image classification labeling job where the input data files were stored in an Amazon S3 `AWSDOC-EXAMPLE-BUCKET` and the label attribute name was defined as `sport`. In this example the JSON object is formatted for readability, in the actual output file the JSON object is on a single line. For more information about the data format, see JSON Lines.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/image_example.png",
  "sport": 0,
  "sport-metadata":
  {
    "class-name": "football",
    "confidence": 0.00,
    "type": "groundtruth/image-classification",
    "job-name": "identify-sport",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256"
  }
}
```

The value of the label can be any valid JSON. In this case the label's value is the index of the class in the classification list. Other job types, such as bounding box, have more complex values.

Any key-value pair in the input manifest file other than the label attribute is unchanged in the output file. You can use this to pass data to your application.

The output from a labeling job can be used as the input to another labeling job. You can use this when you are chaining together labeling jobs. For example, you can send one labeling job to determine the sport that is being played. Then you send another using the same data to determine if the sport is being played indoors or outdoors. By using the output data from the first job as the manifest for the second job, you can consolidate the results of the two jobs into one output file for easier processing by your applications.

The output data file is written to the output location periodically while the job is in progress. These intermediate files contain one line for each line in the manifest file. If an object is labeled, the label is included. If the object hasn't been labeled, it is written to the intermediate output file identically to the manifest file.

**Output Directories**

Ground Truth creates several directories in your Amazon S3 output path. These directories contain the results of your labeling job and other artifacts of the job. The top-level directory for a labeling job is given the same name as your labeling job; the output directories are placed beneath it. For example, if you named your labeling job `find-people`, your output would be in the following directories:

- `s3://AWSDOC-EXAMPLE-BUCKET/find-people/activelearning`
- `s3://AWSDOC-EXAMPLE-BUCKET/find-people/annotations`
- `s3://AWSDOC-EXAMPLE-BUCKET/find-people/inference`
- `s3://AWSDOC-EXAMPLE-BUCKET/find-people/manifests`
- `s3://AWSDOC-EXAMPLE-BUCKET/find-people/training`

Each directory contains the following output:

**Active Learning Directory**

The activelearning directory is only present when you are using automated data labeling. It contains the input and output validation set for automated data labeling, and the input and output folder for automatically labeled data.
Annotations Directory

The annotations directory contains all of the annotations made by the workforce. These are the responses from individual workers that have not been consolidated into a single label for the data object.

There are three subdirectories in the annotations directory.

- The first, worker-response, contains the responses from individual workers. This contains a subdirectory for each iteration, which in turn contains a subdirectory for each data object in that iteration. The worker response data for each data object is stored in a timestamped JSON file that contains the answers submitted by each worker for that data object, and if you use a private workforce, metadata about those workers. To learn more about this metadata, see Worker Metadata (p. 893).
- The second, consolidated-annotation, contains information required to consolidate the annotations in the current batch into labels for your data objects.
- The third, intermediate, contains the output manifest for the current batch with any completed labels. This file is updated as the label for each data object is completed.

Note

We recommend that you do not use files that are not mentioned in the documentation.

Inference Directory

The inference directory is only present when you are using automated data labeling. This directory contains the input and output files for the SageMaker batch transform used while labeling data objects.

Manifest Directory

The manifest directory contains the output manifest from your labeling job. There is one subdirectory in the manifest directory, output. The output directory contains the output manifest file for your labeling job. The file is named output.manifest.

Training Directory

The training directory is only present when you are using automated data labeling. This directory contains the input and output files used to train the automated data labeling model.

Confidence Score

When you have more than one worker annotate a single task, your label results from annotation consolidation. Ground Truth calculates a confidence score for each label. A confidence score is a number between 0 and 1 that indicates how confident Ground Truth is in the label. You can use the confidence score to compare labeled data objects to each other, and to identify the least or most confident labels.

You should not interpret the value of a confidence score as an absolute value, or compare confidence scores across labeling jobs. For example, if all of the confidence scores are between 0.98 and 0.998, you should only compare the data objects with each other and not rely on the high confidence scores.

You should not compare the confidence scores of human-labeled data objects and auto-labeled data objects. The confidence scores for humans are calculated using the annotation consolidation function for the task, while the confidence scores for automated labeling are calculated using a model that incorporates object features. The two models generally have different scales and average confidence.

For a bounding box labeling job, Ground Truth calculates a confidence score per box. You can compare confidence scores within one image or across images for the same labeling type (human or auto). You can't compare confidence scores across labeling jobs.
If a single worker annotates a task (NumberOfHumanWorkersPerDataObject is set to 1 or in the console, you enter 1 for **Number of workers per dataset object**), the confidence score is set to 0.00.

**Worker Metadata**

Ground Truth provides information that you can use to track individual workers in task output data. The following data is located in the directories under the worker-response located in the Annotations Directory (p. 892):

- The **acceptanceTime** is the time that the worker accepted the task. The format of this date and time stamp is **YYYY-MM-DDTHH:MM:SS.mmmZ** for the year (**YYYY**), month (**MM**), day (**DD**), hour (**HH**), minute (**MM**), second (**SS**) and millisecond (**mmm**). The date and time are separated by a **T**.
- The **submissionTime** is the time that the worker submitted their annotations using the **Submit** button. The format of this date and time stamp is **YYYY-MM-DDTHH:MM:SS.mmmZ** for the year (**YYYY**), month (**MM**), day (**DD**), hour (**HH**), minute (**MM**), second (**SS**) and millisecond (**mmm**). The date and time are separated by a **T**.
- **timeSpentInSeconds** reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- **workerId** is unique to each worker.
- If you use a **private workforce**, in workerMetadata, you see the following.
  - The **identityProviderType** is the service used to manage the private workforce.
  - The **issuer** is the Cognito user pool or OIDC Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique sub identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) using this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the **identityProviderType**.

```json
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3cdefg4h5i67",
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Cognito",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

The following is an example of the **workerMetadata** you may see if you use your own OIDC IdP to create a private workforce:

```json
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Oidc",
    "issuer": "https://example-oidc-idp.com/adfs",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

To learn more about using private workforces, see Use a Private Workforce (p. 981).
Output Metadata

The output from each job contains metadata about the label assigned to data objects. These elements are the same for all jobs with minor variations. The following example shows the metadata elements:

```
"confidence": 0.00,
"type": "groundtruth/image-classification",
"job-name": "identify-animal-species",
"human-annotated": "yes",
"creation-date": "2020-10-18T22:18:13.527256"
```

The elements have the following meaning:

- **confidence** – The confidence that Ground Truth has that the label is correct. For more information, see [Confidence Score](#).
- **type** – The type of classification job. For job types, see [Built-in Task Types](#).
- **job-name** – The name assigned to the job when it was created.
- **human-annotated** – Whether the data object was labeled by a human or by automated data labeling. For more information, see [Automate Data Labeling](#).
- **creation-date** – The date and time that the label was created.

**Classification Job Output**

The following are sample outputs (output manifest files) from an image classification job and a text classification job. They include the label that Ground Truth assigned to the data object, the value for the label, and metadata that describes the label.

In addition to the standard metadata elements, the metadata for a classification job includes the text value of the label's class. For more information, see [Image Classification - MXNet](#).

The red, italicized text in the examples below depends on labeling job specifications and output data.
Multi-label Classification Job Output

The following are example output manifest files from a multi-label image classification job and a multi-label text classification job. They include the labels that Ground Truth assigned to the data object (for example, the image or piece of text) and metadata that describes the labels the worker saw when completing the labeling task.
