4. Use `TaskAvailabilityLifetimeInSeconds` to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.
5. Use `NumberOfHumanWorkersPerDataObject` to specify the number of workers per dataset object.
6. Use `PublicWorkforceTaskPrice` to set the price per task. This is the amount of money a worker receives for completing a single task.
7. Use `DataAttributes` to specify that your input data is free of confidential information, personal information, or protected health information.

   Ground Truth *requires* that your input data is free of personally identifiable information (PII) if you use the Mechanical Turk workforce. If you use Mechanical Turk and do not specify that your input data is free of PII using the `FreeOfPersonallyIdentifiableInformation` flag, your labeling job will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker AI may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: Ground Truth Jupyter Notebook Examples.

Use Mechanical Turk with Amazon A2I

You can specify that you want to use Mechanical Turk with Amazon A2I when you create a human review workflow, also referred to as a *flow definition*, in the console, or with the `CreateFlowDefinition` API operation. When you use this human review workflow to configure human loops, you must specify that your input data is free of PII.

To use Mechanical Turk when you create a human review workflow (console):

1. Use the following to create a human review workflow in the Augmented AI section of the SageMaker AI console: Create a Human Review Workflow (Console).
2. When you are selecting **Worker types** in the **Workers** section, select **Amazon Mechanical Turk**.
3. Select the **Price per task** using the dropdown list. This is the amount of money a worker receives for completing a single task.
4. (Optional) You can specify the **Number of workers per dataset object** under **Additional configuration**. For example, if you enter 3 in this field, each data object will be labeled by 3 workers.
5. (Optional) Specify the total amount of time workers have to complete a task using **Task timeout**.
6. (Optional) Specify the total amount of time a task remains available to workers in **Task expiration**. This is how long workers have to pick up a task before it fails.
7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter `FlowDefinitionArn`. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, `StartHumanLoop`. To learn more, see Create and Start a Human Loop.

When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` content classifier in `DataAttributes`. If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker AI may restrict the Mechanical Turk workers that can view your task if it contains adult content.

To use Mechanical Turk when you create a human review workflow (API):

1. Use the following to create a human review workflow using the `CreateFlowDefinition` operation: Create a Human Review Workflow (API).
2. Use the following for the `WorkteamArn`. Replace *`region`* with the AWS Region you are using to create the labeling job.

   ```
   arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default
   ```
3. Use `TaskTimeLimitInSeconds` to specify the total amount of time workers have to complete a task.
4. Use `TaskAvailabilityLifetimeInSeconds` to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.
5. Use `TaskCount` to specify the number of workers per dataset object. For example, if you specify 3 for this parameter, each data object will be labeled by 3 workers.
6. Use `PublicWorkforceTaskPrice` to set the price per task. This is the amount of money a worker receives for completing a single task.
7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter `FlowDefinitionArn`. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, `StartHumanLoop`. To learn more, see Create and Start a Human Loop.

   When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` content classifier in `DataAttributes`.

If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker AI may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: Amazon A2I Jupyter Notebook Examples.

When is Mechanical Turk Not Supported?

This workforce is not supported under the following scenarios. In each scenario, you must use a private or vendor workforce.

- This workforce is not supported for Ground Truth video frame labeling jobs and 3D point cloud labeling jobs.
- You cannot use this workforce if your input data contains personally identifiable information (PII).
- Mechanical Turk is not available in some of the AWS special regions. If applicable, refer to the documentation for your special region for more information.

Subscribe to vendor workforces

You can use a vendor-managed workforce to label your data using Amazon SageMaker Ground Truth (Ground Truth) and Amazon Augmented AI (Amazon A2I). Vendors have extensive experience in providing data labeling services for the purpose of machine learning. Vendor workforces for these two services must be created and managed seperately through the Amazon SageMaker AI console.

Vendors make their services available via the AWS Marketplace. You can find details of the vendor's services on their detail page, such as the number of workers and the hours that they work. You can use these details to make estimates of how much the labeling job will cost and the amount of time that you can expect the job to take. Once you have chosen a vendor you subscribe to their services using the AWS Marketplace.

A subscription is an agreement between you and the vendor. The agreement spells out the details of the agreement, such as price, schedule, or refund policy. You work directly with the vendor if there are any issues with your labeling job.

You can subscribe to any number of vendors to meet your data annotation needs. When you create a labeling job or human review worklow you can specify that the job be routed to a specific vendor.

> **Important**
>
> Before you send sensitive data to a vendor, check the vendor's security and compliance practices on their detail page and review the end user license agreement (EULA) that is part of your subscription agreement. You are responsible for ensuring that the vendor meets your compliance requirements for personal or confidential information. Do not share protected health information with this workforce.

You must use the console to subscribe to a vendor workforce. Once you have a subscription, you can use the `ListSubscribedWorkteams` operation to list your subscribed vendors.

To subscribe to a vendor workforce

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose the appropriate page in the SageMaker AI console.
   - For Ground Truth labeling jobs, choose **Labeling workforces**, choose **Vendor**, and then choose **Find data labeling services**.
   - For Amazon A2I human review workflows, choose **Human review workforces**, choose **Vendor**, and then choose **Find human review services**.
3. The console opens the AWS Marketplace with:
   - data labeling services category selected for Ground Truth
   - human review services category selected for Amazon A2I

   Here you see a list of the vendor services available for this service.
4. Choose a vendor. The AWS Marketplace shows detailed information about the data labeling or human review service. Use this information to determine if the vendor meets your requirements for your task.

5. If the vendor meets your requirements, choose **Continue to subscribe**.
6. Review the details of the subscription. If you agree to the terms, choose **Subscribe** to complete your subscription to the service.

Private workforce

A **private workforce** is a group of workers that *you* choose. These can be employees of your company or a group of subject matter experts from your industry. For example, if the task is to label medical images, you could create a private workforce of people knowledgeable about the images in question.

Each AWS account has access to a single private workforce per region, and the owner has the ability to create multiple **private work teams** within that workforce. A single private work team is used to complete a labeling job or human review task, or a *job*. You can assign each work team to a separate job or use a single team for multiple jobs. A single worker can be in more than one work team.

Your private workforce can either be created and managed using Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP).

If you are a new user of Amazon SageMaker Ground Truth or Amazon Augmented AI and do not require your workers to be managed with your own IdP, it is recommended that you use Amazon Cognito to create and manage your private workforce.

After you create a workforce, in addition to creating and managing work teams, you can do the following:

- Track worker performance
- Create and manage Amazon SNS topics to notify workers when labeling tasks are available
- Manage Private Workforce Access to Tasks Using IP Addresses

> **Note**
>
> Your private workforce is shared between Ground Truth and Amazon A2I. To create and manage private work teams used by Augmented AI, use the Ground Truth section of the SageMaker AI console.

Topics

Amazon Cognito Workforces

Create and manage your private workforce using Amazon Cognito when you want to create your workforce using the Amazon SageMaker AI console or you don't want the overhead of managing worker credentials and authentication. When you create a private workforce with Amazon Cognito, it provides authentication, authorization, and user management for your private workers.

Topics

Create a Private Workforce (Amazon Cognito)

When you use Amazon Cognito, you can create a private workforce in one of the following ways:

- Create a new workforce while you are creating your labeling job. To learn how, see Create an Amazon Cognito Workforce When Creating a Labeling Job.
- Create a new workforce before you create your labeling job. To learn how, see Create an Amazon Cognito Workforce Using the Labeling Workforces Page.
- Import an existing workforce after creating a user pool in the Amazon Cognito console. To learn how, see Create a Private Workforce (Amazon Cognito Console).

Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon Augmented AI human review workflows tasks.

If you are new to Amazon SageMaker AI and want to test Ground Truth or Amazon A2I, we suggest that you create a private work team consisting of people from your organization using the console.

Use this work team when creating labeling or human review workflows (flow definitions) to test your worker UI and job workflow.

Topics

- Create a Private Workforce (Amazon SageMaker AI Console)
- Create a Private Workforce (Amazon Cognito Console)

Create a Private Workforce (Amazon SageMaker AI Console)

You can create a private workforce in the Amazon SageMaker AI console in one of two ways:

- When creating a labeling job in the **Labeling jobs** page of the Amazon SageMaker Ground Truth section.
- Using the **Labeling workforces** page of the Amazon SageMaker Ground Truth section. If you are creating a private workforce for an Amazon A2I human review workflow, use this method.

Both of these methods also create a default work team containing all of the members of the workforce. This private workforce is available to use for both Ground Truth and Amazon Augmented AI jobs.

When you create a private workforce using the console, SageMaker AI uses Amazon Cognito as an identity provider for your workforce. If you want to use your own OpenID Connect (OIDC) Identity Provider (IdP) to create and manage your private workforce, you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP).

Create an Amazon Cognito Workforce When Creating a Labeling Job

If you haven't created a private workforce when you create your labeling job and you choose to use private workers, you are prompted to create a work team. This will create a private workforce using Amazon Cognito.

To create a workforce while creating a labeling job (console)

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Labeling jobs** and fill in all required fields. For instructions on how to start a labeling job, see Getting started: Create a bounding box labeling job with Ground Truth. Choose **Next**.

3. Choose **Private** for the workforce type.
4. In the **Workers** section, enter:

   a. The **Team name**.

   b. Email addresses for up to 100 workforce members. Email addresses are case sensitive. Your workers must log in using the same case used when the address was initially entered. You can add additional workforce members after the job has been created.

   c. The name of your organization. SageMaker AI uses this to customize the email sent to the workers.

   d. A contact email address for workers to report issues related to the task.

When you create the labeling job, an email is sent to each worker inviting them to join the workforce. After creating the workforce, you can add, delete, and disable workers using the SageMaker AI console or the Amazon Cognito console.

Create an Amazon Cognito Workforce Using the Labeling Workforces Page

To create and manage your private workforce using Amazon Cognito, you can use the **Labeling workforces** page. When following the instructions below, you have the option to create a private workforce by entering worker emails importing a pre-existing workforce from an Amazon Cognito user pool. To import a workforce, see [Create a Private Workforce (Amazon Cognito Console)](#).

To create a private workforce using worker emails

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. Paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

8. Click the **Create private team** button.

After you import your private workforce, refresh the page. On the **Private workforce summary** page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce.

> **Note**
>
> If you delete all of your private work teams, you have to repeat this process to use a private workforce in that region.

Create a Private Workforce (Amazon Cognito Console)

Amazon Cognito is used to define and manage your private workforce and your work teams. It is a service that you can use to create identities for your workers and authenticate these identities with identity providers. A private workforce corresponds to a single **Amazon Cognito user pool**. Private work teams correspond to **Amazon Cognito user groups** within that user pool.

Example identity providers supported by Amazon Cognito:

- Social sign-in providers such as Facebook and Google
- OpenID Connect (OIDC) providers
- Security Assertion Markup Language (SAML) providers such as Active Directory
- The Amazon Cognito built-in identity provider

For more information, see [What Is Amazon Cognito?](#).

To create a private workforce using Amazon Cognito, you must have an existing Amazon Cognito user pool containing at least one user group. See [Tutorial: Creating a User Pool](#) to learn how to create a user pool. See [Adding Groups to a User Pool](#) to learn how to add a user group to a pool.

Once your user pool has been created, follow the steps below to create a private workforce by importing that user pool into Amazon SageMaker AI.

To create a private workforce by importing a Amazon Cognito user pool

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.

3. Choose **Private**.
4. Choose **Create private team**. This creates a private workforce and a work team.
5. Choose **Import workers from existing Amazon Cognito user groups**.
6. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the **Domain name** options on the **App integration** page of the Amazon Cognito console for your group.
7. Choose an app client. We recommend using a client generated by SageMaker AI.
8. Choose a user group from your pool to import its members.
9. Optionally choose an Amazon Simple Notification Service (Amazon SNS) topic to which to subscribe the team so that workers are notified by email when new labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
10. Choose **Create private team**.

> **Important**
>
> After you create a workforce using an Amazon Cognito user pool, it should not be deleted without first deleting all work teams associated with that pool in the SageMaker AI console.

After you import your private workforce, refresh the page to see the **Private workforce summary** page. On this page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce. This workforce is now available to use in both Amazon Augmented AI and Amazon SageMaker Ground Truth for human review tasks and data labeling jobs respectively.

Manage a Private Workforce (Amazon Cognito)

After you have created a private workforce using Amazon Cognito, you can create and manage work teams using the Amazon SageMaker AI console and API operations.

You can do the following using either the SageMaker AI console or Amazon Cognito console.

- Add and delete work teams.

- Add workers to your workforce and one or more work teams.
- Disable or remove workers from your workforce and one or more workteams. If you add workers to a workforce using the Amazon Cognito console, you must use the same console to remove the worker from the workforce.

You can restrict access to tasks to workers at specific IP addresses using the SageMaker API. For more information, see Private workforce management using the Amazon SageMaker API.

Topics

Manage a Workforce (Amazon SageMaker AI Console)

You can use the Amazon SageMaker AI console to create and manage the work teams and individual workers that make up a private workforce.

Use a work team to assign members of your private workforce to a labeling or human review *job*. When you create your workforce using the SageMaker AI console, there is a work team called **Everyone-in-private-workforce** that enables you to assign your entire workforce to a job. Because an imported Amazon Cognito user pool may contain members that you don't want to include in your work teams, a similar work team is not created for Amazon Cognito user pools.

You have two choices to create a new work team:

- You can create a work team in the SageMaker AI console and add members from your workforce to the team.
- You can create a user group by using the Amazon Cognito console and then create a work team by importing the user group. You can import more than one user group into each work team. You manage the members of the work team by updating the user group in the Amazon Cognito console. See Manage a Private Workforce (Amazon Cognito Console) for more information.

Create a Work Team Using the SageMaker AI Console

You can create a new Amazon Cognito user group or import an existing user group using the SageMaker AI console, on the **Labeling workforces** page. For more information on creating a user group in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console).

To create a work team using the SageMaker AI console

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Labeling workforces** from the left menu.
3. Under **Private**, choose **Create private team**.
4. Under **Team details**, enter a **Team name**. The name must be unique in your account in an AWS Region.
5. Under **Add workers**, choose a method to add workers to the team using a user group.
   - If you chose **Create a team by adding workers to a new Amazon Cognito user group**, select the workers to add to the team.
   - If you chose **Create a team by importing existing Amazon Cognito user groups**, choose the user groups that are part of the new team.
6. If you select an **SNS topic**, all workers added to the team are subscribed to the Amazon SNS topic and notified when new work items are available to the team. Select from a list of your existing Ground Truth related Amazon SNS topics or select **Create new topic** to open a topic-creation dialog.

   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Workers in a workteam subscribed to a topic receive notifications when a new Ground Truth labeling job for that team becomes available and when one is about to expire.

Read Create the Amazon SNS topic for more information about using Amazon SNS topic.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the Amazon SNS topic to which its members are subscribed by visiting the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. Read Create and manage Amazon SNS topics for your work teams for more information on creating and managing the Amazon SNS topic.

Add or Remove Workers

A *work team* is a group of workers within your workforce to whom you can assign jobs. A worker can be added to more than one work team. Once a worker has been added to a work team, that worker can be disabled or removed.

Add Workers to the Workforce

Adding a worker to the workforce enables you to add that worker to any work team within that work force.

To add workers using the private workforce summary page

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Labeling workforces** to navigate to your private workforce summary page.
3. Choose **Private**.
4. Choose **Invite new workers**.
5. Paste or type a list of email addresses, separated by commas, into the email addresses box. You can have up to 50 email addresses in this list.

Add a Worker to a Work Team

A worker must be added to the workforce before being added to a work team. To add a worker to a work team, first navigate to the **Private workforce summary** page using the steps above.

To add a worker to a work team from the private workforce summary page

1. In the **Private teams** section, choose the team to which you want to add the workers.
2. Choose the **Workers** tab.
3. Choose **Add workers to team** and choose the boxes next to the workers that you want to add.
4. Click **Add workers to team**.

Disable and Remove a Worker from the Workforce

Disabling a worker stops the worker from receiving a job. This action does not remove the worker from the workforce, or from any work team with which the worker is associated. To disable or remove a worker from a work team, first navigate to the private workforce summary page using the steps above.

To deactivate a worker using the private workforce summary page

1. In the **Workers** section, choose the worker that you would like to disable.
2. Choose **Disable**.

If desired, you can subsequently **Enable** a worker after they have been disabled.

You can remove workers from your private workforce directly in the SageMaker AI console if that worker was added in this console. If you added the worker (user) in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console) to learn how to remove the worker in the Amazon Cognito console.

To remove a worker using the private workforce summary page

1. In the **Workers** section, choose the worker that you would like to delete.
2. If the worker has not been disabled, choose **Disable**.
3. Select the worker and choose **Delete**.

Manage a Private Workforce (Amazon Cognito Console)

A private workforce corresponds to a single **Amazon Cognito user pool**. Private work teams correspond to **Amazon Cognito user groups** within that user pool. Workers correspond to **Amazon Cognito users** within those groups.

After your workforce has been created, you can add work teams and individual workers through the Amazon Cognito console. You can also delete workers from your private workforce or remove them from individual teams in the Amazon Cognito console.

> **Important**
>
> You can't delete work teams from the Amazon Cognito console. Deleting a Amazon Cognito user group that is associated with an Amazon SageMaker AI work team will result in an error. To remove work teams, use the SageMaker AI console.

Create Work Teams (Amazon Cognito Console)

You can create a new work team to complete a job by adding a Amazon Cognito user group to the user pool associated with your private workforce. To add a Amazon Cognito user group to an existing worker pool, see Adding groups to a User Pool.

To create a work team using an existing Amazon Cognito user group

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Workforces**.
3. For **Private teams**, choose **Create private team**.
4. Under **Team details**, give the team a name. The name must be unique in your account in an AWS Region.
5. For **Add workers,** choose **Import existing Amazon Cognito user groups**, and choose one or more user groups that are part of the new team.
6. If you choose an **SNS topic**, all workers added to the team are subscribed to the Amazon Simple Notification Service (Amazon SNS) topic and notified when new work items are available to the team. Choose from a list of your existing SNS topics related to SageMaker Ground Truth or Amazon Augmented AI or choose **Create new topic** to create one.

   Note

   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the SNS topic to which its members are subscribed using the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. For more information, see Create the Amazon SNS topic.

Add and Remove Workers (Amazon Cognito Console)

When using the Amazon Cognito console to add workers to a work team, you must add a user to the user pool associated with the workforce before adding that user to a user group. Users can be added to a user pool in various ways. For more information, see [Signing Up and Confirming User Accounts](#).

Add a Worker to a Work Team

After a user has been added to a pool, the user can be associated with user groups inside of that pool. After a user has been added to a user group, that user becomes a worker on any work team created using that user group.

To add a user to a user group

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.
4. Under **General Settings**, choose **Users and Groups** and do one of the following:
   - Choose **Groups**, choose the group that you want to add the user to, and choose **Add users**. Choose the users that you want to add by choosing the plus-icon to the right of the user's name.
   - Choose **Users**, choose the user that you want to add to the user group, and choose **Add to group**. From the dropdown menu, choose the group and choose **Add to group**.

Disable and Remove a Worker From a Work Team

Disabling a worker stops the worker from receiving jobs. This action doesn't remove the worker from the workforce, or from any work team the worker is associated with. To remove a user from a work team in Amazon Cognito, you remove the user from the user group associated with that team.

To deactivate a worker (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.

4. Under **General Settings**, choose **Users and Groups**.
5. Choose the user that you want to disable.
6. Choose **Disable User**.

You can enable a disabled user by choosing **Enable User**.

To remove a user from a user group (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.
4. Under **General Settings**, choose **Users and Groups**.
5. For **User** tab, choose the **X** icon to the right of the group from which you want to remove the user.

OIDC IdP Workforces

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to manage and authenticate your workers using your own OIDC IdP. Individual worker credentials and other data will be kept private. Ground Truth and Amazon A2I will only have visibility into worker information you provide through the claims that you send to these services. To create a workforce using an OIDC IdP, your IdP must support *groups* because Ground Truth and Amazon A2I map one or more groups in your IdP to a work team. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I.

If you are a new user of Ground Truth or Amazon A2I, you can test your worker UI and job workflow by creating a private work team and adding yourself as a worker. Use this work team when you create a labeling job or human review workflow. First, create a private OIDC IdP workforce using the instructions in Create a Private Workforce (OIDC IdP). Next, refer to Manage a Private Workforce (OIDC IdP) to learn how to create a work team.

Topics

- Create a Private Workforce (OIDC IdP)
- Manage a Private Workforce (OIDC IdP)

Create a Private Workforce (OIDC IdP)

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to authenticate and manage workers using your own identity provider. Use this page to learn how to configure your IdP to communicate with Amazon SageMaker Ground Truth (Ground Truth) or Amazon Augmented AI (Amazon A2I) and to learn how to create a workforce using your own IdP.

To create a workforce using an OIDC IdP, your IdP must support *groups* because Ground Truth and Amazon A2I use one or more groups that you specify to create work teams. You use work teams to specify workers for your labeling jobs and human review tasks. Because groups are not a standard claim, your IdP may have a different naming convention for a group of users (workers). Therefore, you must identify one or more user groups to which a worker belongs using the custom claim `sagemaker:groups` that is sent to Ground Truth or Amazon A2I from your IdP. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I.

You create an OIDC IdP workforce using the SageMaker API operation `CreateWorkforce`. Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon A2I human review workflows tasks. To learn more, see Create an OIDC IdP Workforce.

Send Required and Optional Claims to Ground Truth and Amazon A2I

When you use your own IdP, Ground Truth and Amazon A2I use your `Issuer`, `ClientId`, and `ClientSecret` to authenticate workers by obtaining an authentication CODE from your `AuthorizationEndpoint`.

Ground Truth and Amazon A2I will use this CODE to obtain a custom claim from either your IdP's `TokenEndpoint` or `UserInfoEndpoint`. You can either configure `TokenEndpoint` to return a JSON web token (JWT) or `UserInfoEndpoint` to return a JSON object. The JWT or JSON object must contain required and optional claims that you specify. A claim is a key-value pair that contains information about a worker or metadata about the OIDC service. The following table lists the claims that must be included, and that can optionally be included in the JWT or JSON object that your IdP returns.

> **Note**
>
> Some of the parameters in the following table can be specified using a `:` or a `-`. For example, you can specify the groups a worker belongs to using `sagemaker:groups` or `sagemaker-groups` in your claim.

Name	Required	Accepted Format and Values	Description	Example
`sagemaker:groups` or `sagemaker-groups`	Yes	**Data type**: If a worker belongs to a single group, identify the group using a string. If a worker belongs to multiple groups, use a list of up to 10 strings. **Allowable characters**: Regex: [\p{L}\p{M}\p{S}\p{N}\p{P}]+ **Quotas**: 10 groups per worker 63 characters per group name	Assigns a worker to one or more groups. Groups are used to map the worker into work teams.	Example of worker that belongs to a single group: `"work_team1"` Example of a worker that belongs to more than one groups: `["work_team1", "work_team2"]`
`sagemaker:sub` or `sagemaker-sub`	Yes	**Data type**: String	This is mandatory to track a worker identity inside the Ground Truth platform for auditing and to identify tasks worked on by that worker.	`"111011101-123456789-3687056437-1111"`

Name	Required	Accepted Format and Values	Description	Example
			For ADFS: Customers must use the Primary Security Identifier (SID).	
`sagemaker:client_id` or `sagemaker-client_id`	Yes	**Data type**: String **Allowable characters**: Regex: [\w+-]+ **Quotes**: 128 characters	A client ID. All tokens must be issued for this client ID.	`"00b600bb-1f00-05d0-bd00-00be00fbd0e0"`
`sagemaker:name` or `sagemaker-name`	Yes	**Data type**: String	The worker name to be displayed in the worker portal.	`"Jane Doe"`

Name	Required	Accepted Format and Values	Description	Example
`email`	No	**Data type**: String	The worker email. Ground Truth uses this email to notify workers that they have been invited to work on labeling tasks. Ground Truth will also use this email to notify your workers when labeling tasks become available if you set up an Amazon SNS topic for a work team that this worker is on.	`"example-email@domain.com"`
`email_verified`	No	**Data type**: Bool **Accepted Values:** `True`, `False`	Indicates if the user email was verified or not.	`True`

The following an example of the JSON object syntax your `UserInfoEndpoint` can return.

```
{
    "sub":"122",
    "exp":"10000",
    "sagemaker-groups":["group1","group2"]
    "sagemaker-name":"name",
    "sagemaker-sub":"122",
    "sagemaker-client_id":"123456"
}
```

Ground Truth or Amazon A2I compares the groups listed in `sagemaker:groups` or `sagemaker-groups` to verify that your worker belongs to the work team specified in the labeling job or human review task. After the work team has been verified, labeling or human review tasks are sent to that worker.

Create an OIDC IdP Workforce

You can create a workforce using the SageMaker API operation `CreateWorkforce` and associated language-specific SDKs. Specify a `WorkforceName` and information about your OIDC IDP in the parameter `OidcConfig`. It is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI with the worker portal URL after you create the workforce. To learn more, see Configure your OIDC IdP.

The following shows an example of the request. See `CreateWorkforce` to learn more about each parameter in this request.

```
CreateWorkforceRequest: {
    #required fields
    WorkforceName: "example-oidc-workforce",
    OidcConfig: {
        ClientId: "clientId",
        ClientSecret: "secret",
        Issuer: "https://example-oidc-idp.com/adfs",
        AuthorizationEndpoint: "https://example-oidc-idp.com/adfs/oauth2/authorize",
        TokenEndpoint: "https://example-oidc-idp.com/adfs/oauth2/token",
        UserInfoEndpoint: "https://example-oidc-idp.com/adfs/oauth2/userInfo",
        LogoutEndpoint: "https://example-oidc-idp.com/adfs/oauth2/log-out",
        JwksUri: "https://example-oidc-idp.com/adfs/discovery/keys"
    },
    SourceIpConfig: {
        Cidrs: ["string", "string"]
    }
}
```

Configure your OIDC IdP

How you configure your OIDC IdP depends on the IdP you use, and your business requirements.

When you configure your IdP, you must to specify a callback or redirect URI. After Ground Truth or Amazon A2I authenticates a worker, this URI will redirect the worker to the worker portal where the workers can access labeling or human review tasks. To create a worker portal URL, you need to create a workforce with your OIDC IdP details using the `CreateWorkforce` API operation. Specifically, you must configure your OIDC IdP with required custom sagemaker claims (see the next section for more details). Therefore, it is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI after you create the workforce. See Create an OIDC IdP Workforce to learn how to create a workforce using this API.

You can view your worker portal URL in the SageMaker Ground Truth console, or using the SageMaker API operation, `DescribeWorkforce`. The worker portal URL is in the `SubDomain` parameter in the response.

Important

Make sure you add the workforce subdomain to your OIDC IdP allow list. When you add the subdomain to your allow list, it must end with `/oauth2/idpresponse`.

To view your worker portal URL after creating a private workforce (Console):

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.
3. Select the **Private** tab.
4. In **Private workforce summary** you will see **Labeling portal sign-in URL**. This is your worker portal URL.

To view your worker portal URL after creating a private workforce (API):

When you create a private workforce using `CreateWorkforce`, you specify a `WorkforceName`. Use this name to call `DescribeWorkforce`. The following table includes examples of requests using the AWS CLI and AWS SDK for Python (Boto3).

SDK for Python (Boto3)

```
response = client.describe_workforce(WorkforceName='string')
print(f'The workforce subdomain is: {response['SubDomain']}')
```

AWS CLI

```
$ C:\>  describe-workforce --workforce-name 'string'
```

Validate Your OIDC IdP Workforce Authentication Response

After you have created your OIDC IdP workforce, you can use the following procedure to validate its authentication workflow using cURL. This procedure assumes you have access to a terminal, and that you have cURL installed.

To validate your OIDC IdP authorization response:

1. Get an authorization code using a URI configured as follows:

```
{AUTHORIZE ENDPOINT}?client_id={CLIENT ID}&redirect_uri={REDIRECT
 URI}&scope={SCOPE}&response_type=code
```

   a. Replace *{AUTHORIZE ENDPOINT}* with the authorize endpoint for your OIDC IdP.
   b. Replace *{CLIENT ID}* with the Client ID from your OAuth client.
   c. Replace *{REDIRECT URI}* with the worker portal URL. If it is not already present, you must add `/oauth2/idpresponse` to the end of the URL.
   d. If you have a custom scope, use it to replace *{SCOPE}*. If you do not have a custom scope, replace *{SCOPE}* with `openid`.

   The following is an example of a URI after the modifications above are made:

```
https://example.com/authorize?
client_id=f490a907-9bf1-4471-97aa-6bfd159f81ac&redirect_uri=https%3A%2F%2F
%2Fexample.labeling.sagemaker.aws
%2Foauth2%2Fidpresponse&response_type=code&scope=openid
```

2. Copy and paste the modified URI from step 1 into your browser and press Enter on your keyboard.
3. Authenticate using your IdP.
4. Copy the authentication code query parameter in the URI. This parameter beings with `code=`. The following is an example of what the response might look like. In this example, copy `code=MCNYDB...` and everything thereafter.

```
https://example.labeling.sagemaker.aws/oauth2/idpresponse?code=MCNYDB....
```

5. Open a terminal and enter the following command after making required modifications listed below:

```
curl --request POST \
  --url '{TOKEN ENDPOINT}' \
  --header 'content-type: application/x-www-form-urlencoded' \
  --data grant_type=authorization_code \
  --data 'client_id={CLIENT ID}' \
  --data client_secret={CLIENT SECRET} \
  --data code={CODE} \
  --data 'redirect_uri={REDIRECT URI}'
```

a. Replace *{TOKEN ENDPOINT}* with the token endpoint for your OIDC IdP.

b. Replace *{CLIENT ID}* with the Client ID from your OAuth client.

c. Replace *{CLIENT SECRET}* with the Client Secret from your OAuth client.

d. Replace *{CODE}* with the authentication code query parameter you copied in step 4.

e. Replace *{REDIRECT URI}* with the worker portal URL.

The following is an example of the cURL request after making the modifications described above:

```
curl --request POST \
  --url 'https://example.com/token' \
  --header 'content-type: application/x-www-form-urlencoded' \
  --data grant_type=authorization_code \
  --data 'client_id=f490a907-9bf1-4471-97aa-6bfd159f81ac' \
  --data client_secret=client-secret \
  --data code=MCNYDB... \
  --data 'redirect_uri=https://example.labeling.sagemaker.aws/oauth2/idpresponse'
```

6. This step depends on the type of `access_token` your IdP returns, a plain text access token or a JWT access token.

   - If your IdP does not support JWT access tokens, `access_token` may be plain text (for example, a UUID). The response you see may look similar to the following. In this case, move to step 7.

```
{
  "access_token":"179c144b-fccb-4d96-a28f-eea060f39c13",
  "token_type":"Bearer",
  "expires_in":3600,
```

```
  "refresh_token":"ef43e52e-9b4f-410c-8d4c-d5c5ee57631a",
  "scope":"openid"
}
```

- If your IdP supports JWT access tokens, step 5 should generate an access token in JWT format. For example, the response may look similar to the following:

```
{
    "access_token":"eyJh...JV_adQssw5c",
    "refresh_token":"i6mapTIAVSp2oJkgUnCACKKfZxt_H5MBLiqcybBBd04",
    "refresh_token_expires_in":6327,
    "scope":"openid",
    "id_token":"eyJ0eXAiOiJK9...-rDaQzUHl6cQQWNiDpWOl_lxXjQEvQ"
}
```

  Copy the JWT and decode it. You can use python script or a third party website to decode it. For example, you can go to the website https://jwt.io/ and paste the JWT into the **Encoded** box to decode it.

  Make sure the decoded response contains the following:

  - The **Required** SageMaker AI claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I. If it does not, you must reconfigure your OIDC IdP to contain these claims.
  - The Issuer you specified when you set up the IdP workforce.

7. In a terminal and enter the following command after making required modifications listed below:

```
curl -X POST -H 'Authorization: Bearer {ACCESS TOKEN}' -d '' -k -v {USERINFO ENDPOINT}
```

   a. Replace *{USERINFO ENDPOINT}* with the user info endpoint for your OIDC IdP.

   b. Replace *{ACCESS TOKEN}* with the access token in the response you received in step 7. This is the entry for the `"access_token"` parameter.

   The following is an example of the cURL request after making the modifications described above:

```
curl -X POST -H 'Authorization: Bearer eyJ0eX...' -d '' -k -v https://example.com/
userinfo
```

8. The response to the final step in the procedure above may look similar to the following code block.

   If the `access_token` returned in step 6 was plain text, you must verify that this response contains required information. In this case, the response must contain the **Required** SageMaker AI claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I. For example, `sagemaker-groups`, `sagamaker-name`.

```
{
    "sub":"122",
    "exp":"10000",
    "sagemaker-groups":["group1","group2"]
    "sagemaker-name":"name",
    "sagemaker-sub":"122",
    "sagemaker-client_id":"123456"
}
```

Next Steps

Once you've created a private workforce using your IdP and verified your IdP authentication response, you can create work teams using your IdP groups. To learn more, see Manage a Private Workforce (OIDC IdP).

You can restrict worker access to tasks to specific IP addresses, and update or delete your workforce using the SageMaker API. To learn more, see Private workforce management using the Amazon SageMaker API.

Manage a Private Workforce (OIDC IdP)

Once you've created a private workforce using your OpenID Connect (OIDC) Identity Provider (IdP), you can manage your workers using your IdP. For example, you can add, remove, and group workers directly through your IdP.

To add workers to an Amazon SageMaker Ground Truth (Ground Truth) labeling job or Amazon Augmented AI (Amazon A2I) human review task, you create work teams using 1-10 IdP groups and assign that work team to the job or task. You assign a work team to a job or task by specifing that work team when you create a labeling job (Ground Truth) or a human review workflow (Amazon A2I).

You can only assign one team to each labeling job or human review workflow. You can use the same team to create multiple labeling jobs or human review tasks. You can also create multiple work teams to work on different labeling jobs or human review tasks.

Prerequisites

To create and manage private work teams using your OIDC IdP groups, first you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP).

Add work teams

You can use the SageMaker AI console to create a private work team using your OIDC IdP workforce on the **Labeling workforces** page under **Ground Truth**. If you are creating a Ground Truth labeling job, you can also create a private work team while creating a labeling job.

> **Note**
>
> You create and manage work teams for Amazon A2I in the Ground Truth area of the SageMaker AI console.

You can also use the SageMaker API and associated language-specific SDKs to create a private work team.

Use the following procedures to learn how to create a private work team using the SageMaker AI console and API.

To create a private work team on the Labeling workforces page (console)

1. Go to the Ground Truth area of the SageMaker AI console: https://console.aws.amazon.com/sagemaker/groundtruth.
2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private teams** section, select **Create private team**.

5. In the **Team details** section, enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group. All workers associated with this group in your IdP are added to this work team.
7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. (Optional) For Ground Truth labeling jobs, if you provide an email for workers in your JWT, Ground Truth notifies workers when a new labeling task is available if you select an SNS topic.
9. Select **Create private team**.

To create a private work team while creating a Ground Truth labeling job (console)

1. Go to the Ground Truth area of the SageMaker AI console: https://console.aws.amazon.com/sagemaker/groundtruth.
2. Select **Labeling jobs**.
3. Use the instructions in Create a Labeling Job (Console) to create a labeling job. Stop when you get to the **Workers** section on the second page.
4. Select **Private** for your worker type.
5. Enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group under **User groups**. All workers associated with this group in your IdP are added to this work team.

   > **Important**
   >
   > The group names you specify for **User groups** must match the group names specified in your OIDC IdP.

7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. Complete all remaining steps to create your labeling job.

The private team that you create is used for this labeling job, and is listed in the **Labeling workforces** section of the SageMaker AI console.

To create a private work team using the SageMaker API

You can create a private work team using the SageMaker API operation CreateWorkteam.

When you use this operation, list all user groups that you want included in the work team in the `OidcMemberDefinition` parameter `Groups`.

> **Important**
>
> The group names you specify for `Groups` must match the group names specified in your OIDC IdP.

For example, if your user group names are `group1`, `group2`, and `group3` in your OIDC IdP, configure `OidcMemberDefinition` as follows:

```
"OidcMemberDefinition": {
   "Groups": ["group1", "group2", "group3"]
 }
```

Additionally, you must give the work team a name using the `WorkteamName` parameter.

Add or remove IdP groups from work teams

After you've created a work team, you can use the SageMaker API to manage that work team. Use the `UpdateWorkteam` operation to update the IdP user groups included in that work team.

- Use the `WorkteamName` parameter to identify the work team that you want to update.
- When you use this operation, list all user groups that you want included in the work team in the `OidcMemberDefinition` parameter `Groups`. If a user group is associated with a work team and you do *not* include it in this list, that user group is no longer associated with this work team.

Delete a work team

You can delete a work team using the SageMaker AI console and SageMaker API.

To delete a private work team in the SageMaker AI console

1. Go to the Ground Truth area of the SageMaker AI console: https://console.aws.amazon.com/sagemaker/groundtruth.
2. Select **Labeling workforces**.

3. Select **Private**.
4. In the **Private teams** section, select the work team that you want to delete.
5. Select **Delete**.

To delete a private work team (API)

You can delete a private work team using the SageMaker API operation `DeleteWorkteam`.

Manage Individual Workers

When you create a workforce using your own OIDC IdP, you cannot use Ground Truth or Amazon A2I to manage individual workers.

- To add a worker to a work team, add that worker to a group associated with that work team.
- To remove a worker from a work team, remove that worker from all user groups associated with that work team.

Update, Delete, and Describe Your Workforce

You can update, delete, and describe your OIDC IdP workforce using the SageMaker API. The following is a list of API operations that you can use to manage your workforce. For additional details, including how you can locate your workforce name, see Private workforce management using the Amazon SageMaker API.

- `UpdateWorkforce` – You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in `OidcConfig` using this operation.

  You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. To learn how to delete work teams, see Delete a work team.
- `DeleteWorkforce` – Use this operation to delete your private workforce. If you have any work teams associated with your workforce, you must delete those work teams before you delete your work force. For more information, see Delete a work team.
- `DescribeWorkforce` – Use this operation to list private workforce information, including workforce name, Amazon Resource Name (ARN), and, if applicable, allowed IP address ranges (CIDRs).

Private workforce management using the Amazon SageMaker API

You can use Amazon SageMaker API operations to manage, update, and delete your private workforce. For each API operation listed on the following topics, you can find a list of supported language-specific SDKs and their documentation in the **See Also** section of the API documentation.

Topics

Find your workforce name

Some of the SageMaker AI workforce-related API operations require your workforce name as input. You can see your Amazon Cognito or OIDC IdP private and vendor workforce names in an AWS Region using the `ListWorkforces` API operation in that AWS Region. If you created your workforce using your own OIDC IdP, you can find your workforce name in the Ground Truth area of the SageMaker AI console.

To find your workforce name in the SageMaker AI console

1. Go to the Ground Truth area of the SageMaker AI console: https://console.aws.amazon.com/sagemaker/groundtruth.
2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private workforce summary** section, locate your workforce ARN. Your workforce name is located at the end of this ARN. For example, if the ARN is `arn:aws:sagemaker:us-east-2:111122223333:workforce/example-workforce`, the workforce name is `example-workforce`.

Restrict worker access to tasks to allowable IP addresses

By default, a workforce isn't restricted to specific IP addresses. You can use the `UpdateWorkforce` operation to require that workers use a specific range of IP addresses (CIDRs) to access tasks. If you specify one or more CIDRs, workers who attempt to access tasks using any IP address outside the specified ranges are denied and will get a HTTP 204 No Content error message on the worker portal. You can specify up to 10 CIDR values using `UpdateWorkforce`.

After you have restricted your workforce to one or more CIDRs, the output of `UpdateWorkforce` lists all allowable CIDRs. You can also use the [`DescribeWorkforce`](#) operation to view all allowable CIDRs for a workforce.

Enable a dual-stack workforce

You can enable a dual-stack workforce by using the [CreateWorkforce](#) and [UpdateWorkforce](#) API operations. Creating a dual-stack workforce, updating an existing workforce to dual-stack, and changing a workforce from dual-stack back to IPv4 are not supported in AWS Management Console.

> **Important**
>
> A workforce without a defined `IpAddressType` defaults to `IPv4`.

Create a dual-stack workforce

The process for creating a dual-stack workforce is similar to creating an IPv4-only workforce, with the exceptions noted below. For more information, see [CreateWorkforce](#).

- To attach a VPC to the private workforce, ensure the VPC is also dual-stack, with IPv6 CIDR blocks associated with the VPC's subnets.
- To use the `SourceIpConfig` parameter to restrict traffic to a specific IP address range, ensure that IPv6 CIDR blocks are also included in the list.
- To implement policies with `SourceIp` conditions on S3 buckets accessed by your tasks, ensure those policies are updated to be dual-stack compatible.
- Your identity provider authentication endpoint supports dual-stack. For more information, see [Authentication flow](#).

Example `CreateWorkforce` SDK call using boto3

For more information, see [create_workforce](#).

```
import boto3
```

```
client = boto3.resource('sagemaker')

# IpAddressType = 'dualstack'|'ipv4'
client.create_workforce(
    WorkforceName='string',
    IpAddressType='dualstack',
    WorkforceConfig={
        'CognitoConfig': {
            'UserPool': 'string',
            'Client': 'string'
        }
    }
)
```

Update a dual-stack workforce

When updating an existing workforce to be dual-stack, note the following. For more information, see UpdateWorkforce and IPv6 support for your VPC.

- If a VPC is attached to the workforce, you must update the VPC to be dual-stack. Also ensure that any security groups for the VPC allow IPv6 traffic.
- If you're using the `SourceIpConfig` parameter, update it to include IPv6 CIDR blocks.
- To implement policies with `SourceIp` conditions on S3 buckets accessed by your tasks, ensure those policies are updated to be dual-stack compatible.
- Your identity provider authentication endpoint supports dual-stack. For more information, see Authentication flow.

Example `UpdateWorkforce` SDK call using boto3

For more information, see update_workforce.

```
import boto3

client = boto3.resource('sagemaker')

# IpAddressType = 'dualstack'|'ipv4'
client.update_workforce(
    WorkforceName='string',
    IpAddressType='dualstack'
```

```
)
```

Update OIDC Identity Provider workforce configuration

You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in `OidcConfig` using the `UpdateWorkforce` operation.

> **Important**
>
> You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. You can delete a private work team using the `DeleteWorkteam` operation.

Delete a private workforce

You can only have one private workforce in each AWS Region. You may want to delete your private workforce in an AWS Region when:

- You want to create a workforce using a new Amazon Cognito user pool.
- You have already created a private workforce using Amazon Cognito and you want to create a workforce using your own OpenID Connect (OIDC) Identity Provider (IdP).

To delete a private workforce, use the `DeleteWorkforce` API operation. If you have any work teams associated with your workforce, you must delete those work teams before you delete your workforce. You can delete a private work team using the `DeleteWorkteam` operation.

Track Worker Performance Metrics

Amazon SageMaker Ground Truth logs worker events to Amazon CloudWatch, such as when a worker starts or submits a task. Use Amazon CloudWatch metrics to measure and track throughput across a team or for individual workers.

> **Important**
>
> Worker event tracking is not available for Amazon Augmented AI human review workflows.

Enable Tracking

During the set-up process for a new work team, the permissions for Amazon CloudWatch logging of worker events are created. Since this feature was added in August 2019, work teams created prior to that may not have the correct permissions. If all of your work teams were created before August 2019, create a new work team. It does not need any members and may be deleted after creation, but by creating it, you establish the permissions and apply them to all of your work teams, regardless of when they were created.

Track Metrics Using Logs

After tracking is enabled, the activity of your workers is logged. Open the Amazon CloudWatch console and choose **Logs** in the navigation pane. You should see a log group named **/aws/sagemaker/groundtruth/WorkerActivity**.

Each completed task is represented by a log entry, which contains information about the worker, their team, the job, when the task was accepted, and when it was submitted.

Example Log entry

```
{
  "worker_id": "cd449a289e129409",
  "cognito_user_pool_id": "us-east-2_IpicJXXXX",
  "cognito_sub_id": "d6947aeb-0650-447a-ab5d-894db61017fd",
  "task_accepted_time": "Wed Aug 14 16:00:59 UTC 2019",
  "task_submitted_time": "Wed Aug 14 16:01:04 UTC 2019",
  "task_returned_time": "",
  "task_declined_time": "",
  "workteam_arn": "arn:aws:sagemaker:us-east-2:############:workteam/private-crowd/
Sample-labeling-team",
  "labeling_job_arn": "arn:aws:sagemaker:us-east-2:############:labeling-job/metrics-
demo",
  "work_requester_account_id": "############",
  "job_reference_code": "############",
  "job_type": "Private",
  "event_type": "TasksSubmitted",
  "event_timestamp": "1565798464"
}
```

A useful data point in each event is the `cognito_sub_id`. You can match that to an individual worker.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Under the **Ground Truth** section, choose **Workforces**.
3. Choose **Private**.
4. Choose the name of a team in the **Private teams** section.
5. In the **Team summary** section, choose the user group identified under **Amazon Cognito user group**. That will take you to the group in the Amazon Cognito console.
6. The **Group** page lists the users in the group. Choose any user's link in the **Username** column to see more information about the user, including a unique **sub** ID.

To get information about all of the team's members, use the ListUsers action (examples) in the Amazon Cognito API.

Track Metrics Using the CloudWatch Console

If you don't want to write your own scripts to process and visualize the raw log information, Amazon CloudWatch metrics provide insights into worker activity for you.

To view metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the `AWS/SageMaker/Workteam` name space, then explore the available metrics. For example, selecting the **Workteam** and **Workforce** metrics lets you calculate the average time per submitted task for a specific labeling job.

For more information, see Using Amazon CloudWatch Metrics.

Create the Amazon SNS topic

The steps for creating Amazon SNS topics for work team notifications are similar to the steps in Getting Started in the *Amazon SNS Developer Guide*, with one significant addition—you must add an access policy so that Amazon SageMaker AI can publish messages to the topic on your behalf.

If you create a work team using the console, the console provides an option to create a new topic for the team so that you don't have to perform these steps.

> **Important**
>
> The Amazon SNS feature is not supported by Amazon A2I. If you subscribe your work team to an Amazon SNS topic, workers will only receive notifications about Ground Truth labeling jobs. Workers will not receive notifications about new Amazon A2I human review tasks.

To add the policy when you create the topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In **Create topic**, enter the name of your topic and then choose **Next steps**.
3. In **Access policy**, choose **Advanced**.
4. In the **JSON editor**, find the `Resource` property, which displays the topic's ARN.
5. Copy the `Resource` ARN value.
6. Before the final closing brace (]), add the following policy.

```
    , {
        "Sid": "AwsSagemaker_SnsAccessPolicy",
        "Effect": "Allow",
        "Principal": {
            "Service": "sagemaker.amazonaws.com"
        },
        "Action": "sns:Publish",
        "Resource": "arn:partition:sns:region:111122223333:MyTopic", # ARN of the
 topic you copied in the previous step
        "Condition": {
            "ArnLike": {
                "aws:SourceArn":
 "arn:partition:sagemaker:region:111122223333:workteam/*" # Workteam ARN
            },
            "StringEquals": {
                "aws:SourceAccount": "111122223333" # SNS topic account
            }
        }
    }
```

7. Create the topic.

After you create the topic, it appears in your **Topics** summary screen. For more information about creating topics, see Creating a Topic in the *Amazon SNS Developer Guide*.

Manage worker subscriptions

If you subscribe a work team to a topic after you've already created the work team, the individual work team members who were added to the team when the work team was created are not automatically subscribed to the topic. For information about subscribing workers' email addresses to the topic, see Subscribing an Endpoint to an Amazon SNS Topic in the *Amazon SNS Developer Guide*.

The only situation in which workers are automatically subscribed to your topic is when you create or import an Amazon Cognito user group at the time that you create a work team ***and*** you set up the topic subscription when you create that work team. For more information about creating and managing your workteams with Amazon Cognito, see Create Work Teams (Amazon Cognito Console).

Crowd HTML Elements Reference

Crowd HTML Elements are web components, a web standard that abstracts HTML markup, CSS, and JavaScript functionality into an HTML tag or set of tags. Amazon SageMaker AI provides customers with the ability to design their own custom task templates in HTML.

As a starting point, you can use a template built using Crowd HTML Elements from one of the following GitHub repositories:

- Example task UIs for Amazon SageMaker Ground Truth
- Over 60 example task UIs for Amazon Augmented AI (A2I)

These repositories include templates designed for audio, image, text, video, and other types of data labeling and annotation tasks.

For more information about how to implement custom templates in Amazon SageMaker Ground Truth, see Custom labeling workflows. To learn more about custom templates in Amazon Augmented AI, see Create Custom Worker Task Templates.

SageMaker AI Crowd HTML Elements

The following is a list of Crowd HTML Elements that make building a custom template easier and provide a familiar UI for workers. These elements are supported in Ground Truth, Augmented AI, and Mechanical Turk.

crowd-alert

A message that alerts the worker to a current situation.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-alert>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <div id="errorBox"></div>

  <crowd-keypoint
    src="{{ task.input.taskObject | grant_read_access }}"
    labels="['Item A', 'Item B', 'Item C']"
    header="Please locate the centers of each item."
    name="annotatedResult">
    <short-instructions>
      Describe your task briefly here and give examples
    </short-instructions>
    <full-instructions>
      Give additional instructions and good/bad examples here
    </full-instructions>
  </crowd-keypoint>
</crowd-form>

<script>
  var num_obj = 1;

  document.querySelector('crowd-form').onsubmit = function(e) {
    const keypoints = document.querySelector('crowd-keypoint').value.keypoints ||
 document.querySelector('crowd-keypoint')._submittableValue.keypoints;
    const labels = keypoints.map(function(p) {
```

```
      return p.label;
    });

    // 1. Make sure total number of keypoints is correct.
    var original_num_labels = document.getElementsByTagName("crowd-keypoint")
[0].getAttribute("labels");

    original_num_labels = original_num_labels.substring(2, original_num_labels.length -
 2).split("\",\"");
    var goalNumKeypoints = num_obj*original_num_labels.length;
    if (keypoints.length != goalNumKeypoints) {
      e.preventDefault();
      errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must add all
 keypoint annotations and use each label only once.</crowd-alert>';
      errorBox.scrollIntoView();
      return;
    }

    // 2. Make sure all labels are unique.
    labelCounts = {};
    for (var i = 0; i < labels.length; i++) {
      if (!labelCounts[labels[i]]) {
        labelCounts[labels[i]] = 0;
      }
      labelCounts[labels[i]]++;
    }
    const goalNumSingleLabel = num_obj;

    const numLabels = Object.keys(labelCounts).length;

    Object.entries(labelCounts).forEach(entry => {
      if (entry[1] != goalNumSingleLabel) {
        e.preventDefault();
        errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must use each
 label only once.</crowd-alert>';
        errorBox.scrollIntoView();
      }
    })
  };
</script>
```

Attributes

The following attributes are supported by this element.

dismissible

A Boolean switch that, if present, allows the message to be closed by the worker.

type

A string that specifies the type of message to be displayed. The possible values are "info" (the default), "success", "error", and "warning".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-badge

An icon that floats over the top right corner of another element to which it is attached.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-badge>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Choose the correct category for this image."
    categories="['Person', 'Umbrella', 'Chair', 'Dolphin']"
```

```
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>

    <short-instructions id="short-instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <crowd-badge icon="star" for="short-instructions"/>
    </short-instructions>
  </crowd-image-classifier>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

for

A string that specifies the ID of the element to which the badge is attached.

icon

A string that specifies the icon to be displayed in the badge. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

This attribute overrides the *label* attribute.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-badge>` HTML element. Replace *`icon-name`* with the name of the icon you'd like to use from this Icons set.

```
<crowd-badge icon="icon-name" for="short-instructions"/>
```

label

The text to display in the badge. Three characters or less is recommended because text that is too large will overflow the badge area. An icon can be displayed instead of text by setting the *icon* attribute.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-button

A styled button that represents some action.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the <crowd-button> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Please select the correct category for this image"
    categories="['Person', 'Umbrella', 'Chair', 'Dolphin']"
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <crowd-button>
        <iron-icon icon="question-answer"/>
      </crowd-button>
    </short-instructions>
```

```
  </crowd-image-classifier>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents clicks.

form-action

A switch that either submits its parent crowd-form element, if set to "submit", or resets its parent <crowd-form> element, if set to "reset".

href

The URL to an online resource. Use this property if you need a link styled as a button.

icon

A string that specifies the icon to be displayed next to the button's text. The string must be the name of an icon from the open-source *iron-icons* set, which is pre-loaded. For example, to insert the search iron-icon, use the following:

```
<crowd-button>
    <iron-icon icon="search"/>
</crowd-button>
```

The icon is positioned to either the left or the right of the text, as specified by the *icon-align* attribute.

To use a custom icon see **icon-url**.

icon-align

The left or right position of the icon relative to the button's text. The default is "left".

icon-url

A URL to a custom image for the icon. A custom image can be used in place of a standard icon that is specified by the *icon* attribute.

loading

A Boolean switch that, if present, displays the button as being in a loading state. This attribute has precedence over the *disabled* attribute if both attributes are present.

target

When you use the `href` attribute to make the button act as a hyperlink to a specific URL, the `target` attribute optionally targets a frame or window where the linked URL should load.

variant

The general style of the button. Use "primary" for primary buttons, "normal" for secondary buttons, "link" for tertiary buttons, or "icon" to display only the icon without text.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-bounding-box

A widget for drawing rectangles on an image and assigning a label to the portion of the image that is enclosed in each rectangle.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-bounding-box>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

```
<crowd-form>
  <crowd-bounding-box
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Draw bounding boxes around all the cats and dogs in this image"
    labels="['Cat', 'Dog']"
  >
    <full-instructions header="Bounding Box Instructions" >
      <p>Use the bounding box tool to draw boxes around the requested target of
 interest:</p>
      <ol>
        <li>Draw a rectangle using your mouse over each instance of the target.</li>
        <li>Make sure the box does not cut into the target, leave a 2 - 3 pixel
 margin</li>
        <li>
          When targets are overlapping, draw a box around each object,
          include all contiguous parts of the target in the box.
          Do not include parts that are completely overlapped by another object.
        </li>
        <li>
          Do not include parts of the target that cannot be seen,
          even though you think you can interpolate the whole shape of the target.
        </li>
        <li>Avoid shadows, they're not considered as a part of the target.</li>
        <li>If the target goes off the screen, label up to the edge of the image.</li>
      </ol>
    </full-instructions>

    <short-instructions>
      Draw boxes around the requested target of interest.
    </short-instructions>
  </crowd-bounding-box>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array of JSON objects, each of which sets a bounding box when the component is loaded. Each JSON object in the array contains the following properties. Bounding boxes set via the `initial-value` property can be adjusted and whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-bounding-box> element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

  You can extract the bounding box initial value from a manifest file of a previous job in a custom template using the Liquid templating language:

```
initial-value="[
  {% for box in task.input.manifestLine.label-attribute-name-from-prior-job.annotations %}
    {% capture class_id %}{{ box.class_id }}{% endcapture %}
    {% assign label = task.input.manifestLine.label-attribute-name-from-prior-job-metadata.class-map[class_id] %}
    {
      label: {{label | to_json}},
      left: {{box.left}},
      top: {{box.top}},
      width: {{box.width}},
      height: {{box.height}},
    },
  {% endfor %}
 ]"
```

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a rectangle. **Limit:** 10 labels.

name

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw bounding boxes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw bounding boxes.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

boundingBoxes

An array of JSON objects, each of which specifies a bounding box that has been created by the worker. Each JSON object in the array contains the following properties.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-bounding-box> element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.

- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example : Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

Single Label, Single Box / Multiple Label, Single Box

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

Single Label, Multiple Box

```
[
```

```
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        },
        {
          "height": 283,
          "label": "Dog",
          "left": 684,
          "top": 120,
          "width": 116
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

Multiple Label, Multiple Box

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 395,
          "label": "Dog",
          "left": 241,
          "top": 125,
          "width": 158
        },
        {
          "height": 298,
          "label": "Cat",
          "left": 699,
```

```
          "top": 116,
          "width": 101
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

You could have many labels available, but only the ones that are used appear in the output.

See Also

- Crowd HTML Elements Reference

crowd-card

A box with an elevated appearance for displaying information.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template designed for sentiment analysis tasks that uses the `<crowd-card>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<style>
  h3 {
    margin-top: 0;
  }

  crowd-card {
    width: 100%;
  }

  .card {
```

```
    margin: 10px;
  }

  .left {
    width: 70%;
    margin-right: 10px;
    display: inline-block;
    height: 200px;
  }

  .right {
    width: 20%;
    height: 200px;
    display: inline-block;
  }
</style>

<crowd-form>
  <short-instructions>
    Your short instructions here.
  </short-instructions>

  <full-instructions>
    Your full instructions here.
  </full-instructions>

  <div class="left">
    <h3>What sentiment does this text convey?</h3>
    <crowd-card>
      <div class="card">
        Nothing is great.
      </div>
    </crowd-card>
  </div>

  <div class="right">
    <h3>Select an option</h3>

    <select name="sentiment1" style="font-size: large" required>
      <option value="">(Please select)</option>
      <option>Negative</option>
      <option>Neutral</option>
      <option>Positive</option>
      <option>Text is empty</option>
```

```
    </select>
  </div>

  <div class="left">
    <h3>What sentiment does this text convey?</h3>
    <crowd-card>
      <div class="card">
        Everything is great!
      </div>
    </crowd-card>
  </div>

  <div class="right">
    <h3>Select an option</h3>

    <select name="sentiment2" style="font-size: large" required>
      <option value="">(Please select)</option>
      <option>Negative</option>
      <option>Neutral</option>
      <option>Positive</option>
      <option>Text is empty</option>
    </select>
  </div>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

heading

The text displayed at the top of the box.

image

A URL to an image to be displayed within the box.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-checkbox

A UI component that can be checked or unchecked allowing a user to select multiple options from a set.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-checkbox>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>

  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <crowd-input name="website" placeholder="http://example.com"></crowd-input>

  <crowd-checkbox name="website-found">Website Found</crowd-checkbox>

</crowd-form>
```

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the check box as checked.

The following is an example of the syntx used to check a checkbox by default.

```
<crowd-checkbox name="checkedBox" value="checked" checked>This box is checked</crowd-checkbox>
```

disabled

A Boolean switch that, if present, displays the check box as disabled and prevents it from being checked.

The following is an example of the syntax used to disable a checkbox.

```
<crowd-checkbox name="disabledCheckBox" value="Disabled" disabled>Cannot be selected</crowd-checkbox>
```

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

The following is an example of the syntax used to require a checkbox be selected.

```
<crowd-checkbox name="work_verified" required>Instructions were clear</crowd-checkbox>
```

value

A string used as the name for the check box state in the output. Defaults to "on" if not specified.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

Provides a JSON object. The `name` string is the object name and the `valuestring` is the property name for a Boolean value based on the check box state; true if checked, false if not checked.

Example : Sample Element Outputs

Using the same name value for multiple boxes.

```
<!-- INPUT -->
<div><crowd-checkbox name="image_attributes" value="blurry"> Blurry </crowd-checkbox></
div>
<div><crowd-checkbox name="image_attributes" value="dim"> Too Dim </crowd-checkbox></
div>
<div><crowd-checkbox name="image_attributes" value="exposed"> Too Bright </crowd-
checkbox></div>
```

```
//Output with "blurry" and "dim" checked
[
  {
    "image_attributes": {
      "blurry": true,
      "dim": true,
      "exposed": false
    }
  }
]
```

Note that all three color values are properties of a single object.

Using different name values for each box.

```
<!-- INPUT -->
<div><crowd-checkbox name="Stop" value="Red"> Red </crowd-checkbox></div>
<div><crowd-checkbox name="Slow" value="Yellow"> Yellow </crowd-checkbox></div>
<div><crowd-checkbox name="Go" value="Green"> Green </crowd-checkbox></div>
```

```
//Output with "Red" checked
[
  {
    "Go": {
      "Green": false
    },
    "Slow": {
      "Yellow": false
    },
```

```
    "Stop": {
      "Red": true
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-classifier

A widget for classifying non-image content, such as audio, video, or text.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using `crowd-classifier`. This example uses the Liquid template language to automate:

- Label categories in the `categories` parameter
- The objects that are being classified in the `classification-target` parameter.

Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <crowd-classifier
      name="category"
      categories="{{ task.input.labels | to_json | escape }}"
      header="What type of a document is this?"
    >
      <classification-target>
        <iframe style="width: 100%; height: 600px;" src="{{ task.input.taskObject  |
 grant_read_access }}" type="application/pdf"></iframe>
      </classification-target>
```

```
      <full-instructions header="Document Classification Instructions">
        <p>Read the task carefully and inspect the document.</p>
        <p>Choose the appropriate label that best suits the document.</p>
      </full-instructions>

      <short-instructions>
        Please choose the correct category for the document
      </short-instructions>
    </crowd-classifier>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

categories

A JSON formatted array of strings, each of which is a category that a worker can assign to the text. You should include "other" as a category, otherwise the worker my not be able to provide an answer.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

name

The name of this widget. It is used as a key for the widget's input in the form output.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: classification-target, full-instructions, short-instructions

Regions

The following regions are supported by this element.

classification-target

The content to be classified by the worker. This can be plain text or HTML. Examples of how the HTML can be used include *but are not limited to* embedding a video or audio player, embedding a PDF, or performing a comparison of two or more images.

full-instructions

General instructions about how to do text classification.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The output of this element is an object using the specified `name` value as a property name, and a string from the `categories` as the property's value.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>"
    }
  }
]
```

See Also

For more information, see the following.

- [Training data labeling using humans with Amazon SageMaker Ground Truth]
- [Crowd HTML Elements Reference]

crowd-classifier-multi-select

A widget for classifying various forms of content—such as audio, video, or text—into one or more categories. The content to classify is referred to as an *object*.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <crowd-classifier-multi-select
      name="category"
      categories="['Positive', 'Negative', 'Neutral']"
      header="Select the relevant categories"
      exclusion-category="{ text: 'None of the above' }"
    >
      <classification-target>
        {{ task.input.taskObject }}
      </classification-target>

      <full-instructions header="Text Categorization Instructions">
        <p><strong>Positive</strong> sentiment include: joy, excitement, delight</p>
        <p><strong>Negative</strong> sentiment include: anger, sarcasm, anxiety</p>
        <p><strong>Neutral</strong>: neither positive or negative, such as stating a
 fact</p>
        <p><strong>N/A</strong>: when the text cannot be understood</p>
        <p>When the sentiment is mixed, such as both joy and sadness, choose both
 labels.</p>
      </full-instructions>

      <short-instructions>
       Choose all categories that are expressed by the text.
      </short-instructions>
    </crowd-classifier-multi-select>
</crowd-form>
```

Attributes

The following attributes are supported by the `crowd-classifier-multi-select` element. Each attribute accepts a string value or string values.

categories

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the object.

header

Required. The text to display above the image. This is typically a question or simple instruction for workers.

name

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

exclusion-category

Optional. A JSON-formatted string with the following format: `"{ text: 'default-value' }"`. This attribute sets a default value that workers can choose if none of the labels applies to the object shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: crowd-form
- **Child elements**: classification-target, full-instructions, short-instructions

Regions

This element uses the following regions.

classification-target

The content to be classified by the worker. Content can be plain text or an object that you specify in the template using HTML. For example, you can use HTML elements to include a video or audio player, embedding a PDF file, or include a comparison of two or more images.

full-instructions

General instructions about how to classify text.

short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is an object that uses the specified `name` value as a property name, and a string from `categories` as the property's value.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
        labels: ["label_a", "label_b"]
    }
  }
]
```

See Also

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-entity-annotation

A widget for labeling words, phrases, or character strings within a longer text. Workers select a label, and highlight the text that the label applies to.

> **Important: Self-contained Widget**
>
> Do not use `<crowd-entity-annotation>` element with the `<crowd-form>` element. It contains its own form submission logic and **Submit** button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-entity-annotation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-entity-annotation
  name="crowd-entity-annotation"
  header="Highlight parts of the text below"
  labels="[{'label': 'person', 'shortDisplayName': 'per', 'fullDisplayName': 'Person'},
 {'label': 'date', 'shortDisplayName': 'dat', 'fullDisplayName': 'Date'}, {'label':
 'company', 'shortDisplayName': 'com', 'fullDisplayName': 'Company'}]"
  text="Amazon SageMaker Ground Truth helps you build highly accurate training datasets
 for machine learning quickly."
>
  <full-instructions header="Named entity recognition instructions">
    <ol>
      <li><strong>Read</strong> the text carefully.</li>
      <li><strong>Highlight</strong> words, phrases, or sections of the text.</li>
      <li><strong>Choose</strong> the label that best matches what you have
 highlighted.</li>
      <li>To <strong>change</strong> a label, choose highlighted text and select a new
 label.</li>
      <li>To <strong>remove</strong> a label from highlighted text, choose the X next
 to the abbreviated label name on the highlighted text.</li>
      <li>You can select all of a previously highlighted text, but not a portion of
 it.</li>
    </ol>
  </full-instructions>

  <short-instructions>
    Apply labels to words or phrases.
  </short-instructions>

    <div id="additionalQuestions" style="margin-top: 20px">
      <h3>
        What is the overall subject of this text?
      </h3>
      <crowd-radio-group>
        <crowd-radio-button name="tech" value="tech">Technology</crowd-radio-button>
        <crowd-radio-button name="politics" value="politics">Politics</crowd-radio-
button>
      </crowd-radio-group>
```

```
    </div>
</crowd-entity-annotation>

<script>
  document.addEventListener('all-crowd-elements-ready', () => {
    document
      .querySelector('crowd-entity-annotation')
      .shadowRoot
      .querySelector('crowd-form')
      .form
      .appendChild(additionalQuestions);
  });
</script>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON formatted array of objects, each of which defines an annotation to apply to the text at initialization. Objects contain a `label` value that matches one in the `labels` attribute, an integer `startOffset` value for labeled span's starting unicode offset, and an integer `endOffset` value for the ending unicode offset.

Example

```
[
  {
    label: 'person',
    startOffset: 0,
    endOffset: 16
  },
  ...
]
```

labels

A JSON formatted array of objects, each of which contains:

- **`label`** (required): The name used to identify entities.
- **`fullDisplayName`** (optional): Used for the label list in the task widget. Defaults to the label value if not specified.
- **`shortDisplayName`** (optional): An abbreviation of 3-4 letters to display above selected entities. Defaults to the label value if not specified.

> **`shortDisplayName` is highly recommended**
>
> Values displayed above the selections can overlap and create difficulty managing labeled entities in the workspace. Providing a 3-4 character `shortDisplayName` for each label is highly recommended to prevent overlap and keep the workspace manageable for your workers.

Example

```
[
  {
    label: 'person',
    shortDisplayName: 'per',
    fullDisplayName: 'person'
  }
]
```

name

Serves as the widget's name in the DOM. It is also used as the label attribute name in form output and the output manifest.

text

The text to be annotated. The templating system escapes quotes and HTML strings by default. If your code is already escaped or partially escaped, see Variable filters for more ways to control escaping.

Element Hierarchy

This element has the following parent and child elements.

- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

entities

A JSON object that specifies the start, end, and label of an annotation. This object contains the following properties.

- **label** – The assigned label.
- **startOffset** – The Unicode offset of the beginning of the selected text.
- **endOffset** – The Unicode offset of the first character after the selection.

Example : Sample Element Outputs

The following is a sample of the output from this element.

```
{
  "myAnnotatedResult": {
    "entities": [
      {
        "endOffset": 54,
        "label": "person",
```

```
          "startOffset": 47
        },
        {
          "endOffset": 97,
          "label": "event",
          "startOffset": 93
        },
        {
          "endOffset": 219,
          "label": "date",
          "startOffset": 212
        },
        {
          "endOffset": 271,
          "label": "location",
          "startOffset": 260
        }
      ]
    }
}
```

crowd-fab

A floating button with an image in its center.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-fab>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
    <crowd-image-classifier
```

```
        src="${image_url}"
        categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
        header="Choose the correct category for the image"
        name="category">

        <short-instructions>
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.</p>
            <p>If there is an issue with the image or tools, please select
              <b>None of the Above</b>, describe the issue in the text box and click
 the
              button below.</p>
            <crowd-input label="Report an Issue" name="template-issues"></crowd-input>
            <crowd-fab id="button1" icon="report-problem" title="Issue"/>
        </short-instructions>

        <full-instructions header="Classification Instructions">
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.
            Use the <b>None of the Above</b> option if none of the other labels suit
 the image.</p>
        </full-instructions>

    </crowd-image-classifier>
</crowd-form>

<script>
  [
    button1,
  ].forEach(function(button) {
    button.addEventListener('click', function() {
      document.querySelector('crowd-form').submit();
    });
  });
</script>
```

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the floating button as disabled and prevents clicks.

icon

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-fab>` HTML element. Replace *icon-name* with the name of the icon you'd like to use from this Icons set.

```
<crowd-fab "id="button1" icon="icon-name" title="Issue"/>
```

label

A string consisting of a single character that can be used instead of an icon. Emojis or multiple characters may result in the button displaying an ellipsis instead.

title

A string that will display as a tool tip when the mouse hovers over the button.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-form

The form wrapper for all custom tasks. Sets and implements important actions for the proper submission of your form data.

If a crowd-button of type "submit" is not included inside the <crowd-form> element, it will automatically be appended within the <crowd-form> element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the <crowd-form> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <crowd-image-classifier
        src="${image_url}"
        categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
        header="Choose the correct category for the image"
        name="category">

        <short-instructions>
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.</p>
        </short-instructions>

        <full-instructions header="Classification Instructions">
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.
            Use the <b>None of the Above</b> option if none of the other labels suit
 the image.</p>
        </full-instructions>

    </crowd-image-classifier>
</crowd-form>
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: none
- **Child elements**: Any of the UI Template elements

Element Events

The `crowd-form` element extends the [standard HTML `form` element] and inherits its events, such as `onclick` and `onsubmit`.

See Also

For more information, see the following.

- Crowd HTML Elements Reference

crowd-icon-button

A button with an image placed in the center. When the user touches the button, a ripple effect emanates from the center of the button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-icon-button>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
    <crowd-image-classifier
        src="${image_url}"
        categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
        header="Choose the correct category for the image"
        name="category">

        <short-instructions>
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.</p>
            <p>If there is an issue with the image or tools, please select
              <b>None of the Above</b>, describe the issue in the text box and click
 the
              button below.</p>
            <crowd-input label="Report an Issue" name="template-issues"/></crowd-input>
```

```
            <crowd-icon-button id="button1" icon="report-problem" title="Issue"/>
        </short-instructions>

        <full-instructions header="Classification Instructions">
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.
            Use the <b>None of the Above</b> option if none of the other labels suit
 the image.</p>
        </full-instructions>

    </crowd-image-classifier>
</crowd-form>

<script>
  [
    button1,
  ].forEach(function(button) {
    button.addEventListener('click', function() {
      document.querySelector('crowd-form').submit();
    });
  });
</script>
```

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents clicks.

icon

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-icon-button>` HTML element. Replace *`icon-name`* with the name of the icon you'd like to use from this Icons set.

```
<crowd-icon-button id="button1" icon="icon-name" title="Issue"/>
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-image-classifier

A widget for classifying an image. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the `<crowd-image-classifier>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
    <crowd-image-classifier
        src="${image_url}"
        categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
        header="Choose the correct category for the image"
        name="category">

        <short-instructions>
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.</p>
        </short-instructions>

        <full-instructions header="Classification Instructions">
```

```
            <p>Read the task carefully and inspect the image.</p>
            <p>Choose the appropriate label that best suits the image.
            Use the <b>None of the Above</b> option if none of the other labels suit
 the image.</p>
        </full-instructions>

    </crowd-image-classifier>
</crowd-form>
```

Attributes

The following attributes are required by this element.

categories

A JSON formatted array of strings, each of which is a category that a worker can assign to the image. You should include "other" as a category, so that the worker can provide an answer. You can specify up to 10 categories.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

name

The name of this widget. It is used as a key for the widget's input in the form output.

overlay

Information to be overlaid on the source image. This is for verification workflows of bounding-box, semantic-segmentation, and instance-segmentation tasks.

It is a JSON object containing an object with the name of the task-type in camelCase as the key. That key's value is an object that contains the labels and other necessary information from the previous task.

An example of a `crowd-image-classifier` element with attributes for verifying a bounding-box task follows:

```
<crowd-image-classifier
    name="boundingBoxClassification"
```

```
    header="Rate the quality of the annotations based on the background section
       in the instructions on the left hand side."
    src="https://i.imgur.com/CIPKVJo.jpg"
    categories="['good', 'bad', 'okay']"
    overlay='{
        "boundingBox": {
            labels: ["bird", "cat"],
            value: [
                {
                  height: 284,
                  label: "bird",
                  left: 230,
                  top: 974,
                  width: 223
                },
                {
                  height: 69,
                  label: "bird",
                  left: 79,
                  top: 889,
                  width: 247
                }
            ]
        },
    }'
> ... </crowd-image-classifier>
```

A semantic segmentation verification task would use the `overlay` value as follows:

```
<crowd-image-classifier
  name='crowd-image-classifier'
  categories='["good", "bad"]'
  src='URL of image to be classified'
  header='Please classify'
  overlay='{
    "semanticSegmentation": {
      "labels": ["Cat", "Dog", "Bird", "Cow"],
      "labelMappings": {
        "Bird": {
          "color": "#ff7f0e"
        },
        "Cat": {
          "color": "#2ca02c"
```

```
        },
        "Cow": {
          "color": "#d62728"
        },
        "Dog": {
          "color": "#2acf59"
        }
      },
      "src": "URL of overlay image",
    }
  }'
> ... </crowd-image-classifier>
```

An instance-segmentation task would use the `overlay` value as follows:

```
<crowd-image-classifier
  name='crowd-image-classifier'
  categories='["good", "bad"]'
  src='URL of image to be classified'
  header='Please classify instances of each category'
  overlay='{
    "instanceSegmentation": {
       "labels": ["Cat", "Dog", "Bird", "Cow"],
       "instances": [
        {
         "color": "#2ca02c",
         "label": "Cat"
        },
        {
         "color": "#1f77b4",
         "label": "Cat"
        },
        {
         "color": "#d62728",
         "label": "Dog"
        }
       ],
       "src": "URL of overlay image",
    }
  }'
> ... </crowd-image-classifier>
```

src

The URL of the image to be classified.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions, worker-comment

Regions

The following regions are used by this element.

full-instructions

General instructions for the worker on how to classify an image.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

worker-comment

Use this in verification workflows when you need workers to explain why they made the choice they did. Use the text between the opening and closing tags to provide instructions for workers on what information should be included in the comment.

It uses the following attributes:

header

A phrase with a call to action for leaving a comment. Used as the title text for a modal window where the comment is added.

Optional. Defaults to "Add a comment."

link-text

This text appears below the categories in the widget. When clicked, it opens a modal window where the worker may add a comment.

Optional. Defaults to "Add a comment."

placeholder

An example text in the comment text area that is overwritten when worker begins to type. This does not appear in output if the worker leaves the field blank.

Optional. Defaults to blank.

Output

The output of this element is a string that specifies one of the values defined in the *categories* attribute of the <crowd-image-classifier> element.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>"
      "workerComment": "Comment - if no comment is provided, this field will not be present"
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-image-classifier-multi-select

A widget for classifying an image into one or more categories. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this crowd element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier-multi-select
    name="animals"
    categories="['Cat', 'Dog', 'Horse', 'Pig', 'Bird']"
    src="https://images.unsplash.com/photo-1509205477838-a534e43a849f?
ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1998&q=80"
    header="Please identify the animals in this image"
    exclusion-category="{ text: 'None of the above' }"
  >
    <full-instructions header="Classification Instructions">
      <p>If more than one label applies to the image, select multiple labels.</p>
      <p>If no labels apply, select <b>None of the above</b></p>
    </full-instructions>

    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label(s) that best suit the image.</p>
    </short-instructions>
  </crowd-image-classifier-multi-select>
</crowd-form>
```

Attributes

The following attributes are supported by the `crowd-image-classifier-multi-select` element. Each attribute accepts a string value or string values.

categories

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the image. A worker must choose at least one category and can choose all categories.

header

Required. The text to display above the image. This is typically a question or simple instruction for workers.

name

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

src

Required. The URL of the image to be classified.

exclusion-category

Optional. A JSON-formatted string with the following format: `"{ text: 'default-value' }"`. This attribute sets a default value that workers can choose if none of the labels applies to the image shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions, worker-comment

Regions

This element uses the following regions

full-instructions

General instructions for the worker on how to classify an image.

short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is a string that specifies one or more of the values defined in the `categories` attribute of the `<crowd-image-classifier-multi-select>` element.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
```

```
        labels: ["label_a", "label_b"]
    }
  }
]
```

See Also

For more information, see the following:

- Create an image classification job (Multi-label)
- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-input

A box that accepts input data.

> **Cannot be self-closing**
>
> Unlike the `input` element in the HTML standard, this element cannot be self-closed by putting a slash before the ending bracket, e.g. `<crowd-input ... />`. It must be followed with a `</crowd-input>` to close the element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-input>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <img style="max-width: 35vw; max-height: 50vh" src="{{ task.input.taskObject | 
 grant_read_access }}">
  <crowd-input name="tag1" label="Word/phrase 1" required></crowd-input>
  <crowd-input name="tag2" label="Word/phrase 2" required></crowd-input>
  <crowd-input name="tag3" label="Word/phrase 3" required></crowd-input>
```

```
  <short-instructions>
    Your custom quick instructions and examples
  </short-instructions>

  <full-instructions>
    Your custom detailed instracutions and more examples
  </full-instructions>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

allowed-pattern

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

auto-focus

When the value is set to true, the browser places focus inside the input area after loading. This way, the worker can start typing without having to select it first.

auto-validate

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

disabled

A Boolean switch that, if present, displays the input area as disabled.

error-message

The text to be displayed below the input field, on the left side, if validation fails.

label

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

max-length

A maximum number of characters the input will accept. Input beyond this limit is ignored.

min-length

A minimum length for the input in the field

name

Sets the name of the input to be used in the DOM and the output of the form.

placeholder

A string value that is used as placeholder text, displayed until the worker starts entering data into the input, It is not used as a default value.

required

A Boolean switch that, if present, requires the worker to provide input.

type

Takes a string to set the HTML5 `input-type` behavior for the input. Examples include `file` and `date`.

value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

Provides a `name` string as the property name, and the text that was entered in the field as its value.

Example : Sample JSON Output

The values for multiple elements are output in the same object, with their `name` attribute value as their property name. Elements with no input do not appear in the output. For example, let's use three inputs:

```
<crowd-input name="tag1" label="Word/phrase 1"></crowd-input>
<crowd-input name="tag2" label="Word/phrase 2"></crowd-input>
<crowd-input name="tag3" label="Word/phrase 3"></crowd-input>
```

This is the output if only two have input:

```
[
  {
    "tag1": "blue",
    "tag2": "red"
  }
]
```

This means any code built to parse these results should be able to handle the presence or absence of each input in the answers.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-instance-segmentation

A widget for identifying individual instances of specific objects within an image and creating a colored overlay for each labeled instance.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-instance-segmentation>`. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-instance-segmentation
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please label each of the requested objects in this image"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Segmentation Instructions">
      <ol>
          <li><strong>Read</strong> the task carefully and inspect the image.</li>
          <li><strong>Read</strong> the options and review the examples provided to
 understand more about the labels.</li>
          <li><strong>Choose</strong> the appropriate label that best suits the
 image.</li>
      </ol>
    </full-instructions>

    <short-instructions>
      <p>Use the tools to label all instances of the requested items in the image</p>
    </short-instructions>
  </crowd-instance-segmentation>
</crowd-form>
```

Use a template similar to the following to allow workers to add their own categories (labels).

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-instance-segmentation
    id="annotator"
    name="myTexts"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Click Instructions to add new labels."
    labels="['placeholder']"
  >
    <short-instructions>
      <h3>Add a label to describe each type of object in this image.</h3>
      <h3>Cover each instance of each object with a segmentation mask.</h3>
      <br>
      <h3>
        Add new label
      </h3>
```

```
      <crowd-input name="_customLabel" id="customLabel"></crowd-input>
      <crowd-button id="addLabel">Add</crowd-button>

      <br><br><br>
      <h3>
      Manage labels
      </h3>
      <div id="labelsSection"></div>
    </short-instructions>

    <full-instructions>
      Describe your task in more detail here.
    </full-instructions>
  </crowd-instance-segmentation>
</crowd-form>

<script>
  document.addEventListener('all-crowd-elements-ready', function(event) {
    document.querySelector('crowd-instance-segmentation').labels = [];
  });

  function populateLabelsSection() {
    labelsSection.innerHTML = '';
    annotator.labels.forEach(function(label) {
      const labelContainer = document.createElement('div');
      labelContainer.innerHTML = label + ' <a href="javascript:void(0)">(Delete)</a>';
      labelContainer.querySelector('a').onclick = function() {
        annotator.labels = annotator.labels.filter(function(l) {
          return l !== label;
        });
        populateLabelsSection();
      };
      labelsSection.appendChild(labelContainer);
    });
  }

  addLabel.onclick = function() {
    annotator.labels = annotator.labels.concat([customLabel.value]);
    customLabel.value = null;

    populateLabelsSection();
  };
</script>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to an instance of an object in the image. Workers can generate different overlay colors for each relevant instance by selecting "add instance" under the label in the tool.

name

The name of this widget. It is used as a key for the labeling data in the form output.

src

The URL of the image that is to be labeled.

initial-value

A JSON object containing the color mappings of a prior instance segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute will appear as follows:

```
initial-value="{
  "instances": [
    {
      "color": "#2ca02c",
      "label": "Cat"
    },
    {
      "color": "#1f77b4",
      "label": "Cat"
    },
    {
```

```
        "color": "#d62728",
        "label": "Dog"
      }
    ],
    "src": {{ "S3 file URL for image" | grant_read_access }}
  }"
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to do image segmentation.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

instances

A JSON Array containing objects with the instance labels and colors.

- **color** – The hexadecimal value of the label's RGB color in the `labeledImage` PNG.
- **label** – The label given to overlay(s) using that color. This value may repeat, because the different instances of the label are identified by their unique color.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example : Sample Element Outputs

The following is an example of output from this element.

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 533,
        "width": 800
      },
      "instances": [
        {
          "color": "#1f77b4",
          "label": "<Label 1>":
        },
        {
          "color": "#2ca02c",
          "label": "<Label 1>":
        },
        {
          "color": "#ff7f0e",
          "label": "<Label 3>":
        },
      ],
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    }
  }
]
```

See Also

- [Training data labeling using humans with Amazon SageMaker Ground Truth]
- [Crowd HTML Elements Reference]

crowd-instructions

An element that displays instructions on three tabbed pages, **Summary**, **Detailed Instructions**, and **Examples**, when the worker clicks on a link or button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that used the `<crowd-instructions>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
   <crowd-instructions link-text="View instructions" link-type="button">
    <short-summary>
      <p>Given an image, write three words or short phrases that summarize its
 contents.</p>
    </short-summary>
    <detailed-instructions>
      <p>Imagine that you are describing an image to a friend or tagging it for a news
 website. Provide three specific words or short phrases that describe it.</p>
    </detailed-instructions>
    <positive-example>
      <p><img src="https://s3.amazonaws.com/cv-demo-images/highway.jpg"/></p>
      <p>
       <ul>
        <li>Highway</li>
        <li>Cars</li>
        <li>Gas station</li>
       </ul>
      </p>
    </positive-example>
    <negative-example>
      <p><img src="https://s3.amazonaws.com/cv-demo-images/highway.jpg"/></p>
```

```
        <p>
         These are not specific enough:
         <ol>
          <li>Trees</li>
          <li>Outside</li>
          <li>Daytime</li>
         </ol>
        </p>
      </negative-example>
  </crowd-instructions>
      <p><strong>Instructions: </strong>Given an image, write three words or short
  phrases that summarize its contents.</p>
      <p>If someone were to see these three words or phrases, they should understand the
  subject and context of the image, as well as any important actions.</p>
  <p>View the instructions for detailed instructions and examples.</p>
  <p><img style="max-width: 100%; max-height: 100%" src="{{ task.input.taskObject |
  grant_read_access }}"></p>
   <crowd-input name="tag1" label="Word/phrase 1" required></crowd-input>
   <crowd-input name="tag2" label="Word/phrase 2" required></crowd-input>
   <crowd-input name="tag3" label="Word/phrase 3" required></crowd-input>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

link-text

The text to display for opening the instructions. The default is **Click for instructions**.

link-type

A string that specifies the type of trigger for the instructions. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Regions

The following regions are supported by this element.

detailed-instructions

Content that provides specific instructions for a task. This appears on the page of the "Detailed Instructions" tab.

negative-example

Content that provides examples of inadequate task completion. This appears on the page of the "Examples" tab. More than one example may be provided within this element.

positive-example

Content that provides examples of proper task completion. This appears on the page of the "Examples" tab.

short-summary

A brief statement that summarizes the task to be completed. This appears on the page of the "Summary" tab. More than one example may be provided within this element.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-keypoint

Generates a tool to select and annotate key points on an image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an Liquid template that uses the `<crowd-keypoint>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

```
<crowd-form>
  <div id="errorBox"></div>

  <crowd-keypoint
    src="{{ task.input.taskObject | grant_read_access }}"
    labels="['Item A', 'Item B', 'Item C']"
    header="Please locate the centers of each item."
    name="annotatedResult">
    <short-instructions>
      Describe your task briefly here and give examples
    </short-instructions>
    <full-instructions>
      Give additional instructions and good/bad examples here
    </full-instructions>
  </crowd-keypoint>
</crowd-form>

<script>
  var num_obj = 1;

  document.querySelector('crowd-form').onsubmit = function(e) {
    const keypoints = document.querySelector('crowd-keypoint').value.keypoints ||
 document.querySelector('crowd-keypoint')._submittableValue.keypoints;
    const labels = keypoints.map(function(p) {
      return p.label;
    });

    // 1. Make sure total number of keypoints is correct.
    var original_num_labels = document.getElementsByTagName("crowd-keypoint")
[0].getAttribute("labels");

    original_num_labels = original_num_labels.substring(2, original_num_labels.length -
 2).split("\",\"");
    var goalNumKeypoints = num_obj*original_num_labels.length;
    if (keypoints.length != goalNumKeypoints) {
      e.preventDefault();
      errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must add all
 keypoint annotations and use each label only once.</crowd-alert>';
      errorBox.scrollIntoView();
      return;
    }

    // 2. Make sure all labels are unique.
    labelCounts = {};
```

```
    for (var i = 0; i < labels.length; i++) {
      if (!labelCounts[labels[i]]) {
        labelCounts[labels[i]] = 0;
      }
      labelCounts[labels[i]]++;
    }
    const goalNumSingleLabel = num_obj;

    const numLabels = Object.keys(labelCounts).length;

    Object.entries(labelCounts).forEach(entry => {
      if (entry[1] != goalNumSingleLabel) {
        e.preventDefault();
        errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must use each
 label only once.</crowd-alert>';
        errorBox.scrollIntoView();
      }
    })
  };
</script>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array, in JSON format, of keypoints to be applied to the image on start. For example:

```
initial-value="[
  {
    'label': 'Left Eye',
    'x': 1022,
    'y': 429
  },
  {
    'label': 'Beak',
    'x': 941,
```

```
    'y': 403
  }
]
```

Note

Please note that label values used in this attribute must have a matching value in the `labels` attribute or the point will not be rendered.

labels

An array, in JSON format, of strings to be used as keypoint annotation labels.

name

A string used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

src

The source URI of the image to be annotated.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required by this element.

full-instructions

General instructions about how to annotate the image.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

keypoints

An array of JSON objects containing the coordinates and label of a keypoint. Each object contains the following properties.

- **label** – The assigned label for the keypoint.
- **x** – The X coordinate, in pixels, of the keypoint on the image.
- **y** – The Y coordinate, in pixels, of the keypoint on the image.

> **Note**
>
> X and Y coordinates are based on 0,0 being the top left corner of the image.

Example : Sample Element Outputs

The following is a sample output from using this element.

```
[
  {
    "crowdKeypoint": {
      "inputImageProperties": {
        "height": 1314,
        "width": 962
      },
      "keypoints": [
        {
```

```
            "label": "dog",
            "x": 155,
            "y": 275
          },
          {
            "label": "cat",
            "x": 341,
            "y": 447
          },
          {
            "label": "cat",
            "x": 491,
            "y": 513
          },
          {
            "label": "dog",
            "x": 714,
            "y": 578
          },
          {
            "label": "cat",
            "x": 712,
            "y": 763
          },
          {
            "label": "cat",
            "x": 397,
            "y": 814
          }
        ]
      }
    }
]
```

You may have many labels available, but only the ones that are used appear in the output.

crowd-line

A widget for drawing lines on an image. Each line is associated with a label, and output data will report the starting and ending points of each line.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](#).

The following is an example of a Liquid template that uses the `<crowd-line>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this [GitHub repository](#).

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-line
    name="crowdLine"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Add header here to describe the task"
    labels="['car','pedestrian','street car']"
  >
    <short-instructions>
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image.</p>
        <p>Draw a line on each objects that the label applies to.</p>
    </short-instructions>

    <full-instructions>
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image.
        <p>Draw a line along each object that the image applies to.
            Make sure that the line does not extend beyond the boundaries
            of the object.
        </p>
        <p>Each line is defined by a starting and ending point. Carefully
        place the starting and ending points on the boundaries of the object.</p>
    </full-instructions>

  </crowd-line>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a line when the component is loaded. Each JSON object in the array contains the following properties:

- **label** – The text assigned to the line as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the `<crowd-line>` element.
- **vertices** – the `x` and `y` pixel corrdinates of the start point and end point of the line, relative to the top-left corner of the image.

```
initial-value="{
    lines: [
    {
        label: 'sideline', // label of this line annotation
        vertices:[         // an array of vertices which decide the position of the
 line
        {
            x: 84,
            y: 110
        },
        {
            x: 60,
            y: 100
        }
        ]
    },
    {
        label: 'yardline',
        vertices:[
        {
            x: 651,
            y: 498
        },
        {
            x: 862,
            y: 869
        }
```

```
        ]
      }
    ]
}"
```

Lines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

labels

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

Limit: 10 labels

label-colors

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

name

Required. The name of this widget. It's used as a key for the widget's input in the form output.

src

Required. The URL of the image on which to draw lines.

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw lines.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: short-instructions, full-instructions

Output

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

lines

A JSON Array containing objects with the line labels and vertices.

- **label** – The label given to a line.
- vertices – the x and y pixel corrdinates of the start point and end point of the line, relative to the top-left corner of the image.

Example : Sample Element Outputs

The following is an example of output from this element.

```
{
    "crowdLine": { //This is the name you set for the crowd-line
      "inputImageProperties": {
        "height": 1254,
        "width": 2048
      },
      "lines": [
        {
          "label": "yardline",
          "vertices": [
            {
              "x": 58,
              "y": 295
            },
            {
              "x": 1342,
              "y": 398
            }
          ]
```

```
        },
        {
          "label": "sideline",
          "vertices": [
            {
              "x": 472,
              "y": 910
            },
            {
              "x": 1480,
              "y": 600
            }
          ]
        }
      ]
    }
  }
```

See Also

crowd-modal

A small window that pops up on the display when it is opened.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the `<crowd-modal>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-modal
link-text = "See Examples"
link-type = "button">
Example Modal Text</crowd-modal>
```

Attributes

The following attributes are supported by this element.

link-text

The text to display for opening the modal. The default is "Click to open modal".

link-type

A string that specifies the type of trigger for the modal. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Crowd HTML Elements Reference

crowd-polygon

A widget for drawing polygons on an image and assigning a label to the portion of the image that is enclosed in each polygon.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polygon>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
```

```
  <crowd-polygon
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Draw a polygon around each of the requested target(s) of interest"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Polygon instructions">
      <ul>
        <li>Make the polygon tight around the object</li>
        <li>You need to select a label before starting a polygon</li>
        <li>You will need to select a label again after completing a polygon</li>
        <li>To select a polygon, you can click on its borders</li>
        <li>You can start drawing a polygon from inside another polygon</li>
        <li>You can undo and redo while you're drawing a polygon to go back and forth
 between points you've placed</li>
        <li>You are prevented from drawing lines that overlap other lines from the same
 polygon</li>
      </ul>
    </full-instructions>

    <short-instructions>
      <p>Draw a polygon around each of the requested target(s) of interest</p>
      <p>Make the polygon tight around the object</p>
    </short-instructions>
  </crowd-polygon>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a polygon.

name

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw polygons.

initial-value

An array of JSON objects, each of which defines a polygon to be drawn when the component is loaded. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-polygon> element.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon.

Example

An `initial-value` attribute might look something like this.

```
initial-value =
  '[
     {
     "label": "dog",
     "vertices":
       [
         {
            "x": 570,
            "y": 239
         },
        ...
         {
            "x": 759,
            "y": 281
         }
       ]
     }
  ]'
```

Because this will be within an HTML element, the JSON array must be enclosed in single or double quotes. The example above uses single quotes to encapsulate the JSON and double quotes within the JSON itself. If you must mix single and double quotes inside your JSON, replace them with their HTML entity codes (`"` for double quote, `'` for single) to safely escape them.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required.

full-instructions

General instructions about how to draw polygons.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

polygons

An array of JSON objects, each of which describes a polygon that has been created by the worker. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon. The top left corner of the image is 0,0.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example : Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

Single Label, Single Polygon

```
{
    "annotatedResult":
    {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons":
      [
        {
          "label": "dog",
          "vertices":
          [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        }
      ]
    }
  }
```

```
]
```

Single Label, Multiple Polygons

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        },
        {
          "label": "dog",
          "vertices": [
            {
              "x": 870,
              "y": 278
```

```
            },
            {
              "x": 908,
              "y": 446
            },
            {
              "x": 1009,
              "y": 602
            },
            {
              "x": 1116,
              "y": 519
            },
            {
              "x": 1174,
              "y": 498
            },
            {
              "x": 1227,
              "y": 479
            },
            {
              "x": 1179,
              "y": 405
            },
            {
              "x": 1179,
              "y": 337
            }
          ]
        }
      ]
    }
  }
]
```

Multiple Labels, Multiple Polygons

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
```

```
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        },
        {
          "label": "cat",
          "vertices": [
            {
              "x": 870,
              "y": 278
            },
            {
              "x": 908,
              "y": 446
            },
            {
              "x": 1009,
              "y": 602
            },
            {
```

```
                "x": 1116,
                "y": 519
              },
              {
                "x": 1174,
                "y": 498
              },
              {
                "x": 1227,
                "y": 479
              },
              {
                "x": 1179,
                "y": 405
              },
              {
                "x": 1179,
                "y": 337
              }
            ]
          }
        ]
      }
    }
]
```

You could have many labels available, but only the ones that are used appear in the output.

crowd-polyline

A widget for drawing polylines or lines on an image. Each polyline is associated with a label and can include two or more vertices. A polyline can intersect itself and its starting and ending points can be placed anywhere on the image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the <crowd-polyline> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-polyline
    name="crowdPolyline"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Add header here to describe the task"
    labels="['car','pedestrian','street car']"
  >
    <full-instructions>
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image.</p>
        <p>Draw a polyline around the boundaries of all objects
        that the label applies to.</p>
        <p>Use the <b>Enter</b> key to complete a polyline.</p>
        <p>Make sure that the polyline fits tightly around the boundary
        of the object.</p>
    </full-instructions>

    <short-instructions>
        <p>Read the task carefully and inspect the image.</p>
        <p>Review the tool guide to learn how to use the polyline tool.</p>
        <p>Choose the appropriate label that best suits the image.</p>
        <p>To draw a polyline, select a label that applies to an object of interest
            and add a single point to the photo by clicking on that point. Continue to
            draw the polyline around the object by adding additional points
            around the object boundary.</p>
        <p>After you place the final point on the polyline, press <b>Enter</b> on your
        keyboard to complete the polyline.</p>

    </short-instructions>
  </crowd-polyline>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a polyline when the component is loaded. Each JSON object in the array contains the following properties:

- **label** – The text assigned to the polyline as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the `<crowd-polyline>` element.
- **vertices** – the `x` and `y` pixel corrdinates of the vertices of a polyline, relative to the top-left corner of the image.

```
initial-value= "{
   polylines: [
   {
       label: 'sideline', // label of this line annotation
       vertices:[         // an array of vertices which decide the position of the 
line
       {
           x: 84,
           y: 110
       },
       {
           x: 60,
           y: 100
       }
       ]
   },
   {
       label: 'yardline',
       vertices:[
       {
           x: 651,
           y: 498
       },
       {
           x: 862,
           y: 869
       },
```

```
        {
            x: 1000,
            y: 869
        }
        ]
    }
   ]
}"
```

Polylines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

labels

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

Limit: 10 labels

label-colors

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

name

Required. The name of this widget. It's used as a key for the widget's input in the form output.

src

Required. The URL of the image on which to draw polylines.

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw polylines.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: short-instructions, full-instructions

Output

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

polylines

A JSON Array containing objects with polylines' labels and vertices.

- **label** – The label given to a line.
- vertices – the x and y pixel corrdinates of the vertices of a polyline, relative to the top-left corner of the image.

Example : Sample Element Outputs

The following is an example of output from this element.

```
{
   "crowdPolyline": { //This is the name you set for the crowd-polyline
     "inputImageProperties": {
       "height": 1254,
       "width": 2048
     },
     "polylines": [
       {
         "label": "sideline",
```

```
          "vertices": [
            {
              "x": 651,
              "y": 498
            },
            {
              "x": 862,
              "y": 869
            },
            {
              "x": 1449,
              "y": 611
            }
          ]
        },
        {
          "label": "yardline",
          "vertices": [
            {
              "x": 1148,
              "y": 322
            },
            {
              "x": 1705,
              "y": 474
            },
            ,
            {
              "x": 1755,
              "y": 474
            }
          ]
        }
      ]
    }
  }
```

crowd-radio-button

A button that can be either checked or unchecked. When radio buttons are inside a radio group, exactly one radio button in the group can be checked at any time. The following is an example of how to configure a `crowd-radio-button` element inside of a `crowd-radio-group` element.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](#).

The following is an example of the syntax that you can use with the `<crowd-radio-button>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-radio-group>
    <crowd-radio-button name="tech" value="tech">Technology</crowd-radio-button>
    <crowd-radio-button name="politics" value="politics">Politics</crowd-radio-button>
</crowd-radio-group>
</crowd-form>
```

The previous example can be seen in a custom worker task template in this GitHub example: [entity recognition labeling job custom template](#).

Crowd HTML Element radio buttons do not support the HTML tag, `required`. To make a radio button selection required, use `<input type="radio">` elements to create radio buttons and add the `required` tag. The `name` attribute for all `<input>` elements that belong to the same group of radio buttons must be the same. For example, the following template requires the user to select a radio button in the `animal-type` group before submitting.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <p>Select an animal type:</p>
<img src="https://images.unsplash.com/photo-1537151608828-ea2b11777ee8?
ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1539&q=80"
 style="height: 500; width: 400;"/>
<br><br>
<div>
  <input type="radio" id="cat" name="animal-type" value="cat" required>
  <label for="cat">Cat</label>
</div>
<div>
```

```
  <input type="radio" id="dog" name="animal-type" value="dog">
  <label for="dog">Dog</label>
</div>
<div>
  <input type="radio" id="unknown" name="animal-type" value="unknown">
  <label for="unknown">Unknown</label>
</div>
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the radio button as checked.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents it from being checked.

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

> **Note**
>
> If you use the buttons outside of a crowd-radio-group element, but with the same `name` string and different `value` strings, the `name` object in the output will contain a Boolean value for each `value` string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group element and use different name values.

value

A property name for the element's boolean value. If not specified, it uses "on" as the default, e.g. `{ "<name>": { "<value>": <true or false> } }`.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-radio-group
- **Child elements**: none

Output

Outputs an object with the following pattern: `{ "<name>": { "<value>": <true or false> } }`. If you use the buttons outside of a crowd-radio-group element, but with the same `name` string and different `value` strings, the name object will contain a Boolean value for each `value` string. To ensure that only one in a group of buttons is selected, make them children of a crowd-radio-group element and use different name values.

Example Sample output of this element

```
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

See Also

crowd-radio-group

A group of radio buttons. Only one radio button within the group can be selected. Choosing one radio button clears any previously chosen radio button within the same group. For an example of a custom UI template that uses the `crowd-radio-group` element, see this [entity recognition labeling job custom template](#).

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](#).

The following is an example of the syntax that you can use with the `<crowd-radio-group>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<style>
 body {
  padding-left: 20px;
  margin-bottom: 20px;
 }
 #outer-container {
     display: flex;
     justify-content: space-around;
     max-width: 900px;
     margin-left: 100px;
 }
 .left-container {
     margin-right: auto;
     padding-right: 50px;
 }
 .right-container {
     margin-left: auto;
     padding-left: 50px;
 }
 #vertical-separator {
     border: solid 1px #d5dbdb;
 }
</style>

<crowd-form>
    <div>
        <h1>Instructions</h1>
```

```

    </div>
    <div id="outer-container">
 <span class="left-container">
      <h2>Option 1</h2>
      <p>Nulla facilisi morbi tempus iaculis urna. Orci dapibus ultrices in iaculis nunc
 sed augue lacus.</p>
 </span>
 <span id="vertical-separator"></span>
 <span class="right-container">
      <h2>Option 2</h2>
      <p>Ultrices vitae auctor eu augue ut. Pellentesque massa placerat duis ultricies
 lacus sed turpis tincidunt id.</p>
 </span>
    </div>
    <div>
        <h2>Question</h2>
      <p>Which do you agree with?</p>
 <crowd-radio-group>
      <crowd-radio-button name="option1" value="Option 1">Option 1</crowd-radio-button>
      <crowd-radio-button name="option2" value="Option 2">Option 2</crowd-radio-button>
 </crowd-radio-group>

      <p>Why did you choose this answer?</p>
 <crowd-text-area name="explanation" placeholder="Explain how you reached your
 conclusion..."></crowd-text-area>
    </div>
</crowd-form>
```

Attributes

No special attributes are supported by this element.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form

- **Child elements**: crowd-radio-button

Output

Outputs an array of objects representing the crowd-radio-button elements within it.

Example Sample of Element Output

```
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-semantic-segmentation

A widget for segmenting an image and assigning a label to each image segment.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-semantic-segmentation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-semantic-segmentation
    name="annotatedResult"
```

```
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please label each of the requested objects in this image"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Segmentation Instructions">
      <ol>
          <li><strong>Read</strong> the task carefully and inspect the image.</li>
          <li><strong>Read</strong> the options and review the examples provided to
 understand more about the labels.</li>
          <li><strong>Choose</strong> the appropriate label that best suits the
 image.</li>
      </ol>
    </full-instructions>

    <short-instructions>
      <p>Use the tools to label the requested items in the image</p>
    </short-instructions>
  </crowd-semantic-segmentation>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON object containing the color mappings of a prior semantic segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute would appear as follows:

```
  initial-value='{
    "labelMappings": {
        "Bird": {
          "color": "#ff7f0e"
        },
        "Cat": {
```

```
          "color": "#2ca02c"
        },
        "Cow": {
          "color": "#d62728"
        },
        "Dog": {
          "color": "#1f77b4"
        }
      },
    "src": {{ "S3 file URL for image" | grant_read_access }}
  }'
```

When using Ground Truth built in task types with annotation consolidation (where more than one worker labels a single image), label mappings are included in individual worker output records, however the overall result is represented as the `internal-color-map` in the consolidated results.

You can convert the `internal-color-map` to `label-mappings` in a custom template using the Liquid templating language:

```
initial-value="{
  'src' : '{{ task.input.manifestLine.label-attribute-name-from-prior-job|
 grant_read_access }}',
  'labelMappings': {
     {% for box in task.input.manifestLine.label-attribute-name-from-prior-job-
metadata.internal-color-map %}
       {% if box[1]['class-name'] != 'BACKGROUND' %}
         {{ box[1]['class-name'] | to_json }}: {
           'color': {{ box[1]['hex-color'] | to_json }}
         },
       {% endif %}
     {% endfor %}
   }
}"
```

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to a segment of the image.

name

The name of this widget. It is used as a key for the widget's input in the form output.

src

The URL of the image that is to be segmented.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to do image segmentation.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

labelMappings

A JSON Object containing objects with named with the segmentation labels.

- **color** – The hexadecimal value of the label's RGB color in the `labeledImage` PNG.

initialValueModified

A boolean representing whether the initial values have been modified. This is only included when the output is from an adjustment task.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 533,
        "width": 800
      },
      "labelMappings": {
        "<Label 2>": {
          "color": "#ff7f0e"
        },
        "<label 3>": {
          "color": "#2ca02c"
        },
        "<label 1>": {
          "color": "#1f77b4"
        }
      },
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth

- Crowd HTML Elements Reference

crowd-slider

A bar with a sliding knob that allows a worker to select a value from a range of values by moving the knob. The slider makes it a great choice for settings that reflect intensity levels, such as volume, brightness, or color saturation.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a survey template that uses the `<crowd-slider>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
<crowd-instructions link-text="View instructions" link-type="button">
  <short-summary>
    <p>Provide a brief instruction here</p>
  </short-summary>

  <detailed-instructions>
    <h3>Provide more detailed instructions here</h3>
    <p>Include additional information</p>
  </detailed-instructions>

  <positive-example>
    <p>Provide an example of a good answer here</p>
    <p>Explain why it's a good answer</p>
  </positive-example>

  <negative-example>
    <p>Provide an example of a bad answer here</p>
    <p>Explain why it's a bad answer</p>
  </negative-example>
</crowd-instructions>

<div>
  <p>What is your favorite color for a bird?</p>
  <crowd-input name="favoriteColor" placeholder="example: pink" required></crowd-input>
```

```
</div>

<div>
  <p>Check this box if you like birds</p>
  <crowd-checkbox name="likeBirds" checked="true" required></crowd-checkbox>
</div>

<div>
  <p>On a scale of 1-10, how much do you like birds?</p>
  <crowd-slider name="howMuch" min="1" max="10" step="1" pin="true" required></crowd-
slider>
</div>

<div>
  <p>Write a short essay describing your favorite bird</p>
  <crowd-text-area name="essay" rows="4" placeholder="Lorem ipsum..." required></crowd-
text-area>
</div>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the slider as disabled.

editable

A Boolean switch that, if present, displays an up/down button that can be chosen to select the value.

Selecting the value via the up/down button is an alternative to selecting the value by moving the knob on the slider. The knob on the slider will move synchronously with the up/down button choices.

max

A number that specifies the maximum value on the slider.

min

A number that specifies the minimum value on the slider.

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

pin

A Boolean switch that, if present, displays the current value above the knob as the knob is moved.

required

A Boolean switch that, if present, requires the worker to provide input.

secondary-progress

When used with a `crowd-slider-secondary-color` CSS attribute, the progress bar is colored to the point represented by the `secondary-progress`. For example, if this was representing the progress on a streaming video, the `value` would represent where the viewer was in the video timeline. The `secondary-progress` value would represent the point on the timeline to which the video had buffered.

step

A number that specifies the difference between selectable values on the slider.

value

A preset that becomes the default if the worker does not provide input.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

```

Attributes

This element has no attributes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: crowd-tab

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-text-area

A field for text input.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed to transcribe audio clips that uses the `<crowd-text-area>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <audio controls>
      <source src="{{ task.input.taskObject | grant_read_access }}" type="audio/mpeg">
      Your browser does not support the audio element.
  </audio>
  <h3>Instructions</h3>
  <p>Transcribe the audio</p>
  <p>Ignore "umms", "hmms", "uhs" and other non-textual phrases</p>
  <crowd-text-area name="transcription" rows="4"></crowd-text-area>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

allowed-pattern

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

auto-focus

A Boolean switch that, if present, puts the cursor in this element on-load so that users can immediately begin typing without having to click inside the element.

auto-validate

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

char-counter

A Boolean switch that, if present, puts a small text field beneath the lower-right corner of the element, displaying the number of characters inside the element.

disabled

A Boolean switch that, if present, displays the input area as disabled.

error-message

The text to be displayed below the input field, on the left side, if validation fails.

label

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

max-length

An integer that specifies the maximum number of characters allowed by the element. Characters typed or pasted beyond the maximum are ignored.

max-rows

An integer that specifies the maximum number of rows of text that are allowed within a crowd-text-area. Normally the element expands to accommodate new rows. If this is set, after the number of rows exceeds it, content scrolls upward out of view and a scrollbar control appears.

name

A string used to represent the element's data in the output.

placeholder

A string presented to the user as placeholder text. It disappears after the user puts something in the input area.

rows

An integer that specifies the height of the element in rows of text.

value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

This element outputs the name as a property name and the element's text contents as the value. Carriage returns in the text are represented as \n.

Example Sample output for this element

```
[
  {
    "textInput1": "This is the text; the text that\nmakes the crowd go wild."
  }
]
```

See Also

For more information, see the following.

- Crowd HTML Elements Reference

crowd-toast

A subtle notification that temporarily appears on the display. Only one crowd-toast is visible.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-toast>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <crowd-input name="website" placeholder="http://example.com"></crowd-input>

  <crowd-toast duration="10000" opened>
    This is a message that you want users to see when opening the template. This
 message will disappear in 10 seconds.
   </crowd-toast>

</crowd-form>
```

Attributes

The following attributes are supported by this element.

duration

A number that specifies the duration, in milliseconds, that the notification appears on the screen.

text

The text to display in the notification.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-toggle-button

A button that acts as an ON/OFF switch, toggling a state.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following example shows different ways you can use to use the `<crowd-toggle-button>` HTML element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <!--Toggle button without value-->
  <crowd-toggle-button name="toggleButtonWithoutValue"></crowd-toggle-button>

  <!--Toggle button with value-->
  <crowd-toggle-button name="toggleButtonWithValue" value="someValue"></crowd-toggle-
button>

  <!--Toggle button disabled-->
  <crowd-toggle-button name="toggleButtonDisabled" disabled></crowd-toggle-button>

  <!--Toggle button marked invalid-->
  <crowd-toggle-button name="toggleButtonInvalid" invalid></crowd-toggle-button>

  <!--Toggle button marked required-->
  <crowd-toggle-button name="toggleButtonRequired" required></crowd-toggle-button>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the button switched to the ON position.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents toggling.

invalid

When in an off position, a button using this attribute, will display in an alert color. The standard is red, but may be changed in CSS. When toggled on, the button will display in the same color as other buttons in the on position.

name

A string that is used to identify the answer submitted by the worker. This value matches a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

value

A value used in the output as the property name for the element's Boolean state. Defaults to "on" if not provided.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

This element outputs the `name` as the name of an object, containing the `value` as a property name and the element's state as Boolean value for the property. If no value for the element is specified, the property name defaults to "on."

Example Sample output for this element

```
[
  {
    "theToggler": {
      "on": true
```

```
    }
  }
]
```

Crowd HTML Elements V2

Crowd HTML V2 Elements introduce enhanced labeling capabilities designed to support workers, with new features tailored for GenAI model training use cases. These V2 elements are compatible with the Crowd HTML Elements crowd-form, short-instructions, crowd-button, crowd-tabs, and crowd-tab. If you use other elements with V2 elements, the annotation application won't work properly.

crowd-text-ranking

A widget for workers to slide and rank various text inputs based on dimensions that you specify.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

```
<script src="https://assets.crowd.aws/crowd-html-elements-v2.js"></script>

<crowd-form>
  <crowd-text-ranking
    name="textRanking"
    ordinal-ranking-dimensions='[{"name":"Clarity","allowTie":true},
{"name":"Inclusivity","allowTie":false}]'
    text="Explain why you can see yourself in a mirror at a level that a 16 year old
 can understand."
    responses='["When light is emitted from light source like a light bulb, some of
 it travels toward your body, where it may be reflected toward the mirror with some
 probability or it may be absorbed. If it were reflected off your body, then some of it
 could travel toward the mirror, where it could be reflected again. If it is the case
 where light strikes the mirror, the light is then again redirected as a reflection.
 If that light is pointed in the direction of your eyes, then the light will enter your
 eyes. Then, your brain processes the electrical signal made by your eyes and sees it
 as an image.","You can see yourself because of a series of light reflections. Light
```

```
travels from the light source, hits and reflects off of your body and travels toward
the mirror. Then, it reflects off of the mirror and travels to your eyes, where your
brain registers it as a picture of yourself.","Light travels in various directions
from a light source like a light bulb. Some of the light reflects off of your body
with some probability, after which some of it travels to the mirror. Upon striking the
mirror, the some of the light again reflects off the mirror and travels toward your
eyes, wherein your eyes detect the light after absorbing it. After this process, your
brain processes the signal as an image of yourself.","The phenomenon of self-visual
perception via a mirror at an ontological plane derives from the intricate interplay
of photons within the electromagnetic spectrum, quantum mechanical principles, and the
neurocognitive processes underpinning self-recognition. In essence, the mirror serves
as an interface wherein incident photons, emitted from an external object, interact
with the reflective surface at a specific angle of incidence governed by the laws of
geometric optics. This interaction culminates in the process of specular reflection,
leading to the formation of a virtual image."]'
  >
    <short-instructions>
      <h1>Hello these are my instructions 1</h1>
      <p>Hello these are my instructions 2</p>
      <p>Hello these are my instructions 3</p>
    </short-instructions>
  </crowd-text-ranking>
</crowd-form>
```

Attributes

The following are attributes supported by this element.

text

The text or S3 reference to the text to reference when ranking the responses.

ordinal-ranking-dimensions

A required array of the `ordinal-ranking-dimensions` object, which specify the dimension on which to rank the responses. This dimension contains a **name** and a property named **allowTie**, which determines whether a worker can give responses the same ranking.

responses

A required array of the `ordinal-ranking-dimensions` object, which specify the dimension on which to rank the responses. This dimension contains a **name** and a property named **allowTie**, which determines whether a worker can give responses the same ranking.

name

A required string field that identifies the answer submitted that the worker submits. It matches a key in the output data contract of the worker submission.

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-question-answer-generation

A widget for workers to highlight sections of text and assign question and answer pairs based on your instructions

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

```
<script src="https://assets.crowd.aws/crowd-html-elements-v2.js"></script>

<crowd-form>
  <crowd-question-answer-generation
    name="questionAnswerGeneration"
    text='The Amazon rainforest (Portuguese: Floresta Amazônica or Amazônia; Spanish:
 Selva Amazónica, Amazonía or usually Amazonia; French: Forêt amazonienne; Dutch:
 Amazoneregenwoud), also known in English as Amazonia or the Amazon Jungle, is a moist
 broadleaf forest that covers most of the Amazon basin of South America. This basin
 encompasses 7,000,000 square kilometres (2,700,000 sq mi), of which 5,500,000 square
 kilometres (2,100,000 sq mi) are covered by the rainforest. This region includes
 territory belonging to nine nations. The majority of the forest is contained within
 Brazil, with 60% of the rainforest, followed by Peru with 13%, Colombia with 10%, and
 with minor amounts in Venezuela, Ecuador, Bolivia, Guyana, Suriname and French Guiana.
 States or departments in four nations contain "Amazonas" in their names. The Amazon
 represents over half of the planet's remaining rainforests, and comprises the largest
 and most biodiverse tract of tropical rainforest
    in the world, with an estimated 390 billion individual trees divided into 16,000
 species. For a long time, it was thought that the
    Amazon rainforest was only ever sparsely populated, as it was impossible to sustain
 a large population through agriculture given the poor soil.
    Archeologist Betty Meggers was a prominent proponent of this idea, as described in
 her book Amazonia: Man and Culture in a Counterfeit Paradise.
    She claimed that a population density of 0.2 inhabitants per square kilometre
 (0.52/sq mi) is the maximum that can be sustained in the rainforest
```

```
    through hunting, with agriculture needed to host a larger population. However,
 recent anthropological findings have suggested that the region was
    actually densely populated. Some 5 million people may have lived in the Amazon
 region in AD 1500, divided between dense coastal settlements, such as that at
    Marajó, and inland dwellers. By 1900 the population had fallen to 1 million and by
 the early 1980s it was less than 200,000.'
    min-questions="1"
    max-questions="10"
    question-min-words="1"
    question-max-words="100"
    answer-min-words="1"
    answer-max-words="100"
    question-tags='[
      "tag1",
      "tag2",
      "tag3"
    ]'
    allow-custom-question-tags="true"
  >
    <short-instructions>
      <p>User instructions will be displayed here.</p>
    </short-instructions>
  </crowd-question-answer-generation>
</crowd-form>
```

Attributes

The following are attributes supported by this element.

text

The text or S3 reference to the text to reference when ranking the responses.

min-questions

Optional integer that specifies the minimum amount of questions that a worker would have to create during the task. If not provided, you will be asked to write at least one question and answer pair.

max-questions

Optional integer that specifies the maximum amount of questions a worker can create during the task.

question-min-words

Optional integer that specifies the minimum amount of words allowed in an question. If not provided, you will be asked to provide at least one word in the question.

question-max-words

Optional integer that specifies the maximum amount of words allowed in an question.

answer-min-words

Optional integer that specifies the minimum amount of words allowed in an answer. If not provided, you will be asked to write at least one word in the answer.

answer-max-words

Optional integer that specifies the maximum amount of words allowed in an answer.

question-tags

A required array of strings that specifies the possible tags a worker can assign to a question-answer pair. If this array is empty, then question-tags field isn't visible.

allow-custom-question-tags

Required Boolean field that indicates whether a worker can specify a custom question tag.

name

A required string field that identifies the answer submitted that the worker submits. It matches a key in the output data contract of the worker submission.

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

Augmented AI Crowd HTML Elements

The following Crowd HTML Elements are only available for Amazon Augmented AI human workflow tasks.

crowd-textract-analyze-document

A widget to enable human review of a Amazon Textract document analysis result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

initialValue

This sets initial values for attributes found in the worker UI.

The following is an example of an `initialValue` input:

```
[
            {
                "blockType": "KEY_VALUE_SET",
                "confidence": 38.43309020996094,
                "geometry": {
                    "boundingBox": {
                        "width": 0.32613086700439453,
                        "weight": 0.0942094624042511,
                        "left": 0.4833833575248718,
                        "top": 0.5227988958358765
                    },
                    "polygon": [
                        {"x": 0.123, "y": 0.345}, ...
                    ]
                }
                "id": "8c97b240-0969-4678-834a-646c95da9cf4",
                "relationships": [
                    {
                        "type": "CHILD",
                        "ids": [
                            "7ee7b7da-ee1b-428d-a567-55a3e3affa56",
```

```
                                "4d6da730-ba43-467c-a9a5-c6137ba0c472"
                            ]
                        },
                        {
                            "type": "VALUE",
                            "ids": [
                                "6ee7b7da-ee1b-428d-a567-55a3e3affa54"
                            ]
                        }
                    ],
                    "entityTypes": [
                        "KEY"
                    ],
                    "text": "Foo bar"
                },
]
```

blockTypes

This determines the kind of analysis the workers can do. Only `KEY_VALUE_SET` is currently supported.

keys

This specifies new keys and the associated text value the worker can add. The input values for `keys` can include the following elements:

- `importantFormKey` accepts strings, and is used to specify a single key.
- `importantFormKeyAliases` can be used to specify aliases that are acceptable alternatives to the keys supplied. Use this element to identify alternative spellings or presentations of your keys. This parameter accepts a list of one or more strings.

The following is an example of an input for `keys`.

```
[
      {
        importantFormKey: 'Address',
        importantFormKeyAliases: [
          'address',
          'Addr.',
          'Add.',
```

```
        ]
      },
      {
        importantFormKey: 'Last name',
        importantFormKeyAliases: ['Surname']
      }
]
```

no-key-edit

This prevents the workers from editing the keys of annotations passed through `initialValue`. This prevents workers from editing the keys that have been detected on your documents. This is required.

no-geometry-edit

This prevents workers from editing the polygons of annotations passed through `initialValue`. For example, this would prevent the worker from editing the bounding box around a given key. This is required.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions, short-instructions

Regions

The following regions are supported by this element. You can use custom HTML and CSS code within these regions to format your instructions to workers. For example, use the `short-instructions` section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example of a Worker Template Using the crowd Element

An example of a worker template using this crowd element would look like the following.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.document.s3Object.bucket }}/
{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they
 don't match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="['KEY_VALUE_SET']"
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
        .instructionsImage {
          display: inline-block;
          max-width: 100%;
        }
      </style>
      <p class='instructions'>Click on a key-value block to highlight the corresponding
 key-value pair in the document.

If it is a valid key-value pair, review the content for the value. If the content is
 incorrect, correct it.

The text of the value is incorrect, correct it.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/
correct-value-text.png" />

A wrong value is identified, correct it.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/
correct-value.png" />
```

```
If it is not a valid key-value relationship, choose No.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/not-a-key-value-pair.png" />

If you can’t find the key in the document, choose Key not found.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/key-is-not-found.png" />

If the content of a field is empty, choose Value is blank.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/value-is-blank.png" />

<b>Examples</b>
Key and value are often displayed next or below to each other.

Key and value displayed in one line.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/sample-key-value-pair-1.png" />

Key and value displayed in two lines.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/sample-key-value-pair-2.png" />

If the content of the value has multiple lines, enter all the text without line break.
 Include all value text even if it extends beyond the highlight box.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/multiple-lines.png" /></p>
    </short-instructions>

    <full-instructions header="Instructions"></full-instructions>
  </crowd-textract-analyze-document>
</crowd-form>
```

Output

The following is a sample of the output from this element. You can find a detailed explanation of this output in the Amazon Textract AnalyzeDocument API documentation.

```
{
  "AWS/Textract/AnalyzeDocument/Forms/V1": {
    blocks: [
      {
        "blockType": "KEY_VALUE_SET",
```

```
        "id": "8c97b240-0969-4678-834a-646c95da9cf4",
        "relationships": [
          {
            "type": "CHILD",
            "ids": ["7ee7b7da-ee1b-428d-a567-55a3e3affa56", "4d6da730-ba43-467c-a9a5-
c6137ba0c472"]
          },
          {
            "type": "VALUE",
            "ids": ["6ee7b7da-ee1b-428d-a567-55a3e3affa54"]
          }
        ],
        "entityTypes": ["KEY"],
        "text": "Foo bar baz"
      }
    ]
  }
}
```

crowd-rekognition-detect-moderation-labels

A widget to enable human review of an Amazon Rekognition image moderation result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

categories

This supports `categories` as an array of strings **or** an array of objects where each object has a `name` field.

If the categories come in as objects, the following applies:

- The displayed categories are the value of the `name` field.
- The returned answer contains the **full** objects of any selected categories.

If the categories come in as strings, the following applies:

- The returned answer is an array of all the strings that were selected.

exclusion-category

By setting this attribute you create a button underneath the categories in the UI.

- When a user chooses the button, all categories are deselected and disabled.
- Choosing the button again re-enables the categories so that users can choose them.
- If you submit after choosing the button, it returns an empty array.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions, short-instructions

AWS Regions

The following AWS Regions are supported by this element. You can use custom HTML and CSS code within these Regions to format your instructions to workers. For example, use the `short-instructions` section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example Worker Template with the crowd Element

An example of a worker template using the crowd element would look like the following.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/
{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}
```

```
<crowd-form>
  <crowd-rekognition-detect-moderation-labels
    categories='[
      {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
        {
          name: "{{ label.name }}",
          parentName: "{{ label.parentName }}",
        },
      {% endfor %}
    ]'
    src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
      </style>
      <p class='instructions'>Review the image and choose all applicable categories.
If no categories apply, choose None.

<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Graphic Male Nudity</b>
Visuals depicting full frontal male nudity, often close ups

<b>Graphic Female Nudity</b>
Visuals depicting full frontal female nudity, often close ups

<b>Sexual Activity</b>
Visuals depicting various types of explicit sexual activities and pornography

<b>Illustrated Nudity or Sexual Activity</b>
Visuals depicting animated or drawn sexual activity, nudity or pornography

<b>Adult Toys</b>
Visuals depicting adult toys, often in a marketing context

<b>Female Swimwear or Underwear</b>
Visuals depicting female person wearing only swimwear or underwear
```

```
<b>Male Swimwear Or Underwear</b>
Visuals depicting male person wearing only swimwear or underwear

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses, such as deep cut dresses

<b>Graphic Violence or Gore</b>
Visuals depicting prominent blood or bloody injuries

<b>Physical Violence</b>
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades

<b>Self Injury</b>
Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns
 using sharp objects

<b>Emaciated Bodies</b>
Visuals depicting extremely malnourished human bodies

<b>Corpses</b>
Visuals depicting human dead bodies

<b>Hanging</b>
Visuals depicting death by hanging</p>
    </short-instructions>

    <full-instructions header="Instructions"></full-instructions>
  </crowd-rekognition-detect-moderation-labels>
</crowd-form>
```

Output

The following is a sample of the output from this element. For details about this output, see Amazon Rekognition DetectModerationLabels API documentation.

```
{
  "AWS/Rekognition/DetectModerationLabels/Image/V3": {
    "ModerationLabels": [
        { name: 'Gore', parentName: 'Violence' },
        { name: 'Corpses', parentName: 'Violence' },
    ]
  }
}
```

Using Amazon Augmented AI for Human Review

When you use AI applications such as Amazon Rekognition, Amazon Textract, or your custom machine learning (ML) models, you can use Amazon Augmented AI to get human review of low-confidence predictions or random prediction samples.

What is Amazon Augmented AI?

Amazon Augmented AI (Amazon A2I) is a service that brings human review of ML predictions to all developers by removing the heavy lifting associated with building human review systems or managing large numbers of human reviewers.

Many ML applications require humans to review low-confidence predictions to ensure the results are correct. For example, extracting information from scanned mortgage application forms can require human review due to low-quality scans or poor handwriting. Building human review systems can be time-consuming and expensive because it involves implementing complex processes or *workflows*, writing custom software to manage review tasks and results, and managing large groups of reviewers.

Amazon A2I streamlines building and managing human reviews for ML applications. Amazon A2I provides built-in human review workflows for common ML use cases, such as content moderation and text extraction from documents. You can also create your own workflows for ML models built on SageMaker AI or any other tools. Using Amazon A2I, you can allow human reviewers to step in when a model is unable to make a high-confidence prediction or to audit its predictions on an ongoing basis.

Amazon A2I Use Case Examples

The following examples demonstrate how you can use Amazon A2I to integrate a human review loop into your ML application. For each of these examples, you can find a Jupyter Notebook that demonstrates that workflow in [Use Cases and Examples Using Amazon A2I](#).

- **Use Amazon A2I with Amazon Textract** – Have humans review important key-value pairs in single-page documents or have Amazon Textract randomly sample and send documents from your dataset to humans for review.
- **Use Amazon A2I with Amazon Rekognition** – Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low-confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.
- **Use Amazon A2I to review real-time ML inferences** – Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker AI hosted endpoint and incrementally train your model using Amazon A2I output data.
- **Use Amazon A2I with Amazon Comprehend** – Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.
- **Use Amazon A2I with Amazon Transcribe** – Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.
- **Use Amazon A2I with Amazon Translate** – Have humans review low-confidence translations returned from Amazon Translate.
- **Use Amazon A2I to review tabular data** – Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Get Started with Amazon Augmented AI

To get started using Amazon Augmented AI, review the Core Components of Amazon A2I and Prerequisites to Using Augmented AI. Then, use the following documentation to learn how to use the Amazon A2I console and API.

- Tutorial: Get Started in the Amazon A2I Console
- Tutorial: Get Started Using the Amazon A2I API

You can also get stared using the Amazon A2I API by following a Jupyter Notebook tutorial. See Use Cases and Examples Using Amazon A2I for a list of notebooks and use cases.

Core Components of Amazon A2I

Review the following terms to familiarize yourself with the core components of Amazon A2I.

Task Types

The AI/ML workflow into which you integrate Amazon A2I defines an Amazon A2I *task type*.

Amazon A2I supports:

- Two *built-in task types*: Amazon Textract key-value pair extraction and Amazon Rekognition image moderation.

- A custom task type: Use a custom task type to integrate a human review loop into *any* machine learning workflow. You can use a custom task type to integrate Amazon A2I with other AWS services like Amazon Comprehend, Amazon Transcribe, and Amazon Translate, as well as your own custom machine learning workflows. To learn more, see Use Cases and Examples Using Amazon A2I.

Select a tab in the following table to see diagrams that illustrate how Amazon A2I works with each task type. Select the task type page using the links in the preceding list to learn more about that task type.

Amazon Textract – Key-value pair extraction

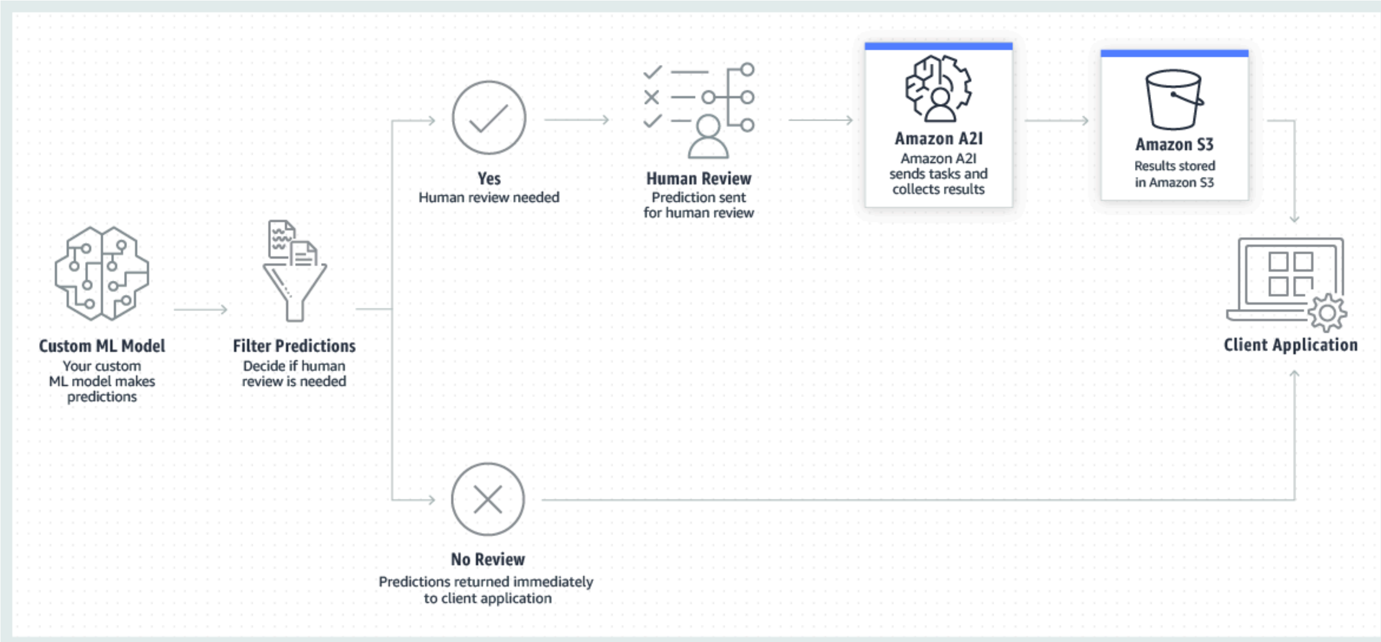
This image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

Amazon Rekognition – Image moderation

This image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

Custom Task Type

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.



Human Review Workflow (Flow Definition)

You use a human review workflow to specify your human *work team*, to set up your worker UI using a *worker task template*, and to provide information about how workers should complete the review task.

For built-in task types, you also use the human review workflow to identify the conditions under which a human loop is initiated. For example, Amazon Rekognition can perform image content moderation using machine learning. You can use the human review workflow to specify that an image is sent to a human for content moderation review if Amazon Rekognition's confidence is too low.

You can use a human review workflow to create multiple human loops.

You can create a flow definition in the SageMaker AI console or with the SageMaker API. To learn more about both of these options, see [Create a Human Review Workflow](#).

Work Team

A *work team* is a group of human workers to whom you send your human review tasks.

When you create a human review workflow, you specify a single work team.

Your work team can come from the [Amazon Mechanical Turk workforce](#), a [vendor-managed workforce](#), or your own [private workforce](#). When you use the private workforce, you can create multiple work teams. Each work team can be used in multiple human review workflows. To learn how to create a workforce and work teams, see Workforces.

Worker Task Template and Human Task UI

You use a *worker task template* to create a worker UI (a *human task UI*) for your human review tasks.

The human task UI displays your input data, such as documents or images, and instructions to workers. It also provides interactive tools that the worker uses to complete your tasks.

For built-in task types, you must use the Amazon A2I worker task template provided for that task type.

Human Loops

A *human loop* is used to create a single human review job. For each human review job, you can choose the number of workers that are sent a *task* to review a single data object. For example, if you set the number of workers per object to 3 for an image classification labeling job, three workers classify each input image. Increasing the number of workers per object can improve label accuracy.

A human loop is created using a human review workflow as follows:

- For built-in task types, the conditions specified in the human review workflow determine when the human loop is created.
- Human review tasks are sent to the work team specified in the human review workflow.
- The worker task template specified in the human review workflow is used to render the human task UI.

When do human loops get created?

When you use one of the *built-in task types*, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your human review workflow are met. For example:

- When you use Augmented AI with Amazon Textract, you can integrate Amazon A2I into a document review task using the API operation `AnalyzeDocument`. A human loop is created every time Amazon Textract returns inferences about key-value pairs that meet the conditions you specify in your human review workflow.

- When you use Augmented AI with Amazon Rekognition, you can integrate Amazon A2I into an image moderation task using the API operation `DetectModerationLabels`. A human loop is created every time Amazon Rekognition returns inferences about image content that meet the conditions you specify in your human review workflow.

When using a *custom task type*, you start a human loop using the Amazon Augmented AI Runtime API. When you call `StartHumanLoop` in your custom application, a task is sent to human reviewers.

To learn how to create and start a human loop, see Create and Start a Human Loop.

To generate these resources and create a human review workflow, Amazon A2I integrates multiple APIs, including the Amazon Augmented AI Runtime Model, the SageMaker APIs, and APIs associated with your task type. To learn more, see Use APIs in Amazon Augmented AI.

> **Note**
>
> AWS Region availability may differ when you use Augmented AI with other AWS services, such as Amazon Textract. Create Augmented AI resources in the same AWS Region that you use to interact with those AWS services. For AWS Region availability for all services, see the Region Table.

Prerequisites to Using Augmented AI

Amazon A2I uses resources in IAM, SageMaker AI, and Amazon S3 to create and run your human review workflows. You can create some of these resources in the Amazon A2I console when you create a human review workflow. To learn how, see Tutorial: Get Started in the Amazon A2I Console.

To use Amazon A2I, you need the following resources:

- One or more Amazon S3 buckets in the same AWS Region as the workflow for your input and output data. To create a bucket, follow the instructions in Create a Bucket in the *Amazon Simple Storage Service Console User Guide*.
- An IAM role with required permissions to create a human review workflow and an IAM user or role with permission to access Augmented AI. For more information, see Permissions and Security in Amazon Augmented AI.

- A public, private, or vendor workforce for your human review workflows. If you plan to use a private workforce, you need to set one up ahead of time in the same AWS Region as your Amazon A2I workflow. To learn more about these workforce types, see Workforces.

> **Important**
>
> To learn about the compliance programs that cover Amazon Augmented AI at this time, see AWS Services in Scope by Compliance Program. If you use Amazon Augmented AI in conjunction with other AWS services (such as Amazon Rekognition and Amazon Textract), note that Amazon Augmented AI may not be in scope for the same compliance programs as those other services. You are responsible for how you use Amazon Augmented AI, including understanding how the service processes or stores customer data and any impact on the compliance of your data environment. You should discuss your workload objectives and goals with your AWS account team; they can help you evaluate whether the service is a good fit for your proposed use case and architecture.

Tutorial: Get Started in the Amazon A2I Console

The following tutorial shows you how to get started using Amazon A2I in the Amazon A2I console.

The tutorial gives you the option to use Augmented AI with Amazon Textract for document review or Amazon Rekognition for image content review.

Prerequisites

To get started using Amazon A2I, complete the following prerequisites.

- Create an Amazon S3 bucket in the same AWS Region as the workflow for your input and output data. For example, if you are using Amazon A2I with Amazon Textract in us-east-1, create your bucket in us-east-1. To create a bucket, follow the instructions in Create a Bucket in the *Amazon Simple Storage Service Console User Guide*.
- Do one of the following:
  - If you want to complete the tutorial using Amazon Textract, download the following image and place it in your Amazon S3 bucket.

Employment Application

Application Information

Full Name: Jane Doe

Phone number: 550-0100

Home address: 123 Any Street, Any Town, USA

Mail address:

~~123 Any Street, Any Town, USA~~

234 Main Street, Any Town, USA

Sample

- If you want to complete the tutorial using Amazon Rekognition, download the following image and place it in your Amazon S3 bucket.

Note

The Amazon A2I console is embedded in the SageMaker AI console.

Step 1: Create a Work Team

First, create a work team in the Amazon A2I console and add yourself as a worker so that you can preview the worker review task.

Important

This tutorial uses a private work team. The Amazon A2I private workforce is configured in the Ground Truth area of the SageMaker AI console and is shared between Amazon A2I and Ground Truth.

To create a private workforce using worker emails

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Labeling workforces** under **Ground Truth**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. For this tutorial, enter your email and any others that you want to be able to preview the human task UI. You can paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an Amazon SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to Amazon SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Choose **Create private team**.

If you add yourself to a private work team, you receive an email from `no-reply@verificationemail.com` with login information. Use the link in this email to reset your password and log in to your worker portal. This is where your human review tasks appear when you create a human loop.

Step 2: Create a Human Review Workflow

In this step, you create a human review workflow. Each human review workflow is created for a specific task type. This tutorial allows you to choose between the built-in task types: Amazon Rekognition and Amazon Textract.

To create a human review workflow:

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the **Human review workflows** page.
2. Select **Create human review workflow**.
3. In **Workflow settings**, enter a workflow **Name**, **S3 bucket**, and the **IAM role** that you created for this tutorial, with the AWS managed policy `AmazonAugmentedAIIntegratedAPIAccess` attached.

4. For **Task type**, select **Textract – Key-value pair extraction** or **Rekognition – Image moderation**.
5. Select the task type that you chose from the following table for instructions for that task type.

   Amazon Textract – Key-value pair extraction

   1. Select **Trigger a human review for specific form keys based on the form key confidence score or when specific form keys are missing**.

   2. For **Key name**, enter `Mail Address`.

   3. Set the identification confidence threshold between `0` and `99`.

   4. Set the qualification confidence threshold between `0` and `99`.

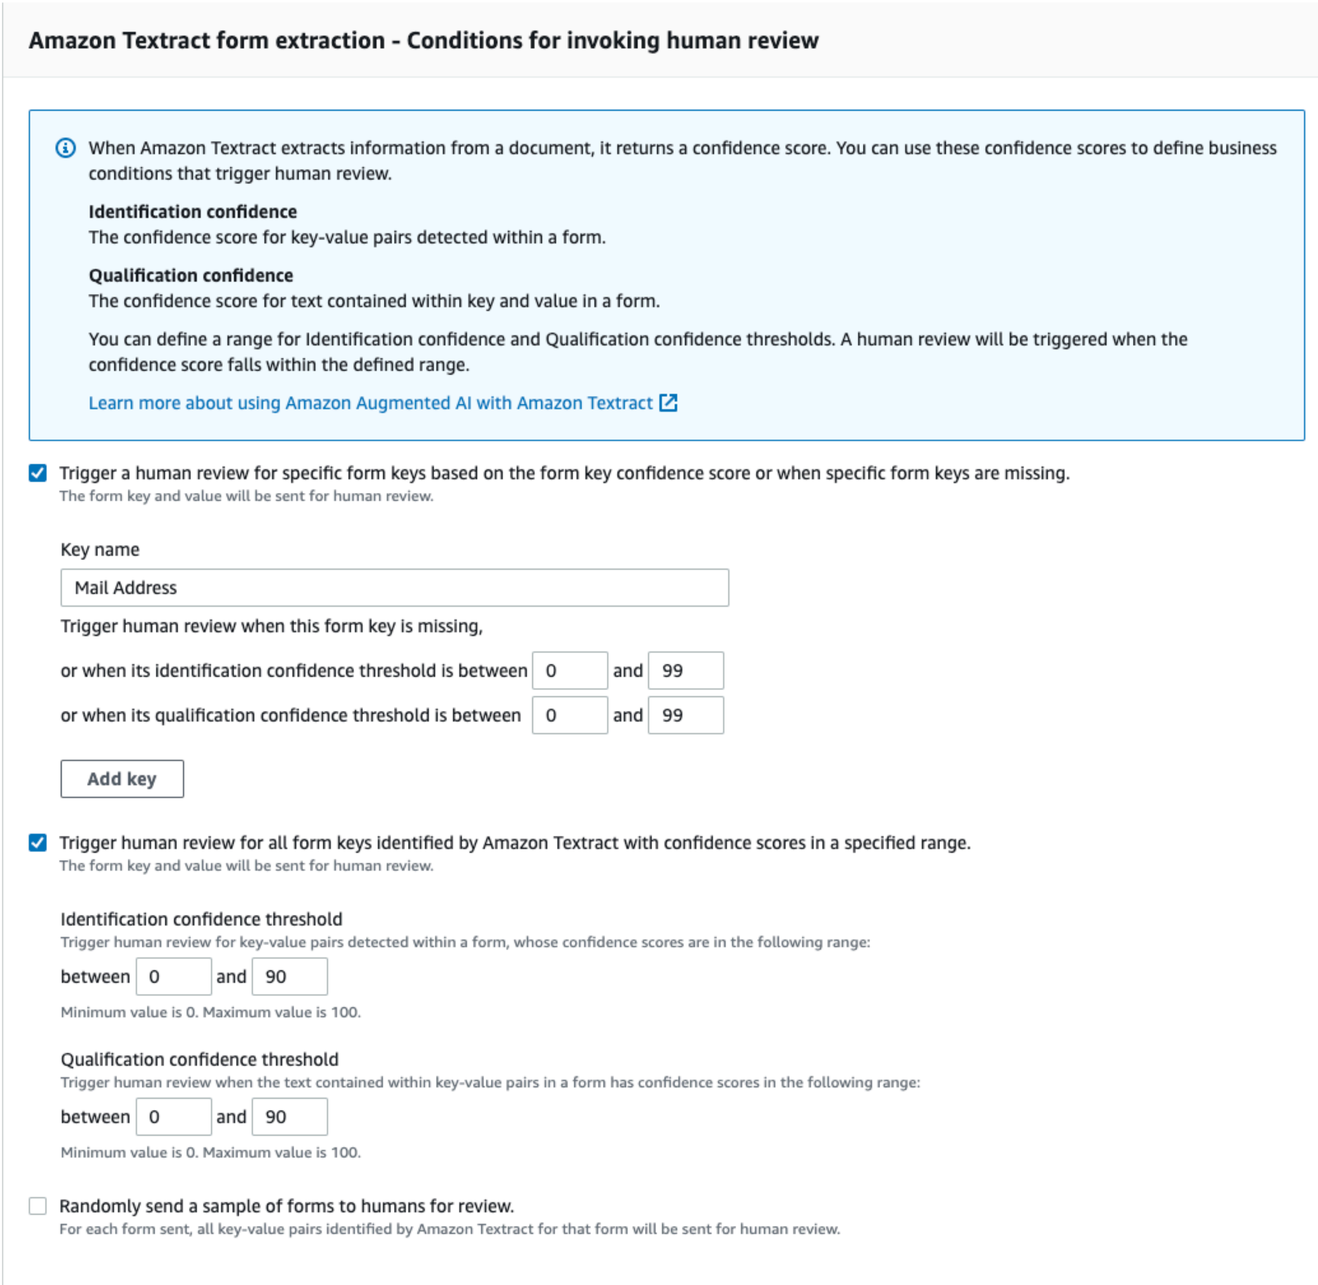
   5. Select **Trigger a human review for all form keys identified by Amazon Textract with confidence scores in a specific range**.

   6. Set the identification confidence threshold between `0` and `90`.

   7. Set the qualification confidence threshold between `0` and `90`.

   This initiates a human review if Amazon Textract returns a confidence score that is less than `99` for `Mail Address` and its key, or if it returns a confidence score less than `90` for any key value pair detected in the document.

   The following image shows the Amazon Textract form extraction - Conditions for invoking human review section of the Amazon A2I console. In the image, the check boxes for the two types of triggers explained in the proceeding paragraph are checked, and `Mail Address` is used as a **Key name** for the first trigger. The identification confidence threshold is defined using confidence scores for key-value pairs detect within the form and is set between 0 and 99. The qualification confidence threshold is defined using confidence scores for text contained within keys and values in a form and is set between 0 and 99.



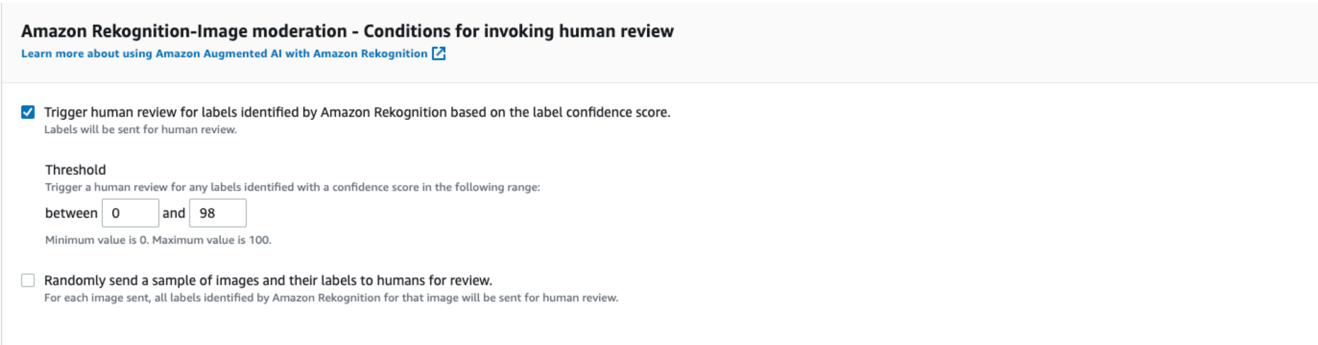
Amazon Rekognition – Image moderation

1. Select **Trigger human review for labels identified by Amazon Rekognition based on label confidence score**.

2. Set the **Threshold** between `0` and 98.

This initiates a human review if Amazon Rekognition returns a confidence score that is less than 98 for an image moderation job.

The following image shows how you can select the **Trigger human review for labels identified by Amazon Rekognition based on label confidence score** option and enter a **Threshold** between 0 and 98 in the Amazon A2I console.



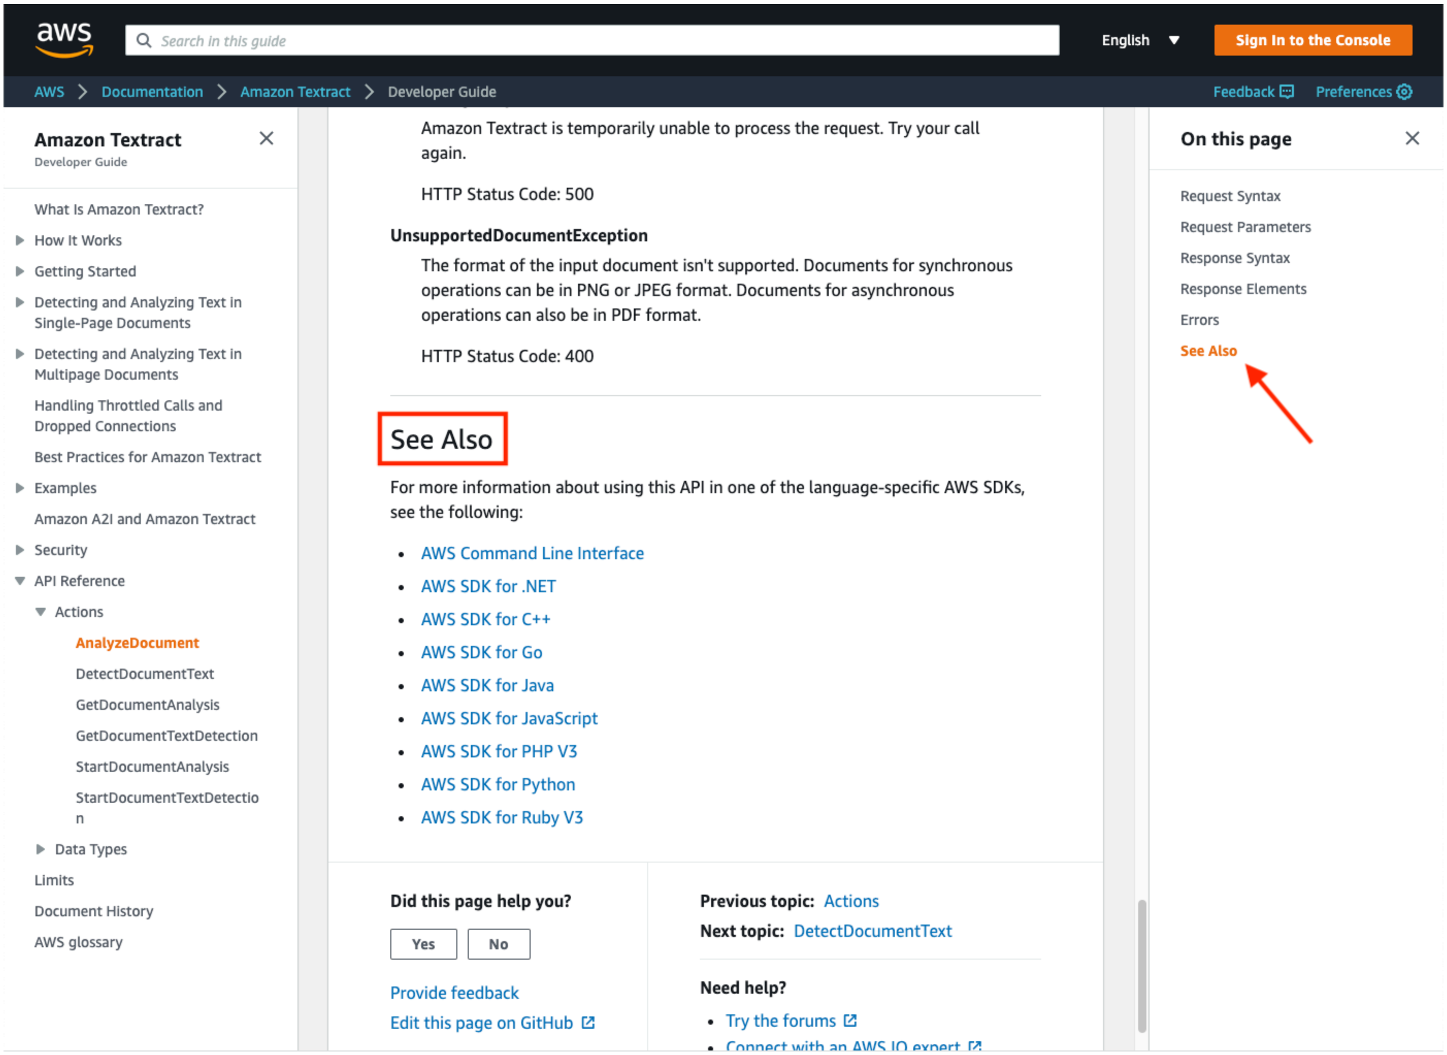
6. Under **Worker task template creation**, select **Create from a default template**.
7. Enter a **Template name**.
8. In **Task description** field, enter the following text:

   ```
   Read the instructions carefully and complete the task.
   ```
9. Under **Workers**, select **Private**.
10. Select the private team that you created.
11. Choose **Create**.

Once your human review workflow is created, it appears in the table on the **Human review workflows** page. When the **Status** is `Active`, copy and save the Workflow ARN. You need it for the next step.

Step 3: Start a Human Loop

You must use an API operation to start a human loop. There are a variety of language-specific SDKs that you can use to interact with these API operations. To see documentation for each of these SDKs, refer to the **See Also** section in the API documentation, as shown in the following image.



For this tutorial, you use one of the following APIs:

- If you chose the Amazon Textract task type, you use the `AnalyzeDocument` operation.
- If you chose the Amazon Rekognition task type, you use the `DetectModerationLabels` operation.

You can interact with these APIs using a SageMaker notebook instance (recommended for new users) or the AWS Command Line Interface (AWS CLI). Choose one of the following to learn more about these options:

- To learn more about and set up a notebook instance, see Amazon SageMaker notebook instances.
- To learn more about and get started using the AWS CLI, see What Is the AWS Command Line Interface? in the *AWS Command Line Interface User Guide*.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the [DataAttributes]() parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the [analyze_document]() documention in the *AWS SDK for Python (Boto) API Reference*.

```
response = client.analyze_document(
        Document={
                "S3Object": {
                    "Bucket": "amzn-s3-demo-bucket",
                    "Name": "document-name.pdf"
                }
        },
        HumanLoopConfig={
            "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
            "HumanLoopName":"human-loop-name",
            "DataAttributes" : {
                "ContentClassifiers":
["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]
            }
        },
        FeatureTypes=["TABLES", "FORMS"])
```

Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the [DataAttributes]() parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the [detect_moderation_labels]() documentation in the *AWS SDK for Python (Boto) API Reference*.

```
response = client.detect_moderation_labels(
        Image={
            "S3Object":{
```

```
                        "Bucket": "amzn-s3-demo-bucket",
                        "Name": "image-name.png"
                    }
                },
                HumanLoopConfig={
                   "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
                   "HumanLoopName":"human-loop-name",
                   "DataAttributes":{
                        ContentClassifiers:
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]
                    }
                 })
```

Step 4: View Human Loop Status in Console

When you start a human loop, you can view its status in the Amazon A2I console.

To view your human loop status

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the **Human review workflows** page.
2. Select the human review workflow that you used to start your human loop.
3. In the **Human loops** section, you can see your human loop. View its status in the **Status** column.

Step 5: Download Output Data

Your output data is stored in the Amazon S3 bucket you specified when you created a human review workflow.

To view your Amazon A2I output data

1. Open the Amazon S3 console.
2. Select the Amazon S3 bucket you specified when you created your human review workflow in step 2 of this example.
3. Starting with the folder that is named after your human review workflow, navigate to your output data by selecting the folder with the following naming convention:

```
s3://output-bucket-specified-in-human-review-workflow/human-review-workflow-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
```

4. Select `output.json` and choose **Download**.

Tutorial: Get Started Using the Amazon A2I API

This tutorial explains the API operations you can use to get started using Amazon A2I.

To use a Jupyter Notebook to run these operations, select a Jupyter Notebook from Use Cases and Examples Using Amazon A2I and use Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook to learn how to use it in a SageMaker AI notebook instance.

To learn more about the API operations you can use with Amazon A2I, see Use APIs in Amazon Augmented AI.

Create a Private Work Team

You can create a private work team and add yourself as a worker so that you can preview Amazon A2I.

If you are not familiar with Amazon Cognito, we recommend that you use the SageMaker AI console to create a private workforce and add yourself as a private worker. For instructions, see Step 1: Create a Work Team.

If you are familiar with Amazon Cognito, you can use the following instructions to create a private work team using the SageMaker API. After you create a work team, note the work team ARN (`WorkteamArn`).

To learn more about the private workforce and other available configurations, see Private workforce.

Create a private workforce

If you have not created a private workforce, you can do so using an Amazon Cognito user pool. Make sure that you have added yourself to this user pool. You can create a private work team using the AWS SDK for Python (Boto3) `create_workforce` function. For other language-specific SDKs, refer to the list in CreateWorkforce.

```
response = client.create_workforce(
    CognitoConfig={
        "UserPool": "Pool_ID",
        "ClientId": "app-client-id"
    },
    WorkforceName="workforce-name"
)
```

Create a private work team

After you have created a private workforce in the AWS Region to configure and start your human loop, you can create a private work team using the AWS SDK for Python (Boto3) `create_workteam` function. For other language-specific SDKs, refer to the list in `CreateWorkteam`.

```
response = client.create_workteam(
    WorkteamName="work-team-name",
    WorkforceName= "workforce-name",
    MemberDefinitions=[
        {
            "CognitoMemberDefinition": {
                "UserPool": "<aws-region>_ID",
                "UserGroup": "user-group",
                "ClientId": "app-client-id"
            },
        }
    ]
)
```

Access your work team ARN as follows:

```
workteamArn = response["WorkteamArn"]
```

List private work teams in your account

If you have already created a private work team, you can list all work teams in a given AWS Region in your account using the AWS SDK for Python (Boto3) `list_workteams` function. For other language-specific SDKs, refer to the list in `ListWorkteams`.

```
    response = client.list_workteams()
```

If you have numerous work teams in your account, you may want to use `MaxResults`, `SortBy`, and `NameContains` to filter your results.

Create a Human Review Workflow

You can create a human review workflow using the Amazon A2I [`CreateFlowDefinition`](#) operation. Before you create your human review workflow, you need to create a human task UI. You can do this with the [`CreateHumanTaskUi`](#) operation.

If you are using Amazon A2I with the Amazon Textract or Amazon Rekognition integrations, you can specify activation conditions using a JSON.

Create a Human Task UI

If you are creating a human review workflow to be used with Amazon Textract or Amazon Rekognition integrations, you need to use and modify pre-made worker task template. For all custom integrations, you can use your own custom worker task template. Use the following table to learn how to create a human task UI using a worker task template for the two built-in integrations. Replace the template with your own to customize this request.

Amazon Textract – Key-value pair extraction

To learn more about this template, see Custom Template Example for Amazon Textract.

```
template = r"""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.document.s3Object.bucket }}/
{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}
<crowd-form>
  <crowd-textract-analyze-document
      src="{{ s3_uri | grant_read_access }}"
      initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
      header="Review the key-value pairs listed on the right and correct them if
 they don"t match the following document."
      no-key-edit=""
      no-geometry-edit=""
      keys="{{ task.input.humanLoopContext.importantFormKeys }}"
      block-types='["KEY_VALUE_SET"]'>
    <short-instructions header="Instructions">
```

```
        <p>Click on a key-value block to highlight the corresponding key-value pair
 in the document.
        </p><p><br></p>
        <p>If it is a valid key-value pair, review the content for the value. If the
 content is incorrect, correct it.
        </p><p><br></p>
        <p>The text of the value is incorrect, correct it.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/correct-value-
text.png">
        </p><p><br></p>
        <p>A wrong value is identified, correct it.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/correct-value.png">
        </p><p><br></p>
        <p>If it is not a valid key-value relationship, choose No.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/not-a-key-value-
pair.png">
        </p><p><br></p>
        <p>If you can’t find the key in the document, choose Key not found.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/key-is-not-
found.png">
        </p><p><br></p>
        <p>If the content of a field is empty, choose Value is blank.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/value-is-
blank.png">
        </p><p><br></p>
        <p><strong>Examples</strong></p>
        <p>Key and value are often displayed next or below to each other.
        </p><p><br></p>
        <p>Key and value displayed in one line.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/sample-key-value-
pair-1.png">
        </p><p><br></p>
        <p>Key and value displayed in two lines.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/sample-key-value-
pair-2.png">
        </p><p><br></p>
        <p>If the content of the value has multiple lines, enter all the text
 without line break.
        Include all value text even if it extends beyond the highlight box.</p>
        <p><img src="https://assets.crowd.aws/images/a2i-console/multiple-
lines.png"></p>
    </short-instructions>
    <full-instructions header="Instructions"></full-instructions>
  </crowd-textract-analyze-document>
```

```
</crowd-form>
"""
```

Amazon Rekognition – Image moderation

To learn more about this template, see Custom Template Example for Amazon Rekognition.

```
template = r"""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/
{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-rekognition-detect-moderation-labels
    categories='[
      {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
        {
          name: "{{ label.name }}",
          parentName: "{{ label.parentName }}",
        },
      {% endfor %}
    ]'
    src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
      </style>
      <p class="instructions">Review the image and choose all applicable categories.
If no categories apply, choose None.

<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses
```

```
<b>Physical Violence</b>
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades
    </short-instructions>

    <full-instructions header="Instructions"></full-instructions>
  </crowd-rekognition-detect-moderation-labels>
</crowd-form>"""
```

Custom Integration

The following is an example template that can be used in a custom integration. This template is used in this notebook, demonstrating a custom integration with Amazon Comprehend.

```
template = r"""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <crowd-classifier
      name="sentiment"
      categories='["Positive", "Negative", "Neutral", "Mixed"]'
      initial-value="{{ task.input.initialValue }}"
      header="What sentiment does this text convey?"
    >
      <classification-target>
        {{ task.input.taskObject }}
      </classification-target>

      <full-instructions header="Sentiment Analysis Instructions">
        <p><strong>Positive</strong> sentiment include: joy, excitement, delight</p>
        <p><strong>Negative</strong> sentiment include: anger, sarcasm, anxiety</p>
        <p><strong>Neutral</strong>: neither positive or negative, such as stating a
 fact</p>
        <p><strong>Mixed</strong>: when the sentiment is mixed</p>
      </full-instructions>

      <short-instructions>
       Choose the primary sentiment that is expressed by the text.
```

```
        </short-instructions>
    </crowd-classifier>
</crowd-form>
"""
```

Using the template specified above, you can create a template using the AWS SDK for Python (Boto3) `create_human_task_ui` function. For other language-specific SDKs, refer to the list in `CreateHumanTaskUi`.

```
response = client.create_human_task_ui(
    HumanTaskUiName="human-task-ui-name",
    UiTemplate={
        "Content": template
    }
)
```

This response element contains the human task UI ARN. Save this as follows:

```
humanTaskUiArn = response["HumanTaskUiArn"]
```

Create JSON to specify activation conditions

For Amazon Textract and Amazon Rekognition built-in integrations, you can save activation conditions in a JSON object and use this in your `CreateFlowDefinition` request.

Next, select a tab to see example activation conditions you can use for these built-in integrations. For additional information about activation condition options, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI.

Amazon Textract – Key-value pair extraction

This example specifies conditions for specific keys (such as `Mail address`) in the document. If Amazon Textract's confidence falls outside of the thresholds set here, the document is sent to a human for review, with the specific keys that initiated the human loop prompted to the worker.

```
import json

humanLoopActivationConditions = json.dumps(
```

```
        {
            "Conditions": [
                {
                  "Or": [

                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail
address:", "Mailing Add:","Mailing Addresses"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "MissingImportantFormKey",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail
address:","Mailing Add:","Mailing Addresses"]
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Phone Number",
                            "ImportantFormKeyAliases": ["Phone number:", "Phone
No.:", "Number:"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                      "ConditionType": "ImportantFormKeyConfidenceCheck",
                      "ConditionParameters": {
                        "ImportantFormKey": "*",
                        "KeyValueBlockConfidenceLessThan": 100,
                        "WordBlockConfidenceLessThan": 100
                      }
                    },
                    {
                      "ConditionType": "ImportantFormKeyConfidenceCheck",
                      "ConditionParameters": {
```

```
                        "ImportantFormKey": "*",
                        "KeyValueBlockConfidenceGreaterThan": 0,
                        "WordBlockConfidenceGreaterThan": 0
                      }
                    }
            ]
        }
            ]
        }
    )
```

Amazon Rekognition – Image moderation

The human loop activation conditions used here are tailored towards Amazon Rekognition content moderation; they are based on the confidence thresholds for the `Suggestive` and `Female Swimwear Or Underwear` moderation labels.

```
        import json

        humanLoopActivationConditions = json.dumps(
        {
            "Conditions": [
                {
                  "Or": [
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Suggestive",
                            "ConfidenceLessThan": 98
                        }
                    },
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Female Swimwear Or Underwear",
                            "ConfidenceGreaterThan": 98
                        }
                    }
                  ]
                }
            ]
        }
```

```
    )
```

Create a human review workflow

This section gives an example of the `CreateFlowDefinition` AWS SDK for Python (Boto3) request using the resources created in the previous sections. For other language-specific SDKs, refer to the list in CreateFlowDefinition. Use the tabs in the following table to see the requests to create a human review workflow for Amazon Textract and Amazon Rekognition built-in integrations.

Amazon Textract – Key-value pair extraction

If you use the built-in integration with Amazon Textract, you must specify `"AWS/Textract/AnalyzeDocument/Forms/V1"` for `"AwsManagedHumanLoopRequestSource"` in `HumanLoopRequestSource`.

```
    response = client.create_flow_definition(
        FlowDefinitionName="human-review-workflow-name",
        HumanLoopRequestSource={
            "AwsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/
V1"
        },
        HumanLoopActivationConfig={
            "HumanLoopActivationConditionsConfig": {
                "HumanLoopActivationConditions": humanLoopActivationConditions
            }
        },
        HumanLoopConfig={
            "WorkteamArn": workteamArn,
            "HumanTaskUiArn": humanTaskUiArn,
            "TaskTitle": "Document entry review",
            "TaskDescription": "Review the document and instructions. Complete the
 task",
            "TaskCount": 1,
            "TaskAvailabilityLifetimeInSeconds": 43200,
            "TaskTimeLimitInSeconds": 3600,
            "TaskKeywords": [
                "document review",
            ],
        },
```

```
        OutputConfig={
            "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
        },
        RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
        Tags=[
            {
                "Key": "string",
                "Value": "string"
            },
        ]
    )
```

Amazon Rekognition – Image moderation

If you use the built-in integration with Amazon Rekognition, you must specify `"AWS/Rekognition/DetectModerationLabels/Image/V3"` for `"AwsManagedHumanLoopRequestSource"` in `HumanLoopRequestSource`.

```
    response = client.create_flow_definition(
        FlowDefinitionName="human-review-workflow-name",
        HumanLoopRequestSource={
            "AwsManagedHumanLoopRequestSource": "AWS/Rekognition/
DetectModerationLabels/Image/V3"
        },
        HumanLoopActivationConfig={
            "HumanLoopActivationConditionsConfig": {
                "HumanLoopActivationConditions": humanLoopActivationConditions
            }
        },
        HumanLoopConfig={
            "WorkteamArn": workteamArn,
            "HumanTaskUiArn": humanTaskUiArn,
            "TaskTitle": "Image content moderation",
            "TaskDescription": "Review the image and instructions. Complete the
 task",
            "TaskCount": 1,
            "TaskAvailabilityLifetimeInSeconds": 43200,
            "TaskTimeLimitInSeconds": 3600,
            "TaskKeywords": [
                "content moderation",
            ],
        },
```

```
        OutputConfig={
            "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
        },
        RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
        Tags=[
            {
                "Key": "string",
                "Value": "string"
            },
        ]
    )
```

Custom Integration

If you use a custom integration, exclude the following parameters: `HumanLoopRequestSource`, `HumanLoopActivationConfig`.

```
    response = client.create_flow_definition(
        FlowDefinitionName="human-review-workflow-name",
        HumanLoopConfig={
            "WorkteamArn": workteamArn,
            "HumanTaskUiArn": humanTaskUiArn,
            "TaskTitle": "Image content moderation",
            "TaskDescription": "Review the image and instructions. Complete the
 task",
            "TaskCount": 1,
            "TaskAvailabilityLifetimeInSeconds": 43200,
            "TaskTimeLimitInSeconds": 3600,
            "TaskKeywords": [
                "content moderation",
            ],
        },
        OutputConfig={
            "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
        },
        RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
        Tags=[
            {
                "Key": "string",
                "Value": "string"
            },
        ]
```

```
    )
```

After you create a human review workflow, you can retrieve the flow definition ARN from the response:

```
humanReviewWorkflowArn = response["FlowDefinitionArn"]
```

Create a Human Loop

The API operation you use to start a human loop depends on the Amazon A2I integration you use.

- If you use the Amazon Textract built-in integration, you use the AnalyzeDocument operation.
- If you use the Amazon Rekognition built-in integration, you use the DetectModerationLabels operation.
- If you use a custom integration, you use the StartHumanLoop operation.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the analyze_document documention in the *AWS SDK for Python (Boto) API Reference*.

```
response = client.analyze_document(
        Document={"S3Object": {"Bucket": "amzn-s3-demo-bucket", "Name": "document-name.pdf"},
        HumanLoopConfig={
            "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-definition/flow-definition-name",
            "HumanLoopName":"human-loop-name",
            "DataAttributes" : {ContentClassifiers:["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
        }
        FeatureTypes=["FORMS"]
```

```
    )
```

Human loops are only created if Amazon Textract's confidence for document analysis task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see [`HumanLoopActivationOutput`](#).

```
    if "HumanLoopArn" in analyzeDocumentResponse["HumanLoopActivationOutput"]:
        # A human loop has been started!
        print(f"A human loop has been started with ARN:
 {analyzeDocumentResponse["HumanLoopActivationOutput"]["HumanLoopArn"]}"
```

Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the [`DataAttributes`](#) parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the [detect_moderation_labels](#) documention in the *AWS SDK for Python (Boto) API Reference*.

```
   response = client.detect_moderation_labels(
            Image={"S3Object":{"Bucket": "amzn-s3-demo-bucket", "Name": "image-
name.png"}},
            HumanLoopConfig={
               "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
               "HumanLoopName":"human-loop-name",
               "DataAttributes":{ContentClassifiers:
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
             }
    )
```

Human loops are only created if Amazon Rekognition's confidence for an image moderation task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see [`HumanLoopActivationOutput`](#).

```
    if "HumanLoopArn" in response["HumanLoopActivationOutput"]:
        # A human loop has been started!
        print(f"A human loop has been started with ARN:
 {response["HumanLoopActivationOutput"]["HumanLoopArn"]}")
```

Custom Integration

The following example uses the AWS SDK for Python (Boto3) to call `start_human_loop` in us-west-2. Replace the italicized red text with your resources. Include the [`DataAttributes`](#) parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the [start_human_loop](#) documention in the *AWS SDK for Python (Boto) API Reference*.

```
   response = client.start_human_loop(
        HumanLoopName= "human-loop-name",
        FlowDefinitionArn= "arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
        HumanLoopInput={"InputContent": inputContentJson},
        DataAttributes={"ContentClassifiers":
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
   )
```

This example stores input content in the variable *`inputContentJson`*. Assume that the input content contains two elements: a text blurb and sentiment (such as `Positive`, `Negative`, or `Neutral`), and it is formatted as follows:

```
    inputContent = {
        "initialValue": sentiment,
         "taskObject": blurb
     }
```

The keys `initialValue` and `taskObject` must correspond to the keys used in the liquid elements of the worker task template. Refer to the custom template in [Create a Human Task UI](#) to see an example.

To create *`inputContentJson`*, do the following:

```
    import json
```

```
inputContentJson = json.dumps(inputContent)
```

A human loop starts each time you call `start_human_loop`. To check the status of your human loop, use describe_human_loop:

```
human_loop_info = a2i.describe_human_loop(HumanLoopName="human_loop_name")
print(f"HumanLoop Status: {resp["HumanLoopStatus"]}")
print(f"HumanLoop Output Destination: {resp["HumanLoopOutput"]}")
```

Use Cases and Examples Using Amazon A2I

You can use Amazon Augmented AI to incorporate a human review into your workflow for *built-in task types*, Amazon Textract and Amazon Rekognition, or your own custom tasks using a *custom task type*.

When you create a human review workflow using one of the built-in task types, you can specify conditions, such as confidence thresholds, that initiate a human review. The service (Amazon Rekognition or Amazon Textract) creates a human loop on your behalf when these conditions are met and supplies your input data directly to Amazon A2I to send to human reviewers. To learn more about the built-in task types, use the following:

- Use Amazon Augmented AI with Amazon Textract
- Use Amazon Augmented AI with Amazon Rekognition

When you use a custom task type, you create and start a human loop using the Amazon A2I Runtime API. Use the custom task type to incorporate a human review workflow with other AWS services or your own custom ML application.

- For more details, see Use Amazon Augmented AI with Custom Task Types

The following table outlines a variety of Amazon A2I use cases that you can explore using SageMaker AI Jupyter Notebooks. To get started with a Jupyter Notebook, use the instructions in Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook. For more examples, see this GitHub repository.

Use Case	Description	Task Type
Use Amazon A2I with Amazon Textract	Have humans review single-page documents to review important form key-value pairs, or have Amazon Textract randomly sample and send documents from your dataset to humans for review.	Built-in
Use Amazon A2I with Amazon Rekognition	Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.	Built-in
Use Amazon A2I with Amazon Comprehend	Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.	Custom
Use Amazon A2I with Amazon Transcribe	Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.	Custom

Use Case	Description	Task Type
Use Amazon A2I with Amazon Translate	Have humans review low-confidence translations returned from Amazon Translate.	Custom
Use Amazon A2I to review real time ML inferences	Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker AI hosted endpoint and incrementally train your model using Amazon A2I output data.	Custom
Use Amazon A2I to review tabular data	Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.	Custom

Topics

Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook

For an end-to-end example that demonstrates how to integrate an Amazon A2I human review loop into a machine learning workflow, you can use a Jupyter Notebook from this GitHub Repository in a SageMaker notebook instance.

To use an Amazon A2I custom task type sample notebook in an Amazon SageMaker notebook instance:

1. If you do not have an active SageMaker notebook instance, create one by following the instructions in [Create an Amazon SageMaker Notebook Instance for the tutorial](#).
2. When your notebook instance is active, choose **Open JupyterLab** to the right of the notebook instance's name. It may take a few moments for JupyterLab to load.
3. Choose the add Github repository icon

   ()

   to clone a GitHub repository into your workspace.
4. Enter the [amazon-a2i-sample-jupyter-notebooks](#) repository HTTPS URL.
5. Choose **CLONE**.
6. Open the notebook that you would like to run.
7. Follow the instructions in the notebook to configure your human review workflow and human loop and run the cells.
8. To avoid incurring unnecessary charges, when you are done with the demo, stop and delete your notebook instance in addition to any Amazon S3 buckets, IAM roles, and CloudWatch Events resources created during the walkthrough.

Use Amazon Augmented AI with Amazon Textract

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract's `AnalyzeDocument` API operation. You can use `AnalyzeDocument` to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an `AnalyzeDocument` request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for review when the conditions specified in your flow definition are met. For example, if you want a human to review a specific key like `Full name:` and their associated input values, you can create an activation condition that starts a human review any time the `Full name:` key is detected or when the inference confidence for that key falls within a range that you specify.

The following image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team.

These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers,2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can specify when Amazon Textract sends a task to a human worker for review when creating a human review workflow or flow definition by specifying *activation conditions*.

You can set the following activation conditions when using the Amazon Textract task type:

- Initiate a human review for specific form keys based on the form key confidence score.
- Initiate a human review when specific form keys are missing.
- Initiate human review for all form keys identified by Amazon Textract with confidence scores in a specified range.
- Randomly send a sample of forms to humans for review.

When your activation condition depends on form key confidence scores, you can use two types of prediction confidence to initiate human loops:

- **Identification confidence** – The confidence score for key-value pairs detected within a form.

- **Qualification confidence** – The confidence score for text contained within key and value in a form.

In the image in the following section, **Full Name: Jane Doe** is the key-value pair, **Full Name** is the key, and **Jane Doe** is the value.

You can set these activation conditions using the Amazon SageMaker AI console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the `HumanLoopActivationConditions` parameter of `CreateFlowDefinition` API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI and Use Human Loop Activation Conditions JSON Schema with Amazon Textract.

> **Note**
>
> When using Augmented AI with Amazon Textract, create Augmented AI resources in the same AWS Region you use to call `AnalyzeDocument`.

Get Started: Integrate a Human Review into an Amazon Textract Analyze Document Job

To integrate a human review into an Amazon Textract text detection and analysis job, you need to create a flow definition, and then use the Amazon Textract API to integrate that flow definition into your workflow. To learn how to create a flow definition using the SageMaker AI console or Augmented AI API, see the following topics:

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)

After you've created your flow definition, see Using Augmented AI with Amazon Textract to learn how to integrate your flow definition into your Amazon Textract task.

End-to-End Example Using Amazon Textract and Amazon A2I

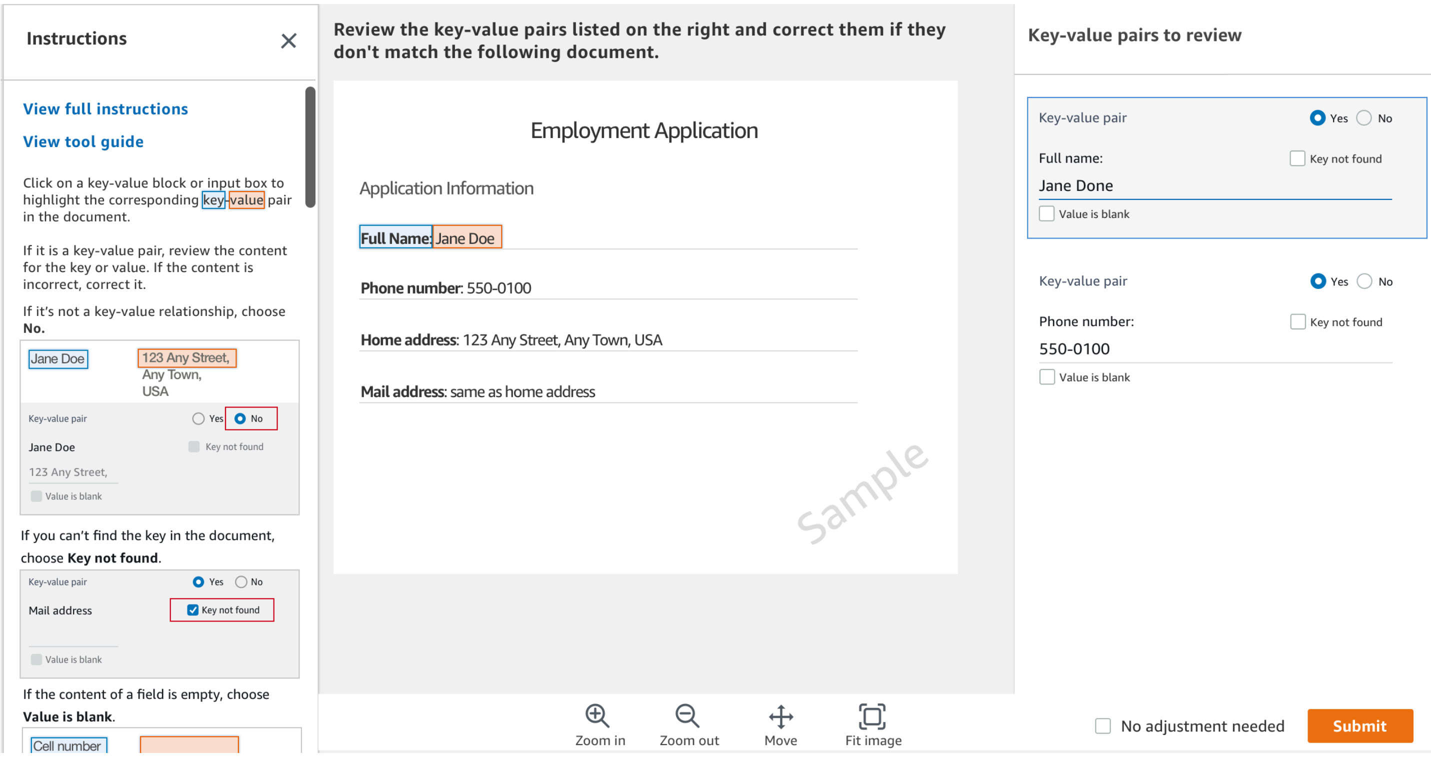
For an end-to-end example that demonstrates how to use Amazon Textract with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console.

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Textract's Analyze Document [Example] in a

SageMaker Notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

A2I Textract Worker Console Preview

When they're assigned a review task in an Amazon Textract workflow, workers might see a user interface similar to the following:



You can customize this interface in the SageMaker AI console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates.

Use Amazon Augmented AI with Amazon Rekognition

Amazon Rekognition makes it easy to add image analysis to your applications. The Amazon Rekognition `DetectModerationLabels` API operation is directly integrated with Amazon A2I so that you can easily create a human loop to review unsafe images, such as explicit adult or violent content. You can use `DetectModerationLabels` to configure a human loop using a flow definition ARN. This enables Amazon A2I to analyze predictions made by Amazon Rekognition and send results to a human for review to ensure they meet the conditions set in your flow definition.

The following image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can set the following activation conditions when using the Amazon Rekognition task type:

- Initiate human review for labels identified by Amazon Rekognition based on the label confidence score.
- Randomly send a sample of images to humans for review.

You can set these activation conditions using the Amazon SageMaker AI console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the `HumanLoopActivationConditions` parameter of the `CreateFlowDefinition` API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI and Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition.

> **Note**
>
> When using Augmented AI with Amazon Rekognition, create Augmented AI resources in the same AWS Region you use to call `DetectModerationLabels`.

Get Started: Integrate a Human Review into an Amazon Rekognition Image Moderation Job

To integrate a human review into an Amazon Rekognition, see the following topics:

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)

After you've created your flow definition, see Using Augmented AI with Amazon Rekognition to learn how to integrate your flow definition into your Amazon Rekognition task.

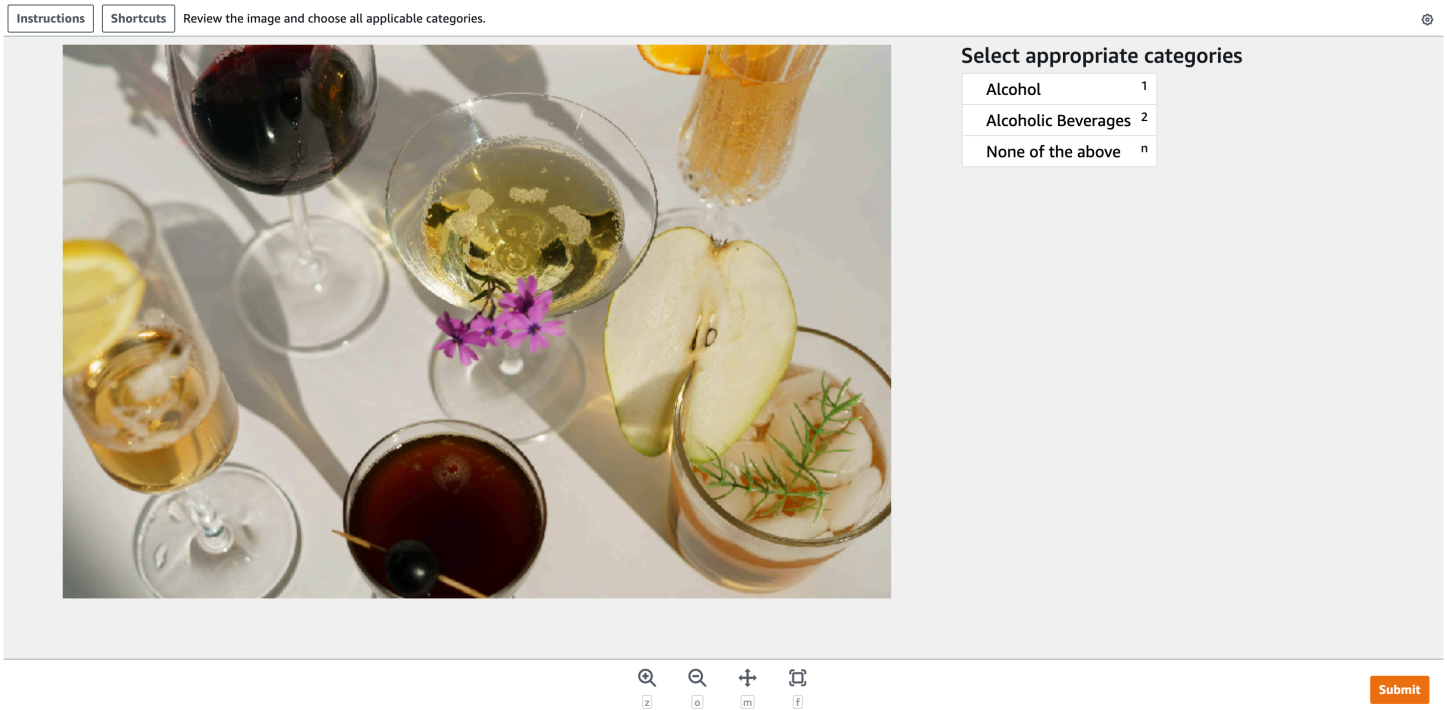
End-to-end Demo Using Amazon Rekognition and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Rekognition with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console.

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition [Example] in a SageMaker notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

A2I Rekognition Worker Console Preview

When they're assigned a review task in an Amazon Rekognition workflow, workers might see a user interface similar to the following:



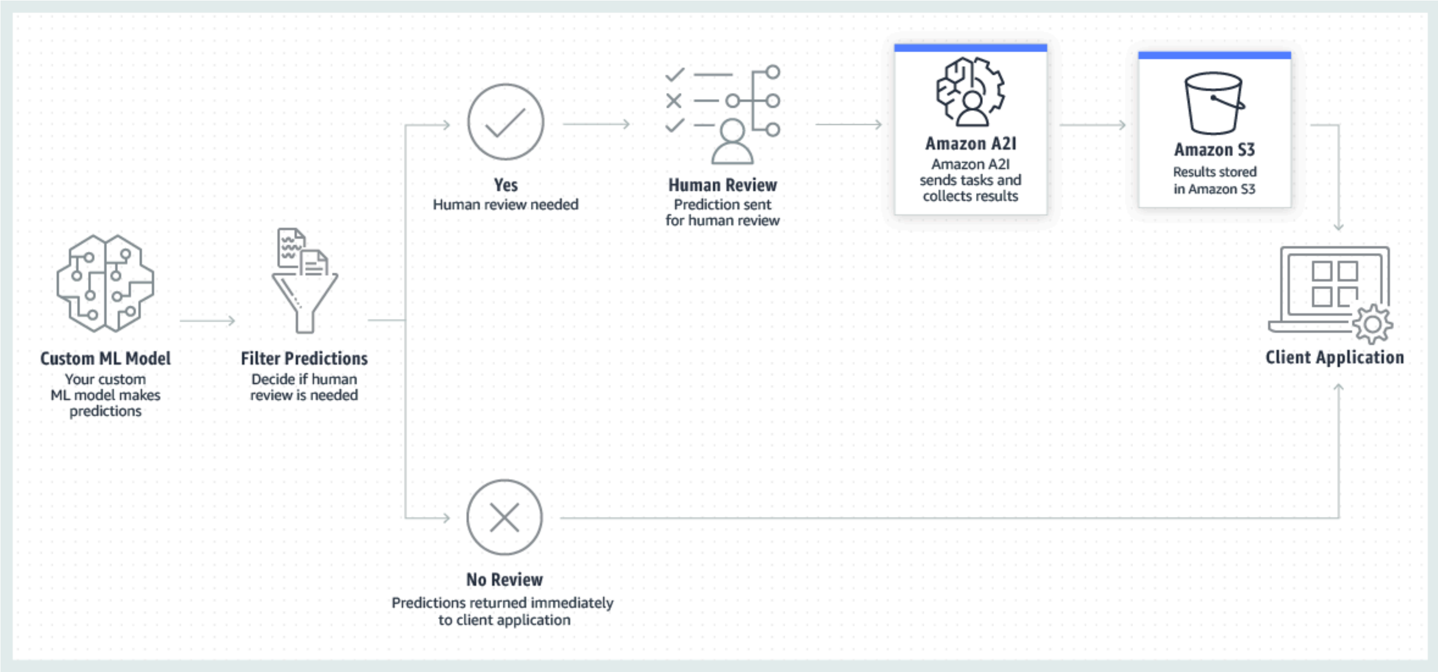
You can customize this interface in the SageMaker AI console when you create your human review definition, or by creating and using a custom template. To learn more, see [Create and Manage Worker Task Templates](#).

Use Amazon Augmented AI with Custom Task Types

You can use Amazon Augmented AI (Amazon A2I) to incorporate a human review (human loop) into *any* machine learning workflow using the *custom task type*. This options gives you the most flexibility to customize the conditions under which your data objects are sent to humans for review, as well as the look and feel of your worker user interface.

When you use a custom task type, you create a custom human review workflow and specify the conditions under which a data object is sent for human review directly in your application.

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.



Use the procedures on this page to learn how to integrate Amazon A2I into any machine learning workflow using the custom task type.

Create a human loop using a flow definition, integrate it into your application, and monitor the results

1. Complete the Amazon A2I [Prerequisites to Using Augmented AI](). Note the following:
   - The path to the Amazon Simple Storage Service (Amazon S3) bucket or buckets where you store your input and output data.
   - The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role with required permissions attached.
   - (Optional) The ARN of your private workforce, if you plan to use one.
2. Using HTML elements, create a custom worker template which Amazon A2I uses to generate your worker task UI. To learn how to create a custom template, see Create Custom Worker Task Templates.
3. Use the custom worker template from step 2 to generate a worker task template in the Amazon SageMaker AI console. To learn how, see Create a Worker Task Template.

   In the next step, you create a flow definition:

- If you want to create a flow definition using the SageMaker API, note the ARN of this worker task template for the next step.
- If you are creating a flow definition using the console, your template automatically appears in **Worker task template** section when you choose **Create human review workflow**.

4. When creating your flow definition, provide the path to your S3 buckets, your IAM role ARN, and your worker template.

   - To learn how to create a flow definition using the SageMaker AI `CreateFlowDefinition` API, see Create a Human Review Workflow (API).
   - To learn how to create a flow definition using the SageMaker AI console, see Create a Human Review Workflow (Console).

5. Configure your human loop using the Amazon A2I Runtime API. To learn how, see Create and Start a Human Loop.
6. To control when human reviews are initiated in your application, specify conditions under which `StartHumanLoop` is called in your application. Human loop activation conditions, such as confidence thresholds that initiate the human loop, are not available when using Amazon A2I with custom task types. Every `StartHumanLoop` invocation results in a human review.

Once you have started a human loop, you can manage and monitor your loops using the Amazon Augmented AI Runtime API and Amazon EventBridge (also known as Amazon CloudWatch Events). To learn more, see Monitor and Manage Your Human Loop.

End-to-end Tutorial Using Amazon A2I Custom Task Types

For an end-to-end examples that demonstrates how to integrate Amazon A2I into a variety of ML workflows, see the table in Use Cases and Examples Using Amazon A2I. To get started using one of these notebooks, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

Create a Human Review Workflow

Use an Amazon Augmented AI (Amazon A2I) *human review workflow*, or *flow definition*, to specify the following:

- For the Amazon Textract and Amazon Rekognition built-in task types, the conditions under which your human loop is called
- The workforce to which your tasks are sent

- The set of instructions that your workforce receives, which is called a *worker task template*
- The configuration of your worker tasks, including the number of workers that receive a task and time limits to complete tasks
- Where your output data is stored

You can create a human review workflow in the SageMaker AI console or using the SageMaker AI `CreateFlowDefinition` operation. You can build a worker task template using the console for Amazon Textract and Amazon Rekognition task types while creating your flow definition.

> **Important**
>
> Human loop activation conditions, which initiate the human loop—for example, confidence thresholds—aren't available for Amazon A2I custom task types. When using the console to create a flow definition for a custom task type, you can't specify activation conditions. When using the Amazon A2I API to create a flow definition for a custom task type, you can't set the `HumanLoopActivationConditions` attribute of the `HumanLoopActivationConditionsConfig` parameter. To control when human reviews are initiated, specify conditions under which `StartHumanLoop` is called in your custom application. In this case, every `StartHumanLoop` invocation results in a human review. For more information, see Use Amazon Augmented AI with Custom Task Types.

Prerequisites

To create a human review workflow definition, you must have completed the prerequisites described in Prerequisites to Using Augmented AI.

If you use the API to create a flow definition for any task type, or if you use a custom task type when creating a flow definition in the console, first create a worker task template. For more information, see Create and Manage Worker Task Templates.

If you want to preview your worker task template while creating a flow definition for a built-in task type in the console, ensure that you grant the role that you use to create the flow definition permission to access the Amazon S3 bucket that contains your template artifacts using a policy like the one described in Enable Worker Task Template Previews .

Topics

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)
- JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

Create a Human Review Workflow (Console)

Use this procedure to create a Amazon Augmented AI (Amazon A2I) human review workflow using the SageMaker AI console. If you are new to Amazon A2I, we recommend that you create a private work team using people in your organization, and use this work team's ARN when creating your flow definition. To learn how to set up a private workforce and create a work team, see Create a Private Workforce (Amazon SageMaker AI Console). If you have already set up a private workforce, see Create a Work Team Using the SageMaker AI Console to learn how to add a work team to that workforce.

If you are using Amazon A2I with one of the built-in task types, you can create worker instructions using a default worker task template provided by Augmented AI while creating a human review workflow in the console. To see samples of the default templates provided by Augmented AI, see the built-in task types in Use Cases and Examples Using Amazon A2I.

To create flow definition (console)

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows** and then choose **Create human review workflow**.
3. In **Overview**, do the following:
   a. For **Name**, enter a unique workflow name. The name must be lowercase, unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
   b. For **S3 location for output**, enter the S3 bucket where you want to store the human review results. The bucket must be located in the same AWS Region as the workflow.
   c. For **IAM role**, choose the role that has the required permissions. If you choose a built-in task type and want to preview your worker template in the console, provide a role with the type of policy described in Enable Worker Task Template Previews attached.
4. For **Task type**, choose the task type that you want the human worker to perform.

5. If you chose the Amazon Rekognition or Amazon Textract task type, specify the conditions that invoke human review.

   - For Amazon Rekognition image moderation tasks, choose an inference confidence score threshold interval that initiates human review.
   - For Amazon Textract tasks, you can initiate a human review when specific form keys are missing or when form key detection confidence is low. You can also initiate a human review if, after evaluating all of the form keys in the text, confidence is lower than your required threshold for any form key. Two variables specify your confidence thresholds: **Identification confidence** and **Qualification confidence**. To learn more about these variables, see Use Amazon Augmented AI with Amazon Textract.
   - For both task types, you can randomly send a percentage of data objects (images or forms) and their labels to humans for review.

6. Configure and specify your worker task template:

   a. If you are using the Amazon Rekognition or Amazon Textract task type:

      - In the **Create template** section:

        - To create instructions for your workers using the Amazon A2I default template for Amazon Rekognition and Amazon Textract task types, choose **Build from a default template**.

          - If you choose **Build from a default template**, create your instructions under **Worker task design**:

            - Provide a **Template name** that is unique in the AWS Region you are in.
            - In the **Instructions** section, provide detailed instructions on how to complete your task. To help workers achieve greater accuracy, provide good and bad examples.
            - (Optional) In **Additional instructions**, provide your workers with additional information and instructions.

              For information on creating effective instructions, see Creating Good Worker Instructions.

        - To select a custom template that you've created, choose it from the **Template** menu and provide a **Task description** to briefly describe the task for your workers. To learn how to create a custom template, see Create a Worker Task Template.

b. If you are using the custom task type:

   - In the **Worker task template** section, select your template from the list. All of the templates that you have created in the SageMaker AI console appear in this list. To learn how to create a template for custom task types, see Create and Manage Worker Task Templates.

7. (Optional) Preview your worker template:

   For Amazon Rekognition and Amazon Textract task types, you have the option to choose **See a sample worker task** to preview your worker task UI.

   If you are creating a flow definition for a custom task type, you can preview your worker task UI using the `RenderUiTemplate` operation. For more information, see Preview a Worker Task Template.

8. For **Workers**, choose a workforce type.

9. Choose **Create**.

Next Steps

After you've created a human review workflow, it appears in the console under **Human review workflows**. To see your flow definition's Amazon Resource Name (ARN) and configuration details, choose the workflow by selecting its name.

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (for example, the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both options, see Create and Start a Human Loop.

Create a Human Review Workflow (API)

To create a flow definition using the SageMaker API, you use the `CreateFlowDefinition` operation. After you complete the Prerequisites to Using Augmented AI, use the following procedure to learn how to use this API operation.

For an overview of the `CreateFlowDefinition` operation, and details about each parameter, see `CreateFlowDefinition`.

To create a flow definition (API)

1. For FlowDe#nitionName, enter a unique name. The name must be unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
2. For RoleArn, enter the ARN of the role that you configured to grant access to your data sources.
3. For HumanLoopConfig, enter information about the workers and what they should see. For information about each parameter in HumanLoopConfig, see HumanLoopConfig.
4. (Optional) If you are using a built-in task type, provide conditions that initiate a human loop in HumanLoopActivationCon#g. To learn how to create the input required for the HumanLoopActivationCon#g parameter, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI. If you do not specify conditions here, when you provide a flow definition to the AWS service associated with a built-in task type (for example, Amazon Textract or Amazon Rekognition), that service sends every task to a human worker for review.

   If you are using a custom task type, HumanLoopActivationConfig is disabled. To learn how to control when tasks are sent to human workers using a custom task type, see Use Amazon Augmented AI with Custom Task Types.
5. (Optional) If you are using a built-in task type, specify the integration source (for example, Amazon Rekognition or Amazon Textract) in the HumanLoopRequestSource parameter.
6. For OutputConfig, indicate where in Amazon Simple Storage Service (Amazon S3) to store the output of the human loop.
7. (Optional) Use Tags to enter key-value pairs to help you categorize and organize a flow definition. Each tag consists of a key and a value, both of which you define.

Amazon Textract – Key-value pair extraction

The following is an example of a request to create an Amazon Textract human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use 'AWS/Textract/AnalyzeDocument/Forms/V1' to create a Amazon Textract human loop. Only include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
```

```
    HumanLoopRequestSource={
         'AwsManagedHumanLoopRequestSource': 'AWS/Textract/AnalyzeDocument/Forms/V1'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-
task-ui/template_name',
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Amazon Rekognition – Image moderation

The following is an example of a request to create an Amazon Rekognition human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use `'AWS/Rekognition/DetectModerationLabels/Image/V3'` to create an Amazon Rekognition flow definition. Only include `PublicWorkforceTaskPrice` if you are using the Mechanical Turk workforce.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
         'AwsManagedHumanLoopRequestSource': 'AWS/Rekognition/
DetectModerationLabels/Image/V3'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-
task-ui/template_name',
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },

            'Value': 'ValueName'
        },
    ]
)
```

Custom Workflow

The following is an example of a request to create a human review workflow (flow definition) for a custom integration. To create this type of human review workflow, omit `HumanLoopRequestSource` from the flow definition request. You only need to include `PublicWorkforceTaskPrice` if you are using the Mechanical Turk workforce.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_acount_number:human-
task-ui/template_name',
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
```

```
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Next Steps

The return value of a successful call of the `CreateFlowDefinition` API operation is a flow definition Amazon Resource Name (ARN).

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (i.e. the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both of these options, see Create and Start a Human Loop.

JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

The `HumanLoopActivationConditions` is an input parameter of the `CreateFlowDefinition` API. This parameter is a JSON-formatted string. The JSON models the conditions under which a human loop is created when those conditions are evaluated against the response from an integrating AI service API (such as `Rekognition.DetectModerationLabels` or `Textract.AnalyzeDocument`). This response is referred to as an *inference*. For example, Amazon Rekognition sends an inference of a moderation label with an associated confidence score. In this example, the inference is the model's best estimate of the appropriate label for an image. For Amazon Textract, inference is made on the association between blocks of text (*key-value pairs*), such as the association between `Name:` and `Sue` in a form as well as content within a block of text, or *word block*, such as 'Name'.

The following is the schema for the JSON. At the top level, the `HumanLoopActivationConditions` has a JSON array, `Conditions`. Each member of this array is an independent condition that, if evaluated to `true`, results in Amazon A2I creating a human loop. Each such independent condition can be a simple condition or a complex condition. A simple condition has the following attributes:

- `ConditionType`: This attribute identifies the type of condition. Each AWS AI service API that integrates with Amazon A2I defines its own set of allowed `ConditionTypes`.
  - Rekognition `DetectModerationLabels` – This API supports the `ModerationLabelConfidenceCheck` and `Sampling` `ConditionType` values.
  - Textract `AnalyzeDocument` – This API supports the `ImportantFormKeyConfidenceCheck`, `MissingImportantFormKey`, and `Sampling` `ConditionType` values.
- `ConditionParameters` – This is a JSON object that parameterizes the condition. The set of allowed attributes of this object is dependent on the value of the `ConditionType`. Each `ConditionType` defines its own set of `ConditionParameters`.

A member of the `Conditions` array can model a complex condition. This is accomplished by logically connecting simple conditions using the `And` and `Or` logical operators and nesting the underlying simple conditions. Up to two levels of nesting are supported.

```
{
    "$schema": "http://json-schema.org/draft-07/schema#",
    "definitions": {
        "Condition": {
            "type": "object",
            "properties": {
                "ConditionType": {
                    "type": "string"
                },

- Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

Use Human Loop Activation Conditions JSON Schema with Amazon Textract

When used with Amazon A2I, the `AnalyzeDocument` operation supports the following inputs in the `ConditionType` parameter:

- `ImportantFormKeyConfidenceCheck` – Use this condition to create a human loop when inference confidence is within a specified range for document form keys and word blocks. A *form key* is any word in a document that is associated with an input. The input is called a *value*. Together, form keys and values are referred to as *key-value pairs*. A *word block* refers to the words that Amazon Textract recognizes inside of a detected block of text. To learn more about Amazon Textract document blocks, see Documents and Block Objects in the *Amazon Textract Developer Guide*.
- `MissingImportantFormKey` – Use this condition to create a human loop when Amazon Textract did not identify the key or its associated aliases within the document.
- `Sampling` – Use this condition to specify a percentage of forms to send to humans for review, regardless of inference confidence scores. Use this condition to do the following:
  - Audit your ML model by randomly sampling all forms analyzed by your model and sending a specified percentage to humans for review.

- Using the `ImportantFormKeyConfidenceCheck` condition, randomly sample a percentage of the inferences that met the conditions specified in `ImportantFormKeyConfidenceCheck` to start a human loop and send only the specified percentage to humans for review.

> **Note**
>
> If you send the same request to `AnalyzeDocument` multiple times, the result of `Sampling` does not change for the inference of that input. For example, if you make an `AnalyzeDocument` request once, and `Sampling` doesn't initiate a human loop, subsequent requests to `AnalyzeDocument` with the same configuration do not initiate a human loop.

`ImportantFormKeyConfidenceCheck` Inputs and Results

The `ImportantFormKeyConfidenceCheck` `ConditionType` supports the following `ConditionParameters`:

- `ImportantFormKey` – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers. If the value of this parameter is the special catch-all value (*), then all keys are considered to be matched to the condition. You can use this to model the case where any key-value pair satisfying certain confidence thresholds needs human review.
- `ImportantFormKeyAliases` – An array that represents alternate spellings or logical equivalents for the important form key.
- `KeyValueBlockConfidenceEquals`
- `KeyValueBlockConfidenceLessThan`
- `KeyValueBlockConfidenceLessThanEquals`
- `KeyValueBlockConfidenceGreaterThan`
- `KeyValueBlockConfidenceGreaterThanEquals`
- `WordBlockConfidenceEquals`
- `WordBlockConfidenceLessThan`
- `WordBlockConfidenceLessThanEquals`
- `WordBlockConfidenceGreaterThan`

- WordBlockConfidenceGreaterThanEquals

When you use the ImportantFormKeyConfidenceCheck ConditionType, Amazon A2I sends the key-value block and word block inferences of the key-value blocks and associated aliases that you specified in ImportantFormKey and ImportantFormKeyAliases for human review.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the Amazon SageMaker AI console, key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the {{ task.input.selectedAiServiceResponse.blocks }} element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract.

MissingImportantFormKey Inputs and Results

The MissingImportantFormKey ConditionType supports the following ConditionParameters:

- ImportantFormKey – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers.
- ImportantFormKeyAliases – An array that represents alternate spellings or logical equivalents for the important form key.

When you use the MissingImportantFormKey ConditionType, if the key in ImportantFormKey or aliases in ImportantFormKeyAliases are not included in the Amazon Textract inference, that form is sent to human for review and no predicted key-value pairs are included. For example, if Amazon Textract only identified Address and Phone in a form, but was missing the ImportantFormKey Name (in the MissingImportantFormKey condition type) that form would be sent to humans for review without any of the form keys detected (Address and Phone).

If you use the default worker task template that is provided in the SageMaker AI console, a task is created asking workers to identify the key in ImportantFormKey and associated value. If you use a custom worker task template, you need to include the <task.input.humanLoopContext> custom HTML element to configure this task.

Sampling Inputs and Results

The `Sampling` `ConditionType` supports the `RandomSamplingPercentage` `ConditionParameters`. The input for `RandomSamplingPercentage` must be real number between 0.01 and 100. This number represents the percentage of data that qualifies for a human review and is sent to humans for review. If you use the `Sampling` condition without any other conditions, this number represents the percentage of all resulting inferences made by the `AnalyzeDocument` operation from a single request that is sent to humans for review.

If you specify the `Sampling` condition without any other condition type, all key-value and block inferences are sent to workers for review.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the SageMaker AI console, all key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the `{{ task.input.selectedAiServiceResponse.blocks }}` element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see [Custom Template Example for Amazon Textract](#).

Examples

While only one condition needs to evaluate to `true` to initiate a human loop, Amazon A2I evaluates all conditions for each object analyzed by Amazon Textract. The human reviewers are asked to review the important form keys for all the conditions that evaluated to `true`.

Example 1: Detect important form keys with confidence scores in a specified range that initiate a human loop

The following example shows a `HumanLoopActivationConditions` JSON that initiates a human loop if any one of the following three conditions is met:

- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Employee Name`, `Name`, or `EmployeeName`, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block being less than 65 and the confidences of each of the word blocks making up the key and value being less than 85.

- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Gross Pay`, `GrossPay`, or `GrossAmount`, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.

```
{
    "Conditions": [
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Employee Name",
                "ImportantFormKeyAliases": [
                    "Name",
                    "EmployeeName"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 85
            }
        },
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
            }
        },
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Gross Pay",
                "ImportantFormKeyAliases": [
                    "GrossPay",
                    "GrossAmount"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 85
            }
```

```
        }
    ]
}
```

Example 2: Use `ImportantFormKeyConfidenceCheck`

In the following example, if Amazon Textract detects a key-value pair whose confidence for the key-value block is less than 60 and is less than 90 for any underlying word blocks, it creates a human loop. The human reviewers are asked to review all the form key-value pairs that matched the confidence value comparisons.

```
{
    "Conditions": [
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "*",
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 90
            }
        }
    ]
}
```

Example 3: Use Sampling

In the following example, 5% of inferences resulting from an Amazon Textract `AnalyzeDocument` request are sent to human workers for review. All detected key-value pairs returned by Amazon Textract are sent to workers for review.

```
{
  "Conditions": [
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use `MissingImportantFormKey`

In the following example, if `Mailing Address` or its alias, `Mailing Address:`, is missing from keys detected by Amazon Textract, a human review is initiated. When using the default worker task template, the worker UI asks workers to identify the key `Mailing Address` or `Mailing Address:` and its associated value.

```
{
    "ConditionType": "MissingImportantFormKey",
    "ConditionParameters": {
        "ImportantFormKey": "Mailing Address",
        "ImportantFormKeyAliases": ["Mailing Address:"]
    }
}
```

Example 5: Use Sampling and `ImportantFormKeyConfidenceCheck` with the And operator

In this example, 5% of key-value pairs detected by Amazon Textract whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85, are sent to workers for review.

```
{
  "Conditions": [
    {
      "And": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
            }
```

```
        }
      ]
    }
  ]
}
```

Example 6: Use Sampling and `ImportantFormKeyConfidenceCheck` with the And operator

Use this example to configure your human review workflow to always send low confidence inferences of a specified key-value pair for human review and sample high confidence inference of a key-value pair at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Key-value pairs detected whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with key-value and word block confidences less than 60, are sent for human review. Only the `Pay Date` form key (and its aliases) and associated values are sent to workers to review.
- 5% of key-value pairs detected whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with key-value and word block confidences greater than 90, are sent for human review. Only the `Pay Date` form key (and its aliases) and associated values are sent to workers to review.

```
{
  "Conditions": [
    {
      "Or": [
       {
          "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 60
            }
        },
        {
            "And": [
```

```
                {
                    "ConditionType": "Sampling",
                    "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                    }
                },
                {
                    "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Pay Date",
                            "ImportantFormKeyAliases": [
                                "PayDate",
                                "DateOfPay",
                                "pay-date"
                        ],
                        "KeyValueBlockConfidenceLessThan": 90
                        "WordBlockConfidenceGreaterThan": 90
                    }
                }
            ]
        }
      ]
    }
  ]
}
```

Example 7: Use Sampling and `ImportantFormKeyConfidenceCheck` with the `Or` operator

In the following example, the Amazon Textract `AnalyzeDocument` operation returns a key-value pair whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85. Additionally, 5% of all other forms initiate a human loop. For each form randomly chosen, all key-value pairs detected for that form are sent to humans for review.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
```

```
        },
        {
           "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
            }
          }
        }
      ]
    }
  ]
}
```

Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

When used with Amazon A2I, the Amazon Rekognition `DetectModerationLabels` operation supports the following inputs in the `ConditionType` parameters:

- `ModerationLabelConfidenceCheck` – Use this condition type to create a human loop when inference confidence is low for one or more specified labels.
- `Sampling` – Use this condition to specify a percentage of all inferences to send to humans for review. Use this condition to do the following:
  - Audit your ML model by randomly sampling all of your model's inferences and sending a specified percentage to humans for review.
  - Using the `ModerationLabelConfidenceCheck` condition, randomly sample a percentage of the inferences that met the conditions specified in `ModerationLabelConfidenceCheck` to start a human loop and send only the specified percentage to humans for review.

Note

If you send the same request to `DetectModerationLabels` multiple times, the result of `Sampling` does not change for the inference of that input. For example, if you make a

> `DetectModerationLabels` request once, and `Sampling` does not initiate a human loop, subsequent requests to `DetectModerationLabels` with the same configuration don't initiate a human loop.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the Amazon SageMaker AI console, inferences sent for human review by these activation conditions are included in the worker UI when a worker opens your task. If you use a custom worker task template, you need to include the `<task.input.selectedAiServiceResponse.blocks>` custom HTML element to access these inferences. For an example of a custom template that uses this HTML element, see [Custom Template Example for Amazon Rekognition](#).

`ModerationLabelConfidenceCheck` Inputs

For the `ModerationLabelConfidenceCheck` `ConditionType`, the following `ConditionParameters` are supported:

- `ModerationLabelName` – The exact (case-sensitive) name of a [ModerationLabel](#) detected by the Amazon Rekognition `DetectModerationLabels` operation. You can specify the special catch-all value (*) to denote any moderation label.
- `ConfidenceEquals`
- `ConfidenceLessThan`
- `ConfidenceLessThanEquals`
- `ConfidenceGreaterThan`
- `ConfidenceGreaterThanEquals`

When you use the `ModerationLabelConfidenceCheck` `ConditionType`, Amazon A2I sends label inferences for the labels that you specified in `ModerationLabelName` for human review.

Sampling Inputs

The `Sampling` `ConditionType` supports the `RandomSamplingPercentage` `ConditionParameters`. The input for the `RandomSamplingPercentage` prameter should be real number between 0.01 and 100. This number represents the percentage of inferences that qualifies for a human review that are sent to humans for review. If you use the `Sampling` condition without any other conditions, this number represents the percentage of all inferences that result from a single `DetectModerationLabel` request that are sent to humans for review.

Examples

Example 1: Use `ModerationLabelConfidenceCheck` with the `And` operator

The following example of a `HumanLoopActivationConditions` condition initiates a human loop when one or more of the following conditions are met:

- Amazon Rekognition detects the `Graphic Male Nudity` moderation label with a confidence between 90 and 99.
- Amazon Rekognition detects the `Graphic Female Nudity` moderation label with a confidence between 80 and 99.

Note the use of the `Or` and `And` logical operators to model this logic.

Although only one of the two conditions under the `Or` operator needs to evaluate to `true` for a human loop to be created, Amazon Augmented AI evaluates all conditions. Human reviewers are asked to review the moderation labels for all the conditions that evaluated to `true`.

```
{
     "Conditions": [{
         "Or": [{
                 "And": [{
                         "ConditionType": "ModerationLabelConfidenceCheck",
                         "ConditionParameters": {
                             "ModerationLabelName": "Graphic Male Nudity",
                             "ConfidenceLessThanEquals": 99
                         }
                     },
                     {
                         "ConditionType": "ModerationLabelConfidenceCheck",
                         "ConditionParameters": {
                             "ModerationLabelName": "Graphic Male Nudity",
                             "ConfidenceGreaterThanEquals": 90
                         }
                     }
                 ]
             },
             {
```

```
                  "And": [{
                          "ConditionType": "ModerationLabelConfidenceCheck",
                          "ConditionParameters": {
                              "ModerationLabelName": "Graphic Female Nudity",
                              "ConfidenceLessThanEquals": 99
                          }
                      },
                      {
                          "ConditionType": "ModerationLabelConfidenceCheck",
                          "ConditionParameters": {
                              "ModerationLabelName": "Graphic Female Nudity",
                              "ConfidenceGreaterThanEquals": 80
                          }
                      }
                  ]
              }
          ]
      }]
}
```

Example 2: Use `ModerationLabelConfidenceCheck` with the catch-all value (*)

In the following example, if any moderation label with a confidence greater than or equal to 75 is detected, a human loop is initiated. Human reviewers are asked to review all moderation labels with confidence scores greater than or equal to 75.

```
{
    "Conditions": [
        {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
                "ModerationLabelName": "*",
                "ConfidenceGreaterThanEquals": 75
            }
        }
    ]
}
```

Example 3: Use Sampling

In the following example, 5% of Amazon Rekognition inferences from a `DetectModerationLabels` request are sent to human workers. When using the default worker task template provided in the SageMaker AI console, all moderation labels returned by Amazon Rekognition are sent to workers for review.

```
{
  "Conditions": [
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use Sampling and `ModerationLabelConfidenceCheck` with the And operator

In this example, 5% of Amazon Rekognition inferences of the `Graphic Male Nudity` moderation label with a confidence greater than 50 are sent workers for review. When using the default worker task template provided in the SageMaker AI console, only the inferences of the `Graphic Male Nudity` label are sent to workers for review.

```
{
  "Conditions": [
    {
      "And": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
          }
        }
      ]
    }
  ]
}
```

Example 5: Use Sampling and `ModerationLabelConfidenceCheck` with the And operator

Use this example to configure your human review workflow to always send low-confidence inferences of a specified label for human review and sample high-confidence inferences of a label at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Inferences for the `Graphic Male Nudity` moderation label the with confidence scores less than 60 are always sent for human review. Only the `Graphic Male Nudity` label is sent to workers to review.
- 5% of all inferences for the `Graphic Male Nudity` moderation label the with confidence scores greater than 90 are sent for human review. Only the `Graphic Male Nudity` label is sent to workers to review.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceLessThan": 60
          }
        },
        {
            "And": [
                {
                    "ConditionType": "Sampling",
                    "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                    }
                },
                {
                    "ConditionType": "ModerationLabelConfidenceCheck",
                    "ConditionParameters": {
                        "ModerationLabelName": "Graphic Male Nudity",
                        "ConfidenceGreaterThan": 90
                    }
                }
```

```
            ]
          }
        ]
      }
    ]
}
```

Example 6: Use Sampling and `ModerationLabelConfidenceCheck` with the `Or` operator

In the following example, a human loop is created if the Amazon Rekognition inference response contains the 'Graphic Male Nudity' label with inference confidence greater than 50. Additionally, 5% of all other inferences initiate a human loop.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
          }
        }
      ]
    }
  ]
}
```

Delete a Human Review Workflow

When you delete a human review workflow or you delete your AWS account while a human loop is in process, your human review workflow status changes to `Deleting`. Amazon A2I automatically stops and deletes all associated human loops if workers have not started tasks created by those human loops. If human workers are already working on a task, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human review workflow's status is `Deleting`. If these tasks are completed, the results are stored in the Amazon S3 bucket specified in your flow definition.

Deleting a flow definition does not remove any worker answers from your S3 bucket. If the tasks are completed, but you deleted your AWS account, the results are stored in the Augmented AI service bucket for 30 days and then permanently deleted.

After all human loops have been deleted, the human review workflow is permanently deleted. When a human review workflow has been deleted, you can reuse its name to create a new human review workflow.

You might want to delete a human review workflow for any of the following reasons:

- You have sent data to a set of human reviewers and you want to delete all non-started human loops because you do not want those workers to work on those tasks any longer.
- The worker task template used to generate your worker UI does not render correctly or is not functioning as expected.

After you delete a human review workflow, the following changes occur:

- The human review workflow no longer appears on the **Human review workflows** page in the Augmented AI area of the Amazon SageMaker AI console.
- When you use the human review workflow name as input to the API operations `DescribeFlowDefinition` or `DeleteFlowDefinition`, Augmented AI returns a `ResourceNotFound` error.
- When you use `ListFlowDefinitions`, deleted human review workflows aren't included in the results.
- When you use the human review workflow ARN as input to the Augmented AI Runtime API operation `ListHumanLoops`, Augmented AI returns a `ResourceNotFoundException`.

Delete a Flow Definition Using the Console or the SageMaker API

You can delete a human review workflow on the **Human review workflows** page in the Augmented AI area of the SageMaker AI console or by using the SageMaker AI API.

Flow definitions can only be deleted if their status is `Active`.

Delete a human review workflow (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows**.
3. Select the hyperlinked name of the human review workflow that you want to delete.
4. On the **Summary** page of your human review workflow, choose **Delete**.
5. In the dialog box asking you to confirm that you want to delete your human review workflow, choose **Delete**.

You're automatically redirected to the **Human review workflows** page. While your human review workflow is being deleted, the status **Deleting** appears in the status column for that workflow. After it's deleted, it doesn't appear in the list of workflows on this page.

Delete a human review workflow (API)

You can delete a human review workflow (flow definition) using the SageMaker AI DeleteFlowDefinition API operation. This API operation is supported through the AWS CLI and a variety of language specific SDKs. The following table shows example requests using SDK for Python (Boto3) and the AWS CLI to delete the human review workflow, *example-flow-definition*.

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3) to delete the human review workflow. For more information, see delete_flow_definition in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.delete_flow_definition(FlowDefinitionName='example-flow-definition')
```

AWS CLI

The following request example uses the AWS CLI to delete the human review workflow. For more information, see delete-flow-definition in the *AWS CLI Command Reference*.

```
$ aws sagemaker delete-flow-definition --flow-definition-name 'example-flow-definition'
```

If the action is successful, Augmented AI sends back an HTTP 200 response with an empty HTTP body.

Create and Start a Human Loop

A *human loop* starts your human review workflow and sends data review tasks to human workers. When you use one of the Amazon A2I built-in task types, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your flow definition are met. If no conditions are specified in your flow definition, a human loop is created for each object. When using Amazon A2I for a custom task, a human loop starts when your application calls `StartHumanLoop`.

Use the following instructions to configure a human loop with Amazon Rekognition or Amazon Textract built-in task types and custom task types.

Prerequisites

To create and start a human loop, you must attach the `AmazonAugmentedAIFullAccess` policy to the AWS Identity and Access Management (IAM) user or role that configures or starts the human loop. This is the identity that you use to configure the human loop using `HumanLoopConfig` for built-in task types. For custom task types, this is the identity that you use to call `StartHumanLoop`.

Additionally, when using a built-in task type, your user or role must have permission to invoke API operations of the AWS service associated with your task type. For example, if you are using Amazon Rekognition with Augmented AI, you must attach permissions required to call `DetectModerationLabels`. For examples of identity-based policies you can use to grant these permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples. You can also use the more general policy `AmazonAugmentedAIIntegratedAPIAccess` to grant these permissions. For more information, see Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations.

To create and start a human loop, you need a flow definition ARN. To learn how to create a flow definition (or human review workflow), see Create a Human Review Workflow.

> **Important**
>
> Amazon A2I requires all S3 buckets that contain human loop input image data to have a CORS policy attached. To learn more about this change, see CORS Permission Requirement.

Create and Start a Human Loop for a Built-in Task Type

To start a human loop using a built-in task type, use the corresponding service's API to provide your input data and to configure the human loop. For Amazon Textract, you use the `AnalyzeDocument` API operation. For Amazon Rekognition, you use the `DetectModerationLabels` API operation. You can use the AWS CLI or a language-specific SDK to create requests using these API operations.

> **Important**
>
> When you create a human loop using a built-in task type, you can use `DataAttributes` to specify a set of `ContentClassifiers` related to the input provided to the `StartHumanLoop` operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.
> To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA. Include the `FreeOfPersonallyIdentifiableInformation` content classifier. If you do not use this content classifier, SageMaker AI does not send your task to Mechanical Turk. If your data is free of adult content, also include the `'FreeOfAdultContent'` classifier. If you do not use these content classifiers, SageMaker AI may restrict the Mechanical Turk workers that can view your task.

After you start your ML job using your built-in task type's AWS service API, Amazon A2I monitors the inference results of that service. For example, when running a job with Amazon Rekognition, Amazon A2I checks the inference confidence score for each image and compares it to the confidence thresholds specified in your flow definition. If the conditions to start a human review task are satisfied, or if you didn't specify conditions in your flow definition, a human review task is sent to workers.

Create an Amazon Textract Human Loop

Amazon A2I integrates with Amazon Textract so that you can configure and start a human loop using the Amazon Textract API. To send a document file to Amazon Textract for document analysis, you use the Amazon Textract `AnalyzeDocument` API operation. To add a human loop to this document analysis job, you must configure the parameter `HumanLoopConfig`.

When you configure your human loop, the flow definition you specify in `FlowDefinitionArn` of `HumanLoopConfig` must be located in the same AWS Region as the bucket identified in `Bucket` of the `Document`parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see analyze_document in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

textract = boto3.client('textract', aws_region)

response = textract.analyze_document(
            Document={'S3Object': {'Bucket': bucket_name, 'Name': document_name}},
            FeatureTypes=["TABLES", "FORMS"],
            HumanLoopConfig={
                'FlowDefinitionArn':
 'arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name',
                'HumanLoopName': 'human_loop_name',
                'DataAttributes': {'ContentClassifiers':
 ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}
            }
          )
```

AWS CLI

The following request example uses the AWS CLI. For more information, see analyze-document in the *AWS CLI Command Reference*.

```
$ aws textract analyze-document \
```

```
     --document '{"S3Object":{"Bucket":"bucket_name","Name":"document_name"}}' \
     --human-loop-config
 HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws-
region:aws_account_number:flow-
definition/
flow_def_name",DataAttributes='{ContentClassifiers=["FreeOfPersonallyIdentifiableInformation
 "FreeOfAdultContent"]}' \
     --feature-types '["TABLES", "FORMS"]'
```

```
$ aws textract analyze-document \
     --document '{"S3Object":{"Bucket":"bucket_name","Name":"document_name"}}' \
     --human-loop-config \

 '{"HumanLoopName":"human_loop_name","FlowDefinitionArn":"arn:aws:sagemaker:aws_region:aws_a
definition/flow_def_name","DataAttributes": {"ContentClassifiers":
["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}}' \
     --feature-types '["TABLES", "FORMS"]'
```

After you run `AnalyzeDocument` with a human loop configured, Amazon A2I monitors the results from `AnalyzeDocument` and checks it against the flow definition's activation conditions. If the Amazon Textract inference confidence score for one or more key-value pairs meets the conditions for review, Amazon A2I starts a human review loop and includes the [`HumanLoopActivationOutput`] object in the `AnalyzeDocument` response.

Create an Amazon Rekognition Human Loop

Amazon A2I integrates with Amazon Rekognition so that you can configure and start a human loop using the Amazon Rekognition API. To send images to Amazon Rekognition for content moderation, you use the Amazon Rekognition `DetectModerationLabels` API operation. To configure a human loop, set the `HumanLoopConfig` parameter when you configure `DetectModerationLabels`.

When you configure your human loop, the flow definition you specify in `FlowDefinitionArn` of `HumanLoopConfig` must be located in the same AWS Region as the S3 bucket identified in `Bucket` of the `Image` parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see detect_moderation_labels in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

rekognition = boto3.client("rekognition", aws_region)

response = rekognition.detect_moderation_labels( \
        Image={'S3Object': {'Bucket': bucket_name, 'Name': image_name}}, \
        HumanLoopConfig={ \
            'HumanLoopName': 'human_loop_name', \
            'FlowDefinitionArn': ,
 "arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name" \
            'DataAttributes': {'ContentClassifiers':
 ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}
         })
```

AWS CLI

The following request example uses the AWS CLI. For more information, see detect-moderation-labels in the *AWS CLI Command Reference*.

```
$ aws rekognition detect-moderation-labels \
    --image "S3Object={Bucket='bucket_name',Name='image_name'}" \
    --human-loop-config
 HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws_region:aws_account
definition/
flow_def_name",DataAttributes='{ContentClassifiers=["FreeOfPersonallyIdentifiableInformation
 "FreeOfAdultContent"]}'
```

```

$ aws rekognition detect-moderation-labels \
    --image "S3Object={Bucket='bucket_name',Name='image_name'}" \
    --human-loop-config \
        '{"HumanLoopName": "human_loop_name", "FlowDefinitionArn":
 "arn:aws:sagemaker:aws_region:aws_account_number:flow-
definition/flow_def_name", "DataAttributes": {"ContentClassifiers":
 ["FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"]}}'
```

After you run `DetectModerationLabels` with a human loop configured, Amazon A2I monitors the results from `DetectModerationLabels` and checks it against the flow definition's activation conditions. If the Amazon Rekognition inference confidence score for an image meets the conditions for review, Amazon A2I starts a human review loop and includes the response element `HumanLoopActivationOutput` in the `DetectModerationLabels` response.

Create and Start a Human Loop for a Custom Task Type

To configure a human loop for a custom human review task, use the `StartHumanLoop` operation within your application. This section provides an example of a human loop request using the AWS SDK for Python (Boto3) and the AWS Command Line Interface (AWS CLI). For documentation on other language-specific SDKs that support `StartHumanLoop`, use the **See Also** section of StartHumanLoop in the Amazon Augmented AI Runtime API documentation. Refer to Use Cases and Examples Using Amazon A2I to see examples that demonstrate how to use Amazon A2I with a custom task type.

Prerequisites

To complete this procedure, you need:

- Input data formatted as a string representation of a JSON-formatted file
- The Amazon Resource Name (ARN) of your flow definition

To configure the human loop

1. For `DataAttributes`, specify a set of `ContentClassifiers` related to the input provided to the `StartHumanLoop` operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

   To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA, and include the `FreeOfPersonallyIdentifiableInformation` content classifier. If you do not use this content classifier, SageMaker AI does not send your task to Mechanical Turk. If your data is free of adult content, also include the `'FreeOfAdultContent'` classifier. If you do not use these content classifiers, SageMaker AI may restrict the Mechanical Turk workers that can view your task.
2. For `FlowDefinitionArn`, enter the Amazon Resource Name (ARN) of your flow definition.

3. For `HumanLoopInput`, enter your input data as a string representation of a JSON-formatted file. Structure your input data and custom worker task template so that your input data is properly displayed to human workers when you start your human loop. See Preview a Worker Task Template to learn how to preview your custom worker task template.
4. For `HumanLoopName`, enter a name for the human loop. The name must be unique within the Region in your account and can have up to 63 characters. Valid characters are a-z, 0-9, and - (hyphen).

To start a human loop

- To start a human loop, submit a request similar to the following examples using your preferred language-specific SDK.

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see Boto 3 Augmented AI Runtime in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')

response = a2i_runtime_client.start_human_loop(
    HumanLoopName='human_loop_name',
    FlowDefinitionArn='arn:aws:sagemaker:aws-region:xyz:flow-
definition/flow_def_name',
    HumanLoopInput={
        'InputContent': '{"InputContent": {\"prompt\":\"What is the answer?\"}}'
    },
    DataAttributes={
        'ContentClassifiers': [
            'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
        ]
    }
)
```

AWS CLI

The following request example uses the AWS CLI. For more information, see start-human-loop in the *AWS CLI Command Reference*.

```
$ aws sagemaker-a2i-runtime start-human-loop
        --flow-definition-arn 'arn:aws:sagemaker:aws_region:xyz:flow-definition/flow_def_name' \
        --human-loop-name 'human_loop_name' \
        --human-loop-input '{"InputContent": "{\"prompt\":\"What is the answer?\"}"}' \
        --data-attributes
 ContentClassifiers="FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent" \
```

When you successfully start a human loop by invoking `StartHumanLoop` directly, the response includes a `HumanLoopARN` and a `HumanLoopActivationResults` object which is set to `NULL`. You can use this the human loop name to monitor and manage your human loop.

Next Steps:

After starting a human loop, you can manage and monitor it with the Amazon Augmented AI Runtime API and Amazon CloudWatch Events. To learn more, see Monitor and Manage Your Human Loop.

Delete a Human Loop

When you delete a human loop, the status changes to `Deleting`. When the human loop is deleted, the associated human review task is no longer available to workers. You might want to delete a human loop in one of the following circumstances:

- The worker task template used to generate your worker user interface does not render correctly or is not functioning as expected.
- A single data object was accidentally sent to workers multiple times.
- You no longer need a data object reviewed by a human.

If the status of a human loop is `InProgress`, you must stop the human loop before deleting it. When you stop a human loop, the status changes to `Stopping` while it is being stopped. When the status changes to `Stopped`, you can delete the human loop.

If human workers are already working on a task when you stop the associated human loop, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human loop's status is `Stopping`. If these tasks are completed, the results are stored in the Amazon S3 bucket URI specified in your human review workflow. If the worker leaves the task without submitting work, it is stopped and the worker can't return to the task. If no worker has started working on the task, it is stopped immediately.

If you delete the AWS account used to create the human loop, it is stopped and deleted automatically.

Human Loop Data Retention and Deletion

When a human worker completes a human review task, the results are stored in the Amazon S3 output bucket you specified in the human review workflow used to create the human loop. Deleting or stopping a human loop does not remove any worker answers from your S3 bucket.

Additionally, Amazon A2I temporarily stores human loop input and output data internally for the following reasons:

- If you configure your human loops so that a single data object is sent to multiple workers for review, Amazon A2I does not write output data to your S3 bucket until all workers have completed the review task. Amazon A2I stores partial answers—answers from individual workers—internally so that it can write full results to your S3 bucket.
- If you report a low-quality human review result, Amazon A2I can investigate and respond to your issue.
- If you lose access to or delete the output S3 bucket specified in the human review workflow used to create a human loop, and the task has already been sent to one or more workers, Amazon A2I needs a place to temporarily store human review results.

Amazon A2I deletes this data internally 30 days after a human loop's status changes to one of the following: `Deleted`, `Stopped`, or `Completed`. In other words, data is deleted 30 days after the human loop has been completed, stopped, or deleted. Additionally, this data is deleted after 30 days if you close the AWS account used to create associated human loops.

Stop and Delete a Flow Definition Using the Console or the Amazon A2I API

You can stop and delete a human loop in the Augmented AI console or by using the SageMaker API. When the human loop has been deleted, the status changes to `Deleted`.

Delete a human loop (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows**.

3. Choose the hyperlinked name of the human review workflow you used to create the human loop you want to delete.
4. In the **Human loops** section at the bottom of the page, select the human loop you want to stop and delete.
5. If the human loop status is `Completed`, `Stopped`, or `Failed`, select **Delete**.

   If the human loop **Status** is `InProgress`, select **Stop**. When the status changes to **Stopped**, select **Delete**.

Delete a human loop (API)

1. Check the status of your human loop using the Augmented AI Runtime API operation [`DescribeHumanLoop`](). See examples using this operation in the following table.

   AWS SDK for Python (Boto3)

   The following example uses the SDK for Python (Boto3) to describe the human loop named *`example-human-loop`*. For more information, see [describe_human_loop]() in the *AWS SDK for Python (Boto) API Reference*.

   ```
   import boto3

   a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
   response = a2i_runtime_client.describe_human_loop(HumanLoopName='example-human-
   loop')
   human_loop_status = response['HumanLoopStatus']
   print(f'example-human-loop status is: {human_loop_status}')
   ```

   AWS CLI

   The following example uses the AWS CLI to describe the human loop named *`example-human-loop`*. For more information, see [describe-human-loop]() in the [*AWS CLI Command Reference*]().

   ```
   $ aws sagemaker-a2i-runtime describe-human-loop --human-loop-name 'example-
   human-loop'
   ```

2. If the flow definition status is `Completed`, `Stopped`, or `Failed`, delete the flow definition using the Augmented AI Runtime API operation [`DeleteHumanLoop`]().

AWS SDK for Python (Boto3)

The following example uses the SDK for Python (Boto3) to delete the human loop named *example-human-loop*. For more information, see delete_human_loop in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
response = a2i_runtime_client.delete_human_loop(HumanLoopName='example-human-loop')
```

AWS CLI

The following example uses the AWS CLI to delete the human loop named *example-human-loop*. For more information, see delete-human-loop in the *AWS CLI Command Reference*.

```
$ aws sagemaker-a2i-runtime delete-human-loop --human-loop-name 'example-human-loop'
```

If the human loop status is `InProgress`, stop the human loop using `StopHumanLoop` and then use `DeleteHumanLoop` to delete it.

AWS SDK for Python (Boto3)

The following example uses the SDK for Python (Boto3) to describe the human loop named *example-human-loop*. For more information, see stop_human_loop in the *AWS SDK for Python (Boto) API Reference*.

```
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
response = a2i_runtime_client.stop_human_loop(HumanLoopName='example-human-loop')
```

AWS CLI

The following example uses the AWS CLI to describe the human loop named *example-human-loop*. For more information, see stop-human-loop in the *AWS CLI Command Reference*.

```
$ aws sagemaker-a2i-runtime stop-human-loop --human-loop-name 'example-human-loop'
```

Create and Manage Worker Task Templates

You can create a task user interface for your workers by creating a *worker task template*. A worker task template is an HTML file that is used to display your input data and instructions to help workers complete your task.

For Amazon Rekognition or Amazon Textract task types, you can customize a pre-made worker task template using a graphical user interface (GUI) and avoid interacting with HTML code. For this option, use the instructions in Create a Human Review Workflow (Console) to create a human review workflow and customize your worker task template in the Amazon SageMaker AI console. Once you create a template using these instructions, it appears on the worker task templates page of the Augmented AI console.

If you are creating a human review workflow for a custom task type, you must create a *custom worker task template* using HTML code. For more information, see Create Custom Worker Task Templates.

If you create your template using HTML, you must use this template to generate an Amazon A2I *human task UI Amazon Resource Name (ARN)* in the Amazon A2I console. This ARN has the following format: `arn:aws:sagemaker:<aws-region>:<aws-account-number>:human-task-ui/<template-name>`. This ARN is associated with a worker task template resource that you can use in one or more human review workflows (flow definitions).

Generate a human task UI ARN using a worker task template by following the instructions found in Create a Worker Task Template or by using the `CreateHumanTaskUi` API operation.

Topics

- Create and Delete Worker Task Templates
- Create Custom Worker Task Templates

- Creating Good Worker Instructions

Create and Delete Worker Task Templates

You can use a worker template to customize the interface and instructions that your workers see when working on your tasks. Use the instructions on this page to create a worker task template in the Augmented AI area of the Amazon SageMaker AI console. A starter template is provided for Amazon Textract and Amazon Rekognition tasks. To learn how to customize your template using HTML crowd elements, see Create Custom Worker Task Templates.

When you create a worker template in the worker task templates page of the Augmented AI area of the SageMaker AI console, a worker task template ARN is generated. Use this ARN as the input to `HumanTaskUiArn` when you create a flow definition using the API operation `CreateFlowDefinition`. You can choose this template when creating a human review workflow on the human review workflows page of the console.

If you are creating a worker task template resource for an Amazon Textract or Amazon Rekognition task type, you can preview the worker UI that is generated from your template on the worker task templates console page. You must attach the policy described in Enable Worker Task Template Previews to the IAM role that you use to preview the template.

Create a Worker Task Template

You can create a worker task template using the SageMaker AI console and using the SageMaker API operation `CreateHumanTaskUi`.

Create a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i/.
2. Under **Amazon Augmented AI** in the left navigation pane, choose **Worker task templates**.
3. Choose **Create template**.
4. In **Template name**, enter a unique name.
5. (Optional) Enter an **IAM role** that grants Amazon A2I the permissions necessary to call services on your behalf.
6. In **Template type**, choose a template type from the dropdown list. If you are creating a template for a **Textract-form extraction** or **Rekognition-image moderation** task, choose the appropriate option.

7. Enter your custom template elements as follows:

   • If you selected the Amazon Textract or Amazon Rekognition task template, the **Template editor** autopopulates with a default template that you can customize.

   • If you are using a custom template, enter your predefined template in the editor.

8. (Optional) To complete this step, you must provide an IAM role ARN with permission to read Amazon S3 objects that get rendered on your user interface in **Step 5**.

   You can only preview your template if you are creating templates for Amazon Textract or Amazon Rekognition.

   Choose **See preview** to preview the interface and instructions that workers see. This is an interactive preview. After you complete the sample task and choose **Submit**, you see the resulting output from the task that you just performed.

   If you are creating a worker task template for a custom task type, you can preview your worker task UI using `RenderUiTemplate`. For more information, see Preview a Worker Task Template.

9. When you're satisfied with your template, choose **Create**.

After you've created your template, you can select that template when you create a human review workflow in the console. Your template also appears in the **Amazon Augmented AI** section of the SageMaker AI console under **Worker task templates**. Choose your template to view its ARN. Use this ARN when using the `CreateFlowDefinition` API operation .

Create a worker task template using a worker task template (API)

To generate a worker task template using the SageMaker API operation `CreateHumanTaskUi`, specify a name for your UI in `HumanTaskUiName` and input your HTML template in `Content` under `UiTemplate`. Find documentation on language-specific SDKs that support this API operation in the **See Also** section of the `CreateHumanTaskUi`.

Delete a Worker Task Template

Once you have created a worker task template, you can delete it using the SageMaker AI console or the SageMaker API operation `DeleteHumanTaskUi`.

When you delete a worker task template, you are not able to use human review workflows (flow definitions) created using that template to start human loops. Any human loops that have already been created using the worker task template that you delete continue to be processed until completion and are not impacted.

Delete a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i/.
2. Under Amazon Augmented AI in the left navigation pane, choose **Worker task templates**.
3. Select the template that you want to delete.
4. Selete **Delete**.
5. A modal appears to confirm your choice. Select **Delete**.

Delete a worker task template (API)

To delete a worker task template using the SageMaker API operation `DeleteHumanTaskUi`, specify a name of your UI in `HumanTaskUiName`.

Create Custom Worker Task Templates

Crowd HTML Elements are web components that provide a number of task widgets and design elements that you can tailor to the question you want to ask. You can use these crowd elements to create a custom worker template and integrate it with an Amazon Augmented AI (Amazon A2I) human review workflow to customize the worker console and instructions.

For a list of all HTML crowd elements available to Amazon A2I users, see Crowd HTML Elements Reference. For examples of templates, see the AWS GitHub repository, which contains over 60 sample custom task templates.

Develop Templates Locally

When in the console to test how your template processes incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding the following code to the top of your HTML file.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

This loads the necessary code to render the custom HTML elements. Use this code if you want to develop your template's look and feel in your preferred editor instead of in the console.

This code won't parse your variables. You might want to replace them with sample content while developing locally.

Use External Assets

Amazon Augmented AI custom templates enable you to embed external scripts and style sheets. For example, the following header embeds a `text/css` style sheet name `stylesheet` located at `https://www.example.com/my-enhancement-styles.css` into the custom template.

Example

```
<script src="https://www.example.com/my-enhancment-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding type for remote scripts is `application/javascript;CHARSET=UTF-8`.

The MIME and encoding type for remote stylesheets is `text/css;CHARSET=UTF-8`.

Track Your Variables

When building a custom template, you must add variables to it to represent the pieces of data that might change from task to task, or worker to worker. If you're starting with one of the sample templates, you need to make sure you're aware of the variables it already uses.

For example, for a custom template that integrates an Augmented AI human review loop with a Amazon Textract text review task, `{{ task.input.selectedAiServiceResponse.blocks }}` is used for initial-value input data. For Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition , `{{ task.input.selectedAiServiceResponse.moderationLabels }}` is used. For a custom task type, you need to determine the input parameter for your task type. Use `{{ task.input.`*`customInputValuesForStartHumanLoop`*`}}` where you specify *`customInputValuesForStartHumanLoop`*.

Custom Template Example for Amazon Textract

All custom templates begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements.

For an Amazon Textract document analysis task, use the `<crowd-textract-analyze-document>` element. It uses the following attributes:

- `src` – Specifies the URL of the image file to be annotated.
- `initialValue` – Sets initial values for attributes found in the worker UI.
- `blockTypes` (required) – Determines the kind of analysis that the workers can do. Only `KEY_VALUE_SET` is currently supported.
- `keys` (required) – Specifies new keys and the associated text value that the worker can add.
- `no-key-edit` (required) – Prevents the workers from editing the keys of annotations passed through `initialValue`.
- `no-geometry-edit` – Prevents workers from editing the polygons of annotations passed through `initialValue`.

For children of the `<crowd-textract-analyze-document>` element, you must have two Regions. You can use arbitrary HTML and CSS elements in these Regions.

- `<full-instructions>` – Instructions that are available from the **View full instructions** link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- `<short-instructions>` – A brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.

An Amazon Textract template would look similar to the following.

Example

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.document.s3Object.bucket }}/
{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
```

```
    header="Review the key-value pairs listed on the right and correct them if they
 don't match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="['KEY_VALUE_SET']"
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
        .instructionsImage {
          display: inline-block;
          max-width: 100%;
        }
      </style>
      <p class='instructions'>Choose a key-value block to highlight the corresponding
 key-value pair in the document.

If it is a valid key-value pair, review the content for the value. If the content is
 incorrect, correct it.

The text of the value is incorrect, correct it.
<img class='instructionsImage' src="https://example-site/correct-value-text.png" />

A wrong value is identified, correct it.
<img class='instructionsImage' src="https://example-site/correct-value.png" />

If it is not a valid key-value relationship, choose No.
<img class='instructionsImage' src="https://example-site/not-a-key-value-pair.png" />

If you can’t find the key in the document, choose Key not found.
<img class='instructionsImage' src="https://example-site/key-is-not-found.png" />

If the content of a field is empty, choose Value is blank.
<img class='instructionsImage' src="https://example-site/value-is-blank.png" />

<b>Examples</b>
Key and value are often displayed next to or below to each other.

Key and value displayed in one line.
<img class='instructionsImage' src="https://example-site/sample-key-value-pair-1.png" /
>
```

```
Key and value displayed in two lines.
<img class='instructionsImage' src="https://example-site/sample-key-value-pair-2.png" /
>

If the content of the value has multiple lines, enter all the text without a line
 break. Include all value text even if it extends beyond the highlight box.
<img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/
multiple-lines.png" /></p>
    </short-instructions>

    <full-instructions header="Instructions"></full-instructions>
  </crowd-textract-analyze-document>
</crowd-form>
```

Custom Template Example for Amazon Rekognition

All custom templates begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements. For an Amazon Rekognition custom task template, use the `<crowd-rekognition-detect-moderation-labels>` element. This element supports the following attributes:

- `categories` – An array of strings *or* an array of objects where each object has a `name` field.
  - If the categories come in as objects, the following applies:
    - The displayed categories are the value of the `name` field.
    - The returned answer contains the *full* objects of any selected categories.
  - If the categories come in as strings, the following applies:
    - The returned answer is an array of all the strings that were selected.
- `exclusion-category` – By setting this attribute, you create a button underneath the categories in the UI. When a user selects the button, all categories are deselected and disabled. If the worker selects the button again, you re-enable users to choose categories. If the worker submits the task by selecting **Submit** after you select the button, that task returns an empty array.

For children of the `<crowd-rekognition-detect-moderation-labels>` element, you must have two Regions.

- `<full-instructions>` – Instructions that are available from the **View full instructions** link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- `<short-instructions>` – Brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.

A template using these elements would look similar to the following.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/
{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-rekognition-detect-moderation-labels
    categories='[
      {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
        {
          name: "{{ label.name }}",
          parentName: "{{ label.parentName }}",
        },
      {% endfor %}
    ]'
    src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
      </style>
      <p class='instructions'>Review the image and choose all applicable categories.
If no categories apply, choose None.

<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Graphic Male Nudity</b>
Visuals depicting full frontal male nudity, often close ups
```

```
<b>Graphic Female Nudity</b>
Visuals depicting full frontal female nudity, often close ups

<b>Sexual Activity</b>
Visuals depicting various types of explicit sexual activities and pornography

<b>Illustrated Nudity or Sexual Activity</b>
Visuals depicting animated or drawn sexual activity, nudity, or pornography

<b>Adult Toys</b>
Visuals depicting adult toys, often in a marketing context

<b>Female Swimwear or Underwear</b>
Visuals depicting female person wearing only swimwear or underwear

<b>Male Swimwear Or Underwear</b>
Visuals depicting male person wearing only swimwear or underwear

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses, such as deep cut dresses

<b>Graphic Violence or Gore</b>
Visuals depicting prominent blood or bloody injuries

<b>Physical Violence</b>
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades

<b>Self Injury</b>
Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns
 using sharp objects

<b>Emaciated Bodies</b>
Visuals depicting extremely malnourished human bodies

<b>Corpses</b>
```

```
Visuals depicting human dead bodies

<b>Hanging</b>
Visuals depicting death by hanging</p>
    </short-instructions>

    <full-instructions header="Instructions"></full-instructions>
  </crowd-rekognition-detect-moderation-labels>
</crowd-form>
```

Add automation with Liquid

The custom template system uses Liquid for automation. *Liquid* is an open-source inline markup language. For more information and documentation, see the Liquid homepage.

In Liquid, the text between single curly braces and percent symbols is an instruction or *tag* that performs an operation like control flow or iteration. Text between double curly braces is a variable or *object* that outputs its value. The following list includes two types of liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you are redirected to the Liquid documentation.

- Control flow: Includes programming logic operators like `if/else`, `unless`, and `case/when`.
- Iteration: Enables you to run blocks of code repeatedly using statements like for loops.

  For example, the following code example demonstrates how you can use the Liquid `for` tag to create a `for` loop. This example loops through the `moderationLabels` returned from Amazon Rekognition and displays the `moderationLabels` attributes `name` and `parentName` for workers to review:

  ```
  {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
     {
       name: &quot;{{ label.name }}&quot;,
       parentName: &quot;{{ label.parentName }}&quot;,
     },
  {% endfor %}
  ```

Use variable filters

In addition to the standard Liquid filters and actions, Amazon Augmented AI (Amazon A2I) offers additional filters. You apply filters by placing a pipe (|) character after the variable name, and then specifying a filter name. To chain filters, use the following format.

Example

```
{{ <content> | <filter> | <filter> }}
```

Autoescape and Explicit Escape

By default, inputs are HTML-escaped to prevent confusion between your variable text and HTML. You can explicitly add the `escape` filter to make it more obvious to someone reading the source of your template that escaping is being done.

escape_once

`escape_once` ensures that if you've already escaped your code, it doesn't get re-escaped again. For example, it ensures that `&` doesn't become `&`.

skip_autoescape

`skip_autoescape` is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

> **Note**
>
> Use `skip_autoescape` sparingly. As a best practice for templates, avoid passing in functional code or markup with `skip_autoescape` unless you are absolutely sure that you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a cross-site scripting attack.

to_json

`to_json` encodes data that you provide to JavaScript Object Notation (JSON). If you provide an object, it serializes it.

grant_read_access

`grant_read_access` takes an Amazon Simple Storage Service (Amazon S3) URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

s3_presign

The `s3_presign` filter works the same way as the `grant_read_access` filter. `s3_presign` takes an Amazon S3 URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

Example Example of the variable filters

Input

```
auto-escape: {{ "Have you read 'James & the Giant Peach'?" }}
explicit escape: {{ "Have you read 'James & the Giant Peach'?" | escape }}
explicit escape_once: {{ "Have you read 'James &amp; the Giant Peach'?" |
 escape_once }}
skip_autoescape: {{ "Have you read 'James & the Giant Peach'?" | skip_autoescape }}
to_json: {{ jsObject | to_json }}
grant_read_access: {{ "s3://amzn-s3-demo-bucket/myphoto.png" | grant_read_access }}
s3_presign: {{ "s3://amzn-s3-demo-bucket/myphoto.png" | s3_presign }}
```

Example

Output

```
auto-escape: Have you read &#39;James &amp; the Giant Peach&#39;?
explicit escape: Have you read &#39;James &amp; the Giant Peach&#39;?
explicit escape_once: Have you read &#39;James &amp; the Giant Peach&#39;?
skip_autoescape: Have you read 'James & the Giant Peach'?
to_json: { "point_number": 8, "coords": [ 59, 76 ] }
grant_read_access: https://s3.amazonaws.com/amzn-s3-demo-bucket/myphoto.png?<access
 token and other params>
s3_presign: https://s3.amazonaws.com/amzn-s3-demo-bucket/myphoto.png?<access token and
 other params>
```

Example Example of an automated classification template.

To automate this simple text classification sample, include the Liquid tag `{{ task.input.source }}`. This example uses the crowd-classifier element.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="['positive', 'negative', 'neutral', 'cannot determine']"
    header="Which term best describes this tweet?"
  >
    <classification-target>
       {{ task.input.source }}
    </classification-target>

    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author
      of the tweet is trying to express.
      If none seems to match, choose "other."
    </full-instructions>

    <short-instructions>
      Pick the term that best describes the sentiment
      of the tweet.
    </short-instructions>

  </crowd-classifier>
</crowd-form>
```

Preview a Worker Task Template

To preview a custom worker task template, use the SageMaker AI `RenderUiTemplate` operation. You can use the `RenderUiTemplate` operation with the AWS CLI or your preferred AWS SDK. For documentation on the supported language specific SDKs for this API operation, see the `See Also` section of the `RenderUiTemplate`.

Prerequisites

To preview your worker task template, the AWS Identity and Access Management (IAM) role Amazon Resource Name (ARN), or `RoleArn`, that you use must have permission to access to the

S3 objects that are used by the template. To learn how to configure your role or user see [Enable Worker Task Template Previews](#).

To preview your worker task template using the `RenderUiTemplate` operation:

1. Provide a **`RoleArn`** of the role with required policies attached to preview your custom template.
2. In the **`Input`** parameter of **`Task`**, provide a JSON object that contains values for the variables defined in the template. These are the variables that are substituted for the `task.input.`*`source`* variable. For example, if you define a task.input.text variable in your template, you can supply the variable in the JSON object as `text`: `sample text`.
3. In the **`Content`** parameter of **`UiTemplate`**, insert your template.

Once you've configured `RenderUiTemplate`, use your preferred SDK or the AWS CLI to submit a request to render your template. If your request was successful, the response includes [`RenderedContent`](#), a Liquid template that renders the HTML for the worker UI.

> **Important**
>
> To preview your template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. For a sample policy that you can attach to your IAM role to grant these permissions, see [Enable Worker Task Template Previews](#).

Creating Good Worker Instructions

Creating good instructions for your human review jobs improves your worker's accuracy in completing their task. You can modify the default instructions that are provided in the console when creating a human review workflow, or you can use the console to create a custom worker template and include your instructions in this template. The instructions are shown to the worker on the UI page where they complete their labeling task.

Create Good Worker Instructions

There are three kinds of instructions in the Amazon Augmented AI console:

- **Task Description –** The description should provide a succinct explanation of the task.

- **Instructions –** These instructions are shown on the same webpage where workers complete a task. These instructions should provide an easy reference to show the worker the correct way to complete the task.
- **Additional Instructions –** These instructions are shown in a dialog box that appears when a worker chooses **View full instructions**. We recommend that you provide detailed instructions for completing the task, and include several examples showing edge cases and other difficult situations for labeling objects.

Add Example Images to Your Instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions, do the following:

1. Place the cursor where the image should go in the instructions editor.
2. Choose the image icon in the editor toolbar.
3. Enter the URL of your image.

If your instruction image is in an S3 bucket that isn't publicly accessible, do the following:

- For the image URL, enter: `{{ 'https://s3.amazonaws.com/your-bucket-name/image-file-name' | grant_read_access }}`.

This renders the image URL with a short-lived, one-time access code that's appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview. See s3_presign for more information about the `grand_read_access` element.

Monitor and Manage Your Human Loop

Once you've started a human review loop, you can check the results of tasks sent to the loop and manage it using the Amazon Augmented AI Runtime API. Additionally, Amazon A2I integrates with Amazon EventBridge (also known as Amazon CloudWatch Events) to alert you when a human review loop status changes to `Completed`, `Failed`, or `Stopped`. This event delivery is guaranteed at least once, which means all events created when human loops finish are successfully delivered to EventBridge.

Use the procedures below to learn how to use the Amazon A2I Runtime API to monitor and manage your human loops. See Use Amazon CloudWatch Events in Amazon Augmented AI to learn how Amazon A2I integrates with Amazon EventBridge.

To check your output data:

1. Check the results of your human loop by calling the `DescribeHumanLoop` operation. The result of this API operation contains information about the reason for and outcome of the loop activation.
2. Check the output data from your human loop in Amazon Simple Storage Service (Amazon S3). In the path to the data, *YYYY*/*MM*/*DD*/*hh*/*mm*/*ss* represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

```
s3://customer-output-bucket-specified-in-flow-definition/flow-definition-
name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
```

You can integrate this structure with AWS Glue or Amazon Athena to partition and analyze your output data. For more information, see Managing Partitions for ETL Output in AWS Glue.

To learn more about Amazon A2I output data format, see Amazon A2I Output Data.

To stop and delete your human loop:

1. Once a human loop has been started, you can stop your human loop by calling the `StopHumanLoop` operation using the `HumanLoopName`. If a human loop was successfully stopped, the server sends back an HTTP 200 response.
2. To delete a human loop for which the status equals `Failed`, `Completed`, or `Stopped`, use the `DeleteHumanLoop` operation.

To list human loops:

1. You can list all active human loops by calling the `ListHumanLoops` operation. You can filter human loops by the creation date of the loop using the `CreationTimeAfter` and `CreateTimeBefore` parameters.

2. If successful, `ListHumanLoops` returns `HumanLoopSummaries` and `NextToken` objects in the response element. `HumanLoopSummaries` contains information about a single human loop. For example, it lists a loop's status and, if applicable, its failure reason.

   Use the string returned in `NextToken` as an input in a subsequent call to `ListHumanLoops` to see the next page of human loops.

Amazon A2I Output Data

When your machine learning workflow sends Amazon A2I a data object, a *human loop* is created and human reviewers receive a *task* to review that data object. The output data from each human review task is stored in the Amazon Simple Storage Service (Amazon S3) output bucket you specify in your human review workflow. In the path to the data, *`YYYY`*/*`MM`*/*`DD`*/*`hh`*/*`mm`*/*`ss`* represents the human loop creation date with year (`YYYY`), month (`MM`), and day (`DD`), and the creation time with hour (`hh`), minute (`mm`), and second (`ss`).

```
s3://customer-output-bucket-specified-in-flow-definition/flow-definition-
name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
```

The content of your output data depends on the type of task type (built-in or custom) and the type of workforce you use. Your output data always includes the response from the human worker. Additionally, output data may include metadata about the human loop, the human reviewer (worker), and the data object.

Use the following sections to learn more about Amazon A2I output data format for different task types and workforces.

Output Data From Built-In Task Types

Amazon A2I built-in task types include Amazon Textract and Amazon Rekognition. In addition to human responses, the output data from one of these tasks includes details about the reason the human loop was created and information about the integrated service used to create the human loop. Use the following table to learn more about the output data schema for all built-in task types. The *value* for each of these parameters depends on the service you use with Amazon A2I. Refer to the second table in this section for more information about these service-specific values.

Parameter	Value Type	Example Values	Description
`awsManagedHumanLoopRequestSource`	String	`AWS/Rekognition/DetectModerationLabels/Image/V3` or `AWS/Textract/AnalyzeDocument/Forms/V1`	The API operation and associated AWS services that requested that Amazon A2I create the a human loop. This is the API operation you use to configure your Amazon A2I human loop.
`flowDefinitionArn`	String	`arn:aws:sagemaker:us-west-2:` *`111122223333`* `:flow-definition/` *`flow-definition-name`*	The Amazon Resource Number (ARN) of the human review workflow (flow definition) used to create the human loop.

`humanAnswers`	List of JSON objects	`{`
		`"answerContent":`
		` {`
		`    "AWS/Rekognition/DetectModerationLabels/Image/V3": {`
		`        "moderationLabels": [...]`
		`    }`
		`},`
		
		or
			A list of JSON objects that contain worker responses in `answerContent` .
			
			This object also contains submission details and, if a private workforce was used, worker metadata. To learn more, see [Track Worker Activity]().

Parameter	Value Type	Example Values	Description
		`{ "answerContent": { "AWS/Textract/AnalyzeDocument/Forms/V1": { "blocks": [...] } },`	For human loop output data produced from Amazon Rekogniti on `DetectModerationLabel` review tasks, this parameter only contains positive responses. For example, if workers select *No content*, this response is not included.
`humanLoopName`	String	`'human-loop-name'`	The name of the human loop.
`inputContent`	JSON object	`{ "aiServiceRequest": {...}, "aiServiceResponse": {...}, "humanTaskActivationConditionResults": {...}, "selectedAiServiceResponse": {...} }`	The input content the AWS service sent to Amazon A2I when it requested a human loop be created.

Parameter	Value Type	Example Values	Description
`aiServiceRequest`	JSON object	`{ "document": {...}, "featureTypes": [ ...], "humanLoopConfig": { ...} }` or `{ "image": {...}, "humanLoopConfig": { ...} }`	The original request sent to the AWS service integrated with Amazon A2I. For example, if you use Amazon Rekognition with Amazon A2I, this includes the request made through the API operation `DetectModerationLabels` . For Amazon Textract integrations, this includes the request made through `AnalyzeDocument` .
`aiServiceResponse`	JSON object	`{ "moderationLabels": [...], "moderationModelVersion": "3.0" }` or `{ "blocks": [...], "documentMetadata": {} }`	The full response from the AWS service. This is the data that is used to determine if a human review is required. This object may contain metadata about the data object that is not shared with human reviewers.

Parameter	Value Type	Example Values	Description

`selectedAiServiceResponse`	JSON object	`{ "moderationLabels": [...], "moderationModelVersion": "3.0" }`
		or
		`{ "blocks": [...], "documentMetadata": {} }`
			The subset of the `aiServiceResponse` that matches the activation conditions in `ActivationConditions` .
			
			All data objects listed in `aiServiceResponse` are listed in `selectedAiServiceResponse` when inferences are randomly sampled, or all inferences initiated activation conditions.

Parameter	Value Type	Example Values	Description
humanTaskActivationConditionResults	JSON object	`{ "Conditions": [ ...] }`	A JSON object in `inputContent` that contains the reason a human loop was created. This includes a list of the activation conditions (`Conditions`) included in your human review workflow (flow definition), and the evaluation result for each condition–this result is either `true` or `false`. To learn more about activation conditions, see [JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI]().

Select a tab on the following table to learn about the task type–specific parameters and see an example output-data code block for each of the built-in task types.

Amazon Textract Task Type Output Data

When you use the Amazon Textract built-in integration, you see `'AWS/Textract/AnalyzeDocument/Forms/V1'` as the value for `awsManagedHumanLoopRequestSource` in your output data.

The `answerContent` parameter contains a `Block` object that includes human responses for all blocks sent to Amazon A2I.

The `aiServiceResponse` parameter also includes a `Block` object with Amazon Textract's response to the original request sent using to `AnalyzeDocument`.

To learn more about the parameters you see in the block object, refer to Block in the *Amazon Textract Developer Guide*.

The following is an example of the output data from an Amazon A2I human review of Amazon Textract document analysis inferences.

```
{
    "awsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1",
    "flowDefinitionArn": "arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",

            ]
        },
        "selectedAiServiceResponse": {
            "blocks": [...]
        }
    }
}
```

Amazon Rekognition Task Type Output Data

When you use the Amazon Textract built-in integration, you see the string `'AWS/Rekognition/DetectModerationLabels/Image/V3'` as the value for `awsManagedHumanLoopRequestSource` in your output data.

The `answerContent` parameter contains a `moderationLabels` object that contains human responses for all moderation labels sent to Amazon A2I.

The `aiServiceResponse` parameter also includes a `moderationLabels` object with Amazon Rekognition's response to the original request sent to `DetectModerationLabels`.

To learn more about the parameters you see in the block object, refer to ModerationLabel in the Amazon Rekognition Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Rekognition image moderation inferences.

```
{
    "awsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/
Image/V3",
    "flowDefinitionArn": "arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
    "humanAnswers": [
        {
```

```
            "answerContent": {
                "AWS/Rekognition/DetectModerationLabels/Image/V3": {
                    "moderationLabels": [...]
                }
            },
            "submissionTime": "2020-09-28T19:22:35.508Z",
            "workerId": "ef7294f850a3d9d1",
            "workerMetadata": {
                "identityData": {
                    "identityProviderType": "Cognito",
                    "issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-
west-2_111111",
                    "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
                }
            }
        }
    ],
    "humanLoopName": "humnan-loop-name",
    "inputContent": {
        "aiServiceRequest": {
            "humanLoopConfig": {
                "flowDefinitionArn": "arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
                "humanLoopName": "humnan-loop-name"
            },
            "image": {

                    "parentName": ""
                }
            ],
            "moderationModelVersion": "3.0"
        }
    }
}
```

Output Data From Custom Task Types

When you add Amazon A2I to a custom human review workflow, you see the following parameters in the output data returned from human review tasks.

Parameter	Value Type	Description
`flowDefinitionArn`	String	The Amazon Resource Number (ARN) of the human review workflow (flow

Parameter	Value Type	Description
		definition) used to create the human loop.
`humanAnswers`	List of JSON objects	A list of JSON objects that contain worker responses in `answerContent` . The value in this parameter is determined by the output received from your worker task template. If you are using a private workforce, worker metadata is included. To learn more, see Track Worker Activity.
`humanLoopName`	String	The name of the human loop.
`inputContent`	JSON Object	The input content sent to Amazon A2I in the request to `StartHumanLoop` .

The following is an example of output data from a custom integration with Amazon A2I and Amazon Transcribe. In this example, the `inputContent` consists of:

- A path to an .mp4 file in Amazon S3 and the video title
- The transcription returned from Amazon Transcribe (parsed from Amazon Transcribe output data)
- A start and end time used by the worker task template to clip the .mp4 file and show workers a relevant portion of the video

    }
}
```

Track Worker Activity

Amazon A2I provides information that you can use to track individual workers in task output data. To identify the worker that worked on the human review task, use the following from the output data in Amazon S3:

- The `acceptanceTime` is the time that the worker accepted the task. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a **T**.
- The `submissionTime` is the time that the worker submitted their annotations using the **Submit** button. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a **T**.

- `timeSpentInSeconds` reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- The `workerId` is unique to each worker.
- If you use a [private workforce](), in `workerMetadata`, you see the following.
  - The `identityProviderType` is the service used to manage the private workforce.
  - The `issuer` is the Amazon Cognito user pool or OpenID Connect (OIDC) Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique `sub` identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) associated with this ID using Amazon Cognito. To learn how, see [Managing and Searching for User Accounts]() in [*Amazon Cognito Developer Guide*]().

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the `identityProviderType`.

```
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3cdefg4h5i67",
"workerMetadata": {
    "identityData": {
        "identityProviderType": "Cognito",
        "issuer": "https://cognito-idp.aws-region.amazonaws.com/aws-region_123456789",
        "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
    }
}
```

The following is an example of the output you may see if you use your own OIDC IdP to create a private workforce:

```
"workerMetadata": {
        "identityData": {
            "identityProviderType": "Oidc",
            "issuer": "https://example-oidc-ipd.com/adfs",
            "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
        }
}
```

To learn more about using private workforces, see Private workforce.

Permissions and Security in Amazon Augmented AI

When using Amazon Augmented AI (Amazon A2I) to create a human review workflow for your ML/AI application, you create and configure *resources* in Amazon SageMaker AI such as a human workforce and worker task templates. To configure and start a human loop, you either integrate Amazon A2I with other AWS services such as Amazon Textract or Amazon Rekognition, or use the Amazon Augmented AI Runtime API. To create a human review workflow and start a human loop, you must attach certain policies to your AWS Identity and Access Management (IAM) role or user. Specifically:

- When you start a human loop using image input data on or after January 12th, 2020, you must add a CORS header policy to the Amazon S3 bucket that contains your input data. See CORS Permission Requirement to learn more.
- When you create a flow definition, you need to provide a role that grants Amazon A2I permission to access Amazon S3 both for reading objects that are rendered in a human task UI and for writing the results of the human review.

  This role must also have a trust policy attached to give SageMaker AI permission to assume the role. This allows Amazon A2I to perform actions in accordance with permissions that you attach to the role.

  See Add Permissions to the IAM Role Used to Create a Flow Definition for example policies that you can modify and attach to the role you use to create a flow definition. These are the policies that are attached to the IAM role that is created in the **Human review workflows** section of the Amazon A2I area of the SageMaker AI console.
- To create and start human loops, you either use an API operation from a built-in task type (such as `DetectModerationLabel` or `AnalyzeDocument`) or the Amazon A2I Runtime API operation `StartHumanLoop` in a custom ML application. You need to attach the `AmazonAugmentedAIFullAccess` managed policy to the user that invokes these API operations to grant permission to these services to use Amazon A2I operations. To learn how, see Create a User That Can Invoke Amazon A2I API Operations.

  This policy does *not* grant permission to invoke the API operations of the AWS service associated with built-in task types. For example, `AmazonAugmentedAIFullAccess` does not grant permission to call the Amazon Rekognition `DetectModerationLabel` API operation or Amazon Textract `AnalyzeDocument` API operation. You can use the more general policy, AmazonAugmentedAIIntegratedAPIAccess, to grant these permissions. For more information, see Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations. This is a good option when you want to grant a user broad permissions to use Amazon A2I and integrated AWS services' API operations.

If you want to configure more granular permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples for identity-based policies you can use to grant permission to use these individual services.

- To preview your custom worker task UI template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. See a policy example in Enable Worker Task Template Previews .

Topics

CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, images would always display in browsers exactly how they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called *orientation value*. This has important implications for the entire machine learning (ML) community. For example, if the EXIF orientation is not considered, applications that are used to annotate images may display images in unexpected orientations and result in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web’s Same-Origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a human loop, you must add a CORS header policy to the S3 buckets that contain your input images.

> **Important**
>
> If you do not add a CORS configuration to the S3 buckets that contains your input data, human review tasks for those input data objects fail.

You can add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

JSON

```
[{
   "AllowedHeaders": [],
   "AllowedMethods": ["GET"],
   "AllowedOrigins": ["*"],
   "ExposeHeaders": []
}]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>*</AllowedOrigin>
   <AllowedMethod>GET</AllowedMethod>
 </CORSRule>
</CORSConfiguration>
```

Add Permissions to the IAM Role Used to Create a Flow Definition

To create a flow definition, attach the policies in this section to the role that you use when creating a human review workflow in the SageMaker AI console, or when using the `CreateFlowDefinition` API operation.

- If you are using the console to create a human review workflow, enter the role Amazon Resource Name (ARN) in the **IAM role** field when creating a human review workflow in the console.
- When creating a flow definition using the API, attach these policies to the role that is passed to the `RoleArn` parameter of the `CreateFlowDefinition` operation.

When you create a human review workflow (flow definition), Amazon A2I invokes Amazon S3 to complete your task. To grant Amazon A2I permission to retrieve and store your files in your Amazon S3 bucket, create the following policy and attach it to your role. For example, if the images, documents, and other files that you are sending for human review are stored in an S3 bucket named `my_input_bucket`, and if you want the human reviews to be stored in a bucket named `my_output_bucket`, create the following policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::my_input_bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::my_output_bucket/*"
            ]
        }
    ]
}
```

In addition, the IAM role must have the following trust policy to give SageMaker AI permission to assume the role. To learn more about IAM trust policies, see Resource-Based Policies section of **Policies and Permissions** in the *AWS Identity and Access Management* documentation.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSageMakerToAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information about creating and managing IAM roles and policies, see the following topics in the *AWS Identity and Access Management User Guide*:

- To create an IAM role, see Creating a Role to Delegate Permissions to an IAM User.
- To learn how to create IAM policies, see Creating IAM Policies.
- To learn how to attach an IAM policy to a role, see Adding and Removing IAM Identity Permissions.

Create a User That Can Invoke Amazon A2I API Operations

To use Amazon A2I to create and start human loops for Amazon Rekognition, Amazon Textract, or the Amazon A2I runtime API, you must use a user that has permissions to invoke Amazon A2I operations. To do this, use the IAM console to attach the `AmazonAugmentedAIFullAccess` managed policy to a new or existing user.

This policy grants permission to a user to invoke API operations from the SageMaker API for flow definition creation and management and the Amazon Augmented AI Runtime API for human loop creation and management. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

`AmazonAugmentedAIFullAccess` does not grant permissions to use Amazon Rekognition or Amazon Textract API operations.

> **Note**
>
> You can also attach the `AmazonAugmentedAIFullAccess` policy to an IAM role that is used to create and start a human loop.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

For more information, see Adding and Removing IAM Identity Permissions in the *AWS Identity and Access Management User Guide*.

Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations

To create a user that has permission to invoke the API operations used by the built-in task types (that is, `DetectModerationLables` for Amazon Rekognition and `AnalyzeDocument` for Amazon Textract) and permission to use all Amazon A2I API operations, attach the IAM managed policy, `AmazonAugmentedAIIntegratedAPIAccess`. You may want to use this policy when you want to grant broad permissions to a user using Amazon A2I with more than one task type. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

> **Note**
>
> You can also attach the `AmazonAugmentedAIIntegratedAPIAccess` policy to an IAM role that is used to create and start a human loop.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

For more information, see Adding and Removing IAM Identity Permissions in the *AWS Identity and Access Management User Guide*.

Enable Worker Task Template Previews

To customize the interface and instructions that your workers see when working on your tasks, you create a worker task template. You can create the template using the `CreateHumanTaskUi` operation or the SageMaker AI console.

To preview your template, you need an IAM role with the following permissions to read Amazon S3 objects that get rendered on your user interface.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::my_input_bucket/*"
            ]
        }
    ]
}
```

For Amazon Rekognition and Amazon Textract task types, you can preview your template using the Amazon Augmented AI section of the SageMaker AI console. For custom task types, you preview your template by invoking the `RenderUiTemplate` operation. To preview your template, follow the instructions for your task type:

- Amazon Rekognition and Amazon Textract task types – In the SageMaker AI console, use the role's Amazon Resource Name (ARN) in the procedure documented in Create a Worker Task Template.
- Custom task types – In the `RenderUiTemplate` operation, use the role's ARN in the `RoleArn` parameter.

Using Amazon A2I with AWS KMS Encrypted Buckets

If you specify an AWS Key Management Service (AWS KMS) customer managed key to encrypt output data in `OutputConfig` of `CreateFlowDefinition`, you must add an IAM policy similar to the following to that key. This policy gives the IAM execution role that you use to create your human loops permission to use this key to perform all of the actions listed in `"Action"`. To learn more about these actions, see AWS KMS permissions in the AWS Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in `"Principal"` with the ARN of the execution role you use to create the human review workflow (flow definition). When you create a labeling job using `CreateFlowDefinition`, this is the ARN you specify for `RoleArn`. Note that you cannot provide a `KmsKeyId` when you create a flow definition in the console.

```
{
    "Sid": "AllowUseOfKmsKey",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*"
}
```

Additional Permissions and Security Resources

- the section called “Control access to SageMaker AI resources by using tags”.
- the section called “Identity-based policies for Amazon SageMaker AI”
- the section called “Control creation of SageMaker AI resources with condition keys”
- the section called “Amazon SageMaker AI API Permissions Reference”
- *Configure security in Amazon SageMaker AI*

Use Amazon CloudWatch Events in Amazon Augmented AI

Amazon Augmented AI uses Amazon CloudWatch Events to alert you when a human review loop status changes to `Completed`, `Failed`, or `Stopped`. This event delivery is guaranteed at least once, which means all events created when human loops finish are successfully delivered to CloudWatch Events (Amazon EventBridge). When a review loop changes to one of these states, Augmented AI sends an event to CloudWatch Events similar to the following.

```
{
```

```
    "version":"0",
    "id":"12345678-1111-2222-3333-12345EXAMPLE",
    "detail-type":"SageMaker A2I HumanLoop Status Change",
    "source":"aws.sagemaker",
    "account":"1111111111111",
    "time":"2019-11-14T17:49:25Z",
    "region":"us-east-1",
    "resources":["arn:aws:sagemaker:us-east-1:111111111111:human-loop/humanloop-
nov-14-1"],
    "detail":{
        "creationTime":"2019-11-14T17:37:36.740Z",
        "failureCode":null,
        "failureReason":null,
        "flowDefinitionArn":"arn:aws:sagemaker:us-east-1:111111111111:flow-definition/
flowdef-nov-12",
        "humanLoopArn":"arn:aws:sagemaker:us-east-1:111111111111:human-loop/humanloop-
nov-14-1",
        "humanLoopName":"humanloop-nov-14-1",
        "humanLoopOutput":{
            "outputS3Uri":"s3://customer-output-bucket-specified-in-flow-definition/
flowdef-nov-12/2019/11/14/17/37/36/humanloop-nov-14-1/output.json"
        },
        "humanLoopStatus":"Completed"
    }
}
```

The details in the JSON output include the following:

`creationTime`

The timestamp when Augmented AI created the human loop.

`failureCode`

A failure code denoting a specific type of failure.

`failureReason`

The reason why a human loop has failed. The failure reason is only returned when the human review loop status is `failed`.

`flowDefinitionArn`

The Amazon Resource Name (ARN) of the flow definition, or *human review workflow*.

`humanLoopArn`

The Amazon Resource Name (ARN) of the human loop.

`humanLoopName`

The name of the human loop.

`humanLoopOutput`

An object containing information about the output of the human loop.

`outputS3Uri`

The location of the Amazon S3 object where Augmented AI stores your human loop output.

`humanLoopStatus`

The status of the human loop.

Send Events from Your Human Loop to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or *events*, for your Amazon A2I human loops, use the AWS Command Line Interface (AWS CLI) [`put-rule`] command. When using the `put-rule` command, specify the following to receive human loop statuses:

- `\"source\":[\"aws.sagemaker\"]`
- `\"detail-type\":[\"SageMaker A2I HumanLoop Status Change\"]`

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace *`"A2IHumanLoopStatusChanges"`* with a unique CloudWatch Events rule name and *`"arn:aws:iam::111122223333:role/MyRoleForThisRule"`* with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached. Replace *`region`* with the AWS Region in which you want to create the rule.

```
aws events put-rule --name "A2IHumanLoopStatusChanges"
    --event-pattern "{\"source\":[\"aws.sagemaker\"],\"detail-type\":[\"SageMaker A2I
 HumanLoop Status Change\"]}"
    --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
    --region "region"
```

To learn more about the `put-rule` request, see Event Patterns in CloudWatch Events in the *Amazon CloudWatch Events User Guide*.

Set Up a Target to Process Events

To process events, you need to set up a target. For example, if you want to receive an email when a human loop status changes, use a procedure in Setting Up Amazon SNS Notifications in the *Amazon CloudWatch User Guide* to set up an Amazon SNS topic and subscribe your email to it. Once you have created a topic, you can use it to create a target.

To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose **Rules**.
3. Choose the rule to which you want to add a target.
4. Choose **Actions**, and then choose **Edit**.
5. Under **Targets**, choose **Add Target** and choose the AWS service you want to act when a human loop status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose **Configure details**.
8. For **Name**, enter a name and, optionally, provide details about the purpose of the rule in **Description**.
9. Make sure that the check box next to **State** is selected so that your rule is listed as **Enabled**.
10. Choose **Update rule**.

Use Human Review Output

After you receive human review results, you can analyze the results and compare them to machine learning predictions. The JSON that is stored in the Amazon S3 bucket contains both the machine learning predictions and the human review results.

More Information

Events that Amazon SageMaker AI sends to Amazon EventBridge

Use APIs in Amazon Augmented AI

You can create a human review workflow or a worker task template programmatically. The APIs you use depend on whether you are creating a Amazon Rekognition, Amazon Textract, or custom task type. This topic provides links to API reference documentation for each task type and programming task.

The following APIs can be used with Augmented AI:

Amazon Augmented AI

Use the Augmented AI API to start, stop, and delete human review loops. You can also list all human review loops and return information about human review loops in your account.

Learn more about human review loop APIs in the Amazon Augmented AI Runtime API Reference.

Amazon Rekognition

Use the **HumanLoopConfig** parameter of the `DetectModerationLabels` API to initiate a human review workflow using Amazon Rekognition.

Amazon SageMaker AI

Use the Amazon SageMaker API to create a `FlowDefinition`, also known as a *human review workflow*. You can also create a `HumanTaskUi` or *worker task template*.

For more information, see the `CreateFlowDefinition` or the `CreateHumanTaskUi` API documentation.

Amazon Textract

Use the **HumanLoopConfig** parameter of the AnalyzeDocument API to initiate a human review workflow using Amazon Textract.

Programmatic Tutorials

The following tutorials provide example code and step-by-step instructions for creating human review workflows and worker task templates programmatically.

- Tutorial: Get Started Using the Amazon A2I API
- Create a Human Review Workflow (API)

- Create and Start a Human Loop
- Using Amazon Augmented AI with Amazon Rekognition in the *Amazon Rekognition Developer Guide*
- Using Amazon Augmented AI with Amazon Textract AnalyzeDocument in the *Amazon Textract Developer Guide*

Recommendations for choosing the right data preparation tool in SageMaker AI

Data preparation in machine learning refers to the process of collecting, preprocessing, and organizing raw data to make it suitable for analysis and modeling. This step ensures that the data is in a format from which machine learning algorithms can effectively learn. Data preparation tasks may include handling missing values, removing outliers, scaling features, encoding categorical variables, assessing potential biases and taking steps to mitigate them, splitting data into training and testing sets, labeling, and other necessary transformations to optimize the quality and usability of the data for subsequent machine learning tasks.

Choose a feature

There are 3 primary use cases for *data preparation* with Amazon SageMaker AI. Choose the use case that aligns with your requirements, and then refer to the corresponding recommended feature.

Use cases

The following are the primary uses cases when performing data preparation for Machine Learning.

- **Use case 1**: For those who prefer a visual interface, SageMaker AI provides ways to explore, prepare, and engineer features for model training through a point-and-click environment.
- **Use case 2**: For users comfortable with coding who want more flexibility and control over data preparation, SageMaker AI integrates tools into its coding environments for exploration, transformations, and feature engineering.
- **Use case 3**: For users focused on scalable data preparation, SageMaker AI offers serverless capabilities that leverage the Hadoop/Spark ecosystem for distributed processing of big data.

Recommended features

The following table outlines the key considerations and tradeoffs for the SageMaker AI features related to each data preparation use case for machine learning. To get started, identify the use case that aligns to your requirements and navigate to its recommended SageMaker AI feature.

Descriptor	Use case 1	Use case 2	Use case 3
SageMaker AI feature	Data Wrangler within Amazon SageMaker Canvas	Data preparation with SQL in Studio	Prepare data using EMR Serverless applications in Studio
Description	SageMaker Canvas is a visual low-code environment for building, training, and deploying machine learning models in SageMaker AI. Its integrated Data Wrangler tool allows users to combine, transform, and clean datasets through point-and-click interactions.	The SQL extension in Studio allows users to connect to Amazon Redshift, Snowflake, Athena, and Amazon S3 to author ad-hoc SQL queries, and preview results in JupyterLab notebooks. The output of these queries can be manipulated using Python and Pandas for additional processing, visualization, and transformation into formats usable for machine learning model development.	The integration between EMR Serverless and Amazon SageMaker Studio provides a scalable serverless environment for large-scale data preparation for machine learning using open-source frameworks such as Apache Spark and Apache Hive. Users can directly access EMR Serverless applications and data from their Studio notebooks to perform their data preparation tasks at scale.
Optimized for	Using a visual interface in which you can: • Create data preparation pipelines • Perform data analysis • Transform data using built-in transforms • Use genAI-powered natural language instructions for data transforms	For users whose data resides in Amazon Redshift, Snowflake, Athena, or Amazon S3 and want to combine exploratory SQL and Python for data analysis and preparation without the need to learn Spark.	For users who prefer a serverless experience with automatic resource provisioning and termination for scaling short-running or intermittent interactive workloads revolving around Apache Spark, while taking advantage of SageMaker AI's machine learning capabilities.

Descriptor	Use case 1	Use case 2	Use case 3
	Optimized for tabular data tasks such as handling missing values, encoding categorical variables, and applying data transformations.		

Descriptor	Use case 1	Use case 2	Use case 3
Considerations	• It may not be the optimal choice if your team already has expertise in Python, Spark, or other languages. • It might not be best suited if you need full flexibility to customize transformations to add complex business logic or require full control over your data processing environment.	• This feature is designed for structured data residing in Amazon Redshift, Snowflake, Athena, or Amazon S3 only. • If the size of your query results exceeds your SageMaker AI instance memory, the following notebook can guide you on getting started with Athena to prepare your data for ingestion by a SageMaker AI algorithm.	• The learning curve for users not familiar with EMR Serverless applications and Spark-based tools can be challenging. • This feature is better suited for interactive data preparation tasks and may not be as efficient as Amazon EMR clusters for large-scale, long-running, or complex data processing requirements involving massive amounts of data, extensive integration with other services, custom applications, or diverse distributed data processing frameworks beyond just Apache Spark. • While serverless computing can be cost-effective for short-lived tasks, it is essential to monitor and manage costs carefully, especially for long-running or resource-intensive workloads.

Descriptor	Use case 1	Use case 2	Use case 3
Recommended environment	Getting started with using SageMaker Canvas	Launch Studio	Launch Studio

Additional options

SageMaker AI offers the following additional options for preparing your data for use in machine learning models.

- the section called "Data preparation using Amazon EMR": For long-running, computationally intensive, large-scale data processing tasks, consider using Amazon EMR clusters from SageMaker Studio. Amazon EMR clusters are designed to handle massive parallelization and can scale to hundreds or thousands of nodes, making them well-suited for big data workloads that require frameworks like Apache Spark, Hadoop, Hive, and Presto. The integration of Amazon EMR with SageMaker Studio allows you to leverage the scalability and performance of Amazon EMR, while keeping your full ML experimentation, model training and deployment, centralized and managed within the SageMaker Studio environment.
- Prepare data using glue interactive sessions: You can use the Apache Spark-based serverless engine from AWS Glue interactive sessions to aggregate, transform, and prepare data from multiple sources in SageMaker Studio.
- Identify bias in training data using Amazon SageMaker Clarify processing jobs: SageMaker Clarify analyzes your data and detect potential biases across multiple facets. For example, you can use Clarify API in Studio to detect if your training data contains imbalanced representations or labeling biases between groups such as gender, race, or age. Clarify can help you identify these biases before training a model to avoid propagating biases into the model's predictions.
- Create, store, and share features: Amazon SageMaker Feature Store optimizes the discovery and reuse of curated features for machine learning. It provides a centralized repository to store feature data that can be searched and retrieved for model training. Storing features in a standardized format enables reuse across ML projects. The Feature Store manages the full lifecycle of features including lineage tracking, statistics, and audit trails for scalable and governed machine learning feature engineering.

- Label data with a human-in-the-loop: You can use SageMaker Ground Truth to manage the data labeling workflows of your training datasets.
- Use SageMaker Processing API: After performing exploratory data analysis and creating your data transformations steps, you can productionize your transformation code using SageMaker AI Processing jobs and automate your preparation workflow using SageMaker Model Building Pipelines.

Data preparation with SQL in Studio

Amazon SageMaker Studio provides a built-in SQL extension. This extension allows data scientists to perform tasks such as sampling, exploratory analysis, and feature engineering directly within their JupyterLab notebooks. It leverages AWS Glue connections to maintain a centralized data source catalog. The catalog stores metadata about various data sources. Through this SQL environment, data scientists can browse data catalogs, explore their data, author complex SQL queries, and further process the results in Python.

This section walks through configuring the SQL extension in Studio. It describes the capabilities enabled by this SQL integration and provides instructions for running SQL queries in JupyterLab notebooks.

To enable SQL data analysis, administrators must first configure AWS Glue connections to the relevant data sources. These connections allow data scientists to seamlessly access authorized datasets from within JupyterLab.

In addition to the administrator-configured AWS Glue connections, the SQL extension allows individual data scientists to create their own data source connections. These user-created connections can be managed independently and scoped to the user's profile through tag-based access control policies. This dual-level connection model - with both administrator-configured and user-created connections - provides data scientists with broader access to the data they need for their analysis and modeling tasks. Users can set up the necessary connections to their own data sources within the JupyterLab environment user interface (UI), without relying solely on the centralized connections established by the administrator.

> **Important**
>
> The user-defined connections creation capability is available as a set of standalone libraries in PyPI. To use this functionality, you need to install the following libraries in your JupyterLab environment:

- [amazon-sagemaker-sql-editor]
- [amazon-sagemaker-sql-execution]
- [amazon-sagemaker-sql-magic]

You can install these libraries by running the following commands in your JupyterLab terminal:

```
pip install amazon-sagemaker-sql-editor>=0.1.13
pip install amazon-sagemaker-sql-execution>=0.1.6
pip install amazon-sagemaker-sql-magic>=0.1.3
```

After installing the libraries, you will need to restart the JupyterLab server for the changes to take effect.

```
restart-jupyter-server
```

With access set up, JupyterLab users can:

- View and browse pre-configured data sources.
- Search, filter, and inspect database information elements such as tables, schemas, and columns.
- Auto-generate the connection parameters to a data source.
- Create complex SQL queries using the syntax-highlighting, auto-completion, and SQL formatting features of the extension's SQL editor.
- Run SQL statements from JupyterLab notebook cells.
- Retrieve the results of SQL queries as pandas DataFrames for further processing, visualization, and other machine learning tasks.

You can access the extension by choosing the SQL extension icon () in the left navigation pane of your JupyterLab application in Studio. Hovering over the icon displays its *Data Discovery* tool tip.

> **Important**
>
> - The JupyterLab image in SageMaker Studio contains the SQL extension by default, starting with SageMaker AI Distribution 1.6. The extension works with Python and SparkMagic kernels only.
> - The extension's user interface for exploring connections and data is only available in JupyterLab within Studio. It is compatible with Amazon Redshift, Amazon Athena, and Snowflake.

- If you are an administrator looking to create generic connections to data sources for the SQL extension, follow these steps:

  1. Enable the network communication between your Studio domain and the data sources to which you want to connect. To learn about the networking requirements, see the section called “Configure network access (for administrators)”.
  2. Check connection properties and instructions to create a secret for your data source in the section called “Create secrets for database access credentials”.
  3. Create the AWS Glue connections to your data sources in the section called “Create admin connections”.
  4. Grant the execution role of your SageMaker domain or user profiles the required permissions in the section called “Required IAM permissions (for administrators)”.

- If you are a data scientist looking to create your own connections to data sources for the SQL extension, follow these steps:

  1. Have your administrator:
     - Enable the network communication between your Studio domain and the data sources to which you want to connect. To learn about the networking requirements, see the section called “Configure network access (for administrators)”.
     - Grant the execution role of your SageMaker domain or user profiles the required permissions in the section called “Required IAM permissions (for administrators)”.

> **Note**
>
> Administrators can restrict user access to connections created within the JupyterLab application by configuring tag-based access control in the execution role.

2. Check connection properties and instructions to create a secret for your data source in the section called "Create secrets for database access credentials".
3. Create your connection in JupyterLab UI using the instructions in the section called "Create user-defined connections".

- If you are a data scientist looking to browse and query your data sources using the SQL extension, ensure that you or your administrator have set up the connections to your data sources first. Then, follow these steps:

  1. Create a private space to launch your JupyterLab application in Studio using the SageMaker distribution image version 1.6 or higher.
  2. If you are a user of the SageMaker distribution image version 1.6, load the SQL extension in a JupyterLab notebook by running `%load_ext amazon_sagemaker_sql_magic` in a notebook cell.

     For users of SageMaker distribution image versions 1.7 and later, no action is needed, the SQL extension loads automatically.
  3. Familiarize with the capabilities of the SQL extension in the section called "Features overview and usage".

Topics

Quickstart: Query data in Amazon S3

Users can analyze data stored in Amazon S3 by running SQL queries from JupyterLab notebooks using the SQL extension. The extension integrates with Athena enabling the functionality for data in Amazon S3 with a few extra steps.

This section walks you through the steps to load data from Amazon S3 into Athena and then query that data from JupyterLab using the SQL extension. You will create an Athena data source and AWS Glue crawler to index your Amazon S3 data, configure the proper IAM permissions to enable JupyterLab access to Athena, and connect JupyterLab to Athena to query the data. Following those few steps, you will be able to analyze Amazon S3 data using the SQL extension in JupyterLab notebooks.

Prerequisites

- Sign in to the AWS Management Console using an AWS Identity and Access Management (IAM) user account with admin permissions. For information on how to sign up for an AWS account and create a user with administrative access, see the section called "Complete Amazon SageMaker AI prerequisites".
- Have a SageMaker AI domain and user profile to access SageMaker Studio. For information on how to set a SageMaker AI environment, see the section called "Use quick setup".
- Have an Amazon S3 bucket and folder to store Athena query results, using the same AWS Region and account as your SageMaker AI environment. For information on how to create a bucket in Amazon S3, see Creating a bucket in the Amazon S3 documentation. You will configure this bucket and folder to be your query output location.

To access and query your data in Amazon S3:

- Step 1: Set up an Athena data source and AWS Glue crawler for your Amazon S3 data
- Step 2: Grant Studio the permissions to access Athena
- Step 3: Enable Athena default connection in JupyterLab
- Step 4: Query data in Amazon S3 from JupyterLab notebooks using the SQL extension

Step 1: Set up an Athena data source and AWS Glue crawler for your Amazon S3 data

Follow these steps to index your data in Amazon S3 and create tables in Athena.

> **Note**
>
> To avoid collisions between table names from different Amazon S3 locations, create a separate data source and crawler for each location. Each data source creates a table named after the folder that contain them unless prefixed.

1. Configure a query result location
   a. Go to the Athena console: https://console.aws.amazon.com/athena/.
   b. From the left menu, choose **Workgroups**.
   c. Follow the link for the `primary` workgroup and choose **Edit**.
   d. In the **Query result configuration** section, enter the Amazon S3 path for your output directory and then choose **Save changes**.
2. Create an Athena data source for your Amazon S3 data
   a. From the left menu in the Athena console, choose **Data sources** and then **Create Data Source**.
   b. Choose **S3 - AWS Glue Data Catalog** and then **Next**.
   c. Leave the default **AWS Glue Data Catalog in this account**, choose **Create a crawler in AWS Glue** and then **Create in AWS Glue**. This opens the AWS Glue console.
3. Use AWS Glue to crawl your data source
   a. Enter a name and a description for your new crawler and then choose **Next**.
   b. Under **Data Sources**, choose **Add a data source**.
      i. If the Amazon Amazon S3 bucket containing your data is in a different AWS account than your SageMaker AI environment, choose **In a different account** for the **Location of the S3 data**.
      ii. Enter the path to your dataset in Amazon S3. For example:

```
s3://dsoaws/nyc-taxi-orig-cleaned-split-parquet-per-year-multiple-files/
ride-info/year=2019/
```

iii. Keep all other default values and then choose **Add an Amazon S3 data source**. You should see a new Amazon S3 data source in the data sources table.

iv. Choose **Next**.

c. Configure the IAM role for the crawler to access your data.

> **Note**
>
> Each role is scoped down to the data source you specify. When reusing a role, edit the JSON policy to add any new resource you want to grant access to or create a new role for this data source.

i. Choose **Create new IAM role**.

ii. Enter a name for the role and then choose **Next**.

4. Create or select a database for your tables

a. If you do not have an existing database in Athena, choose **Add database** and then **Create a new database**.

b. Back to your previous crawler creation tab, in **Output configuration**, choose the **Refresh** button. You should now see your newly created database in the list.

c. Select your database, add an optional prefix in **Table name prefix** and then choose **Next**.

> **Note**
>
> For the previous example where your data is located at `s3://dsoaws/nyc-taxi-orig-cleaned-split-parquet-per-year-multiple-files/ride-info/year=2019/`, adding the prefix `taxi-ride-` will create a table named `taxi-ride-year_2019`. Adding a prefix helps prevent table name collisions when multiple data locations have identically named folders.

5. Choose **Create crawler**.

6. Run your crawler to index your data. Wait for the crawler run to reach a `Completed` status, which may take a few minutes.

To ensure that a new table was created, go to the left menu in AWS Glue and choose **Databases** then **Tables**. You should now see a new table containing your data.

Step 2: Grant Studio the permissions to access Athena

In the following steps you grant the execution role of your user profile permissions to access Athena.

1. Retrieve the ARN of the execution role associated with your user profile
   a. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/ and choose **Domains** in the left menu.
   b. Follow the name for your domain name.
   c. In the **User profiles** list, follow the name for your user profile.
   d. On the **User details** page, copy the ARN of the execution role.
2. Update the policy of your execution role
   a. Find your AWS region and account ID at the top right of the SageMaker AI console. Use these values and your database name to update the placeholders in the following JSON policy in a text editor.

      JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "GetS3AndDataSourcesMetadata",
            "Effect": "Allow",
            "Action": [
                "glue:GetDatabases",
                "glue:GetSchema",
                "glue:GetTables",
                "s3:ListBucket",
                "s3:GetObject",
                "s3:GetBucketLocation",
```

```
                "glue:GetDatabase",
                "glue:GetTable",
                "glue:ListSchemas",
                "glue:GetPartitions"
            ],
            "Resource": [
                "arn:aws:s3:::*",
                "arn:aws:glue:us-east-1:111122223333:catalog",
                "arn:aws:glue:us-east-1:111122223333:database/db-name"
            ]
        },
        {
            "Sid": "ExecuteAthenaQueries",
            "Effect": "Allow",
            "Action": [
                "athena:ListDataCatalogs",
                "athena:ListDatabases",
                "athena:ListTableMetadata",
                "athena:StartQueryExecution",
                "athena:GetQueryExecution",
                "athena:RunQuery",
                "athena:StartSession",
                "athena:GetQueryResults",
                "athena:ListWorkGroups",
                "s3:ListMultipartUploadParts",
                "s3:ListBucket",
                "s3:GetBucketLocation",
                "athena:GetDataCatalog",
                "s3:AbortMultipartUpload",
                "s3:GetObject",
                "s3:PutObject",
                "athena:GetWorkGroup"
            ],
            "Resource": [
                "arn:aws:s3:::*"
            ]
        },
        {
            "Sid": "GetGlueConnectionsAndSecrets",
            "Effect": "Allow",
            "Action": [
                "glue:GetConnections",
                "glue:GetConnection"
            ],
```

```
                "Resource": [
                    "*"
                ]
            }
        ]
    }
```

b. Go to the IAM console: https://console.aws.amazon.com/iam/ and choose **Roles** in the left menu.

c. Search for your role by role name.

> **Note**
>
> You can retrieve an execution role name from its Amazon Resource Name (ARN) by splitting the ARN on `'/'` and taking the last element. For example, in the following example of an ARN `arn:aws:iam::112233445566:role/SageMakerStudio-SQLExtension-ExecutionRole`, the name of the execution role is `SageMakerStudio-SQLExtension-ExecutionRole`.

d. Follow the link for your role.

e. In the **Permissions** tab, choose **Add permissions** then **Create inline policy**.

f. Choose the `JSON` format in the **Policy editor** section.

g. Copy the policy above and then choose **Next**. Ensure that you have replaced all the `account-id`, `region-name`, and `db-name` with their values.

h. Enter a name for your policy and then choose **Create policy**.

Step 3: Enable Athena default connection in JupyterLab

In the following steps, you enable a `default-athena-connection` in your JupyterLab application. The default Athena connection allows running SQL queries in Athena directly from JupyterLab, without needing to manually create a connection.

To enable the default Athena connection

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/ and choose **Studio** in the left menu. Using your domain and user profile, launch Studio.
2. Choose the JupyterLab application.

3. If you have not created a space for your JupyterLab application, choose **Create a JupyterLab space**. Enter a name for the space, keep the space as **Private**, and then choose **Create space**. Run your space using the latest version of the SageMaker AI Distribution image.

   Otherwise, choose **Run space** on your space to launch a JupyterLab application.

4. Enable Athena default connection:

   a. In your JupyterLab application, navigate to the **Settings** menu in the top navigation bar and open the **Settings Editor** menu.

   b. Choose **Data Discovery**.

   c. Check the box for **Enable default Athena connection**.

   d. In your JupyterLab application, choose the SQL extension icon ( ) in the left navigation pane to open the SQL extension.

   e. Choose the **Refresh** button at the bottom of the data discovery panel. You should see a `default-athena-connection` in the list of connections.

Step 4: Query data in Amazon S3 from JupyterLab notebooks using the SQL extension

You are ready to query your data using SQL in your JupyterLab notebooks.

1. Open the connection `default-athena-connection` and then **AWSDataCatalog**.

2. Navigate to your database and choose the three dots icon ( ) on its right. Select **Query in notebook**.

   This automatically populates a notebook cell in JupyterLab with the relevant `%%sm_sql` magic command to connect to the data source. It also adds a sample SQL statement to help you start querying right away.

   > **Note**
   >
   > Ensure to load the extension in the top cell before you run an SQL query.

You can further refine the SQL query using the auto-complete and highlighting features of the extension. See the section called "SQL editor" for more information on using the SQL extension SQL editor.

SQL extension features and usage

This section details the various features of the JupyterLab SQL extension in Studio, and provides instructions on how to use them. Before you can use the SQL extension to access and query data from your JupyterLab notebooks, an administrator must first configure the connection to your data sources. For information on how administrators can create connections to data sources, see the section called "Data source connections".

> **Note**
>
> To use the SQL extension, your JupyterLab application must run on a SageMaker AI distribution image version 1.6 or higher. These SageMaker images have the extension pre-installed.

The extension provides two components to help you access, discover, query, and analyze data from pre-configured data sources.

- Use the *user interface* of the SQL extension to discover and explore your data sources. The UI capabilities can be further divided into the following subcategories.
  - With the **data exploration** UI element, you can browse your data sources and explore their tables, columns, and metadata. For details on the data exploration features of the SQL extension, see the section called "Browse data".
  - The **connection caching** element caches connections for quick access. For details on connection caching in the SQL extension, see the section called "Connection caching".
- Use the *SQL Editor and Executor* to write, edit, and run SQL queries against connected data sources.
  - With the **SQL editor** element, you can write, format, and validate SQL statements within the notebooks of your JupyterLab application in Studio. For details on the SQL editor features, see the section called "SQL editor".

- With the **SQL execution** element, you can run your SQL queries and visualize their results from the notebooks of your JupyterLab application in Studio. For details on the SQL execution capabilities, see the section called "SQL execution".

Browse data using SQL extension

To open the SQL extension user interface (UI), choose the SQL extension icon

()

in the navigation pane of your JupyterLab application in Studio. The left panel data discovery view expands and displays all pre-configured data store connections to Amazon Athena, Amazon Redshift, and Snowflake.

From there, you can:

- Expand a specific connection to explore its databases, schemas, tables or views, and columns.
- Search for a specific connection using the search box in the SQL extension UI. The search returns any databases, schemas, tables, or views that partially match the string you enter.

> **Note**
>
> If Athena is already set up in your AWS account, you can enable a `default-athena-connection` in your JupyterLab application. This allows you to run Athena queries without needing to manually create the connection. To enable the default Athena connection:
>
> 1. Check with your administrator that your execution role has the required permissions to access Athena and the AWS Glue catalog. For details on the permissions required, see Configure an AWS Glue connection for Athena
> 2. In your JupyterLab application, navigate to the **Settings** menu in the top navigation bar and open the **Settings Editor** menu.
> 3. Choose **Data Discovery**.
> 4. Check the box for **Enable default Athena connection**.
> 5. You can update the default `primary` WorkGroup if needed.

To query a database, schema, or table in a JupyterLab notebook, from a given connection in the SQL extension pane:

- Choose the three dots icon ( ) on the right side of any database, schema, or table.
- Select **Query in notebook** from the menu.

  This automatically populates a notebook cell in JupyterLab with the relevant `%%sm_sql` magic command to connect to the data source. It also adds a sample SQL statement to help you start querying right away. You can further refine the SQL query using the auto-complete and highlighting features of the extension. See the section called "SQL editor" for more information on using the SQL extension SQL editor.

At the table level, the three dots icon provides the additional option to choose to **Preview** a table's metadata.

The JupyterLab notebook cell content below shows an example of what is automatically generated when selecting the **Query in notebook** menu on a `redshift-connection` data source in the SQL extension pane.

```
%%sm_sql --metastore-id redshift-connection --metastore-type GLUE_CONNECTION

-- Query to list tables from schema 'dev.public'
SHOW TABLES
FROM
  SCHEMA "dev"."public"
```

Use the *less than* symbol (

) at the top of the SQL extension pane to clear the search box or return to the list of your connections.

> **Note**
>
> The extension caches your exploration results for fast access. If the cached results are outdated or a connection is missing from your list, you can manually refresh the cache

by choosing the **Refresh** button at the bottom of the SQL extension panel. For more information on connection caching, see the section called "Connection caching".

SQL editor features of the JupyterLab SQL extension

The SQL extension provides magic commands that enable the SQL editor functionalities within your JupyterLab notebook cells.

If you are a user of the SageMaker distribution image version 1.6, you must load the SQL extension magic library by running `%load_ext amazon_sagemaker_sql_magic` in a JupyterLab notebook. This turns on SQL editing features.

For users of SageMaker distribution image versions 1.7 and later, no action is needed, the SQL extension loads automatically.

Once the extension is loaded, add the `%%sm_sql` magic command at the beginning of a cell to activate the following capabilities of the SQL editor.

- **Connection-selection dropdown**: Upon adding an `%%sm_sql` magic command to a cell, a dropdown menu appears at the top of the cell with your available data source connections. Select a connection to automatically fill in the parameters needed to query that data source. The following is an example of an `%%sm_sql` magic command string generated by selecting the connection named `connection-name`.

  ```
  %%sm_sql --metastore-type GLUE_CONNECTION --metastore-id connection-name
  ```

  Use the SQL editor's features below to build your SQL queries, then run the query by running the cell. For more information on the SQL execution capabilities, see the section called "SQL execution".
- **Query result dropdown**: You can specify how to render query results by selecting a result type from the dropdown menu next to your connection-selection dropdown menu. Choose between the following two alternatives:
  - **Cell Output**: (default) This option displays the result of your query in the notebook cell output area.
  - **Pandas Dataframe**: This option populates a pandas DataFrame with the query results. An extra input box lets you name the DataFrame when you choose this option.

- **SQL syntax highlight**: The cell automatically visually distinguishes SQL keywords, clauses, operators, and more by color and styling. This makes SQL code easier to read and understand. Keywords such as `SELECT`, `FROM`, `WHERE`, and built-in functions such as `SUM` and `COUNT`, or clauses such as `GROUP BY` and more are highlighted in a different color and bold style.
- **SQL formatting**: You can apply consistent indents, capitalization, spacing, and line breaks to group or separate SQL statements and clauses in one of the following ways. This makes SQL code easier to read and understand.
  - Right-click on the SQL cell and choose **Format SQL**.
  - When the SQL cell is in focus, use the *ALT + F* shortcut on Windows or *Option + F* on MacOS.
- **SQL auto-completion**: The extension provides automatic suggestions and completion of SQL keywords, functions, table names, column names, and more as you type. As you start typing an SQL keyword such as `SELECT` or `WHERE`, the extension displays a pop-up with suggestions to auto-complete the rest of the word. For example, when typing table or column names, it suggests matching table and column names defined in the database schema.

> **Important**
>
> To enable SQL auto-completion in JupyterLab notebooks, users of the SageMaker AI distribution image version 1.6 must run the following `npm install -g vscode-jsonrpc sql-language-server` command in a terminal. After the installation completes, restart the JupyterLab server by running `restart-jupyter-server`. For users of SageMaker distribution image versions 1.7 and later, no action is needed.

The cell offers two methods for auto-completing recognized SQL keywords:

- Explicit invocation (recommended): Choose the **Tab** key to initiate the context-aware suggestion menu, then choose **Enter** to accept the suggested item.
- Continuous hinting: The cell automatically suggests completions as you type.

> **Note**
>
> - Auto-completion is only triggered if the SQL keywords are in uppercase. For instance, entering `SEL` prompts for `SELECT`, but typing `sel` does not.

- The first time you connect to a data source, SQL auto-completion indexes the data source's metadata. This indexing process may take some time to complete depending on the size of your databases.

SQL execution features of the JupyterLab SQL extension

You can execute SQL queries against your connected data sources in the SQL extension of JupyterLab. The following sections explain the most common parameters for running SQL queries inside JupyterLab notebooks:

- Create a simple connection in the section called “Create a simple connection”.
- Save your query results in a pandas DataFrame in the section called “Save results in a DataFrame”.
- Override or add to connection properties defined by your administrator in the section called “Override connection properties”.
- the section called “Provide dynamic values in SQL queries”.

When you run a cell with the `%%sm_sql` magic command, the SQL extension engine executes the SQL query in the cell against the data source specified in the magic command parameters.

To see the details of the magic command parameters and supported formats, run `%%sm_sql?`.

Important

To use Snowflake, users of the SageMaker distribution image version 1.6 must install the Snowflake Python dependency by running the following `micromamba install snowflake-connector-python -c conda-forge` command in a terminal of their JupyterLab application. Restart the JupyterLab server by running `restart-jupyter-server` in the terminal after the installation is complete.
For SageMaker distribution image versions 1.7 and later, the Snowflake dependency is pre-installed. No action is needed.

Create a simple magic command connection string

If your administrator has configured the connections to your data sources, follow these steps to easily create a connection string in a notebook cell:

1. Open a notebook cell that uses `%%sm_sql`.
2. Select a pre-configured connection to your desired data source from the connection dropdown menu above the cell.
3. This will automatically populate the parameters needed to query that data source.

Alternatively, you can specify connection properties inline in the cell.

Choosing a connection from the dropdown menu inserts the following two parameters into the default magic command string. The parameters contain the connection information your administrator configured.

- `--metastore-id`: The name of the connection object that holds your connection parameters.
- `--metastore-type`: The type of meta-store corresponding to `--metastore-id`. The SQL extension uses AWS Glue connections as a connection meta-store. This value is automatically set to `GLUE_CONNECTION`.

For example, the connection string to a pre-configured Amazon Athena data store looks like the following:

```
%%sm_sql --metastore-id athena-connection-name --metastore-type GLUE_CONNECTION
```

Save SQL query results in a pandas DataFrame

You can store the results of your SQL query in a pandas DataFrame. The easiest way to output query results to a DataFrame is to use the the section called "SQL editor" query-result dropdown and choose the **Pandas dataframe** option.

Alternatively, you can add the parameter `--output '{"format": "DATAFRAME", "dataframe_name": "dataframe_name"}'` to your connection string.

For example, the following query extracts details of customers with the highest balance from the `Customer` table in Snowflake's `TPCH_SF1` database, using both pandas and SQL:

- In this example, we extract all the data from the customer table and save then in a DataFrame named `all_customer_data`.

```
%%sm_sql --output '{"format": "DATAFRAME", "dataframe_name": "all_customer_data"}' --
metastore-id snowflake-connection-name --metastore-type GLUE_CONNECTION
SELECT * FROM SNOWFLAKE_SAMPLE_DATA.TPCH_SF1.CUSTOMER
```

```
Saved results to all_customer_data
```

- Next, we extract the details of the highest account balance from the DataFrame.

```
all_customer_data.loc[all_customer_data['C_ACCTBAL'].idxmax()].values
```

```
array([61453, 'Customer#000061453', 'RxNgWcyl5RZD4qOYnyT3', 15,
'25-819-925-1077', Decimal('9999.99'), 'BUILDING','es. carefully regular requests
 among the blithely pending requests boost slyly alo'],
dtype=object)
```

Override connection properties

Your administrator's predefined connection definitions may not have the exact parameters you need to connect to a specific data store. You can add or override parameters in the connection string by using the `--connection-properties` argument.

The arguments are applied in the following order of precedence:

1. Overridden connection properties provided as inline arguments.
2. Connection properties present in the AWS Secrets Manager.
3. Connection properties in the AWS Glue connection.

If the same connection property is present in all three (command line argument, Secrets Manager, and connection), the value provided in the command line argument takes precedence.

For more information on the available connection properties per data source, see the [the section called "Connection parameters"](#).

The following example illustrates a connection property argument that sets the schema name for Amazon Athena.

```
%%sm_sql --connection-properties '{"schema_name": "athena-db-name"}' --metastore-
id athena-connection-name --metastore-type GLUE_CONNECTION
```

Use query parameters to provide dynamic values in SQL queries

Query parameters can be used to provide dynamic values in SQL queries.

In the following example, we pass a query parameter to the `WHERE` clause of the query.

```
# How to use '--query-parameters' with ATHENA as a data store
%%sm_sql --metastore-id athena-connection-name --metastore-type GLUE_CONNECTION --
query-parameters '{"parameters":{"name_var": "John Smith"}}'
SELECT * FROM my_db.my_schema.my_table WHERE name = (%(name_var)s);
```

SQL extension connection caching

The SQL extension extension defaults to caching connections to prevent the creation of multiple connections for the same set of connection properties. The cached connections can be managed using the `%sm_sql_manage` magic command.

The following topics describe how to manage your cached connections.

Topics

- [Create cached connections]
- [List cached connections]
- [Clear cached connections]
- [Disable cached connections]

Create cached connections

You can create cached connections by specifying a connection name in the `--connection-name` parameter of your connection string. This is particularly useful when multiple connection properties are overridden for a specific use case, and there's a need to reuse the same properties without retyping them.

For example, the code below saves an Athena connection with an overridden schema connection property using the name `--connection-name my_athena_conn_with_schema`, and then reuses it in another cell:

```
%%sm_sql --connection-name my_athena_conn_with_schema --connection-properties
 '{"schema_name": "sm-sql-private-beta-db"}' --metastore-id sm-sql-private-beta-athena-
connection --metastore-type GLUE_CONNECTION
SELECT * FROM "covid_table" LIMIT 2
```

```
%%sm_sql --connection-name my_athena_conn_with_schema
SELECT * FROM "covid_table" LIMIT 2
```

List cached connections

You can list your cached connections by running the following command:

```
%sm_sql_manage --list-cached-connections
```

Clear cached connections

To clear all cached connections, run the following command:

```
%sm_sql_manage --clear-cached-connections
```

Disable cached connections

To disable connection caching, run the following command:

```
%sm_sql_manage --set-connection-reuse False
```

Configure network access between Studio and data sources (for administrators)

This section provides information about how administrators can configure a network to enable communication between Amazon SageMaker Studio and Amazon Redshift or Amazon Athena, either within a private Amazon VPC or over the internet. The networking instructions vary based on whether the Studio domain and the data store are deployed within a private Amazon Virtual Private Cloud (VPC) or communicate over the internet.

By default, Studio runs in an AWS managed VPC with internet access. When using an internet connection, Studio accesses AWS resources, such as Amazon S3 buckets, over the internet. However, if you have security requirements to control access to your data and job containers, we recommend that you configure Studio and your data store (Amazon Redshift or Athena) so that your data and containers aren't accessible over the internet. To control access to your resources or run Studio without public internet access, you can specify the `VPC only` network access type when you onboard to [Amazon SageMaker AI domain](). In this scenario, Studio establishes connections with other AWS services via private [VPC endpoints](). For information about configuring Studio in `VPC only` mode, see [Connect Studio to external resources in a VPC]().

> **Note**
>
> To connect to Snowflake, the VPC of the Studio domain must have internet access.

The first two sections describe how to ensure communication between your Studio domain and your data store in VPCs without public internet access. The last section covers how to ensure communication between Studio and your data store using an internet connection. Prior to connecting Studio and your data store without internet access, make sure to establish endpoints for Amazon Simple Storage Service, Amazon Redshift or Athena, SageMaker AI, and for Amazon CloudWatch and AWS CloudTrail (logging and monitoring).

- If Studio and the data store are in different VPCs, either in the same AWS account or in separate accounts, see [Studio and the data store are deployed in separate VPCs]().
- If Studio and the data store are in the same VPC, see [Studio and the data store are deployed in the same VPC]().
- If you chose to connect Studio and the data store over the public internet, see [Studio and the data store communicate over public internet]().

Studio and the data store are deployed in separate VPCs

To allow communication between Studio and a data store deployed in different VPCs:

1. Start by connecting your VPCs through a VPC peering connection.
2. Update the routing tables in each VPC to allow bidirectional network traffic between Studio subnets and the data store subnets.
3. Configure your security groups to allow inbound and outbound traffic.

The configuration steps are the same whether Studio and the data store are deployed in a single AWS account or across different AWS accounts.

1. **VPC peering**

   Create a VPC peering connection to facilitate the networking between the two VPCs (Studio and the data store).

   a. From the Studio account, on the VPC dashboard, choose **Peering connections**, then **Create peering connection**.
   b. Create your request to peer the Studio VPC with the data store VPC. When requesting peering in another AWS account, choose **Another account** in **Select another VPC to peer with**.

      For cross-account peering, the administrator must accept the request from the SQL engine account.

      When peering private subnets, you should enable private IP DNS resolution at the VPC peering connection level.

2. **Routing tables**

   Configure the routing to allow network traffic between Studio and data store VPC subnets in both directions.

   After you establish the peering connection, the administrator (on each account for cross account access) can add routes to the private subnet route tables to route the traffic between Studio and the data store VPCs' subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard.

3. **Security groups**

   Lastly, the security group of Studio's domain VPC must allow outbound traffic, and the security group of the data store's VPC must allow inbound traffic on your data store port from Studio's VPC security group.

Studio and the data store are deployed in the same VPC

If Studio and the data store are in different private subnets in the same VPC, add routes in each private subnet's route table. The routes should allow traffic to flow between the Studio subnets and the data store subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard. If you deployed Studio and the data store in the same VPC and the same subnet, you do not need to route the traffic.

Regardless of any routing table updates, the security group of Studio's domain VPC must allow outbound traffic, and the security group of the data store's VPC must allow inbound traffic on its port from Studio's VPC security group.

Studio and the data store communicate over public internet

By default, Studio provides a network interface that allows communication with the internet through an internet gateway in the VPC associated with the Studio domain. If you choose to connect to your data store through the public internet, your data store needs to accept inbound traffic on its port.

A NAT gateway must be used to allow instances in private subnets of multiple VPCs to share a single public IP address provided by the internet gateway when accessing the internet.

> **Note**
>
> Each port opened for inbound traffic represents a potential security risk. Carefully review custom security groups to ensure that you minimize vulnerabilities.

SQL extension data source connections

Before using the SQL extension in JupyterLab notebooks, administrators or users must create AWS Glue connections to their data sources. The SQL extension allows connecting to data sources such as Amazon Redshift Amazon Athena, or Snowflake.

To set up the connections, administrators must first ensure their network configuration allows communication between Studio and the data sources and then grant the necessary IAM permissions to allow Studio to access the data sources. For information on how administrators can set up the networking, see the section called “Configure network access (for administrators)”. For information on what policies must be setup, see the section called “Required IAM permissions (for administrators)”. Once the connections are set up, data scientists can use the SQL extension in their JupyterLab notebooks to browse and query the connected data sources.

> **Note**
>
> We recommend storing your database access credentials as a secret in Secrets Manager. To learn about how to create secrets for storing Amazon Redshift or Snowflake access credentials, see the section called “Create secrets for database access credentials”.

This section explains how to set up an AWS Glue connection and lists the IAM permissions required for the Studio JupyterLab application to access the data through the connection.

> **Note**
>
> Amazon SageMaker Assets integrates Amazon DataZone with Studio. It includes a SageMaker AI blueprint for administrators to create Studio environments from Amazon DataZone projects within an Amazon DataZone domain.
> Users of a JupyterLab application launched from a Studio domain created with the blueprint can automatically access AWS Glue connections to data assets in their Amazon DataZone catalog when using the SQL extension. This allows querying those data sources without manually setting up connections.

Topics

- Create secrets for database access credentials in Secrets Manager
- Create AWS Glue connections (for administrators)
- Create user-defined AWS Glue connections
- Set up the IAM permissions to access the data sources (for administrators)

Create secrets for database access credentials in Secrets Manager

Before creating your connection, we recommend storing your database access credentials as a secret in AWS Secrets Manager. Alternatively, you can generate temporary database credentials based on permissions granted through an AWS Identity and Access Management (IAM) permissions policy to manage the access that your users have to your database. For more information, see Using IAM authentication to generate database user credentials

Create a secret for Amazon Redshift access credentials

To store Amazon Redshift information in AWS Secrets Manager

1. From the AWS Management Console, navigate to Secrets Manager.
2. Choose **Store a new secret**.
3. Under **Secret type**, choose **Credentials for Amazon Redshift**.
4. Enter the administrator username and password configured when launching the Amazon Redshift cluster.

5. Select the Amazon Redshift cluster associated with the secrets.
6. Name your secret.
7. The remaining settings can be left at their default values for initial secret creation, or customized if required.
8. Create the secret and retrieve its ARN.

Create a secret for Amazon Redshift Serverless access credentials

If you need to connect to Amazon Redshift Serverless, follow these steps

1. From the AWS Management Console, navigate to Secrets Manager.
2. Choose **Store a new secret**.
3. Under **Secret type**, choose **Other type of secret**.
4. In the **Key-value pairs**, choose **Plaintext**, and then copy the following JSON content. Replace the user, and password with their actual values:

```
{
  "user": "redshift_user",
  "password": "redshift_password"
}
```

5. Create the secret and retrieve its ARN..
6. When creating a new connection in SQL extension in JupyterLab, supply all other Amazon Redshift connection parameters as needed.

Create a secret for Snowflake access credentials

This section provides details on the secret and connection properties in JSON definition files that are specific to Snowflake. Before creating your connection, we recommend storing your Snowflake access credentials as a secret in Secrets Manager.

To store Amazon Redshift information in Secrets Manager

1. From the AWS Management Console, navigate to Secrets Manager.
2. Choose **Store a new secret**.
3. Under **Secret type**, choose **Other type of secret**.

4. In the key-value pair, choose **Plaintext**, and then copy the following JSON content. Replace the `user`, `password`, and `account` by their values.

```
{
    "user":"snowflake_user",
    "password":"snowflake_password",
    "account":"account_id"
}
```

5. Name the secret.
6. The remaining settings can be left at their default values for initial secret creation, or customized if required.
7. Create the secret and retrieve its ARN.

Create AWS Glue connections (for administrators)

To use data sources with the SQL extension, administrators can set up AWS Glue connections for each data source. These connections store the necessary configuration details to access and interact with the data sources. Once the connections are created, and the appropriate permissions are granted, the connections become visible to all users of the the section called “Amazon SageMaker Studio spaces” that share the same execution role.

To create these connections:

- First, create a JSON file that defines the connection properties for each data source. The JSON file includes details such as the data source identifier, access credentials, and other relevant configuration parameters to access the data sources through the AWS Glue connections.
- Then use the AWS Command Line Interface (AWS CLI) to create the AWS Glue connection, passing the JSON file as a parameter. The AWS CLI command reads the connection details from the JSON file and establishes the appropriate connection.

> **Note**
>
> The SQL extension supports creating connections using the AWS CLI only.

Before creating AWS Glue connections, ensure that you complete the following steps:

- Install and configure the AWS Command Line Interface (AWS CLI). For more information about how to install and configure the AWS CLI, see About AWS CLI version 2. Ensure that the access keys and tokens of the IAM user or role used to configure the AWS CLI have the required permissions to create AWS Glue connections. Add a policy that allows the `glue:CreateConnection` action otherwise.
- Understand how to use AWS Secrets Manager. We recommend that you use Secrets Manager to provide connection credentials and any other sensitive information for your data store. For more information on using Secrets Manager to store credentials, see Storing connection credentials in AWS Secrets Manager.

Create a connection definition JSON file

To create an AWS Glue connection definition file, create a JSON file to define the connection details on the machine where you have installed and configured the AWS CLI. For this example, name the file `sagemaker-sql-connection.json`.

The connection definition file should follow the following general format:

- **Name** is the name for the connection.
- **Description** is a textual description of the connection.
- **ConnectionType** is the type of connection. Choose `REDSHIFT`, `ATHENA`, or `SNOWFLAKE`.
- **ConnectionProperties** is a map of key-value pairs for the connection properties, such as the ARN of your AWS secret, or the name of your database.

```
{
    "ConnectionInput": {
        "Name": <GLUE_CONNECTION_NAME>,
        "Description": <GLUE_CONNECTION_DESCRIPTION>,
        "ConnectionType": "REDSHIFT | ATHENA | SNOWFLAKE",
        "ConnectionProperties": {
            "PythonProperties": "{\"aws_secret_arn\": <SECRET_ARN>, \"database\":
 <...>}"
        }
    }
}
```

Note

- The properties within the `ConnectionProperties` key consist of stringified key-value pairs. Escape any double quotes used in the keys or values with a backslash (\) character.
- All properties available in Secrets Manager can also be directly provided through `PythonProperties`. However, it is not recommended to include sensitive fields such as passwords in `PythonProperties`. Instead, the preferred approach is to use Secrets Manager.

Connection definition files specific to different data stores can be found in the following sections.

The connection definition files for each data source contain the specific properties and configuration required to connect to those data stores from the SQL extension. Refer to the appropriate section for details on defining connections to that source.

- To create an AWS Glue connection for Amazon Redshift, see the sample definition file in the section called "Configure an AWS Glue connection for Amazon Redshift".
- To create an AWS Glue connection for Amazon Athena, see the sample definition file in the section called "Configure an AWS Glue connection for Athena".
- To create an AWS Glue connection for Snowflake, see the sample definition file in the section called "Configure an AWS Glue connection for Snowflake".

Configure an AWS Glue connection for Amazon Redshift

This section provides details on the secret and connection properties in JSON definition files that are specific to Amazon Redshift. Before creating your connection configuration file, we recommend storing your Amazon Redshift access credentials as a secret in Secrets Manager. Alternatively, you can generate temporary database credentials based on permissions granted through an AWS Identity and Access Management (IAM) permissions policy to manage the access that your users have to your Amazon Redshift database. For more information, see Using IAM authentication to generate database user credentials.

Create a secret for Amazon Redshift access credentials

To store Amazon Redshift information in AWS Secrets Manager

1. From the AWS console, navigate to Secrets Manager.

2. Choose **Store a new secret**.
3. Under **Secret type**, choose **Credentials for Amazon Redshift**.
4. Enter the administrator username and password configured when launching the Amazon Redshift cluster.
5. Select the Amazon Redshift cluster associated with the secrets.
6. Name your secret.
7. The remaining settings can be left at their default values for initial secret creation, or customized if required.
8. Create the secret and retrieve its ARN.

Configure an AWS Glue connection for Amazon Redshift

The SQL extension connects to data sources using custom AWS Glue connections. For general information on creating AWS Glue connections to connect a data source, see the section called "Create admin connections". The following example is a sample AWS Glue connection definition for connecting to Amazon Redshift.

Before creating a new connection, keep these recommendations in mind:

- The properties within the `PythonProperties` key consist of stringified key-value pairs. Escape any double quotes used in the keys or values with a backslash (\) character.
- In the connection definition file, enter the name and description of the connection, replace the ARN of the secret in `aws_secret_arn` with the ARN of the secret previously created.
- Ensure that the database declared by its name in the connection definition above matches the cluster database. You can verify this by going to the cluster details page on Amazon Redshift console, and verifying the database name under **Database configurations** in **Properties** section.
- For additional parameters, see the list of connection properties supported by Amazon Redshift in the section called "Amazon Redshift connection parameters".

> **Note**
>
> - By default, the SQL extension connector for Python runs all queries in a transaction, unless the `auto_commit` in connection properties is set to `true`.
> - You can add all connection parameters, including the `database` name, to a secret.

```
{
  "ConnectionInput": {
      "Name": "Redshift connection name",
      "Description": "Redshift connection description",
      "ConnectionType": "REDSHIFT",
      "ConnectionProperties": {
          "PythonProperties":"{\"aws_secret_arn\":
 \"arn:aws:secretsmanager:region:account_id:secret:secret_name\", \"database\":
\"database_name\", \"database_metadata_current_db_only\": false}"
      }
  }
}
```

Once your definition file is updated, follow the steps in the section called "Create a AWS Glue connection" to create your AWS Glue connection.

Configure an AWS Glue connection for Athena

This section provides details on the connection properties in JSON definition files that are specific to Athena.

Configure an AWS Glue connection for Athena

The SQL extension connects to data sources using custom AWS Glue connections. For general information on creating AWS Glue connections to connect a data source, see the section called "Create admin connections". The following example is a sample AWS Glue connection definition for connecting to Athena.

Before creating a new connection, keep these recommendations in mind:

- The properties within the `ConnectionProperties` key consist of stringified key-value pairs. Escape any double quotes used in the keys or values with a backslash (\) character.
- In the connection definition file, enter the name and description of the connection, replace the `catalog_name` with the name of your catalog, `s3_staging_dir` with the Amazon S3 URI (Uniform Resource Identifier) of your output directory in your Amazon S3 bucket, and the `region_name` with the region of your Amazon S3 bucket.
- For additional parameters, refer to the list of connection properties supported by Athena in the section called "Athena connection parameters".

Note

- You can add all connection parameters, including the `catalog_name` or `s3_staging_dir`, to a secret.
- If you specify a `workgroup`, you don't need to specify `s3_staging_dir`.

```
{
    "ConnectionInput": {
        "Name": "Athena connection name",
        "Description": "Athena connection description",
        "ConnectionType": "ATHENA",
        "ConnectionProperties": {
            "PythonProperties": "{\"catalog_name\": \"catalog_name\",\"s3_staging_dir
\": \"s3://amzn-s3-demo-bucket_in_same_region/output_query_results_dir/\",
 \"region_name\": \"region\"}"
        }
    }
}
```

Once your definition file is updated, follow the steps in the section called "Create a AWS Glue connection" to create your AWS Glue connection.

Configure an AWS Glue connection for Snowflake

This section provides details on the secret and connection properties in JSON definition files that are specific to Snowflake. Before creating your connection configuration file, we recommend storing your Snowflake access credentials as a secret in Secrets Manager.

Create a secret for Snowflake access credentials

To store Amazon Redshift information in Secrets Manager

1. From the AWS console, navigate to AWS Secrets Manager.
2. Choose **Store a new secret**.
3. Under **Secret type**, choose **Other type of secret**.
4. In the key-value pair, choose **Plaintext**, and then copy the following JSON content. Replace the `user`, `password`, and `account` by their values.

```
{
    "user":"snowflake_user",
    "password":"snowflake_password",
    "account":"account_id"
}
```

5. Name the secret.
6. The remaining settings can be left at their default values for initial secret creation, or customized if required.
7. Create the secret and retrieve its ARN.

Configure an AWS Glue connection for Snowflake

The SQL extension connects to data sources using custom AWS Glue connections. For general information on creating AWS Glue connections to connect a data source, see the section called "Create admin connections". The following example is a sample AWS Glue connection definition for connecting to Snowflake.

Before creating a new connection, keep these recommendations in mind:

- The properties within the `ConnectionProperties` key consist of stringified key-value pairs. Escape any double quotes used in the keys or values with a backslash (\) character.
- In the connection definition file, enter the name and description of the connection, then replace the ARN of the secret in `aws_secret_arn` with the ARN of the secret previously created, and your account ID in `account`.
- For additional parameters, refer to the list of connection properties supported by Snowflake in the section called "Snowflake connection parameters".

> **Note**
>
> You can add all connection parameters, including the `account`, to a secret.

```
{
    "ConnectionInput": {
        "Name": "Snowflake connection name",
        "Description": "Snowflake connection description",
```

```
        "ConnectionType": "SNOWFLAKE",
        "ConnectionProperties": {
            "PythonProperties":  "{\"aws_secret_arn\":
 \"arn:aws:secretsmanager:region:account_id:secret:secret_name\", \"account\":
\"account_id\"}"}"
        }
    }
}
```

Once your definition file is updated, follow the steps in the section called "Create a AWS Glue connection" to create your AWS Glue connection.

Create AWS Glue connections

To create an AWS Glue connection through the AWS CLI, use your connection definition file and run this AWS CLI command. Replace the `region` placeholder with your AWS Region name and provide the local path to your definition file.

> **Note**
>
> The path to your configuration definition file must be preceded by `file://`.

```
aws --region region glue create-connection --cli-input-json file://path_to_file/
sagemaker-sql-connection.json
```

Verify that the AWS Glue connection was created by running the following command and check for your connection name.

```
aws --region region glue get-connections
```

Alternatively, you can update an existing AWS Glue connection as follows:

- Modify the AWS Glue connection definition file as required.
- Run the following command to update the connection.

  ```
  aws --region region glue update-connection --name glue_connection_name --cli-input-
  json file://path_to_file/sagemaker-sql-connection.json
  ```

Create user-defined AWS Glue connections

Note

All AWS Glue connections created by users via the SQL extension UI are automatically tagged with the following:

- `UserProfile: user-profile-name`
- `AppType: "JL"`

Those tags applied to the AWS Glue connections created via the SQL extension UI serve two purposes. The `"UserProfile": user-profile-name` tag allows the identification of the specific user profile that created the AWS Glue connection, providing visibility into the user responsible for the connection. The `"AppType": "JL"` tag categorizes the provenance of the connection, associating it with the JupyterLab application. This allows these connections to be differentiated from those that may have been created through other means, such as the AWS CLI.

Prerequisites

Before creating a AWS Glue connection using the SQL extension UI, ensure that you have completed the following tasks:

- Have your administrator:
  - Enable the network communication between your Studio domain and the data sources to which you want to connect. To learn about the networking requirements, see the section called "Configure network access (for administrators)".
  - Ensure that the necessary IAM permissions are set up for managing AWS Glue connections and access to Secrets Manager. To learn about the required permissions, see the section called "Required IAM permissions (for administrators)".

  Note

  Administrators can restrict user access to only the connections that were created by a user within the JupyterLab application. This can be done by configuring tag-based access control scoped down to the user profile.

- Check the connection properties and instructions to create a secret for your data source in the section called "Create secrets for database access credentials".

User workflow

The following steps provide the user workflow when creating user connections:

1. **Select the data source type**: Upon choosing the *Add new connection* icon, a form opens, prompting the user to select the type of data source they want to connect to, such as Amazon Redshift, Athena, or Snowflake.
2. **Provide connection properties**: Based on the selected data source, the relevant connection properties are dynamically loaded. The form indicates which fields are mandatory or optional for the chosen data source. To learn about the available properties for your data source, see the section called "Connection parameters".
3. **Select your AWS Secrets Manager ARN**: For Amazon Redshift and Snowflake data sources, the user is prompted to select the AWS Secrets Manager ARN that stores sensitive information such as the username and password. To learn about the creation of a secret for your data source, see the section called "Create secrets for database access credentials".
4. **Save your connection details**: Upon clicking **Create**, the provided connection properties are saved as a AWS Glue connection.
5. **Test your connection**: If the connection is successful, the associated databases and tables become visible in the explorer. If the connection fails, an error message is displayed, prompting the user to review and correct the connection details.
6. **Familiarize with SQL extension features**: To learn about the capabilities of the extension, see the the section called "Features overview and usage".
7. **(Optional) Update or delete user-created connections**: Provided that the user has been granted the necessary permissions, they can update or delete the connections they have created. To learn more about the required permissions, see the section called "User-defined connections required IAM permissions".

Set up the IAM permissions to access the data sources (for administrators)

Administrators should ensure that the execution role used by the JupyterLab applications has the necessary AWS IAM permissions to access the data through the configured AWS Glue connections.

- **Connections created by administrators using the AWS CLI**: To view the AWS Glue connections created by administrators and access their data, users need to have their administrator attach specific permissions to the SageMaker AI execution role used by their JupyterLab application in Studio. This includes access to AWS Glue, Secrets Manager, and database-specific permissions. Connections created by administrators are visible to all applications sharing the execution role granted the permissions to view specific AWS Glue catalogs or databases. To learn about the list of required permissions per type of data source, see the admin-defined connections permissions in the section called "Admin-defined connections required IAM permissions".
- **Connections created by users using the SQL extension UI in JupyterLab**: Connections created by user profiles sharing the same execution role will also be listed unless the visibility of their connections is scoped down to only those created by the user. Connections created by users are tagged with the user profile that created them. To restrict the ability to view, update, or delete those user-created connections to only the user who created them, administrators can add additional tag-based access control restrictions to the execution role IAM permissions. To learn about the additional tag-based access control required, see the section called "User-defined connections required IAM permissions".

Admin-defined connections required IAM permissions

To grant the SageMaker AI execution role used by your JupyterLab application in Studio access to a data source through an AWS Glue connection, attach the following inline policy to the role.

To view the specific permissions and policy details for each data source or authentication method, choose the relevant connection type below.

> **Note**
>
> We recommend limiting your policy's permissions to only the resources and actions required.
> To scope down policies and grant least privilege access, replace wildcard `"Resource": ["*"]` in your policy with specific ARNs for the exact resources needing access. For more information about how to control access to your resources, see the section called "Fine-tune AWS resource access with granular ARN permissions".

All connection types

Note

We strongly recommend scoping down this policy to only the actions and resources required.

            ]
        }
    ]
}
}
```

User-defined connections required IAM permissions

The IAM policy permissions for a user can account for the presence of the `UserProfile` tag on AWS Glue connection resources.

- **For viewing AWS Glue connections**:
  - Users can view all connections that do not have the `UserProfile` tag (created by an administrator).
  - Users can view connections that have the `UserProfile` tag with the same value as their user profile name.
  - Users cannot view connections that have the `UserProfile` tag with a different value than their user profile name.
- **For updating or deleting AWS Glue connections**:
  - Users can update or delete a connection that has the `UserProfile` tag with the same value as their user profile name.

- Users cannot update or delete a connection that has the `UserProfile` tag with a different value than their user profile name.
- Users cannot update or delete connections that do not have the `UserProfile` tag.

To achieve this, administrators must grant the execution role used by the user profile's JupyterLab application additional permissions beyond their existing admin-defined connections permissions. Specifically, in addition to the permissions required for accessing admin-defined AWS Glue connections, the following two additional IAM permissions must be granted to the user's execution role:

- Permission to create AWS Glue connections and associate the `UserProfile` tag with the value of the user's profile name.
- Permission to view, update, and delete AWS Glue connections that have the `UserProfile` tag matching the user's profile name.

This permission restricts access to AWS Glue connections based on a specific user profile tag value. Update the `UserProfile` tag value with the profile name of the user you want to target.

```
"Action": [
    "glue:GetConnection",
    "glue:GetConnections"
],
"Resource": [
    "arn:aws:glue:region:account_id:connection/*"
],
"Condition": {
    "StringEqualsIfExists": {
        "aws:ResourceTag/UserProfile": "user_profile_name"
    }
}
```

This permission restricts the ability to create, update, and delete user-created connections to only the connections created by the user profile with the specified `UserProfile` tag value.

```
"Action": [
    "glue:DeleteConnection",
    "glue:UpdateConnection",
    "glue:CreateConnection",
```

```
        "glue:TagResource"
    ],
    "Resource": [
        "arn:aws:glue:region:account_id:connection/*"
    ],
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/UserProfile": "user_profile"
        }
    }
```

Fine-tune AWS resource access with granular ARN permissions

For finer-grained control over access to your AWS resources, replace the wildcard resource `"Resource": ["*"]` in your policies with the specific Amazon Resource Names (ARNs) of only those resources that require access. Using the exact ARNs rather than a wildcard restricts access to the intended resources.

- **Use specific Amazon S3 bucket ARNs**

  For example `"arn:aws:s3:::bucket-name"` or `"arn:aws:s3:::bucket-name/*"` for bucket-level or object-level operations.

  For information about all resource types in Amazon S3, see Resource types defined by Amazon S3.
- **Use specific AWS Glue database ARNs**

  For example `"arn:aws:glue:region:account-id:catalog"` or `"arn:aws:glue:region:account-id:database/db-name"`. For information about all resource types in AWS Glue, see Resource types defined by AWS Glue.
- **Use specific Athena workgroup ARNs**

  For example `"arn:aws:athena:region:account-id:workgroup/workgroup-name"`. For information about all resource types in Athena, see Resource types defined by Athena.
- **Use specific AWS Secrets Manager secret ARNs**

  For example `"arn:aws:secretsmanager:region:account-id:secret:secret-name"`. For information about all resource types in AWS Secrets Manager, see Resource types defined by AWS Secrets Manager
- **Use specific Amazon Redshift cluster ARNs**

For example "`arn:aws:redshift:region:account-id:cluster:cluster-name`". For information about resource types in Amazon Redshift, see Resource types defined by Amazon Redshift. For information about all resource types in Redshift Serverless, see Resource types defined by Redshift Serverless.

Frequently asked questions

The following FAQs answer common general questions for the SQL extension in JupyterLab.

Q: Where do I find the logs for the SQL extension?

A: The SQL extension writes its log in the general log file of your JupyterLab application in Studio. You can find those logs at `/var/log/apps/app_container.log`.

Q: I am getting an error: "UsageError: Cell magic `%%sm_sql` not found."

A: Create a new cell and load the extension again using `%load_ext amazon_sagemaker_sql_magic`.

Q: How do I list the various parameters of my `%%sm_sql` command?

A: Use `%%sm_sql?` to get the help content of the command.

Q: I cannot see the data discovery view on the right side panel.

A: Ensure that your space uses a SageMaker distribution image version 1.6 or higher. These SageMaker images come pre-installed with the extension.

If you updated the image of your JupyterLab application space in Studio, refresh your browser.

Q: The right panel does not accurately reflect the AWS Glue connections that are configured.

A: Try refreshing the right panel using the **Refresh** button in the bottom right corner of the SQL extension UI in your notebook.

Q: SQL statements do not run as expected or run incorrectly.

A: Try clearing the cached connections by running the following magic command `%sm_sql_manage --clear-cached-connections`.

Q: I am getting an error: "Actual statement count 2 did not match the desired statement count 1."

A: The SQL extension only supports running one SQL query at a time.

Snowflake FAQs

The following FAQs answer common general questions for users of the SQL extension using Snowflake as their data source.

Q: I am getting an error: "No active warehouse selected in the current session." Select an active warehouse with the 'use warehouse' command.

A: This can happen if the default warehouse for a user is not selected. Run the command `USE WAREHOUSE warehouse_name` for each session.

Q: I am getting an error: "object '*foo*' does not exist or not authorized."

A: Ensure that your Snowflake user has access to the given object.

Connection parameters

The following tables detail the supported Python properties for AWS Glue connections per data store.

Amazon Redshift connection parameters

The following Python connection parameters are supported by AWS Glue connections to Amazon Redshift.

Key	Type	Description	Constraints	Required
`auto_create`	Type: `boolean`	Indicates whether the user should be created if they do not exist. Defaults to `false`.	`true`, `false`	No

Key	Type	Description	Constraints	Required
aws_secret_arn	Type: string	The ARN of the secret used to retrieve the additional parameters for the connection.	Valid ARN	No
cluster_identifier	Type: string - maxLength: 63	The cluster identifier of the Amazon Redshift cluster.	^(?!.*—)[a-z][a-z0-9-]{0,61}[a-z0-9]$	No
database	Type: string - maxLength: 127	The name of the database to connect to.		No
database_metadata_current_db_only	Type: boolean	Indicates if the application supports multi-database datashare catalogs. Defaults to true to indicate that the application does not support multi-database datashare catalogs for backwards compatibility.	true, false	No

Key	Type	Description	Constraints	Required
db_groups	Type: string	A comma-separated list of existing database group names that the db_user joins for the current session.		No
db_user	Type: string	The user ID to use with Amazon Redshift.		No
host	Type: string - maxLength: 256	The hostname of the Amazon Redshift cluster.		No
iam	Type: boolean	Flag to enable or disable IAM based authentic ation for a connection. Defaults to false.	true, false	No

Key	Type	Description	Constraints	Required
`iam_disable_cache`	Type: `boolean`	This option specifies whether the IAM credentials are cached. Defaults to `true`. This improves performance when requests to the API gateway are throttled.	`true`, `false`	No
`max_prepared_statements`	Type: `integer`	The maximum number of prepared statements that can be open at once.		No

Key	Type	Description	Constraints	Required
`numeric_to_float`	Decimal to float	Specifies if `NUMERIC` datatype values will be converted from decimal. By default `NUMERIC` values are received as `decimal.Decimal` Python objects. Enabling this option is not recommended for use cases which prefer the most precision as results may be rounded. Please reference the Python documentation on [`decimal.Decimal`](https://docs.python.org/3/library/decimal.html) to understand the tradeoffs between `decimal.Decimal` and `float` before enabling this option. Defaults to `false`.	`true`, `false`	No

Key	Type	Description	Constraints	Required
`port`	Type: `integer`	The port number of the Amazon Redshift cluster.	Range 1150-65535	No
`profile`	Type: `string` - maxLength: 256	The name of the profile containing the credentials and setting used by the AWS CLI.		No
`region`	Type: `string`	The AWS Region where the cluster is located.	Valid AWS Region	No
`serverless_acct_id`	Type: `string` - maxLength: 256	The AWS account ID that is associated with the Amazon Redshift serverless resource.		No
`serverless_work_group`	Type: `string` - maxLength: 256	The name of the work group for the Amazon Redshift serverless endpoint.		No
`ssl`	Type: `boolean`	`true` if SSL is enabled.	`true`, `false`	No

Key	Type	Description	Constraints	Required
`ssl_mode`	Type: enum[`verify-ca` , `verify-full` , null])	The security of the connection to Amazon Redshift. `verify-ca` (SSL must be used and the server certificate must be verified.) and `verify-full` (SSL must be used. The server certificate must be verified and the server hostname must match the hostname attribute on the certificate.) are supported. For more information, see [Configuring security options for connections](#) in Amazon Redshift documentation. Defaults to `verify-ca` .	`verify-ca` , `verify-full`	No

Key	Type	Description	Constraints	Required
timeout	Type: integer	The number of seconds before the connection to the server times out.	0	No

Athena connection parameters

The following Python connection parameters are supported by AWS Glue connections to Athena.

Key	Type	Description	Constraints	Required
aws_access_key_id	Type: string - maxLength: 256	Specifies an AWS access key associated with an IAM account. We recommend storing this information in the aws_secret .	Length 16-128	No
aws_secret_access_key	Type: string - maxLength: 256	Secret part of an AWS access key. We recommend storing this information in the aws_secret .		No
aws_secret_arn	Type: string	The ARN of the secret used to retrieve the additional	Valid ARN	No

Key	Type	Description	Constraints	Required
		parameters for the connection.		
`catalog_name`	Type: `string` - maxLength: 256	The catalog that contains the databases and the tables that are accessed with the driver. For information about catalogs, see DataCatalog.		No
`duration_seconds`	Type: `number`	The duration, in seconds, of the role session. This setting can have a value from 1 hour to 12 hours. By default the duration is set to 3600 seconds (1 hour).	Range from 900 seconds (15 minutes) up to the maximum session duration setting for the role	No
`encryption_option`	Type: enum[SSE_S3, SSE_KMS, CSE_KMS, null])	Encryption at rest for Amazon S3. See the *Encryption at rest* section in Athena guide.	`SSE_S3`, `SSE_KMS`, `CSE_KMS`	No
`kms_key`	Type: `string` - maxLength: 256	AWS KMS key if using `CSE_KMS` in `encrytion_option` .		No

Key	Type	Description	Constraints	Required
`poll_interval`	Type: `number`	Interval in seconds to poll the status of query results in Athena.		No
`profile_name`	Type: `string` - maxLength: 256	The name of the AWS configuration profile whose credentials should be used to authenticate the request to Athena.		No
`region_name`	Type: `string`	The AWS Region where queries are run.	Valid AWS Region	No
`result_reuse_enable`	Type: `boolean`	Enable the reuse of previous query result.	`true`, `false`	No
`result_reuse_minutes`	Type: `integer`	Specifies, in minutes, the maximum age of a previous query result that Athena should consider for reuse. The default is 60.	>= 1	No

Key	Type	Description	Constraints	Required
role_arn	Type: string	Role to be used for running queries.	Valid ARN	No
schema_name	Type: string - maxLength: 256	Name of the default schema to use for the database.		No
s3_staging_dir	Type: string - maxLength: 1024	The location in Amazon S3 where the query results are stored.		Either s3_staging_dir or work_group is required
work_group	Type: string	The workgroup in which queries will run. For information about workgroups, see WorkGroup.	^[a-zA-Z0-9._-]{1,128}$	Either s3_staging_dir or work_group is required

Snowflake connection parameters

The following Python connection parameters are supported by AWS Glue connections to Snowflake.

Snowflake connection parameters

Key	Type	Description	Constraints	Required
account	Type: string - maxLength: 256	The Snowflake account identifier. The account identifier does		Yes

Key	Type	Description	Constraints	Required
		not include the snowflake computing .com suffix.		
arrow_number_to_decimal	Type: boolean	False by default, which means that NUMBER column values are returned as double-precision floating point numbers (float64). Set this to True to return DECIMAL column values as decimal numbers (decimal.Decimal) when calling the fetch_pandas_all() and fetch_pandas_batches() methods.	true, false	No

Key	Type	Description	Constraints	Required
autocommit	Type: boolean	Defaults to false, which honors the Snowflake parameter AUTOCOMMIT . Set to true or false to enable or disable the autocommit mode in the session, respectively.	true, false	No
aws_secret_arn	Type: string	The ARN of the secret used to retrieve the additional parameters for the connection.	Valid ARN	No
client_prefetch_threads	Type: integer	The number of threads used to download the result sets (4 by default). Increasing the value improves the fetch performance but requires more memory.		No

Key	Type	Description	Constraints	Required
`database`	Type: `string` - maxLength: 256	The name of the default database to use.		No
`login_timeout`	Type: `integer`	The timeout in seconds for the login request. Defaults to 60 seconds. The login request gives up after the timeout length if the HTTP response is not `success`.		No
`network_timeout`	Type: `integer`	The timeout in seconds for all other operations. Defaults to none (infinite). A general request gives up after the timeout length if the HTTP response is not `success`.		No

Key	Type	Description	Constraints	Required
`paramstyle`	Type: `string` - maxLength: 256	Placeholder syntaxes used for parameter substitution when executing SQL queries from Python code. Defaults to `pyformat` for client side binding. Specify `qmark` or `numeric` to change the bind variable formats for server side binding.		No
`role`	Type: `string` - maxLength: 256	The name of the default role to use.		No
`schema`	Type: `string` - maxLength: 256	The name of the default schema to use for the database.		No

Key	Type	Description	Constraints	Required
`timezone`	Type: `string` - maxLength: 128	None by default, which honors the Snowflake parameter `TIMEZONE`. Set to a valid time zone (such as `America/Los_Angeles`) to set the session time zone.	Timezone in a format similar to `America/Los_Angeles`	No
`validate_default_parameters`	Type: `boolean`	Set to `true` to raise an exception if the specified database, schema, or warehouse doesn't exist. Defaults to `false`.		No
`warehouse`	Type: `string` - maxLength: 256	The name of the default warehouse to use.		No

Data preparation at scale using Amazon EMR Serverless applications or Amazon EMR clusters in Studio

Amazon SageMaker Studio and its legacy version, Studio Classic, provide data scientists, and machine learning (ML) engineers with tools to perform data analytics and data preparation at scale. Analyzing, transforming, and preparing large amounts of data is a foundational step of any data science and ML workflow. Both Studio and Studio Classic come with built-in integration with Amazon EMR, allowing users to manage large-scale, interactive data preparation and machine learning workflows within their JupyterLab notebooks.

Amazon EMR is a managed big data platform with resources to help you run petabyte-scale distributed data processing jobs using open-source analytics frameworks on AWS such as Apache Spark, Apache Hive, Presto, HBase, and Flink among others. With Studio and Studio Classic integration with Amazon EMR, you can create, browse, discover, and connect to Amazon EMR clusters without leaving your JupyterLab or Studio Classic notebooks. You can additionally monitor and debug your Spark workloads by accessing the Spark UI directly from your notebook with one-click.

You should consider Amazon EMR clusters for your data preparation workloads if you have large-scale, long-running, or complex data processing requirements that involve massive amounts of data, require extensive customization and integration with other services, need to run custom applications, or plan to run a diverse range of distributed data processing frameworks beyond just Apache Spark.

Using SageMaker distribution image `1.10` or higher, you can alternatively connect to interactive EMR Serverless applications directly from your JupyterLab notebooks in SageMaker AI Studio. The integration of Studio with EMR Serverless allows you to run open-source big data analytics frameworks such as Apache Spark and Apache Hive without configuring, managing, or scaling Amazon EMR clusters. EMR Serverless automatically provisions and manages the underlying compute and memory resources based on your EMR Serverless application's needs. It scales resources up and down dynamically, charging you or the amount of vCPU, memory, and storage resources consumed by your applications. This serverless approach allows you to run interactive data preparation workloads from your JupyterLab notebooks without worrying about cluster management, while achieving high instance utilization and cost efficiency.

You should consider EMR Serverless for your interactive data preparation workloads if your workloads are short-lived or intermittent and don't require a persistent cluster; you prefer a serverless experience with automatic resource provisioning and termination, avoiding the overhead of managing infrastructure; or your interactive data preparation tasks primarily revolve around Apache Spark.

Content

- Prepare data using EMR Serverless
- Data preparation using Amazon EMR

Configure network access for your Amazon EMR cluster

Before you get started with using Amazon EMR or EMR Serverless for your data preparation tasks in Studio, ensure that you or your administrator have configured your network to allow communication between Studio and Amazon EMR. Once this communication is enabled, you can choose to:

- Prepare data using EMR Serverless
- Data preparation using Amazon EMR

> **Note**
>
> For EMR Serverless users, the simplest setup involves creating your application in the Studio UI without modifying the default settings for the **Virtual private cloud (VPC)** option. This approach allows the application to be created within your SageMaker domain's VPC, eliminating the need for additional networking configuration. If you choose this option, you can skip the following networking setup section.

The networking instructions vary based on whether Studio and Amazon EMR are deployed within a private Amazon Virtual Private Cloud (VPC) or communicate over the internet.

By default, Studio or Studio Classic run in an AWS managed VPC with internet access. When using an internet connection, Studio and Studio Classic access AWS resources, such as Amazon S3 buckets, over the internet. However, if you have security requirements to control access to your data and job containers, we recommend that you configure Studio or Studio Classic and Amazon EMR so that your data and containers aren't accessible over the internet. To control access to your resources or run Studio or Studio Classic without public internet access, you can specify the `VPC only` network access type when you onboard to Amazon SageMaker AI domain. In this scenario, both Studio and Studio Classic establish connections with other AWS services via private VPC endpoints. For information about configuring Studio or Studio Classic in `VPC only` mode, see Connect SageMaker Studio or Studio Classic notebooks in a VPC to external resources..

The first two sections describe how to ensure communication between Studio or Studio Classic and Amazon EMR in VPCs without public internet access. The last section covers how to ensure communication between Studio or Studio Classic and Amazon EMR using an internet connection. Prior to connecting Studio or Studio Classic and Amazon EMR without internet access, make sure to establish endpoints for Amazon Simple Storage Service (data storage), Amazon CloudWatch (logging and monitoring), and Amazon SageMaker Runtime (fine-grained role-based access control (RBAC)).

To connect Studio or Studio Classic and Amazon EMR:

- If Studio or Studio Classic and Amazon EMR are in separate VPCs, either in the same AWS account or in different accounts, see Studio and Amazon EMR are in separate VPCs.
- If Studio or Studio Classic and Amazon EMR are in the same VPC, see Studio and Amazon EMR are in the same VPC.
- If you chose to connect Studio or Studio Classic and Amazon EMR over public internet, see Studio and Amazon EMR communicate over public internet.

Studio and Amazon EMR are in separate VPCs

To allow communication between Studio or Studio Classic and Amazon EMR when they are deployed in separate VPCs:

1. Start by connecting your VPCs through a VPC peering connection.
2. Update your routing tables in each VPC to route the network traffic between Studio or Studio Classic subnets and Amazon EMR subnets both ways.
3. Configure your security groups to allow inbound and outbound traffic.

The steps to connect Studio or Studio Classic and Amazon EMR are the same whether the resources are deployed in a single AWS account (Single account use case) or across multiple AWS accounts (Cross-account use case).

1. **VPC peering**

   Create a VPC peering connection to facilitate the networking between the two VPCs (Studio or Studio Classic and Amazon EMR).

a. From your Studio or Studio Classic account, on the VPC dashboard, choose **Peering connections**, then **Create peering connection**.

b. Create your request to peer the Studio or Studio Classic VPC with the Amazon EMR VPC. When requesting peering in another AWS account, choose **Another account** in **Select another VPC to peer with**.

   For cross-account peering, the administrator must accept the request from the Amazon EMR account.

   When peering private subnets, you should enable private IP DNS resolution at the VPC peering connection level.

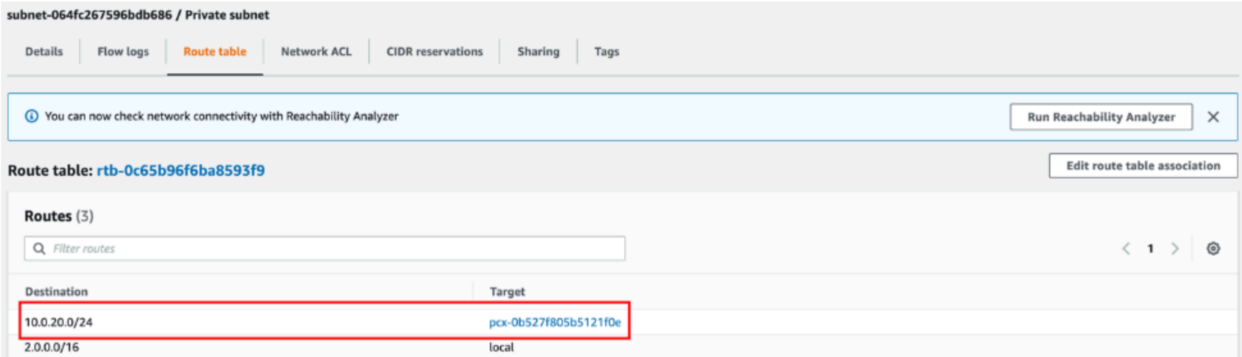
2. **Routing tables**

   Send the network traffic between Studio or Studio Classic subnets and Amazon EMR subnets both ways.

   After you establish the peering connection, the administrator (on each account for cross-account access) can add routes to the private subnet route tables to route the traffic between Studio or Studio Classic and the Amazon EMR subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard.

   The following illustration of the route table of a Studio VPC subnet shows an example of an outbound route from the Studio account to the Amazon EMR VPC IP range (here `2.0.1.0/24`) through the peering connection.

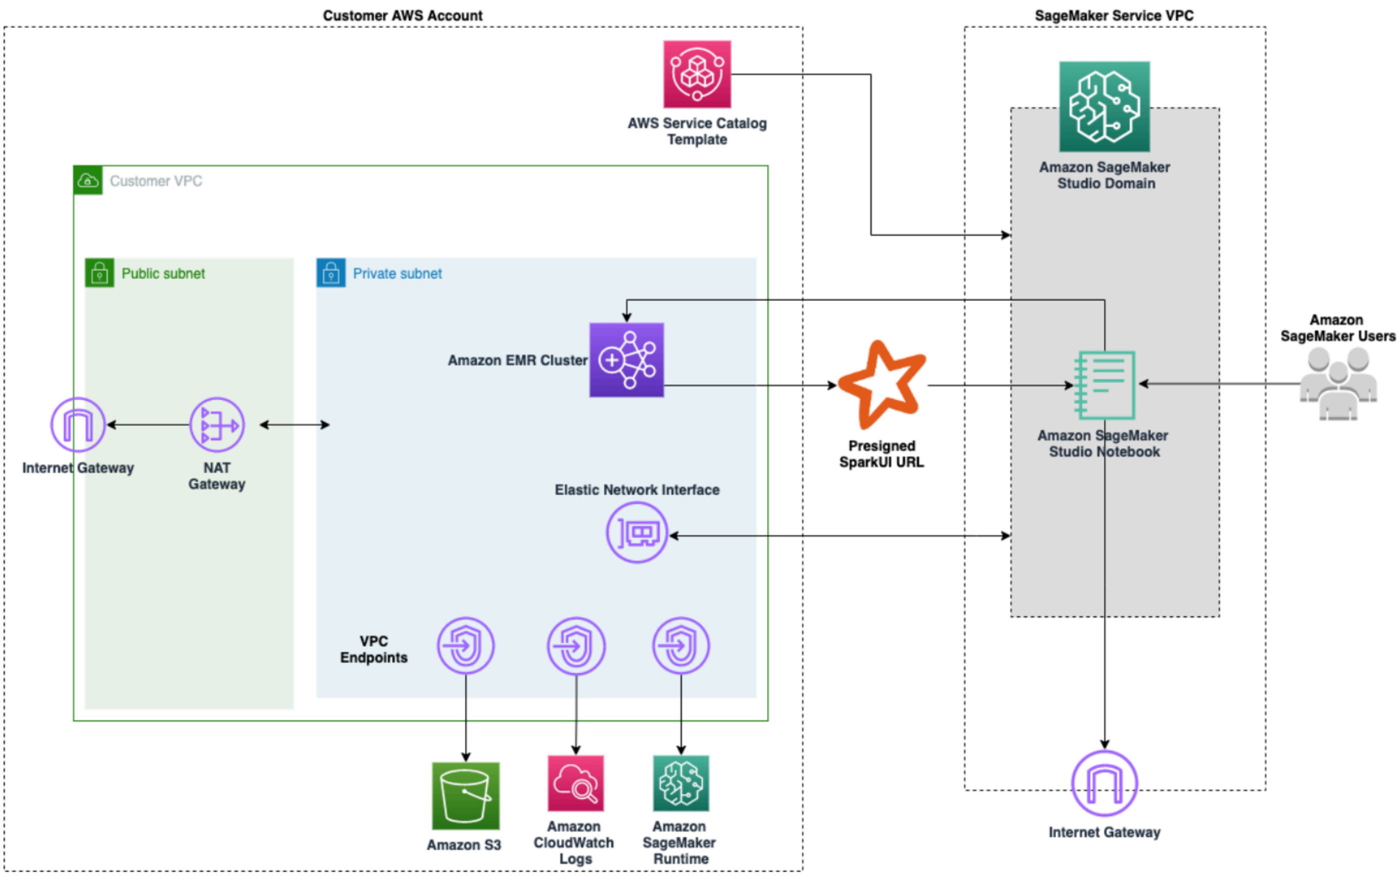
   The following illustration of a route table of an Amazon EMR VPC subnet shows an example of return routes from the Amazon EMR VPC to Studio VPC IP range (here `10.0.20.0/24`) through the peering connection.



3. **Security groups**

   Lastly, the security group of your Studio or Studio Classic domain must allow outbound traffic, and the security group of the Amazon EMR primary node must allow inbound traffic on *Apache Livy*, *Hive*, or *Presto* TCP ports (respectively `8998`, `10000`, and `8889`) from the Studio or Studio Classic instance security group. Apache Livy is a service that enables interaction with Amazon EMR over a REST interface.

The following diagram shows an example of an Amazon VPC setup that enables JupyterLab or Studio Classic notebooks to provision Amazon EMR clusters from AWS CloudFormation templates in the Service Catalog and then connect to an Amazon EMR cluster within the same AWS account. The diagram provides an additional illustration of the required endpoints for a direct connection to various AWS services, such as Amazon S3 or Amazon CloudWatch, when the VPCs have no internet access. Alternatively, a NAT gateway must be used to allow instances in private subnets of multiple VPCs to share a single public IP address provided by the internet gateway when accessing the internet.



Studio and Amazon EMR are in the same VPC

If Studio or Studio Classic and Amazon EMR are in different subnets, add routes to each private subnet route table to route the traffic between Studio or Studio Classic and the Amazon EMR subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard. If you deployed Studio or Studio Classic and Amazon EMR in the same VPC and the same subnet, you do not need to route the traffic between the Studio and the Amazon EMR.

Whether or not you needed to update your routing tables, the security group of your Studio or Studio Classic domain must allow outbound traffic, and the security group of the Amazon EMR primary node must allow inbound traffic on *Apache Livy*, *Hive*,or *Presto* TCP ports (respectively 8998, `10000`, and 8889) from the Studio or Studio Classic instance security group. [Apache Livy](https://livy.apache.org/) is a service that enables interaction with a Amazon EMR over a REST interface.

Studio and Amazon EMR communicate over public internet

By default, Studio and Studio Classic provide a network interface that allows communication with the internet through an internet gateway in the VPC associated with the SageMaker domain. If you choose to connect to Amazon EMR through the public internet, Amazon EMR needs to accept inbound traffic on *Apache Livy*, *Hive*,or *Presto* TCP ports (respectively 8998, 10000, and 8889) from its internet gateway. Apache Livy is a service that enables interaction with Amazon EMR over a REST interface.

Keep in mind that any port on which you allow inbound traffic represents a potential security vulnerability. Carefully review custom security groups to ensure that you minimize vulnerabilities. For more information, see Control network traffic with security groups.

Alternatively, see Blogs and whitepapers for a detailed walkthrough of how to enable Kerberos on Amazon EMR, set the cluster in a private subnet, and access the cluster using a Network Load Balancer (NLB) to expose only specific ports, which are access-controlled via security groups.

> **Note**
>
> When connecting to your Apache Livy endpoint through the public internet, we recommend that you secure communications between Studio or Studio Classic and your Amazon EMR cluster using TLS.
> For information on setting up HTTPS with Apache Livy, see Enabling HTTPS with Apache Livy. For information on setting an Amazon EMR cluster with transit encryption enabled, see Providing certificates for encrypting data in transit with Amazon EMR encryption. Additionally, you need to configure Studio or Studio Classic to access your certificate key as specified in Connect to an Amazon EMR cluster over HTTPS.

Prepare data using EMR Serverless

Beginning with SageMaker distribution image version `1.10`, Amazon SageMaker Studio integrates with EMR Serverless. Within JupyterLab notebooks in SageMaker Studio, data scientists and data engineers can discover and connect to EMR Serverless applications, then interactively explore, visualize, and prepare large-scale Apache Spark or Apache Hive workloads. This integration allows to perform interactive data preprocessing at scale in preparation for ML model training and deployment.

Specifically, the updated version of the `sagemaker-studio-analytics-extension` in SageMaker AI distribution image version `1.10` leverages the integration between Apache Livy and EMR Serverless, allowing the connection to an Apache Livy endpoint through JupyterLab notebooks. This section assumes prior knowledge of EMR Serverless interactive applications.

> **Important**
>
> When using Studio, you can only discover and connect to EMR Serverless applications for JupyterLab applications that are launched from private spaces. Ensure that the EMR Serverless applications are located in the same AWS region as your Studio environment.

Prerequisites

Before you get started running interactive workloads with EMR Serverless from your JupyterLab notebooks, make sure you meet the following prerequisites:

1. Your JupyterLab space must use a SageMaker Distribution image version `1.10` or higher.
2. Create an EMR Serverless interactive application with Amazon EMR version `6.14.0` or higher. You can create an EMR Serverless application from the Studio user interface by following the steps in [Create EMR Serverless applications from Studio](#).

   > **Note**
   >
   > For the simplest setup, you can create your EMR Serverless application in the Studio UI without changing any default settings for the **Virtual private cloud (VPC)** option. This allows the application to be created within your domain VPC without requiring any networking configuration. In this case, you can skip the following networking setup step.

3. Review the networking and security requirements in Configure network access for your Amazon EMR cluster. Specifically, ensure that you:
   - Establish a VPC peering connection between your Studio account and your EMR Serverless account.
   - Add routes to the private subnet route tables in both accounts.
   - Set up the security group attached to your Studio domain to allow outbound traffic, and configure the security group of the VPC where you plan to run the EMR Serverless applications to allow inbound TCP traffic from the Studio instance's security group.
4. To access your interactive applications on EMR Serverless and run workloads submitted from your JupyterLab notebooks in SageMaker Studio, you must assign specific permissions and roles. Refer to the Set up the permissions to enable listing and launching Amazon EMR applications from SageMaker Studio section for details on the necessary roles and permissions.

List of topics

Set up the permissions to enable listing and launching Amazon EMR applications from SageMaker Studio

In this section, we detail the roles and permissions required to list and connect to EMR Serverless applications from SageMaker Studio, considering scenarios where Studio and the EMR Serverless applications are deployed in the same AWS account or across different accounts.

The roles to which you must add the necessary permissions depend on whether Studio and your EMR Serverless applications reside in the same AWS account (*Single Account*) or in separate accounts (*Cross Account*). There are two types of roles involved:

- Execution roles:
  - Runtime execution roles (Role-Based Access Control roles) used by EMR Serverless: These are the IAM roles used by the EMR Serverless job execution environments to access other AWS services and resources needed during runtime, such as Amazon S3 for data access, CloudWatch for logging, access to the AWS Glue Data Catalog or other services based on your workload requirements. We recommend creating these roles in the account where the EMR Serverless applications are running.

    To learn more about runtime roles, see Job runtime roles in the *EMR Serverless User Guide*.

    > **Note**
    >
    > You can define several RBAC roles for your EMR Serverless application. These roles can be based on the responsibilities and access levels needed by different users or groups within your organization. For more information about RBAC permissions, see Security best practices for Amazon Amazon EMR Serverless.

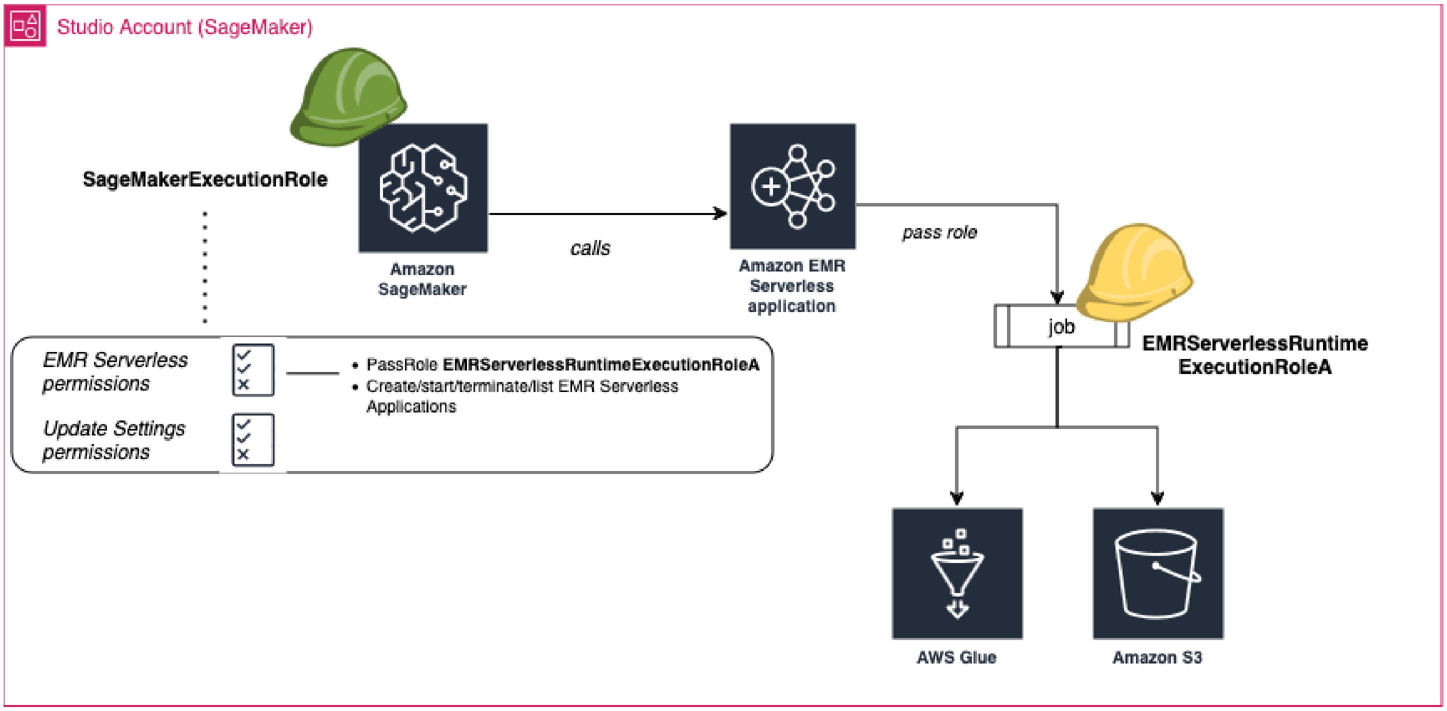
  - SageMaker AI execution role: The execution role allowing SageMaker AI to perform certain tasks like reading data from Amazon S3 buckets, writing logs to CloudWatch, and accessing other AWS services that your workflow might need. The SageMaker AI execution role also has the special permission called `iam:PassRole` which allows SageMaker AI to pass temporary runtime execution roles to the EMR Serverless applications. These roles give the EMR Serverless applications the permissions they need to interact with other AWS resources while they are running.

- Assumable roles (Also referred to as *Service Access Roles*):
  - These are the IAM roles that SageMaker AI's execution role can assume to perform operations related to managing EMR Serverless applications. These roles define the permissions and access policies required when listing, connecting to, or managing EMR Serverless applications. They are typically used in cross-account scenarios, where the EMR Serverless applications are located in a different AWS account than the SageMaker AI domain. Having a dedicated IAM role for your EMR Serverless applications helps to follow the principle of least privilege and ensures that Amazon EMR has only the required permissions to run your jobs while protecting other resources in your AWS account.

By understanding and configuring these roles correctly, you can ensure that SageMaker Studio has the necessary permissions to interact with EMR Serverless applications, regardless of whether they are deployed in the same account or across different accounts.

Single account

The following diagrams illustrate the roles and permissions required to list and connect to EMR Serverless applications from Studio when Studio and the applications are deployed in the same AWS account.



If your Amazon EMR applications and Studio are deployed in the same AWS account, follow these steps:

1. **Step 1**: Retrieve the ARN of the Amazon S3 bucket you use for data sources and output data storage in the Amazon S3 console.

   To learn about how to find a bucket by name, see Accessing and listing an Amazon S3 bucket. For information on how to create an Amazon S3 bucket, see Creating a bucket.

2. **Step 2**: Create at least one job runtime execution role for your EMR Serverless application in your account (The `EMRServerlessRuntimeExecutionRoleA` in the *Single account* use case diagram above). Choose **Custom trust policy** as the trusted entity. Add the permissions required by your job. At a minimum, you need full access to an Amazon S3 bucket, and create and read access to AWS Glue Data Catalog.

   For detailed instructions about how to create a new runtime execution role for your EMR Serverless applications, follow these steps:

   a. Navigate to the IAM console.

   b. In the left navigation pane, choose **Policy**, and then **Create policy**.

   c. Add the permissions required by your runtime role, name the policy, and then choose **Create policy**.

You can refer to Job runtime roles for EMR Serverless to find sample runtime policies for an EMR Serverless runtime role.

d. In the left navigation pane, choose **Roles** and then **Create role**.

e. On the **Create role** page, choose **Custom trust policy** as the trusted entity.

f. Paste in the following JSON document in the **Custom trust policy** section and then choose **Next**.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "emr-serverless.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

g. In the **Add permissions** page, add the policy you created and then choose **Next**.

h. On the **Review** page, enter a name for the role such as `EMRServerlessAppRuntimeRoleA` and an optional description.

i. Review the role details and choose **Create role**.

With these roles, you and your teammates can connect to the same application, each using a runtime role scoped with permissions matching your individual level of access to data.

> **Note**
>
> The Spark sessions operate differently. Spark sessions are isolated based on the execution role used from Studio, so users with different execution roles will have separate, isolated Spark sessions. Additionally, if you have enabled source identity

for your domain, there is further isolation of Spark sessions across different source identities.

3. **Step 3**: Retrieve the ARN of the SageMaker AI execution role used by your private space.

   For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

   Note

   Alternatively, users new to SageMaker AI can simplify their setup process by automatically creating a new SageMaker AI execution role with the appropriate permissions. In this case, skip steps 3 and 4. Instead, users can either:

   - Choose the **Set up for organizations** option when creating a new domain from the **Domain** menu in the left navigation of the SageMaker AI console.
   - Create a new execution role from the **Role manager** menu of the console, and then attach the role to an existing domain or user profile.

   When creating the role, choose the **Run Studio EMR Serverless Applications** option in **What ML activities will users perform?** Then, provide the name of your Amazon S3 bucket and the job runtime execution role you want your EMR Serverless application to use (step 2).
   The SageMaker Role Manager automatically adds the necessary permissions for running and connecting to EMR Serverless applications to the new execution role.Using the SageMaker Role Manager, you can only assign one runtime role to your EMR Serverless application, and the application must run in the same account where Studio is deployed, using a runtime role created within that same account.

4. **Step 4**: Attach the following permissions to the SageMaker AI execution role accessing your EMR Serverless application.

   a. Open the IAM console at https://console.aws.amazon.com/sagemaker/.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

c. Follow the link to your role.

d. Choose **Add permissions** and then **Create inline policy**.

e. In the **JSON** tab, add the Amazon EMR Serverless permissions allowing EMR Serverless access and operations. For details on the policy document, see *EMR Serverless policies* in Reference policies. Replace the `region`, `accountID`, and passed `EMRServerlessAppRuntimeRole`(s) with their actual values before copying the list of statements to the inline policy of your role.

> **Note**
>
> You can include as many ARN strings of runtime roles as needed within the permission, separating them with commas.

f. Choose **Next** and then provide a **Policy name**.

g. Choose **Create policy**.

h. Repeat the **Create inline policy** step to add another inline policy granting the role permissions to update the domains, user profiles, and spaces. For details on the `SageMakerUpdateResourcesPolicy` policy document, see *Domain, user profile, and space update actions policy* in Reference policies. Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

5. **Step 5**:

Associate the list of runtime roles with your user profile or domain so you can visually browse the list of roles and select the one to use when connecting to an EMR Serverless application from JupyterLab. You can use the SageMaker AI console or the following script. Subsequently, all your Apache Spark or Apache Hive jobs created from your notebook will access only the data and resources permitted by the policies attached to the selected runtime role.

> **Important**
>
> Failure to complete this step will prevent you from connecting a JupyterLab notebook to an EMR Serverless application.

SageMaker AI console

To associate your runtime roles with your user profile or domain using the SageMaker AI console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **domain**, and then select the domain using the SageMaker AI execution role whose permissions you updated.
3. - To add your runtime roles to your domain: In the **App Configurations** tab of the **Domain details** page, navigate to the **JupyterLab** section.
   - To add your runtime roles to your user profile: On the **Domain details** page, chose the **User profiles** tab, select the user profile using the SageMaker AI execution role whose permissions you updated. In the **App Configurations** tab, navigate to the **JupyterLab** section.
4. Choose **Edit** and add the ARNs of your EMR Serverless runtime execution roles.
5. Choose **Submit**.

When you next connect to an EMR Serverless application via JupyterLab, the runtime roles should appear in a drop-down menu for selection.

Python script

In a JupyterLab application started from a private space using the SageMaker AI execution role whose permissions you updated, run the following command in a terminal. Replace the `domainID`, `user-profile-name`, `studio-accountID`, and `EMRServerlessRuntimeExecutionRole`(s) with their proper values. This code snippet updates the user profile settings for a specific user profile (`client.update_user_profile`) or domain settings (`client.update_domain`), specifically associating the EMR Serverless runtime execution roles you previously created.

```
import botocore.session
import json
sess = botocore.session.get_session()
client = sess.create_client('sagemaker')

client.update_user_profile(
```

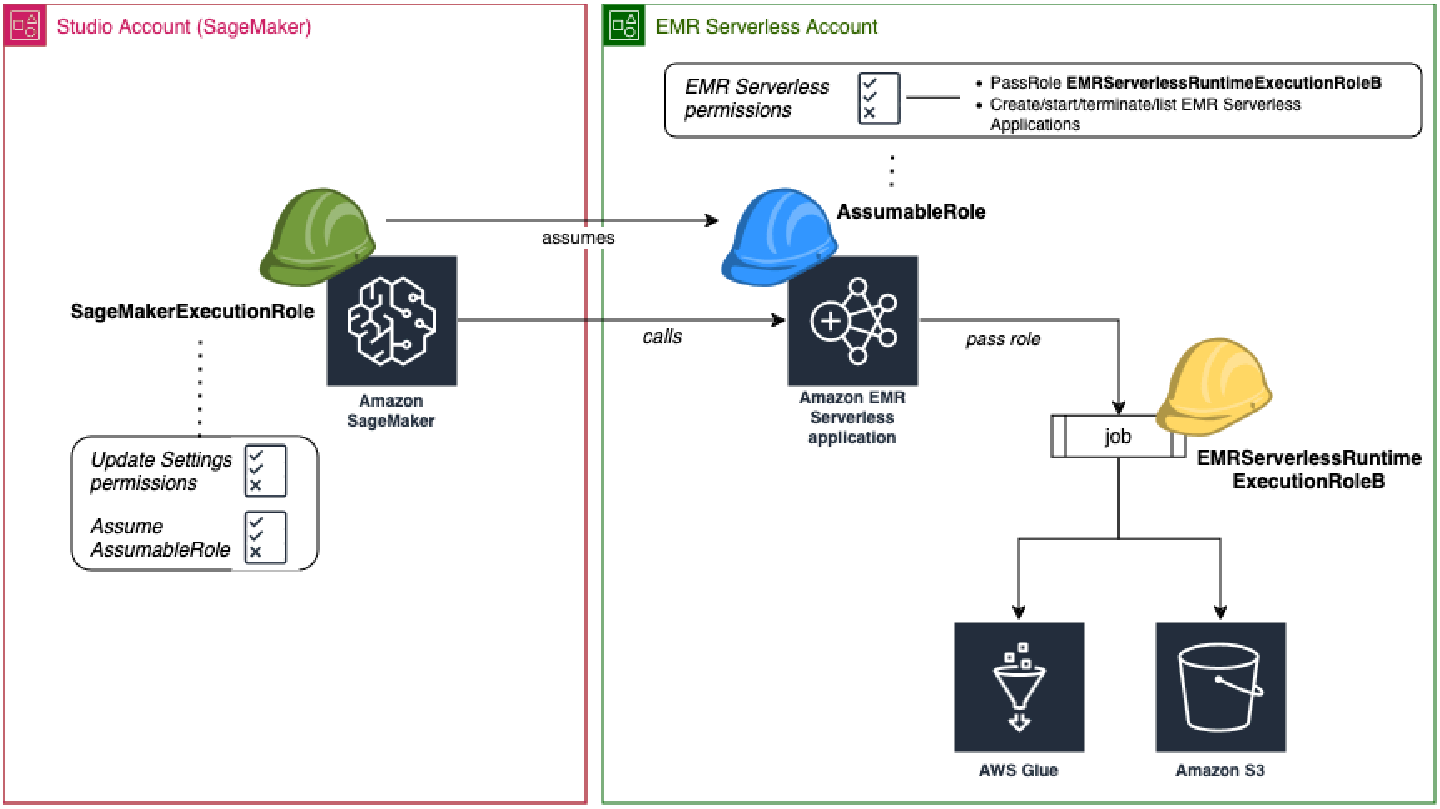
```
DomainId="domainID",
UserProfileName="user-profile-name",
DefaultUserSettings={
    'JupyterLabAppSettings': {
        'EmrSettings': {
            'ExecutionRoleArns': ["arn:aws:iam::studio-
accountID:role/EMRServerlessRuntimeExecutionRoleA",
                                 "arn:aws:iam::studio-
accountID:role/EMRServerlessRuntimeExecutionRoleAA"]
        }

    }
})
resp = client.describe_domain(DomainId="domainID")

resp['CreationTime'] = str(resp['CreationTime'])
resp['LastModifiedTime'] = str(resp['LastModifiedTime'])
print(json.dumps(resp, indent=2))
```

Cross account

The following diagrams illustrate the roles and permissions required to list and connect to EMR Serverless applications from Studio when Studio and the applications are deployed in different AWS accounts.



For more information about creating a role on an AWS account, see https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for-user.html Creating an IAM role (console).

Before you get started:

- Retrieve the ARN of the SageMaker AI execution role used by your private space. For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles. For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.
- Retrieve the ARN of the Amazon S3 bucket you will use for data sources and output data storage in the Amazon S3 console.

  For information on how to create an Amazon S3 bucket, see Creating a bucket. To learn about how to find a bucket by name, see Accessing and listing an Amazon S3 bucket.

If your EMR Serverless applications and Studio are deployed in separate AWS accounts, you configure the permissions on both accounts.

On the EMR Serverless account

Follow these steps to create the necessary roles and policies on the account where your EMR Serverless application is running, also referred to as the *trusting account*:

1. **Step 1**: Create at least one job runtime execution role for your EMR Serverless application in your account (The `EMRServerlessRuntimeExecutionRoleB` in the *Cross account* diagram above). Choose **Custom trust policy** as the trusted entity. Add the permissions required by your job. At a minimum, you need full access to an Amazon S3 bucket, and create and read access to AWS Glue Data Catalog.

   For detailed instructions on how to create a new runtime execution role for your EMR Serverless applications, follow these steps:

   a. Navigate to the IAM console.

   b. In the left navigation pane, choose **Policy**, and then **Create policy**.

   c. Add the permissions required by your runtime role, name the policy, and then choose **Create policy**.

      For sample runtime policies of an EMR Serverless runtime role, see Job runtime roles for Amazon EMR Serverless.

   d. In the left navigation pane, choose **Roles** and then **Create role**.

   e. On the **Create role** page, choose **Custom trust policy** as the trusted entity.

   f. Paste in the following JSON document in the **Custom trust policy** section and then choose **Next**.

      JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "emr-serverless.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
```

```
}
```

g. In the **Add permissions** page, add the policy you created and then choose **Next**.

h. On the **Review** page, enter a name for the role such as `EMRServerlessAppRuntimeRoleB` and an optional description.

i. Review the role details and choose **Create role**.

With these roles, you and your teammates can connect to the same application, each using a runtime role scoped with permissions matching your individual level of access to data.

> **Note**
>
> The Spark sessions operate differently.Spark sessions are isolated based on the execution role used from Studio, so users with different execution roles will have separate, isolated Spark sessions. Additionally, if you have enabled source identity for your domain, there is further isolation of Spark sessions across different source identities.

2. **Step 2**: Create a custom IAM role named `AssumableRole` with the following configuration:

   - Permissions: Grant the necessary permissions (Amazon EMR Serverless policies) to the `AssumableRole` to allow accessing EMR Serverless resources. This role is also known as an *Access role*.
   - Trust relationship: Configure the trust policy for the `AssumableRole` to allow assuming the execution role (The `SageMakerExecutionRole` in the cross-account diagram) from the Studio account that requires access.

   By assuming the role, Studio can gain temporary access to the permissions it needs in the EMR Serverless account.

   For detailed instructions on how to create a new `AssumableRole` in your EMR Serverless AWS account, follow these steps:

   a. Navigate to the [IAM console](https://console.aws.amazon.com/iam).

   b. In the left navigation pane, choose **Policy**, and then **Create policy**.

   c. In the **JSON** tab, add the Amazon EMR Serverless permissions allowing EMR Serverless access and operations. For details on the policy document, see *EMR*

Serverless policies in Reference policies. Replace the `region`, `accountID`, and passed `EMRServerlessAppRuntimeRole`(s) with their actual values before copying the list of statements to the inline policy of your role.

> **Note**
>
> The `EMRServerlessAppRuntimeRole` here is the job runtime execution role created in Step 1 (The `EMRServerlessAppRuntimeRoleB` in the *Cross account* diagram above). You can include as many ARN strings of runtime roles as needed within the permission, separating them with commas.

d. Choose **Next** and then provide a **Policy name**.

e. Choose **Create policy**.

f. In the left navigation pane, choose **Roles** and then **Create role**.

g. On the **Create role** page, choose **Custom trust policy** as the trusted entity.

h. Paste in the following JSON document in the **Custom trust policy** section and then choose **Next**.

Replace `studio-account` with the Studio account ID, and `AmazonSageMaker-ExecutionRole` with the execution role used by your JupyterLab space.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/service-
role/AmazonSageMaker-ExecutionRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

i. In the **Add permissions** page, add the permission `EMRServerlessAppRuntimeRoleB` you created in Step 2 and then choose **Next**.

j. On the **Review** page, enter a name for the role such as `AssumableRole` and an optional description.

k. Review the role details and choose **Create role**.

For more information about creating a role on an AWS account, see Creating an IAM role (console).

On the Studio account

On the account where Studio is deployed, also referred to as the *trusted account*, update the SageMaker AI execution role accessing your EMR Serverless applications with the required permissions to access resources in the trusting account.

1. **Step 1**: Retrieve the ARN of the SageMaker AI execution role used by your space.

   For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

2. **Step 2**: Attach the following permissions to the SageMaker AI execution role accessing your EMR Serverless application.

   a. Open the IAM console at https://console.aws.amazon.com/iam/.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

   c. Follow the link to your role.

   d. Choose **Add permissions** and then **Create inline policy**.

   e. In the **JSON** tab, add the inline policy granting the role permissions to update the domains, user profiles, and spaces. For details on the `SageMakerUpdateResourcesPolicy` policy document, see *Domain, user profile, and space update actions policy* in Reference policies. Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

   f. Choose **Next** and then provide a **Policy name**.

   g. Choose **Create policy**.

h. Repeat the **Create inline policy** step to add another policy granting the execution role the permissions to assume the `AssumableRole` and then perform actions permitted by the role's access policy.

Replace `emr-account` with the Amazon EMR Serverless account ID, and `AssumableRole` with the name of the assumable role created in the Amazon EMR Serverless account.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Sid": "AllowSTSToAssumeAssumableRole",
        "Effect": "Allow",
        "Action": "sts:AssumeRole",
        "Resource": "arn:aws:iam::111122223333:role/AssumableRole"
    }
}
```

3. **Step 3**:

Associate the list of runtime roles with your domain or user profile so you can visually browse the list of roles and select the one to use when [connecting to an EMR Serverless application](#) from JupyterLab. You can use the SageMaker AI console or the following script. Subsequently, all your Apache Spark or Apache Hive jobs created from your notebook will access only the data and resources permitted by the policies attached to the selected runtime role.

> **Important**
>
> Failure to complete this step will prevent you from connecting a JupyterLab notebook to an EMR Serverless application.

SageMaker AI console

To associate your runtime roles with your user profile or domain using the SageMaker AI console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **domain**, and then select the domain using the SageMaker AI execution role whose permissions you updated.
3. • To add your runtime roles to your domain: In the **App Configurations** tab of the **Domain details** page, navigate to the **JupyterLab** section.
   • To add your runtime roles to your user profile: On the **Domain details** page, chose the **User profiles** tab, select the user profile using the SageMaker AI execution role whose permissions you updated. In the **App Configurations** tab, navigate to the **JupyterLab** section.
4. Choose **Edit** and add the ARNs of your assumable role and EMR Serverless runtime execution roles.
5. Choose **Submit**.

When you next connect to an EMR Serverless application via JupyterLab, the runtime roles should appear in a drop-down menu for selection.

Python script

In a JupyterLab application started from a private space using the SageMaker AI execution role whose permissions you updated, run the following command in a terminal. Replace the `domainID`, `user-profile-name`, `studio-accountID`, and `EMRServerlessRuntimeExecutionRole` with their proper values.
This code snippet updates the user profile settings for a specific user profile (`client.update_user_profile`) or domain settings (`client.update_domain`) within a SageMaker AI domain. Specifically, it sets the runtime execution roles for Amazon EMR Serverless, which you have previously created. It also allows the JupyterLab application to assume a particular IAM role (`AssumableRole`) for running EMR Serverless applications within the Amazon EMR account.

```
import botocore.session
import json
sess = botocore.session.get_session()
client = sess.create_client('sagemaker')

client.update_user_profile(
DomainId="domainID",
```

```
UserProfileName="user-profile-name",
DefaultUserSettings={
    'JupyterLabAppSettings': {
        'EmrSettings': {
            'AssumableRoleArns': ["arn:aws:iam::emr-
accountID:role/AssumableRole"],
            'ExecutionRoleArns': ["arn:aws:iam::emr-
accountID:role/EMRServerlessRuntimeExecutionRoleA",
                                  "arn:aws:iam::emr-
accountID:role/AnotherRuntimeExecutionRole"]
        }

    }
})
resp = client.describe_user_profile(DomainId="domainID", UserProfileName=user-
profile-name")

resp['CreationTime'] = str(resp['CreationTime'])
resp['LastModifiedTime'] = str(resp['LastModifiedTime'])
print(json.dumps(resp, indent=2))
```

Reference policies

- **EMR Serverless policies**: This policy allows managing EMR Serverless applications, including listing, creating (with required SageMaker AI tags), starting, stopping, getting details, deleting, accessing Livy endpoints, and getting job run dashboards. It also allows passing the required EMR Serverless application runtime role to the service.
  - `EMRServerlessListApplications`: Allows the ListApplications action on all EMR Serverless resources in the specified region and AWS account.
  - `EMRServerlessPassRole`: Allows passing the specified runtime role(s) in the provided AWS account, but only when the role is being passed to the `emr-serverless.amazonaws.com service`.
  - `EMRServerlessCreateApplicationAction`: Allows the CreateApplication and TagResource actions on EMR Serverless resources in he specified region and AWS account. However, it requires that the resources being created or tagged have specific tag keys (`sagemaker:domain-arn`, `sagemaker:user-profile-arn`, and `sagemaker:space-arn`) present with non-null values.

- `EMRServerlessDenyTaggingAction`: The TagResource and UntagResource actions on EMR Serverless resources in the specified region and AWS account if the resources do not have any of the specified tag keys (`sagemaker:domain-arn`, `sagemaker:user-profile-arn`, and `sagemaker:space-arn`) set.
- `EMRServerlessActions`: Allows various actions (`StartApplication`, `StopApplication`, `GetApplication`, `DeleteApplication`, `AccessLivyEndpoints`, and `GetDashboardForJobRun`) on EMR Serverless resources, but only if the resources have the specified tag keys (`sagemaker:domain-arn`, `sagemaker:user-profile-arn`, and `sagemaker:space-arn`) set with non-null values.

The IAM policy defined in the provided JSON document grants those permissions, but limits that access to the presence of specific SageMaker AI tags on the EMR Serverless applications to ensure that only Amazon EMR Serverless resources associated with a particular SageMaker AI domain, user profile, and space can be managed.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {

```

```
                "emr-serverless:GetApplication",
                "emr-serverless:DeleteApplication",
                "emr-serverless:AccessLivyEndpoints",
                "emr-serverless:GetDashboardForJobRun"
            ],
            "Resource": "arn:aws:emr-serverless:us-east-1:111122223333:/
applications/*",
            "Condition": {
                "Null": {
                    "aws:ResourceTag/sagemaker:domain-arn": "false",
                    "aws:ResourceTag/sagemaker:user-profile-arn": "false",
                    "aws:ResourceTag/sagemaker:space-arn": "false"
                }
            }
        }
    ]
}
```

- **Domain, user profile, and space update actions policy** : The following policy grants permissions to update SageMaker AI domains, user profiles, and spaces within the specified region and AWS account.

  JSON

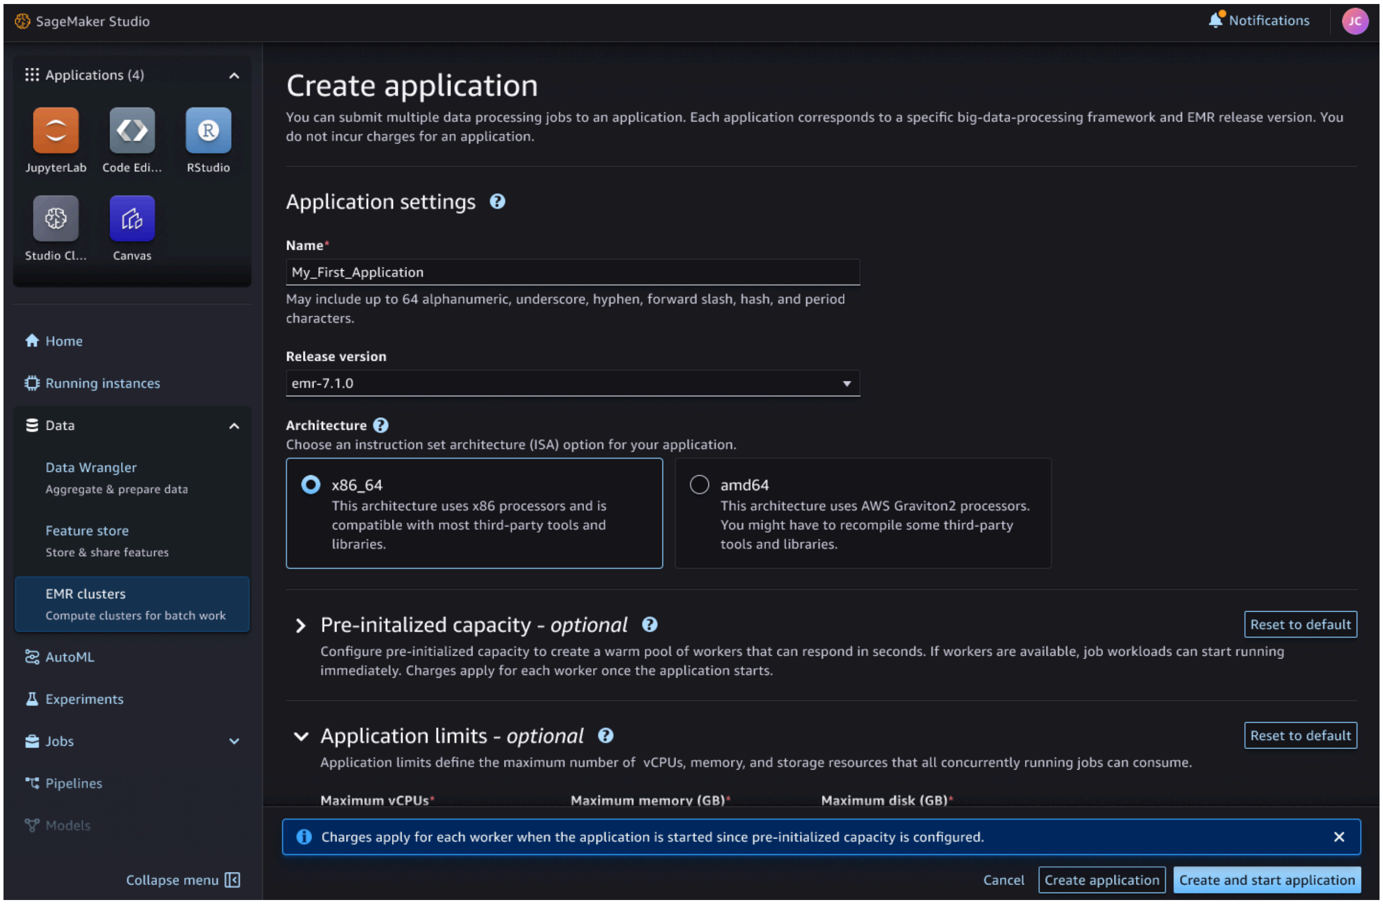
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerUpdateResourcesPolicy",
            "Effect": "Allow",
            "Action": [
                "sagemaker:UpdateDomain",
                "sagemaker:UpdateUserprofile",
                "sagemaker:UpdateSpace"
            ],
            "Resource": [
                "arn:aws:sagemaker:us-east-1:111122223333:domain/*",
                "arn:aws:sagemaker:us-east-1:111122223333:user-profile/*"
            ]
        }
    ]
}
```

Create EMR Serverless applications from Studio

Data scientists and data engineers can create EMR Serverless applications directly from the Studio user interface. Before you begin, ensure that you have configured the necessary permissions as described in the Set up the permissions to enable listing and launching Amazon EMR applications from SageMaker Studio section. These permissions grant Studio the ability to create, start, view, access, and terminate the applications.

To create an EMR Serverless application from Studio:

1. In the Studio UI, navigate to the left-side panel and select the **Data** node in the left navigation menu. Then, scroll and choose the **Amazon EMR applications and clusters** option. This opens up a page that displays the Amazon EMR applications that you can access from within the Studio environment, under the **Serverless applications** tab.
2. Choose the **Create serverless application** button at the top right corner. This opens a **Create application** page resembling the view you would see in the EMR Serverless console when choosing to **Use custom settings** in the **application setup options**.
3. Provide the necessary details for your application, including a name and any specific configurable parameters you wish to set, then choose **Create application**.



All configuration settings have default values and are optional to modify. For detailed information on each available parameter, see [Configuring an application](#) in the EMR Serverless user guide.

> **Note**
>
> - During the application creation process in the Studio UI, you have the option to either **Create application** or **Create and start application**. Based on your choice, the application will enter either the `Creating` or `Starting` state respectively.
>
>   If you opt to create the application without immediately starting it, make sure the **Automatically start application on job submission** option remains selected. This will ensure that the application automatically transitions to the `Starting` state when you later submit a job to run on it.
> - For the simplest setup, we recommend leaving the **Virtual private cloud (VPC)** option set to its default value of **No network connectivity to resources in your VPC**

under the **Network connections** section. This allows the application to be created within your domain VPC without requiring any additional networking configuration.

In any other case, ensure that you perform the following steps:

- Peer your VPCs.
- Add routes to your private subnet route tables.
- Configure your security groups as detailed in Configure network access for your Amazon EMR cluster.

This ensures the proper networking setup for your application, beyond the default **No network connectivity** option.

- For applications created from the Studio Classic UI, the following configuration is automatically applied:
  - An enabled Apache Livy endpoint.
  - The application is tagged with the following:
    - sagemaker:user-profile-arn
    - sagemaker:domain-arn
    - sagemaker:space-arn

  If you create an application outside of Studio, ensure that you manually enable the Apache Livy endpoint and apply the same set of tags to the application.

Once the application is created, the Studio Classic UI displays a *The application has been successfully created* message and the new application appears in the list of **Serverless applications**.

To connect to your EMR Serverless application, see Connect to an EMR Serverless application from Studio

Connect to an EMR Serverless application from Studio

Data scientists and data engineers can discover and then connect to an EMR Serverless application directly from the Studio user interface. Before you begin, ensure that you have created an EMR Serverless application by following the instructions in the section called "Create EMR Serverless applications".

You can connect an EMR Serverless application to a new JupyterLab notebook directly from the Studio UI, or choose to initiate the connection in a notebook of a running JupyterLab application.

> **Important**
>
> When using Studio, you can only discover and connect to EMR Serverless applications for JupyterLab applications that are launched from private spaces. Ensure that the EMR Serverless applications are located in the same AWS region as your Studio environment. Your JupyterLab space must use a SageMaker Distribution image version `1.10` or higher.

To connect an EMR Serverless application to a new JupyterLab notebook from the Studio UI:

1. In the Studio UI, navigate to the left-side panel and select the **Data** node in the left navigation menu. Then, scroll and choose the **Amazon EMR applications and clusters** option. This opens up a page that displays the Amazon EMR applications that you can access from within the Studio environment, under the **Serverless applications** tab.

   > **Note**
   >
   > If you or your administrator have configured the permissions to allow cross-account access to EMR Serverless applications, you can view a consolidated list of applications across all accounts that you have granted access to Studio.

2. Select an EMR Serverless application you want to connect to a new notebook, and then choose **Attach to notebook**. This opens up a modal window displaying the list of your JupyterLab spaces.

3. - Select the private space from which you want to launch a JupyterLab application, and then choose **Open notebook**. This launches a JupyterLab application from your chosen space and opens a new notebook.
   - Alternatively, you can create a new private space by choosing the **Create new space** button at the top of the modal window. Enter a name for your space and then choose **Create space and open notebook**. This creates a private space with the default instance type and latest SageMaker distribution image available, launches a JupyterLab application, and opens a new notebook.

4. Choose the name of the IAM runtime execution role that your EMR Serverless application can assume for the job run. Upon selection, a connection command populates the first cell of your notebook and initiates the connection with the EMR Serverless application.

   > **Important**
   >
   > To successfully connect a JupyterLab notebook to an EMR Serverless application, you must first associate the list of runtime roles with your domain or user profile, as outlined in the section called "Set up permissions". Failing to complete this step will prevent you from establishing the connection.

   Once the connection succeeds, a message confirms the connection, starts your EMR Serverless application, and initiates your Spark session.

   > **Note**
   >
   > When you connect to an EMR Serverless application, its status transitions from either `Stopped` or `Created` to `Started`.

Alternatively, you can connect to a cluster from a JupyterLab notebook.

1. Choose the **Cluster** button at the top right of your notebook. This opens a modal window listing the EMR Serverless applications that you can access. You can see the applications in the **Serverless applications** tab.
2. Select the application to which you want to connect, then choose **Connect**.
3. EMR Serverless supports runtime IAM roles that were preloaded when setting the required permissions as outlined in the section called "Set up permissions". Failing to complete this step will prevent you from establishing the connection.

   You can select your role from the **Amazon EMR execution role** drop down menu. When you connect to an EMR Serverless, Studio adds a code block to an active cell of your notebook to establish the connection.
4. An active cell populates and runs. This cell contains the connection magic command to connect your notebook to your application.

Once the connection succeeds, a message confirms the connection and the start of the Spark application. You can begin submitting your data processing jobs to your EMR Serverless application.

Stop or delete an EMR Serverless application from the Studio UI

You can stop (transition to the `Stopped` state) or delete (transition to the `Deleted` state) an EMR Serverless application from the list of applications in the Studio UI.

To stop or delete an application, navigate to the list of available EMR Serverless applications.

1. In the Studio UI, navigate to the left-side panel and select the **Data** node in the left navigation menu. Then, scroll and choose the **Amazon EMR applications and clusters** option. This opens up a page that displays the Amazon EMR applications that you can access from within the Studio environment, under the **Serverless applications** tab.
2. Select the name of the application that you want to stop or delete, and then choose the corresponding **Stop** or **Delete** button.
3. A confirmation message informs you that any pending job will be lost permanently.

Data preparation using Amazon EMR

> **Important**
>
> Amazon SageMaker Studio and Amazon SageMaker Studio Classic are two of the machine learning environments that you can use to interact with SageMaker AI.
> If your domain was created after November 30, 2023, Studio is your default experience.
> If your domain was created before November 30, 2023, Amazon SageMaker Studio Classic is your default experience. To use Studio if Amazon SageMaker Studio Classic is your default experience, see Migration from Amazon SageMaker Studio Classic.
> When you migrate from Amazon SageMaker Studio Classic to Amazon SageMaker Studio, there is no loss in feature availability. Studio Classic also exists as an application within Amazon SageMaker Studio to help you run your legacy machine learning workflows.

Amazon SageMaker Studio and Studio Classic come with built-in integration with Amazon EMR. Within JupyterLab and Studio Classic notebooks, data scientists and data engineers can discover and connect to existing Amazon EMR clusters, then interactively explore, visualize, and prepare large-scale data for machine learning using Apache Spark, Apache Hive, or Presto. With a single click, they can access the Spark UI to monitor the status and metrics of their Spark jobs without leaving their notebook.

Administrators can create AWS CloudFormation templates that define Amazon EMR clusters. They can then make those cluster templates available in the AWS Service Catalog for Studio and Studio Classic users to launch. Data scientists can then choose a predefined template to self-provision an Amazon EMR cluster directly from their Studio environment. Administrators can further parameterize the templates to let users choose aspects of the cluster within predefined values. For example, users may want to specify the number of core nodes or select the instance type of a node from a dropdown menu.

Using AWS CloudFormation, administrators can control the organizational, security, and networking setup of Amazon EMR clusters. Data scientists and data engineers can then customize those templates for their workloads to create on-demand Amazon EMR clusters directly from Studio and Studio Classic without setting up complex configurations. Users can terminate Amazon EMR clusters after use.

- **If you are an administrator**:

  Ensure that you have enabled communication between Studio or Studio Classic and Amazon EMR clusters. For instructions, see the Configure network access for your Amazon EMR cluster section. Once this communication is enabled, you can:

  - Configure Amazon EMR CloudFormation templates in the Service Catalog
  - Configure listing Amazon EMR clusters
- **If you are a data scientist or data engineer**, you can:
  - Launch an Amazon EMR cluster from Studio or Studio Classic
  - List Amazon EMR clusters from Studio or Studio Classic
  - Connect to an Amazon EMR cluster from SageMaker Studio or Studio Classic
  - Terminate an Amazon EMR cluster from Studio or Studio Classic
  - Access Spark UI from Studio or Studio Classic

Quickstart: Create a SageMaker AI sandbox domain to launch Amazon EMR clusters in Studio

This section walks you through the quick set up of a complete test environment in Amazon SageMaker Studio. You will be creating a new Studio domain that lets users launch new Amazon EMR clusters directly from Studio. The steps provide an example notebook that you can connect to an Amazon EMR cluster to start running Spark workloads. Using this notebook, you will build a Retrieval Augmented Generation System (RAG) using Amazon EMR Spark distributed processing and OpenSearch vector database.

> **Note**
>
> To get started, sign in to the AWS Management Console using an AWS Identity and Access Management (IAM) user account with admin permissions. For information on how to sign up for an AWS account and create a user with administrative access, see the section called "Complete Amazon SageMaker AI prerequisites".

To set up your Studio test environment and start running Spark jobs:

- Step 1: Create a SageMaker AI domain for launching Amazon EMR clusters in Studio
- Step 2: Launch a new Amazon EMR cluster from Studio UI
- Step 3: Connect a JupyterLab notebook to the Amazon EMR cluster
- Step 4: Clean up your AWS CloudFormation stack

Step 1: Create a SageMaker AI domain for launching Amazon EMR clusters in Studio

In the following steps, you apply a AWS CloudFormation stack to automatically create a new SageMaker AI domain. The stack also creates a user profile and configures the needed environment and permissions. The SageMaker AI domain is configured to let you directly launch Amazon EMR clusters from Studio. For this example, the Amazon EMR clusters are created in the same AWS account as SageMaker AI without authentication. You can find additional AWS CloudFormation stacks supporting various authentication methods like Kerberos in the getting_started GitHub repository.

> **Note**
>
> SageMaker AI allows 5 Studio domains per AWS account and AWS Region by default. Ensure your account has no more than 4 domains in your region before you create your stack.

Follow these steps to set up a SageMaker AI domain for launching Amazon EMR clusters from Studio.

1. Download the raw file of this AWS CloudFormation template from the `sagemaker-studio-emr` GitHub repository.
2. Go to the AWS CloudFormation console: https://console.aws.amazon.com/cloudformation
3. Choose **Create stack** and select **With new resources (standard)** from the drop down menu.
4. In **Step 1**:
   a. In the **Prepare template** section, select **Choose an existing template**.
   b. In the **Specify template** section, choose **Upload a template file**.
   c. Upload the downloaded AWS CloudFormation template and choose **Next**.
5. In **Step 2**, enter a **Stack name** and a **SageMakerDomainName** then choose **Next**.
6. In **Step 3**, keep all default values and choose **Next**.
7. In **Step 4**, check the box to acknowledge resource creation and choose **Create stack**. This creates a Studio domain in your account and region.

Step 2: Launch a new Amazon EMR cluster from Studio UI

In the following steps, you create a new Amazon EMR cluster from the Studio UI.

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/ and choose **Domains** in the left menu.
2. Click on your domain name **GenerativeAIDomain** to open the **Domain details** page.
3. Launch Studio from the user profile `genai-user`.

4. In the left navigation pane, go to **Data** then **Amazon EMR Clusters**.
5. On the Amazon EMR clusters page, choose **Create**. Select the template **SageMaker Studio Domain No Auth EMR** created by the AWS CloudFormation stack and then choose **Next**.
6. Enter a name for the new Amazon EMR cluster. Optionally update other parameters such as the instance type of core and master nodes, idle timeout, or number of core nodes.
7. Choose **Create resource** to launch the new Amazon EMR cluster.

   After creating the Amazon EMR cluster, follow the status on the **EMR Clusters** page. When the status changes to `Running/Waiting`, your Amazon EMR cluster is ready to use in Studio.

Step 3: Connect a JupyterLab notebook to the Amazon EMR cluster

In the following steps, you connect a notebook in JupyterLab to your running Amazon EMR cluster. For this example, you import a notebook allowing you to build a Retrieval Augmented Generation (RAG) system using Amazon EMR Spark distributed processing and OpenSearch vector database.

1. **Launch JupyterLab**

   From Studio, launch the JupyterLab application.
2. **Create a private space**

   If you have not created a space for your JupyterLab application, choose **Create a JupyterLab space**. Enter a name for the space, and keep the space as **Private**. Leave all other settings at their default values, and then choose **Create space**.

   Otherwise, run your JupyterLab space to launch a JupyterLab application.
3. **Deploy your LLM and embedding models for inference**

   - From the top menu, choose **File**, **New**, and then **Terminal**.
   - In the terminal, run the following command.

   ```
   wget --no-check-certificate https://raw.githubusercontent.com/
   aws-samples/sagemaker-studio-foundation-models/main/lab-00-setup/
   Lab_0_Warm_Up_Deploy_EmbeddingModel_Llama2_on_Nvidia.ipynb
   mkdir AWSGuides
   cd AWSGuides
   wget --no-check-certificate https://raw.githubusercontent.com/aws-
   samples/sagemaker-studio-foundation-models/main/lab-03-rag/AWSGuides/
   AmazonSageMakerDeveloperGuide.pdf
   ```

```
wget --no-check-certificate https://raw.githubusercontent.com/aws-
samples/sagemaker-studio-foundation-models/main/lab-03-rag/AWSGuides/
EC2DeveloperGuide.pdf
wget --no-check-certificate https://raw.githubusercontent.com/aws-samples/
sagemaker-studio-foundation-models/main/lab-03-rag/AWSGuides/S3DeveloperGuide.pdf
```

This retrieves the the `Lab_0_Warm_Up_Deploy_EmbeddingModel_Llama2_on_Nvidia.ipynb` notebook to your local directory and downloads three PDF files into a local `AWSGuides` folder.

- Open `lab-00-setup/Lab_0_Warm_Up_Deploy_EmbeddingModel_Llama2_on_Nvidia.ipynb`, keep the `Python 3 (ipykernel)` kernel, and run each cell.

> **Warning**
>
> In the **Llama 2 License Agreement** section, ensure to accept the Llama2 EULA before you continue.
>
> The notebook deploys two models, `Llama 2` and `all-MiniLM-L6-v2 Models`, on `ml.g5.2xlarge` for inference.

The deployment of the models and the creation of the endpoints may take some time.

4. **Open your main notebook**

   In JupyterLab, open your terminal and run the following command.

```
cd ..
wget --no-check-certificate https://raw.githubusercontent.com/
aws-samples/sagemaker-studio-foundation-models/main/lab-03-rag/
Lab_3_RAG_on_SageMaker_Studio_using_EMR.ipynb
```

   You should see the additional `Lab_3_RAG_on_SageMaker_Studio_using_EMR.ipynb` notebook in the left panel of JupyterLab.

5. **Choose a PySpark kernel**

   Open your `Lab_3_RAG_on_SageMaker_Studio_using_EMR.ipynb` notebook and ensure that you are using the `SparkMagic PySpark` kernel. You can switch kernel at the top right of your notebook. Choose the current kernel name to open up a kernel selection modal, and then choose `SparkMagic PySpark`.

6. **Connect your notebook to the cluster**

   a. At the top right of your notebook, choose **Cluster**. This action opens a modal window that lists all of the running clusters that you have permission to access.

   b. Select your cluster then choose **Connect**. A new credential type selection modal window opens up.

   c. Choose **No credential** and then **Connect**.

   d. A notebook cell automatically populates and runs. The notebook cell loads the `sagemaker_studio_analytics_extension.magics` extension, which provides functionality to connect to the Amazon EMR cluster. It then uses the `%sm_analytics` magic command to initiate the connection to your Amazon EMR cluster and the Spark application.

Note

Ensure that the connection string to your Amazon EMR cluster has an authentication type set to `None`. This is illustrated by the value `--auth-type None` in the following example. You can modify the field if necessary.

```
%load_ext sagemaker_studio_analytics_extension.magics
%sm_analytics emr connect --verify-certificate False --cluster-id your-
cluster-id --auth-type None --language python
```

   e. Once you successfully establish the connection, your connection cell output message should display your `SparkSession` details including your cluster ID, `YARN` application ID, and a link to the Spark UI to monitor your Spark jobs.

You are ready to use the `Lab_3_RAG_on_SageMaker_Studio_using_EMR.ipynb` notebook. This example notebook runs distributed PySpark workloads for building a RAG system using LangChain and OpenSearch.

Step 4: Clean up your AWS CloudFormation stack

After you are finished, make sure to terminate your two endpoints and delete your AWS CloudFormation stack to prevent continued charges. Deleting the stack cleans up all the resources that were provisioned by the stack.

To delete your AWS CloudFormation stack when you are done with it

1. Go to the AWS CloudFormation console: https://console.aws.amazon.com/cloudformation
2. Select the stack you want to delete. You can search for it by name or find it in the list of stacks.
3. Click the **Delete** button to finalize deleting the stack and then **Delete** again to acknowledge that this will delete all resources created by the stack.

   Wait for the stack deletion to complete. This can take a few minutes. AWS CloudFormation automatically cleans up all resources defined in the stack template.
4. Verify that all resources created by the stack have been deleted. For example, check for any leftover Amazon EMR cluster.

To remove the API endpoints for a model

1. Go to the SageMaker AI console: https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference** and then **Endpoints**.
3. Select the endpoint `hf-allminil6v2-embedding-ep` and then choose **Delete** in the **Actions** drop down list. Repeat the step for the endpoint `meta-llama2-7b-chat-tg-ep`.

Admin guide

This section provides prerequisites, networking instructions for allowing the communication between Studio or Studio Classic and Amazon EMR clusters. It covers different deployment scenarios - when Studio and Amazon EMR are provisioned within private Amazon VPCs without public internet access, as well as when they need to communicate over the internet.

It walks through how administrators can use the AWS Service Catalog to make AWS CloudFormation templates available to Studio, allowing data scientists to discover and self-provision Amazon EMR clusters directly from within Studio. This involves creating a Service Catalog portfolio, granting requisite permissions, referencing the Amazon EMR templates, and parameterizing them to enable customizations during cluster creation.

Last, it provides guidance on configuring discoverability of existing running Amazon EMR clusters from Studio, and Studio Classic, covering single account and cross-account access scenarios along with the necessary IAM permissions.

Topics

Configure Amazon EMR CloudFormation templates in the Service Catalog

This topic assumes administrators are familiar with AWS CloudFormation, portfolios and products in AWS Service Catalog, as well as Amazon EMR.

To simplify the creation of Amazon EMR clusters from Studio, administrators can register an Amazon EMR CloudFormation template as a product in an AWS Service Catalog portfolio. To make the template available to data scientists, they must associate the portfolio with the SageMaker AI execution role used in Studio or Studio Classic. Finally, to allow users to discover templates, provision clusters, and connect to Amazon EMR clusters from Studio or Studio Classic, administrators need to set appropriate access permissions.

The Amazon EMR AWS CloudFormation templates can allow end-users to customize various cluster aspects. For example, administrators can define an approved list of instance types that users can choose from when creating a cluster.

The following instructions use end-to-end CloudFormation stacks to setup a Studio or Studio Classic domain, a user profile, a Service Catalog portfolio, and populate an Amazon EMR launch template. The following steps highlight the specific settings that administrators must apply in their end-to-end stack to enable Studio or Studio Classic to access Service Catalog products and provision Amazon EMR clusters.

> **Note**
>
> The GitHub repository aws-samples/sagemaker-studio-emr contains example end-to-end CloudFormation stacks that deploy the necessary IAM roles, networking, SageMaker domain, user profile, Service Catalog portfolio, and add an Amazon EMR launch CloudFormation template. The templates provide different authentication options between Studio or Studio Classic and the Amazon EMR cluster. In these example templates, the parent CloudFormation stack passes SageMaker AI VPC, security group, and subnet parameters to the Amazon EMR cluster template.
> The sagemaker-studio-emr/cloudformation/emr_servicecatalog_templates repository contains various sample Amazon EMR CloudFormation launch templates, including options for single account and cross-account deployments.
> Refer to Connect to an Amazon EMR cluster from SageMaker Studio or Studio Classic for details on the authentication methods you can use to connect to an Amazon EMR cluster.

To let data scientists discover Amazon EMR CloudFormation templates and provision clusters from Studio or Studio Classic, follow these steps.

Step 0: Check your networking and prepare your CloudFormation stack

Before you start:

- Ensure that you have reviewed the networking and security requirements in Configure network access for your Amazon EMR cluster.
- You must have an existing end-to-end CloudFormation stack that supports the authentication method of your choice. You can find examples of such CloudFormation templates in the aws-samples/sagemaker-studio-emr GitHub repository. The following steps highlight the specific configurations in your end-to-end stack to enable the use of Amazon EMR templates within Studio or Studio Classic.

Step 1: Associate your Service Catalog portfolio with SageMaker AI

In your Service Catalog portfolio, associate your portfolio ID with the SageMaker AI execution role accessing your cluster.

To do so, add the following section (here in YAML format) to your stack. This grants the SageMaker AI execution role access to the specified Service Catalog portfolio containing products like Amazon EMR templates. It allows roles assumed by SageMaker AI to launch those products.

Replace *SageMakerExecutionRole.Arn* and *SageMakerStudioEMRProductPortfolio.ID* with their actual values.

```
SageMakerStudioEMRProductPortfolioPrincipalAssociation:
    Type: AWS::ServiceCatalog::PortfolioPrincipalAssociation
    Properties:
      PrincipalARN: SageMakerExecutionRole.Arn
      PortfolioId: SageMakerStudioEMRProductPortfolio.ID
      PrincipalType: IAM
```

For details on the required set of IAM permissions, see the permissions section.

Step 2: Reference an Amazon EMR template in a Service Catalog product

In a Service Catalog product of your portfolio, reference an Amazon EMR template resource and ensure its visibility in Studio or Studio Classic.

To do so, reference the Amazon EMR template resource in the Service Catalog product definition, and then add the following tag key `"sagemaker:studio-visibility:emr"` set to the value `"true"` (see the example in YAML format).

In the Service Catalog product definition, the AWS CloudFormation template of the cluster is referenced via URL. The additional tag set to true ensures the visibility of the Amazon EMR templates in Studio or Studio Classic.

Note

The Amazon EMR template referenced by the provided URL in the example does not enforce any authentication requirements when launched. This option is meant for demonstration and learning purposes. It is not recommended in a production environment.

```
SMStudioEMRNoAuthProduct:
    Type: AWS::ServiceCatalog::CloudFormationProduct
    Properties:
      Owner: AWS
      Name: SageMaker Studio Domain No Auth EMR
```

```
      ProvisioningArtifactParameters:
        - Name: SageMaker Studio Domain No Auth EMR
          Description: Provisions a SageMaker domain and No Auth EMR Cluster
          Info:
            LoadTemplateFromURL: Link to your CloudFormation template. For example,
 https://aws-blogs-artifacts-public.s3.amazonaws.com/artifacts/astra-m4-sagemaker/end-to-end/CFN-EMR-NoStudioNoAuthTemplate-v3.yaml
      Tags:
        - Key: "sagemaker:studio-visibility:emr"
          Value: "true"
```

Step 3: Parameterize the Amazon EMR CloudFormation template

The CloudFormation template used to define the Amazon EMR cluster within the Service Catalog product allows administrators to specify configurable parameters. Administrators can define `Default` values and `AllowedValues` ranges for these parameters within the template's `Parameters` section. During the cluster launch process, data scientists can provide custom inputs or make selections from those predefined options to customize certain aspects of their Amazon EMR cluster.

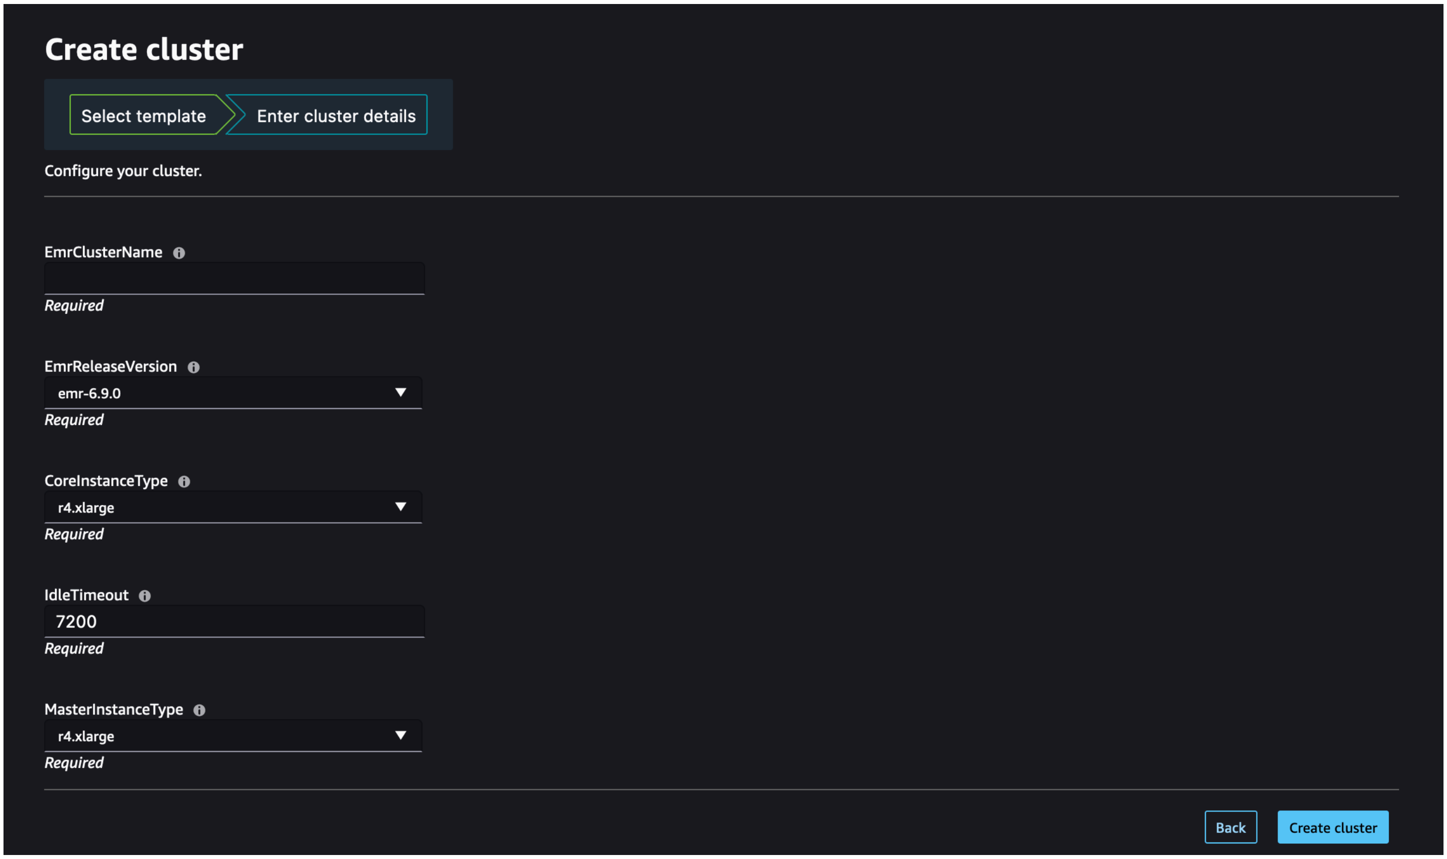
The following example illustrates additional input parameters that administrators can set when creating an Amazon EMR template.

```
"Parameters": {
    "EmrClusterName": {
      "Type": "String",
      "Description": "EMR cluster Name."
    },
    "MasterInstanceType": {
      "Type": "String",
      "Description": "Instance type of the EMR master node.",
      "Default": "m5.xlarge",
      "AllowedValues": [
        "m5.xlarge",
        "m5.2xlarge",
        "m5.4xlarge"
      ]
    },
    "CoreInstanceType": {
      "Type": "String",
      "Description": "Instance type of the EMR core nodes.",
      "Default": "m5.xlarge",
```

```
      "AllowedValues": [
        "m5.xlarge",
        "m5.2xlarge",
        "m5.4xlarge",
        "m3.medium",
        "m3.large",
        "m3.xlarge",
        "m3.2xlarge"
      ]
    },
    "CoreInstanceCount": {
      "Type": "String",
      "Description": "Number of core instances in the EMR cluster.",
      "Default": "2",
      "AllowedValues": [
        "2",
        "5",
        "10"
      ]
    },
    "EmrReleaseVersion": {
      "Type": "String",
      "Description": "The release version of EMR to launch.",
      "Default": "emr-5.33.1",
      "AllowedValues": [
        "emr-5.33.1",
        "emr-6.4.0"
      ]
    }
  }
```

After administrators have made the Amazon EMR CloudFormation templates available within Studio, data scientists can use them to self-provision Amazon EMR clusters. The `Parameters` section defined in the template translates into input fields on the cluster creation form within Studio or Studio Classic. For each parameter, data scientists can either enter a custom value into the input box or select from the predefined options listed in a dropdown menu, which corresponds to the `AllowedValues` specified in the template.

The following illustration shows the dynamic form assembled from a CloudFormation Amazon EMR template to create an Amazon EMR cluster in Studio or Studio Classic.



Visit Launch an Amazon EMR cluster from Studio or Studio Classic to learn about how to launch a cluster from Studio or Studio Classic using those Amazon EMR templates.

Step 4: Set up the permissions to enable listing and launching Amazon EMR clusters from Studio

Last, attach the required IAM permissions to enable listing existing running Amazon EMR clusters and self-provisioning new clusters from Studio or Studio Classic.

The role(s) to which you must add those permissions depends on whether Studio or Studio Classic and Amazon EMR are deployed in the same account (choose *Single Account*) or in different accounts (choose *Cross account*).

> **Important**
>
> You can only discover and connect to Amazon EMR clusters for JupyterLab and Studio Classic applications that are launched from private spaces. Ensure that the Amazon EMR clusters are located in the same AWS region as your Studio environment.

Single account

If your Amazon EMR clusters and Studio or Studio Classic are deployed in the same AWS account, attach the following permissions to the SageMaker AI execution role accessing your cluster.

1. **Step 1**: Retrieve the ARN of the SageMaker AI execution role used by your private space.

   For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.
2. **Step 2**: Attach the following permissions to the SageMaker AI execution role accessing your Amazon EMR clusters.

   a. Navigate to the IAM console.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

   c. Follow the link to your role.

   d. Choose **Add permissions** and then **Create inline policy**.

   e. In the **JSON** tab, add the Amazon EMR permissions allowing Amazon EMR access and operations. For details on the policy document, see *List Amazon EMR policies* in Reference policies. Replace the `region`, and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

   f. Choose **Next** and then provide a **Policy name**.

   g. Choose **Create policy**.

   h. Repeat the **Create inline policy** step to add another policy granting the execution role the permissions to provision new Amazon EMR clusters using AWS CloudFormation templates. For details on the policy document, see *Create Amazon EMRclusters policies* in Reference policies. Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

> **Note**
>
> Users of role-based access control (RBAC) connectivity to Amazon EMR clusters should also refer to the section called "Configure runtime role authentication when your Amazon EMR cluster and Studio are in the same account".

Cross account

Before you get started, retrieve the ARN of the SageMaker AI execution role used by your private space.

For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

If your Amazon EMR clusters and Studio or Studio Classic are deployed in separate AWS accounts, you configure the permissions on both accounts.

> **Note**
>
> Users of role-based access control (RBAC) connectivity to Amazon EMR clusters should also refer to the section called "Configure runtime role authentication when your cluster and Studio are in different accounts".

On the Amazon EMR cluster account

Follow these steps to create the necessary roles and policies on the account where Amazon EMR is deployed, also referred to as the *trusting account*:

1. **Step 1**: Retrieve the ARN of the service role of your Amazon EMR cluster.

   To learn about how to find the ARN of the service role of a cluster, see Configure IAM service roles for Amazon EMR permissions to AWS services and resources.

2. **Step 2**: Create a custom IAM role named `AssumableRole` with the following configuration:

- Permissions: Grant the necessary permissions to `AssumableRole` to allow accessing Amazon EMR resources. This role is also known as an *Access role* in scenarios involving cross-account access.
- Trust relationship: Configure the trust policy for `AssumableRole` to allow assuming the execution role (The `SageMakerExecutionRole` in the cross-account diagram) from the Studio account that requires access.

By assuming the role, Studio or Studio Classic can gain temporary access to the permissions it needs in Amazon EMR.

For detailed instructions on how to create a new `AssumableRole` in your Amazon EMR AWS account, follow these steps:

a. Navigate to the [IAM console](https://console.aws.amazon.com/iam).

b. In the left navigation pane, choose **Policy**, and then **Create policy**.

c. In the **JSON** tab, add the Amazon EMR permissions allowing Amazon EMR access and operations. For details on the policy document, see *List Amazon EMR policies* in [Reference policies](). Replace the `region`, and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

d. Choose **Next** and then provide a **Policy name**.

e. Choose **Create policy**.

f. In the left navigation pane, choose **Roles** and then **Create role**.

g. On the **Create role** page, choose **Custom trust policy** as the trusted entity.

h. Paste in the following JSON document in the **Custom trust policy** section and then choose **Next**.

For users of Studio and JupyterLab

Replace `studio-account` with the Studio account ID, and `AmazonSageMaker-ExecutionRole` with the execution role used by your JupyterLab space.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/service-
role/AmazonSageMaker-ExecutionRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For users of Studio Classic

Replace `studio-account` with the Studio Classic account ID.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

i. In the **Add permissions** page, add the permission you just created and then choose **Next**.

j. On the **Review** page, enter a name for the role such as `AssumableRole` and an optional description.

k. Review the role details and choose **Create role**.

For more information about creating a role on an AWS account, see [Creating an IAM role (console)](#).

On the Studio account

On the account where Studio is deployed, also referred to as the *trusted account*, update the SageMaker AI execution role accessing your clusters with the required permissions to access resources in the trusting account.

1. **Step 1**: Retrieve the ARN of the SageMaker AI execution role used by your private space.

   For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

2. **Step 2**: Attach the following permissions to the SageMaker AI execution role accessing your Amazon EMR clusters.

   a. Navigate to the IAM console.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

   c. Follow the link to your role.

   d. Choose **Add permissions** and then **Create inline policy**.

   e. In the **JSON** tab, add the inline policy granting the role permissions to update the domains, user profiles, and spaces. For details on the policy document, see *Domain, user profile, and space update actions policy* in Reference policies. Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

   f. Choose **Next** and then provide a **Policy name**.

   g. Choose **Create policy**.

   h. Repeat the **Create inline policy** step to add another policy granting the execution role the permissions to assume the `AssumableRole` and then perform actions permitted by the role's access policy. Replace `emr-account` with the Amazon EMR account ID, and `AssumableRole` with the name of the assumable role created in the Amazon EMR account.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Resource": [
                "arn:aws:iam::111122223333:role/AssumableRole"
            ]
        }
    ]
}
```

i. Repeat the **Create inline policy** step to add another policy granting the execution role the permissions to provision new Amazon EMR clusters using AWS CloudFormation templates. For details on the policy document, see *Create Amazon EMRclusters policies* in Reference policies. Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

j. (Optional) To allow listing Amazon EMR clusters deployed in the same account as Studio, add an additional inline policy to your Studio execution role as defined in *List Amazon EMR policies* in Reference policies.

3. **Step 3**: Associate your assumable role(s) (access role) with your domain or user profile. JupyterLab users in Studio can use the SageMaker AI console or the provided script.

Choose the tab that corresponds to your use case.

Associate your assumable roles in JupyterLab using the SageMaker AI console

To associate your assumable roles with your user profile or domain using the SageMaker AI console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **domain**, and then select the domain using the SageMaker AI execution role whose permissions you updated.

3. • To add your assumable role(s) (access role) to your domain: In the **App Configurations** tab of the **Domain details** page, navigate to the **JupyterLab** section.
   • To add your assumable role(s) (access role) to your user profile: On the **Domain details** page, chose the **User profiles** tab, select the user profile using the SageMaker AI execution role whose permissions you updated. In the **App Configurations** tab, navigate to the **JupyterLab** section.
4. Choose **Edit** and add the ARNs of your assumable role (access role).
5. Choose **Submit**.

Associate your assumable roles in JupyterLab using a Python script

In a JupyterLab application started from a space using the SageMaker AI execution role whose permissions you updated, run the following command in a terminal. Replace the `domainID`, `user-profile-name`, `emr-accountID`, and `AssumableRole` (`EMRServiceRole` for [RBAC runtime roles]) with their proper values. This code snippet updates the user profile settings for a specific user profile (use `client.update_userprofile`) or domain settings (use `client.update_domain`) within a SageMaker AI domain. Specifically, it allows the JupyterLab application to assume a particular IAM role (`AssumableRole`) for running Amazon EMR clusters within the Amazon EMR account.

```
import botocore.session
import json
sess = botocore.session.get_session()
client = sess.create_client('sagemaker')

client.update_userprofile(
DomainId="domainID", 
UserProfileName="user-profile-name",
DefaultUserSettings={
    'JupyterLabAppSettings': {
        'EmrSettings': {
            'AssumableRoleArns': ["arn:aws:iam::emr-
accountID:role/AssumableRole"],
            'ExecutionRoleArns': ["arn:aws:iam::emr-
accountID:role/EMRServiceRole",
                                  "arn:aws:iam::emr-
accountID:role/AnotherServiceRole"]
        }
```

```
    }
})
resp = client.describe_user_profile(DomainId="domainID", UserProfileName=user-
profile-name")

resp['CreationTime'] = str(resp['CreationTime'])
resp['LastModifiedTime'] = str(resp['LastModifiedTime'])
print(json.dumps(resp, indent=2))
```

For users of Studio Classic

Provide the ARN of the `AssumableRole` to your Studio Classic execution role. The ARN is loaded by the Jupyter server at launch. The execution role used by Studio assumes that cross-account role to discover and connect to Amazon EMR clusters in the *trusting account*.

You can specify this information by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your domain or a specific user profile. The LCC script that you use must be a JupyterServer configuration. For more information on how to create an LCC script, see Use Lifecycle Configurations with Studio Classic.

The following is an example LCC script. To modify the script, replace `AssumableRole` and `emr-account` with their respective values. The number of cross-accounts is limited to five.

```
# This script creates the file that informs Studio Classic that the role
 "arn:aws:iam::emr-account:role/AssumableRole" in remote account "emr-account"
 must be assumed to list and describe Amazon EMR clusters in the remote account.

#!/bin/bash

set -eux

FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY

cat > "$FILE" <<- "EOF"
{
  emr-cross-account1: "arn:aws:iam::emr-cross-account1:role/AssumableRole",
  emr-cross-account2: "arn:aws:iam::emr-cross-account2:role/AssumableRole"
```

```
}
EOF
```

After the LCC runs and the files are written, the server reads the file `/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE/emr-discovery-iam-role-arns-DO_NOT_DELETE.json` and stores the cross-account ARN.

Configure listing Amazon EMR clusters

Administrators can configure permissions for the SageMaker Studio execution role to grant users the ability to view the list of Amazon EMR clusters they have access to, allowing them to connect to these clusters. The clusters to which you want access can be deployed in the same AWS account as Studio (choose *Single account*) or in separate accounts (choose *Cross account*). The following page describes how to grant the permissions for viewing Amazon EMR clusters from Studio or Studio Classic.

> **Important**
>
> You can only discover and connect to Amazon EMR clusters for JupyterLab and Studio Classic applications that are launched from private spaces. Ensure that the Amazon EMR clusters are located in the same AWS region as your Studio environment.

To let data scientists discover and then connect to Amazon EMRclusters from Studio or Studio Classic, follow these steps.

Single account

If your Amazon EMR clusters and Studio or Studio Classic are deployed in the same AWS account, attach the following permissions to the SageMaker AI execution role accessing your cluster.

1. **Step 1**: Retrieve the ARN of the SageMaker AI execution role used by your private space.

   For information on spaces and execution roles in SageMaker AI, see [Understanding domain space permissions and execution roles](#).

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see [Get your execution role](#).

2. **Step 2**: Attach the following permissions to the SageMaker AI execution role accessing your Amazon EMR clusters.

   a. Navigate to the IAM console.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

   c. Follow the link to your role.

   d. Choose **Add permissions** and then **Create inline policy**.

   e. In the **JSON** tab, add the Amazon EMR permissions allowing Amazon EMR access and operations. For details on the policy document, see *List Amazon EMR policies* in Reference policies. Replace the `region`, and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

   f. Choose **Next** and then provide a **Policy name**.

   g. Choose **Create policy**.

> **Note**
>
> Users of role-based access control (RBAC) connectivity to Amazon EMR clusters should also refer to the section called "Configure runtime role authentication when your Amazon EMR cluster and Studio are in the same account".

Cross account

Before you get started, retrieve the ARN of the SageMaker AI execution role used by your private space.

For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

If your Amazon EMR clusters and Studio or Studio Classic are deployed in separate AWS accounts, you configure the permissions on both accounts.

Note

Users of role-based access control (RBAC) connectivity to Amazon EMR clusters should also refer to the section called "Configure runtime role authentication when your cluster and Studio are in different accounts".

On the Amazon EMR cluster account

Follow these steps to create the necessary roles and policies on the account where Amazon EMR is deployed, also referred to as the *trusting account*:

1. **Step 1**: Retrieve the ARN of the service role of your Amazon EMR cluster.

   To learn about how to find the ARN of the service role of a cluster, see Configure IAM service roles for Amazon EMR permissions to AWS services and resources.

2. **Step 2**: Create a custom IAM role named `AssumableRole` with the following configuration:

   - Permissions: Grant the necessary permissions to `AssumableRole` to allow accessing Amazon EMR resources. This role is also known as an *Access role* in scenarios involving cross-account access.
   - Trust relationship: Configure the trust policy for `AssumableRole` to allow assuming the execution role (The `SageMakerExecutionRole` in the cross-account diagram) from the Studio account that requires access.

   By assuming the role, Studio or Studio Classic can gain temporary access to the permissions it needs in Amazon EMR.

   For detailed instructions on how to create a new `AssumableRole` in your Amazon EMR AWS account, follow these steps:

   a. Navigate to the IAM console.

   b. In the left navigation pane, choose **Policy**, and then **Create policy**.

   c. In the **JSON** tab, add the Amazon EMR permissions allowing Amazon EMR access and operations. For details on the policy document, see *List Amazon EMR policies* in Reference policies. Replace the `region`, and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

d. Choose **Next** and then provide a **Policy name**.

e. Choose **Create policy**.

f. In the left navigation pane, choose **Roles** and then **Create role**.

g. On the **Create role** page, choose **Custom trust policy** as the trusted entity.

h. Paste in the following JSON document in the **Custom trust policy** section and then choose **Next**.

For users of Studio and JupyterLab

Replace `studio-account` with the Studio account ID, and `AmazonSageMaker-ExecutionRole` with the execution role used by your JupyterLab space.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/service-
role/AmazonSageMaker-ExecutionRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For users of Studio Classic

Replace `studio-account` with the Studio Classic account ID.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
                "Effect": "Allow",
                "Principal": {
                    "AWS": "arn:aws:iam::111122223333:root"
                },
                "Action": "sts:AssumeRole"
            }
        ]
    }
```

i. In the **Add permissions** page, add the permission you just created and then choose **Next**.

j. On the **Review** page, enter a name for the role such as `AssumableRole` and an optional description.

k. Review the role details and choose **Create role**.

For more information about creating a role on an AWS account, see Creating an IAM role (console).

On the Studio account

On the account where Studio is deployed, also referred to as the *trusted account*, update the SageMaker AI execution role accessing your clusters with the required permissions to access resources in the trusting account.

1. **Step 1**: Retrieve the ARN of the SageMaker AI execution role used by your private space.

   For information on spaces and execution roles in SageMaker AI, see Understanding domain space permissions and execution roles.

   For more information about how to retrieve the ARN of SageMaker AI's execution role, see Get your execution role.

2. **Step 2**: Attach the following permissions to the SageMaker AI execution role accessing your Amazon EMR clusters.

   a. Navigate to the IAM console.

   b. Choose **Roles** and then search for your execution role by name in the **Search** field. The role name is the last part of the ARN, after the last forward slash (/).

   c. Follow the link to your role.

   d. Choose **Add permissions** and then **Create inline policy**.

e. In the **JSON** tab, add the inline policy granting the role permissions to update the domains, user profiles, and spaces. For details on the policy document, see *Domain, user profile, and space update actions policy* in [Reference policies](). Replace the `region` and `accountID` with their actual values before copying the list of statements to the inline policy of your role.

f. Choose **Next** and then provide a **Policy name**.

g. Choose **Create policy**.

h. Repeat the **Create inline policy** step to add another policy granting the execution role the permissions to assume the `AssumableRole` and then perform actions permitted by the role's access policy. Replace `emr-account` with the Amazon EMR account ID, and `AssumableRole` with the name of the assumable role created in the Amazon EMR account.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Resource": [
                "arn:aws:iam::111122223333:role/AssumableRole"
            ]
        }
    ]
}
```

i. (Optional) To allow listing Amazon EMR clusters deployed in the same account as Studio, add an additional inline policy to your Studio execution role as defined in *List Amazon EMR policies* in [Reference policies]().

3. **Step 3**: Associate your assumable role(s) (access role) with your domain or user profile. JupyterLab users in Studio can use the SageMaker AI console or the provided script.

   Choose the tab that corresponds to your use case.

Associate your assumable roles in JupyterLab using the SageMaker AI console

To associate your assumable roles with your user profile or domain using the SageMaker AI console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **domain**, and then select the domain using the SageMaker AI execution role whose permissions you updated.
3. • To add your assumable role(s) (access role) to your domain: In the **App Configurations** tab of the **Domain details** page, navigate to the **JupyterLab** section.
   • To add your assumable role(s) (access role) to your user profile: On the **Domain details** page, chose the **User profiles** tab, select the user profile using the SageMaker AI execution role whose permissions you updated. In the **App Configurations** tab, navigate to the **JupyterLab** section.
4. Choose **Edit** and add the ARNs of your assumable role (access role).
5. Choose **Submit**.

Associate your assumable roles in JupyterLab using a Python script

In a JupyterLab application started from a space using the SageMaker AI execution role whose permissions you updated, run the following command in a terminal. Replace the `domainID`, `user-profile-name`, `emr-accountID`, and `AssumableRole` (`EMRServiceRole` for [RBAC runtime roles](https://docs.aws.amazon.com/)) with their proper values. This code snippet updates the user profile settings for a specific user profile (use `client.update_userprofile`) or domain settings (use `client.update_domain`) within a SageMaker AI domain. Specifically, it allows the JupyterLab application to assume a particular IAM role (`AssumableRole`) for running Amazon EMR clusters within the Amazon EMR account.

```
import botocore.session
import json
sess = botocore.session.get_session()
client = sess.create_client('sagemaker')

client.update_userprofile(
DomainId="domainID",
```

```
UserProfileName="user-profile-name",
DefaultUserSettings={
    'JupyterLabAppSettings': {
        'EmrSettings': {
            'AssumableRoleArns': ["arn:aws:iam::emr-
accountID:role/AssumableRole"],
            'ExecutionRoleArns': ["arn:aws:iam::emr-
accountID:role/EMRServiceRole",
                                 "arn:aws:iam::emr-
accountID:role/AnotherServiceRole"]
        }

    }
})
resp = client.describe_user_profile(DomainId="domainID", UserProfileName=user-
profile-name")

resp['CreationTime'] = str(resp['CreationTime'])
resp['LastModifiedTime'] = str(resp['LastModifiedTime'])
print(json.dumps(resp, indent=2))
```

For users of Studio Classic

Provide the ARN of the `AssumableRole` to your Studio Classic execution role. The ARN is loaded by the Jupyter server at launch. The execution role used by Studio assumes that cross-account role to discover and connect to Amazon EMR clusters in the *trusting account*.

You can specify this information by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your domain or a specific user profile. The LCC script that you use must be a JupyterServer configuration. For more information on how to create an LCC script, see [Use Lifecycle Configurations with Studio Classic](#).

The following is an example LCC script. To modify the script, replace `AssumableRole` and `emr-account` with their respective values. The number of cross-accounts is limited to five.

```
# This script creates the file that informs Studio Classic that the role
 "arn:aws:iam::emr-account:role/AssumableRole" in remote account "emr-account"
 must be assumed to list and describe Amazon EMR clusters in the remote account.

#!/bin/bash

set -eux
```

```
FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY

cat > "$FILE" <<- "EOF"
{
  emr-cross-account1: "arn:aws:iam::emr-cross-account1:role/AssumableRole",
  emr-cross-account2: "arn:aws:iam::emr-cross-account2:role/AssumableRole"
}
EOF
```

After the LCC runs and the files are written, the server reads the file `/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE/emr-discovery-iam-role-arns-DO_NOT_DELETE.json` and stores the cross-account ARN.

Refer to List Amazon EMR clusters from Studio or Studio Classic to learn about how to discover and connect to Amazon EMR clusters from Studio or Studio Classic notebooks.

Configure IAM runtime roles for Amazon EMR cluster access in Studio

When you connect to an Amazon EMR cluster from your Studio or Studio Classic notebooks, you can visually browse a list of IAM roles, known as runtime roles, and select one on the fly. Subsequently, all your Apache Spark, Apache Hive, or Presto jobs created from your notebook access only the data and resources permitted by policies attached to the runtime role. Also, when data is accessed from data lakes managed with AWS Lake Formation, you can enforce table-level and column-level access using policies attached to the runtime role.

With this capability, you and your teammates can connect to the same cluster, each using a runtime role scoped with permissions matching your individual level of access to data. Your sessions are also isolated from one another on the shared cluster.

To try out this feature using Studio Classic, see Apply fine-grained data access controls with AWS Lake Formation and Amazon EMR from Amazon SageMaker Studio Classic . This blog post helps you set up a demo environment where you can try using preconfigured runtime roles to connect to Amazon EMR clusters.

Prerequisites

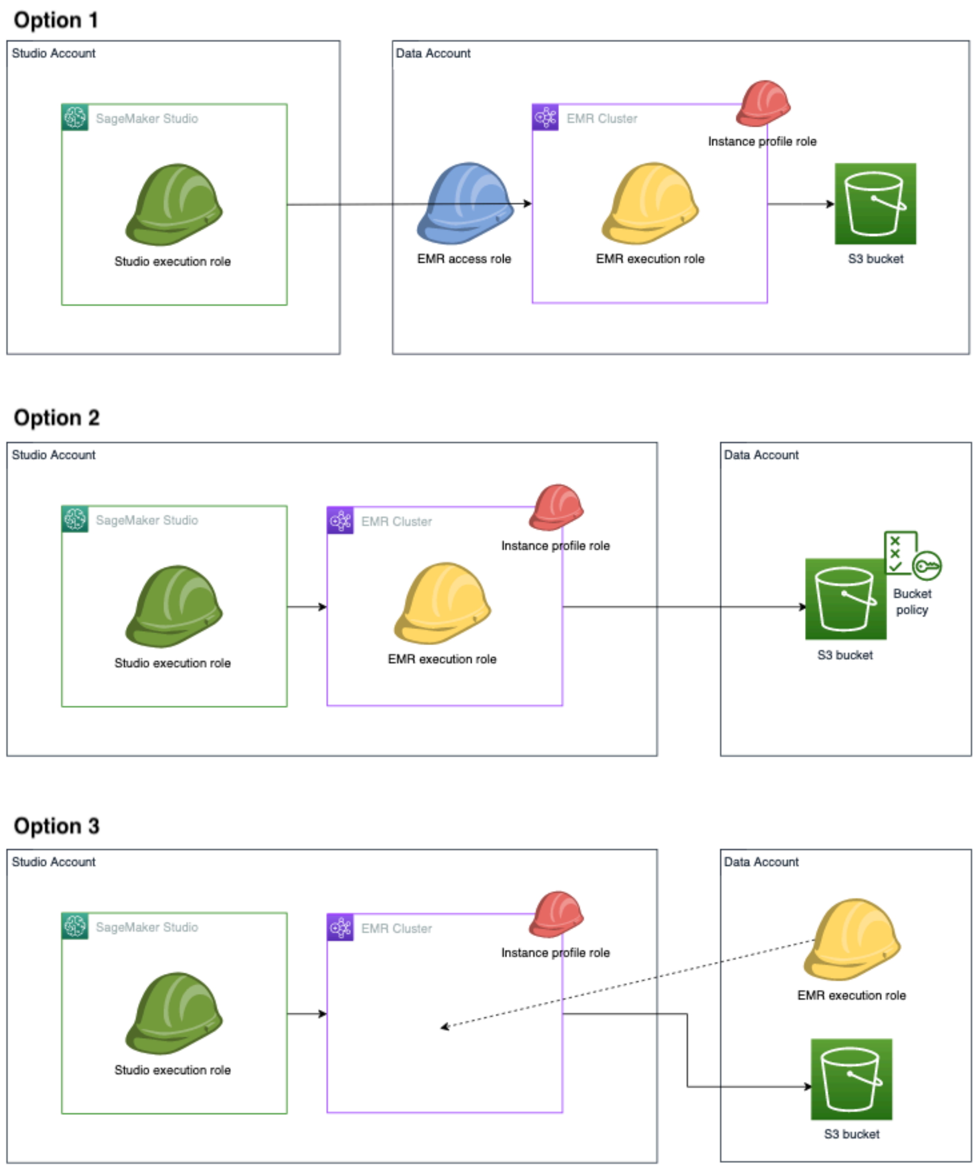
Before you get started, make sure you meet the following prerequisites:

- Use Amazon EMR version 6.9 or above.
- **For Studio Classic users**: Use JupyterLab version 3 in the Studio Classic Jupyter server application configuration. This version supports Studio Classic connection to Amazon EMR clusters using runtime roles.

  For Studio users: Use a SageMaker distribution image version `1.10` or above.
- Allow the use of runtime roles in your cluster's security configuration. For more information, see Runtime roles for Amazon EMR steps.
- Create a notebook with any of the kernels listed in Supported images and kernels to connect to an Amazon EMR cluster from Studio or Studio Classic.
- Make sure you review the instructions in Set up Studio to use runtime IAM roles to configure your runtime roles.

Cross-account connection scenarios

Runtime role authentication supports a variety of cross-account connection scenarios when your data resides outside of your Studio account. The following image shows three different ways you can assign your Amazon EMR cluster, data, and even Amazon EMR runtime execution role between your Studio and data accounts:



In option 1, your Amazon EMR cluster and Amazon EMR runtime execution role are in a separate data account from the Studio account. You define a separate Amazon EMR access role (also referred to as `Assumable role`) permission policy which grants permission to Studio or Studio Classic execution role to assume the Amazon EMR access role. The Amazon EMR access role then calls the Amazon EMR API `GetClusterSessionCredentials` on behalf of your Studio or Studio Classic execution role, giving you access to the cluster.

In option 2, your Amazon EMR cluster and Amazon EMR runtime execution role are in your Studio account. Your Studio execution role has permission to use the Amazon EMR API `GetClusterSessionCredentials` to gain access to your cluster. To access the Amazon S3 bucket, give the Amazon EMR runtime execution role cross-account Amazon S3 bucket access permissions — you grant these permissions within your Amazon S3 bucket policy.

In option 3, your Amazon EMR clusters are in your Studio account, and the Amazon EMR runtime execution role is in the data account. Your Studio or Studio Classic execution role has permission to use the Amazon EMR API `GetClusterSessionCredentials` to gain access to your cluster. Add the Amazon EMR runtime execution role into the execution role configuration JSON. Then you can select the role in the UI when you choose your cluster. For details about how to set up your execution role configuration JSON file, see Preload your execution roles into Studio or Studio Classic.

Set up Studio to use runtime IAM roles

To establish runtime role authentication for your Amazon EMR clusters, configure the required IAM policies, network, and usability enhancements. Your setup depends on whether you handle any cross-account arrangements if your Amazon EMR clusters, Amazon EMR runtime execution role, or both, reside outside of your Studio account. The following section guides you through the policies to install, how to configure the network to allow traffic between cross-accounts, and the local configuration file to set up to automate your Amazon EMR connection.

Configure runtime role authentication when your Amazon EMR cluster and Studio are in the same account

If your Amazon EMR cluster resides in your Studio account, complete the following steps to add necessary permissions to your Studio execution policy:

1. Add the required IAM policy to connect to Amazon EMR clusters. For details, see Configure listing Amazon EMR clusters.
2. Grant permission to call the Amazon EMR API `GetClusterSessionCredentials` when you pass one or more permitted Amazon EMR runtime execution roles specified in the policy.
3. (Optional) Grant permission to pass IAM roles that follow any user-defined naming conventions.
4. (Optional) Grant permission to access Amazon EMR clusters that are tagged with specific user-defined strings.
5. Preload your IAM roles so you can select the role to use when you connect to your Amazon EMR cluster. For details about how to preload your IAM roles, see Preload your execution roles into Studio or Studio Classic.

The following example policy permits Amazon EMR runtime execution roles belonging to the modeling and training groups to call `GetClusterSessionCredentials`. In addition, the policyholder can access Amazon EMR clusters tagged with the strings `modeling` or `training`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "elasticmapreduce:GetClusterSessionCredentials",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "elasticmapreduce:ExecutionRoleArn": [
                        "arn:aws:iam::111122223333:role/emr-execution-role-ml-
modeling*",
                        "arn:aws:iam::111122223333:role/emr-execution-role-ml-
training*"
   ]},
  "StringLike":{
                    "elasticmapreduce:ResourceTag/group": [
                        "*modeling*",
                        "*training*"
                    ]
                }
            }
        }
    ]
}
```

Configure runtime role authentication when your cluster and Studio are in different accounts

If your Amazon EMR cluster is not in your Studio account, allow your SageMaker AI execution role to assume the cross-account Amazon EMR access role so you can connect to the cluster. Complete the following steps to set up your cross-account configuration:

1. Create your SageMaker AI execution role permission policy so that the execution role can assume the Amazon EMR access role. The following policy is an example:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAssumeCrossAccountEMRAccessRole",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::111122223333:role/emr-access-role-name"
        }
    ]
}
```

2. Create the trust policy to specify which Studio account IDs are trusted to assume the Amazon EMR access role. The following policy is an example:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCrossAccountSageMakerExecutionRoleToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::studio_account_id:role/studio_execution_role"
      },
      "Action": "sts:AssumeRole"
    }
}
```

3. Create the Amazon EMR access role permission policy, which grants the Amazon EMR runtime execution role the needed permissions to carry out the intended tasks on the cluster. Configure the Amazon EMR access role to call the API `GetClusterSessionCredentials` with the Amazon EMR runtime execution roles specified in the access role permission policy. The following policy is an example:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "AllowCallingEmrGetClusterSessionCredentialsAPI",
            "Effect": "Allow",
            "Action": "elasticmapreduce:GetClusterSessionCredentials",
            "Resource": "arn:aws:elasticmapreduce:us-
east-1:111122223333:cluster/cluster-id",
            "Condition": {
                "StringLike": {
                    "elasticmapreduce:ExecutionRoleArn": [
                        "arn:aws:iam::111122223333:role/emr-execution-role-
name"
                    ]
                }
            }
        }
    ]
}
```

4. Set up the cross-account network so that traffic can move back and forth between your accounts. For guided instruction, see *the section called "Configure network access"Set up the* . The steps in this section help you complete the following tasks:

   a. VPC-peer your Studio account and your Amazon EMR account to establish a connection.

   b. Manually add routes to the private subnet route tables in both accounts. This permits creation and connection of Amazon EMR clusters from the Studio account to the remote account's private subnet.

   c. Set up the security group attached to your Studio domain to allow outbound traffic and the security group of the Amazon EMR primary node to allow inbound TCP traffic from the Studio instance security group.

5. Preload your IAM runtime roles so you can select the role to use when you connect to your Amazon EMR cluster. For details about how to preload your IAM roles, see Preload your execution roles into Studio or Studio Classic.

Configure Lake Formation access

When you access data from data lakes managed by AWS Lake Formation, you can enforce table-level and column-level access using policies attached to your runtime role. To configure permission for Lake Formation access, see Integrate Amazon EMR with AWS Lake Formation.

Preload your execution roles into Studio or Studio Classic

You can preload your IAM runtime roles so you can select the role to use when you connect to your Amazon EMR cluster. Users of JupyterLab in Studio can use the SageMaker AI console or the provided script.

Preload runtime roles in JupyterLab using the SageMaker AI console

To associate your runtime roles with your user profile or domain using the SageMaker AI console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **domain**, and then select the domain using the SageMaker AI execution role whose permissions you updated.
3. - To add your runtime (and access roles for cross-account use case) to your domain: In the **App Configurations** tab of the **Domain details** page, navigate to the **JupyterLab** section.
   - To add your runtime (and access roles for cross-account use case) to your user profile: On the **Domain details** page, chose the **User profiles** tab, select the user profile using the SageMaker AI execution role whose permissions you updated. In the **App Configurations** tab, navigate to the **JupyterLab** section.
4. Choose **Edit** and add the ARNs of your access role (assumable role) and EMR Serverless runtime execution roles.
5. Choose **Submit**.

When you next connect to an Amazon EMR server, the runtime roles should appear in a drop-down menu for selection.

Preload runtime roles in JupyterLab using a Python script

In a JupyterLab application started from a space using the SageMaker AI execution role whose permissions you updated, run the following command in a terminal. Replace the `domainID`, `user-profile-name`, `emr-accountID`, and `EMRServiceRole` with their proper values. This code snippet updates a user profile settings (`client.update_user_profile`) within a SageMaker AI domain in a cross account use case. Specifically, it sets the service roles for Amazon EMR. It also allows the JupyterLab application to assume a particular IAM role (`AssumableRole` or `AccessRole`) for running Amazon EMR within the Amazon EMR account.

Alternatively, use `client.update_domain` to update the domain settings if your space uses an execution role set at the domain level.

```
import botocore.session
import json
sess = botocore.session.get_session()
client = sess.create_client('sagemaker')

client.update_user_profile(
DomainId="domainID",
UserProfileName="user-profile-name",
UserSettings={
    'JupyterLabAppSettings': {
        'EmrSettings': {
            'AssumableRoleArns': ["arn:aws:iam::emr-accountID:role/AssumableRole"],
            'ExecutionRoleArns': ["arn:aws:iam::emr-accountID:role/EMRServiceRole",
                                 "arn:aws:iam::emr-accountID:role/AnotherServiceRole"]
        }

    }
})
resp = client.describe_user_profile(DomainId="domainID", UserProfileName=user-
profile-name")

resp['CreationTime'] = str(resp['CreationTime'])
resp['LastModifiedTime'] = str(resp['LastModifiedTime'])
print(json.dumps(resp, indent=2))
```

Preload runtime roles in Studio Classic

Provide the ARN of the `AccessRole` (`AssumableRole`) to your SageMaker AI execution role. The ARN is loaded by the Jupyter server at launch. The execution role used by Studio assumes that cross-account role to discover and connect to Amazon EMR clusters in the *trusting account*.

You can specify this information by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your domain or a specific user profile. The LCC script that you use must be a JupyterServer configuration. For more information on how to create an LCC script, see Use Lifecycle Configurations with Studio Classic.

The following is an example LCC script. To modify the script, replace `AssumableRole` and `emr-account` with their respective values. The number of cross-accounts is limited to five.

The following snippet is an example LCC bash script you can apply if your Studio Classic application and cluster are in the same account:

```
#!/bin/bash

set -eux

FILE_DIRECTORY="/home/sagemaker-user/.sagemaker-analytics-configuration-
DO_NOT_DELETE"
FILE_NAME="emr-configurations-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY

cat << 'EOF' > "$FILE"
{
    "emr-execution-role-arns":
    {
      "123456789012": [
          "arn:aws:iam::123456789012:role/emr-execution-role-1",
          "arn:aws:iam::123456789012:role/emr-execution-role-2"
      ]
    }
}
EOF
```

If your Studio Classic application and clusters are in different accounts, specify the Amazon EMR access roles that can use the cluster. In the following example policy, *123456789012* is the Amazon EMR cluster account ID, and *212121212121* and *434343434343* are the ARNs for the permitted Amazon EMR access roles.

```
#!/bin/bash

set -eux

FILE_DIRECTORY="/home/sagemaker-user/.sagemaker-analytics-configuration-
DO_NOT_DELETE"
FILE_NAME="emr-configurations-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY
```

```
cat << 'EOF' > "$FILE"
{
    "emr-execution-role-arns":
    {
      "123456789012": [
          "arn:aws:iam::212121212121:role/emr-execution-role-1",
          "arn:aws:iam::434343434343:role/emr-execution-role-2"
      ]
    }
}
EOF

# add your cross-account EMR access role
FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY

cat << 'EOF' > "$FILE"
{
    "123456789012": "arn:aws:iam::123456789012:role/cross-account-emr-access-role"
}
EOF
```

Reference policies

- **List Amazon EMR policies**: This policy allows performing the following actions:
  - `AllowPresignedUrl` allows generating pre-signed URLs for accessing the Spark UI from within Studio.
  - `AllowClusterDiscovery` and `AllowClusterDetailsDiscovery` allows listing and describing Amazon EMR clusters in the provided region and account.

  JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPresignedUrl",
            "Effect": "Allow",
```

```
            "Action": [
                "elasticmapreduce:CreatePersistentAppUI",
                "elasticmapreduce:DescribePersistentAppUI",
                "elasticmapreduce:GetPersistentAppUIPresignedURL",
                "elasticmapreduce:GetOnClusterAppUIPresignedURL"
            ],
            "Resource": [
                "arn:aws:elasticmapreduce:us-east-1:111122223333:cluster/*"
            ]
        },
        {
            "Sid": "AllowClusterDetailsDiscovery",
            "Effect": "Allow",
            "Action": [
                "elasticmapreduce:DescribeCluster",
                "elasticmapreduce:ListInstances",
                "elasticmapreduce:ListInstanceGroups",
                "elasticmapreduce:DescribeSecurityConfiguration"
            ],
            "Resource": [
                "arn:aws:elasticmapreduce:us-east-1:111122223333:cluster/*"
            ]
        },
        {
            "Sid": "AllowClusterDiscovery",
            "Effect": "Allow",
            "Action": [
                "elasticmapreduce:ListClusters"
            ],
            "Resource": "*"
        }
    ]
}
```

- **Create Amazon EMR clusters policies**: This policy allows performing the following actions:
  - `AllowEMRTemplateDiscovery` allows searching for Amazon EMR templates in the Service Catalog. Studio and Studio Classic use this to show available templates.
  - `AllowSagemakerProjectManagement` enables the creation of What is a SageMaker AI Project?. In Studio or Studio Classic, access to the AWS Service Catalog is managed through What is a SageMaker AI Project?.

The IAM policy defined in the provided JSON grants those permissions. Replace *region* and *accountID* with your actual region and AWS account ID values before copying the list of statements to the inline policy of your role.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowEMRTemplateDiscovery",
            "Effect": "Allow",
            "Action": [
                "servicecatalog:SearchProducts"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowSagemakerProjectManagement",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateProject",
                "sagemaker:DeleteProject"
            ],
            "Resource": "arn:aws:sagemaker:us-east-1:111122223333:project/*"
        }
    ]
}
```

- **Domain, user profile, and space update actions policy** : The following policy grants permissions to update SageMaker AI domains, user profiles, and spaces within the specified region and AWS account.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerUpdateResourcesPolicy",
            "Effect": "Allow",
            "Action": [
```

```
                    "sagemaker:UpdateDomain",
                    "sagemaker:UpdateUserprofile",
                    "sagemaker:UpdateSpace"
                ],
                "Resource": [
                    "arn:aws:sagemaker:us-east-1:111122223333:domain/*",
                    "arn:aws:sagemaker:us-east-1:111122223333:user-profile/*"
                ]
            }
        ]
}
```

User guide

This section covers how data scientist and data engineers can launch, discover, connect to, or terminate an Amazon EMR cluster from Studio or Studio Classic.

Before users can list or launch clusters, administrators must have configured the necessary settings in the Studio environment. For information on how administrators can configure a Studio environment to allow self-provisioning and listing of Amazon EMR clusters, see the section called “Admin guide”.

Topics

Supported images and kernels to connect to an Amazon EMR cluster from Studio or Studio Classic

The following images and kernels come with sagemaker-studio-analytics-extension, the JupyterLab extension that connects to a remote Spark (Amazon EMR) cluster via the SparkMagic library using Apache Livy.

- **For Studio users:** SageMaker Distribution is a Docker environment for data science used as the default image of JupyterLab notebook instances. All versions of SageMaker AI Distribution come with `sagemaker-studio-analytics-extension` pre-installed.
- **For Studio Classic users:** The following images come pre-installed with `sagemaker-studio-analytics-extension`:
  - DataScience – Python 3 kernel
  - DataScience 2.0 – Python 3 kernel
  - DataScience 3.0 – Python 3 kernel
  - SparkAnalytics 1.0 – SparkMagic and PySpark kernels
  - SparkAnalytics 2.0 – SparkMagic and PySpark kernels
  - SparkMagic – SparkMagic and PySpark kernels
  - PyTorch 1.8 – Python 3 kernels
  - TensorFlow 2.6 – Python 3 kernel
  - TensorFlow 2.11 – Python 3 kernel

To connect to Amazon EMR clusters using another built-in image or your own image, follow the instructions in Bring your own image.

Bring your own image

To bring your own image in Studio or Studio Classic and allow your notebooks to connect to Amazon EMR clusters, install the following sagemaker-studio-analytics-extension extension to your kernel. It supports connecting SageMaker Studio or Studio Classic notebooks to Spark(Amazon EMR) clusters through the SparkMagic library.

```
pip install sparkmagic
pip install sagemaker-studio-sparkmagic-lib
pip install sagemaker-studio-analytics-extension
```

Additionally, to connect to Amazon EMR with Kerberos authentication, you must install the kinit client. Depending on your OS, the command to install the kinit client can vary. To bring an Ubuntu (Debian based) image, use the `apt-get install -y -qq krb5-user` command.

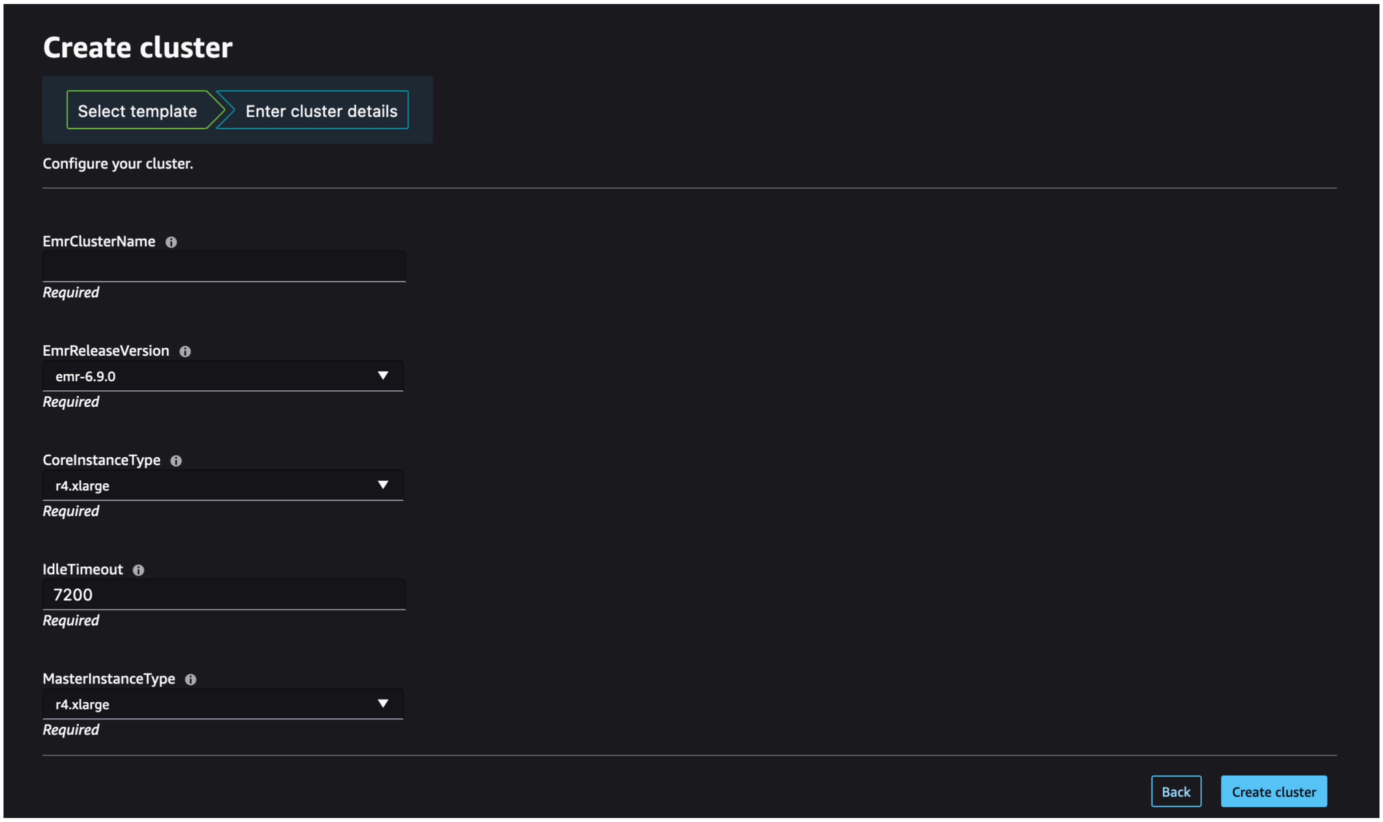
For more information on bringing your own image in SageMaker Studio or Studio Classic, see Bring your own SageMaker image.

Launch an Amazon EMR cluster from Studio or Studio Classic

Data scientists and data engineers can self-provision Amazon EMR clusters from Studio or Studio Classic using AWS CloudFormation templates set up by their administrators. Before users can launch a cluster, administrators must have configured the necessary settings in the Studio environment. For information on how administrators can configure a Studio environment to allow self-provisioning Amazon EMR clusters, see Configure Amazon EMR CloudFormation templates in the Service Catalog.

To provision a new Amazon EMR cluster from Studio or Studio Classic:

1. In the Studio or Studio Classic UI's left-side panel, select the **Data** node in the left navigation menu. Navigate down to **Amazon EMR Clusters**. This opens up a page listing the Amazon EMR clusters that you can access from Studio or Studio Classic.
2. Choose the **Create** button at the top right corner. This opens up a new modal listing the cluster templates available to you.
3. Select a cluster template by choosing a template name and then choose **Next**.
4. Enter the cluster's details, such as a cluster name and any specific configurable parameter set by your administrator, and then choose **Create cluster**. The creation of the cluster might take a couple of minutes.



Once the cluster is provisioned, the Studio or Studio Classic UI displays a *The cluster has been successfully created* message.

To connect to your cluster, see Connect to an Amazon EMR cluster from SageMaker Studio or Studio Classic

List Amazon EMR clusters from Studio or Studio Classic

Data scientists and data engineers can discover, and then connect to Amazon EMR clusters from Studio. The Amazon EMR clusters may be in the same AWS account as Studio or in a different AWS account.

Before users can list or connect to clusters, administrators must have configured the necessary settings in the Studio environment. For information on how administrators can configure a Studio environment to allow discovering running Amazon EMR clusters, see the section called "Admin guide". If your administrator configured the cross-account discovery of Amazon EMR clusters, you can view a consolidated list of clusters. The list includes clusters from the AWS account used by Studio as well as clusters from remote accounts that you have been granted access to.

To view the list of available Amazon EMR clusters from within Studio:

1. In the Studio UI's left navigation menu, scroll down to **EMR Clusters**. This opens up a page listing the Amazon EMR clusters that you have access to.

   The list displays clusters in the following stages: **Bootstrapping**, **Starting Running**, **Waiting**. You can narrow down the displayed clusters by their current status using the filter icon.
2. Choose a particular **Running** cluster you want to connect to, and then refer to Connect to an Amazon EMR cluster from SageMaker Studio or Studio Classic.

Connect to an Amazon EMR cluster from SageMaker Studio or Studio Classic

Data scientists and data engineers can discover and then connect to an Amazon EMR cluster directly from the Studio user interface. Before you begin, ensure that you have configured the necessary permissions as described in the Step 4: Set up the permissions to enable listing and launching Amazon EMR clusters from Studio section. These permissions grant Studio the ability to create, start, view, access, and terminate clusters.

You can connect an Amazon EMR cluster to a new JupyterLab notebook directly from the Studio UI, or choose to initiate the connection in a notebook of a running JupyterLab application.

> **Important**
>
> You can only discover and connect to Amazon EMR clusters for JupyterLab and Studio Classic applications that are launched from private spaces. Ensure that the Amazon EMR clusters are located in the same AWS region as your Studio environment. Your JupyterLab space must use a SageMaker Distribution image version `1.10` or higher.

Connect to an Amazon EMR cluster using the Studio UI

To connect to your cluster using the Studio or Studio Classic UI, you can either initiate a connection from the list of clusters accessed in List Amazon EMR clusters from Studio or Studio Classic, or from a notebook in SageMaker Studio or Studio Classic.

To connect an Amazon EMR cluster to a new JupyterLab notebook from the Studio UI:

1. In the Studio UI's left-side panel, select the **Data** node in the left navigation menu. Navigate down to **Amazon EMR applications and clusters**. This opens up a page listing the Amazon EMR clusters that you can access from Studio in the **Amazon EMR clusters** tab.

> **Note**
>
> If you or your administrator have configured the permissions to allow cross-account access to Amazon EMR clusters, you can view a consolidated list of clusters across all accounts that you have granted access to Studio.

2. Select an Amazon EMR cluster you want to connect to a new notebook, and then choose **Attach to notebook**. This opens up a modal window displaying the list of your JupyterLab spaces.

3. • Select the space from which you want to launch a JupyterLab application, and then choose **Open notebook**. This launches a JupyterLab application from your chosen space and opens a new notebook.

   > **Note**
   >
   > Users of Studio Classic need to select an image and kernel. For a list of supported images, see Supported images and kernels to connect to an Amazon EMR cluster from Studio or Studio Classic or refer to Bring your own image.

   • Alternatively, you can create a new private space by choosing the **Create new space** button at the top of the modal window. Enter a name for your space and then choose **Create space and open notebook**. This creates a private space with the default instance type and latest SageMaker distribution image available, launches a JupyterLab application, and opens a new notebook.

4. If the cluster you select does not use Kerberos, LDAP, or runtime role authentication, Studio prompts you to select the credential type. Choose from **Http basic authentication** or **No credentials**, then enter your credentials, if applicable.

   If the cluster you select supports runtime roles, choose the name of the IAM role that your Amazon EMR cluster can assume for the job run.

   > **Important**
   >
   > To successfully connect a JupyterLab notebook to an Amazon EMR cluster supporting runtime roles, you must first associate the list of runtime roles with your domain or user profile, as outlined in the section called "Configure IAM runtime roles for Amazon

EMR cluster access”. Failing to complete this step will prevent you from establishing the connection.

Upon selection, a connection command populates the first cell of your notebook and initiates the connection with the Amazon EMR cluster.

Once the connection succeeds, a message confirms the connection and the start of the Spark application.

Alternatively, you can connect to a cluster from a JupyterLab or Studio Classic notebook.

1. Choose the **Cluster** button at the top of your notebook. This opens a modal window listing the Amazon EMR clusters in a `Running` state that you can access. You can see the `Running` Amazon EMR clusters in the **Amazon EMR clusters** tab.

> **Note**
>
> For the users of Studio Classic, **Cluster** is only visible when you use a kernel from Supported images and kernels to connect to an Amazon EMR cluster from Studio or Studio Classic or from Bring your own image. If you cannot see **Cluster** at the top of your notebook, ensure that your administrator has configured the discoverability of your clusters and switch to a supported kernel.

2. Select the cluster to which you want to connect, then choose **Connect**.
3. If you configured your Amazon EMR clusters to support runtime IAM roles, you can select your role from the **Amazon EMR execution role** drop down menu.

> **Important**
>
> To successfully connect a JupyterLab notebook to an Amazon EMR cluster supporting runtime roles, you must first associate the list of runtime roles with your domain or user profile, as outlined in the section called “Configure IAM runtime roles for Amazon EMR cluster access”. Failing to complete this step will prevent you from establishing the connection.

Otherwise, if the cluster you choose does not use Kerberos, LDAP, or runtime role authentication, Studio or Studio Classic prompts you to select the credential type. You can choose **HTTP basic authentication** or **No credential**.

4. Studio adds and then run a code block to an active cell to establish the connection. This cell contains the connection magic command to connect your notebook to your application according to your authentication type.

   Once the connection succeeds, a message confirms the connection and the start of the Spark application.

Connect to an Amazon EMR cluster using a connection command

To establish a connection to an Amazon EMR cluster, you can execute connection commands within a notebook cell.

When establishing the connection, you can authenticate using Kerberos, Lightweight Directory Access Protocol (LDAP), or runtime IAM role authentication. The authentication method you choose depends on your cluster configuration.

You can refer to this example Access Apache Livy using a Network Load Balancer on a Kerberos-enabled Amazon EMR cluster to set up an Amazon EMR cluster that uses Kerberos authentication. Alternatively, you can explore the CloudFormation example templates using Kerberos or LDAP authentication in the aws-samples/sagemaker-studio-emr GitHub repository.

If your administrator has enabled cross-account access, you can connect to your Amazon EMR cluster from a Studio Classic notebook, regardless of whether your Studio Classic application and cluster reside in the same AWS account or different accounts.

For each of the following authentication types, use the specified command to connect to your cluster from your Studio or Studio Classic notebook.

- **Kerberos**

  Append the `--assumable-role-arn` argument if you need cross-account Amazon EMR access. Append the `--verify-certificate` argument if you connect to your cluster with HTTPS.

  ```
  %load_ext sagemaker_studio_analytics_extension.magics
  %sm_analytics emr connect --cluster-id cluster_id \
  ```

```
--auth-type Kerberos --language python
[--assumable-role-arn EMR_access_role_ARN ]
[--verify-certificate /home/user/certificateKey.pem]
```

- **LDAP**

  Append the `--assumable-role-arn` argument if you need cross-account Amazon EMR access. Append the `--verify-certificate` argument if you connect to your cluster with HTTPS.

```
%load_ext sagemaker_studio_analytics_extension.magics
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type Basic_Access --language python
[--assumable-role-arn EMR_access_role_ARN ]
[--verify-certificate /home/user/certificateKey.pem]
```

- **NoAuth**

  Append the `--assumable-role-arn` argument if you need cross-account Amazon EMR access. Append the `--verify-certificate` argument if you connect to your cluster with HTTPS.

```
%load_ext sagemaker_studio_analytics_extension.magics
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type None --language python
[--assumable-role-arn EMR_access_role_ARN ]
[--verify-certificate /home/user/certificateKey.pem]
```

- **Runtime IAM roles**

  Append the `--assumable-role-arn` argument if you need cross-account Amazon EMR access. Append the `--verify-certificate` argument if you connect to your cluster with HTTPS.

  For more information on connecting to an Amazon EMR cluster using runtime IAM roles, see [Configure IAM runtime roles for Amazon EMR cluster access in Studio](#).

```
%load_ext sagemaker_studio_analytics_extension.magics
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type Basic_Access \
--emr-execution-role-arn arn:aws:iam::studio_account_id:role/emr-execution-role-name
[--assumable-role-arn EMR_access_role_ARN]
[--verify-certificate /home/user/certificateKey.pem]
```

Connect to an Amazon EMR cluster over HTTPS

If you have configured your Amazon EMR cluster with transit encryption enabled and Apache Livy server for HTTPS and would like Studio or Studio Classic to communicate with Amazon EMR using HTTPS, you need to configure Studio or Studio Classic to access your certificate key.

For self-signed or local Certificate Authority (CA) signed certificates, you can do this in two steps:

1. Download the PEM file of your certificate to your local file system using one of the following options:
   - Jupyter's built-in file upload function.
   - A notebook cell.
   - (For Studio Classic users only) A lifecycle configuration (LCC) script.

     For information on how to use an LCC script, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](#)
2. Enable the validation of the certificate by providing the path to your certificate in the `--verify-certificate` argument of your connection command.

```
%sm_analytics emr connect --cluster-id cluster_id \
--verify-certificate /home/user/certificateKey.pem ...
```

For public CA issued certificates, set the certificate validation by setting the `--verify-certificate` parameter as `true`.

Alternatively, you can disable the certificate validation by setting the `--verify-certificate` parameter as `false`.

You can find the list of available connection commands to an Amazon EMR cluster in [Connect to an Amazon EMR cluster using a connection command](#).

Terminate an Amazon EMR cluster from Studio or Studio Classic

The following procedure shows how to terminate an Amazon EMR cluster from a Studio or Studio Classic notebook.

To terminate a cluster in a `Running` state, navigate to the list of available Amazon EMR clusters.

1. In the Studio UI, scroll down to the **Data** node in the left navigation menu.
2. Navigate down to the **EMR Clusters** node. This opens up a page listing the Amazon EMR clusters that you have access to.
3. Select the name of the cluster that you want to terminate, and then choose **Terminate**.
4. This opens up a confirmation window informing you that any pending work or data on your cluster will be lost permanently after termination. Confirm by choosing **Terminate** again.

Access Spark UI from Studio or Studio Classic

The following sections give instructions for accessing the Spark UI from SageMaker AI Studio or Studio Classic notebooks. The Spark UI allows you to monitor and debug your Spark Jobs submitted to run on Amazon EMR from Studio or Studio Classic notebooks. SSH tunneling and presigned URLs are two ways for accessing the Spark UI.

Set up SSH tunneling for Spark UI access

To set up SSH tunneling to access the Spark UI, follow one of the two options in this section.

Options for setting up SSH tunneling:

- Option 1: Set up an SSH tunnel to the master node using local port forwarding
- Option 2, part 1: Set up an SSH tunnel to the master node using dynamic port forwarding

  Option 2, part 2: Configure proxy settings to view websites hosted on the master node

For information about viewing web interfaces hosted on Amazon EMR clusters, see View web interfaces hosted on Amazon EMR Clusters. You can also visit your Amazon EMR console to get access to the Spark UI.

> **Note**
>
> You can set up an SSH tunnel even if presigned URLs are not available to you.

Presigned URLs

To create one-click URLs that can access Spark UI on Amazon EMR from SageMaker Studio or Studio Classic notebooks, you must enable the following IAM permissions. Choose the option that applies to you:

- **For Amazon EMR clusters that are in the same account as the SageMaker Studio or Studio Classic notebook: Add the following permissions to the SageMaker Studio or Studio Classic IAM execution role.**
- **For Amazon EMR clusters that are in a different account (not SageMaker Studio or Studio Classic notebook): Add the following permissions to the cross-account role that you created for List Amazon EMR clusters from Studio or Studio Classic.**

> **Note**
>
> You can access presigned URLs from the console in the following regions:
>
> - US East (N. Virginia) Region
> - US West (N. California) Region
> - Canada (Central) Region
> - Europe (Frankfurt) Region
> - Europe (Stockholm) Region
> - Europe (Ireland) Region
> - Europe (London) Region
> - Europe (Paris) Region
> - Asia Pacific (Tokyo) Region
> - Asia Pacific (Seoul) Region
> - Asia Pacific (Sydney) Region
> - Asia Pacific (Mumbai) Region
> - Asia Pacific (Singapore) Region
> - South America (São Paulo)

The following policy gives access to presigned URLs for your execution role.

```
{
        "Sid": "AllowPresignedUrl",
        "Effect": "Allow",
        "Action": [
            "elasticmapreduce:DescribeCluster",
            "elasticmapreduce:ListInstanceGroups",
            "elasticmapreduce:CreatePersistentAppUI",
            "elasticmapreduce:DescribePersistentAppUI",

Blogs and whitepapers

The following blogs use a case study of sentiment prediction for a movie review to illustrate the process of executing a complete machine learning workflow. This includes data preparation, monitoring Spark jobs, and training and deploying a ML model to get predictions directly from your Studio or Studio Classic notebook.

- Create and manage Amazon EMR clusters from SageMaker Studio or Studio Classic to run interactive Spark and ML workloads.
- To extend the use case to a cross-account configuration where SageMaker Studio or Studio Classic and your Amazon EMR cluster are deployed in separate AWS accounts, see Create and manage Amazon EMR clusters from SageMaker Studio or Studio Classic to run interactive Spark and ML workloads - Part 2.

See also:

- A walkthrough of the configuration of Access Apache Livy using a Network Load Balancer on a Kerberos-enabled Amazon EMR cluster.
- AWS whitepapers for SageMaker Studio or Studio Classic best practices.

Troubleshooting

When working with Amazon EMR clusters from Studio or Studio Classic notebooks, you may encounter various potential issues or challenges during the connection or usage process. To help you troubleshoot and resolve these errors, this section provides guidance on common problems that can arise.

The following are common errors that might occur while connecting or using Amazon EMR clusters from Studio or Studio Classic notebooks.

Troubleshoot Livy connections hanging or failing

The following are Livy connectivity issues that might occur while using Amazon EMR clusters from Studio or Studio Classic notebooks.

- **Your Amazon EMR cluster encountered an out-of-memory error.**

  A possible reason for a Livy connection via `sparkmagic` hanging or failing is if your Amazon EMR cluster encountered an out-of-memory error.

  By default, the Java configuration parameter of the Apache Spark driver, `spark.driver.defaultJavaOptions`, is set to `-XX:OnOutOfMemoryError='kill -9 %p'`. This means that the default action taken when the driver program encounters an `OutOfMemoryError` is to terminate the driver program by sending a SIGKILL signal. When the Apache Spark driver is terminated, any Livy connection via `sparkmagic` that depends on that driver hangs or fails. This is because the Spark driver is responsible for managing the Spark application's resources, including task scheduling and execution. Without the driver, the Spark application cannot function, and any attempts to interact with it fails.

  If you suspect that your Spark cluster is experiencing memory issues, you can check Amazon EMR logs. Containers killed due to out-of-memory errors typically exit with a code of 137. In such cases, you need to restart the Spark application and establish a new Livy connection to resume interaction with the Spark cluster.

  You can refer to the knowledge base article How do I resolve the error "Container killed by YARN for exceeding memory limits" in Spark on Amazon EMR? on AWS re:Post to learn about various strategies and parameters that can be used to address an out-of-memory issue.

  We recommend reviewing the Amazon EMR Best Practices Guides for best practices and tuning guidance on running Apache Spark workloads on your Amazon EMR clusters.

- **Your Livy session times out when connecting to an Amazon EMR cluster for the first time.**

  When you initially connect to an Amazon EMR cluster using sagemaker-studio-analytics-extension, which enables connection to a remote Spark (Amazon EMR) cluster via the SparkMagic library using Apache Livy, you may encounter a connection timeout error:

  `An error was encountered: Session 0 did not start up in 60 seconds.`

  If your Amazon EMR cluster requires the initialization of a Spark application upon establishing a connection, there is an increased chance of seeing connection timeout errors.

  To reduce the chances of getting timeouts when connecting to an Amazon EMR cluster using Livy through the analytics extension, `sagemaker-studio-analytics-extension` version `0.0.19` and later override the default server session timeout to `120` seconds instead of `sparkmagic`'s default of `60` seconds.

  We recommend upgrading your extension `0.0.18` and sooner by running the following upgrade command.

  ```
  pip install --upgrade sagemaker-studio-analytics-extension
  ```

  Note that when providing a custom timeout configuration in `sparkmagic`, `sagemaker-studio-analytics-extension` honors this override. However, setting the session timeout to `60` seconds automatically triggers the default server session timeout of `120` seconds in `sagemaker-studio-analytics-extension`.

Data preparation using AWS Glue interactive sessions

AWS Glue interactive sessions is a serverless service that you can enlist to collect, transform, clean, and prepare data for storage in your data lakes and data pipelines. AWS Glue interactive sessions provides an on-demand, serverless Apache Spark runtime environment that you can initialize in seconds on a dedicated Data Processing Unit (DPU) without having to provision and manage complex compute cluster infrastructure. After initialization, you can browse the AWS Glue data catalog, run large queries, access data governed by AWS Lake Formation, and interactively analyze and prepare data using Spark, right in your Studio or Studio Classic notebooks. You can then use the prepared data to train, tune, and deploy models using the purpose-built ML tools within SageMaker Studio or Studio Classic. You should consider AWS Glue Interactive Sessions for your data preparation workloads when you want a serverless Spark service with moderate control of configurability and flexibility.

You can initiate an AWS Glue interactive session by starting a JupyterLab notebook in Studio or Studio Classic. When starting your notebook, choose the built-in `Glue PySpark and Ray` or `Glue Spark` kernel. This automatically starts an interactive, serverless Spark session. You do not need to provision or manage any compute cluster or infrastructure. After initialization, you can explore and interact with your data from within your Studio or Studio Classic notebooks.

Before starting your AWS Glue interactive session in Studio or Studio Classic, you need to set the appropriate roles and policies. Additionally, you may need to provide access to additional resources, such as a storage Amazon S3 bucket. For more information about required IAM policies, see [Permissions for AWS Glue interactive sessions in Studio or Studio Classic](#).

Studio and Studio Classic provide a default configuration for your AWS Glue interactive session, however, you can use AWS Glue's full catalog of Jupyter magic commands to further customize your environment. For information about the default and additional Jupyter magics that you can use in your AWS Glue interactive session, see [Configure your AWS Glue interactive session in Studio or Studio Classic](#).

- For Studio Classic users initiating an AWS Glue interactive session, they can select from the following images and kernels:
  - Images: `SparkAnalytics 1.0`, `SparkAnalytics 2.0`
  - Kernel: `Glue Python [PySpark and Ray]` and `Glue Spark`
- For Studio users, use the default [SageMaker Distribution image](#) and select a `Glue Python [PySpark and Ray]` or a `Glue Spark` kernel.

Get Started with AWS Glue Interactive Sessions

In this guide, you learn how to initiate an AWS Glue interactive session in SageMaker AI Studio Classic, and manage your environment with Jupyter magics.

Permissions for AWS Glue interactive sessions in Studio or Studio Classic

This section lists the required policies to run AWS Glue interactive sessions in Studio or Studio Classic and explains how to set them up. In particular, it details how to:

- Attach the `AwsGlueSessionUserRestrictedServiceRole` managed policy to your SageMaker AI execution role.
- Create an inline custom policy on your SageMaker AI execution role.
- Modify the trust relationship of your SageMaker AI execution role.

To attach the `AwsGlueSessionUserRestrictedServiceRole` managed policy to your execution role

1. Open the IAM console.
2. Select **Roles** in the left-side panel.
3. Find the Studio Classic execution role used by your user profile. For information about how to view a user profile, see View user profiles in a domain.
4. Choose your role name to access the role summary page.
5. Under the **Permissions** tab, select **Attach policies** from the **Add Permissions** dropdown menu.
6. Select the checkbox next to the managed policy `AwsGlueSessionUserRestrictedServiceRole`.
7. Choose **Attach policies**.

   The summary page shows your newly-added managed policies.

To create the inline custom policy on your execution role

1. Select **Create inline policy** in the **Add Permissions** dropdown menu.
2. Select the **JSON** tab.
3. Copy and paste in the following policy.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "uniqueStatementId",

            "Effect": "Allow",
```

```
            "Action": [
      "iam:GetRole",
                "iam:PassRole",
                "sts:GetCallerIdentity"
            ],
            "Resource": "arn:aws:iam::*:role/GlueServiceRole*"
        }
    ]
}
```

4. Choose **Review policy**.
5. Enter a **Name** and choose **Create policy**.

   The summary page shows your newly-added custom policy.

To modify the trust relationship of your execution role

1. Select the **Trust relationships** tab.
2. Chose **Edit trust policy**.
3. Copy and paste in the following policy.

   JSON

```
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": [
                "glue.amazonaws.com",
                "sagemaker.amazonaws.com"
            ]
        },
        "Action": "sts:AssumeRole"
    }
]
}
```

4. Choose **Update policy**.

You can add additional roles and policies if you need to access other AWS resources. For a description of the additional roles and policies you can include, see [interactive sessions with IAM] in the AWS Glue documentation.

Tag propagation

Tags are commonly used to track and allocate costs, control access to your session, isolate your resources, and more. To learn about adding metadata to your AWS resources using tagging, or for details on common use cases, see Additional information.

You can enable the automatic propagation of AWS tags to new AWS Glue interactive sessions created from within the Studio or Studio Classic UI. When an AWS Glue interactive session is created from Studio or Studio Classic, any user-defined tags attached to the user profile or shared space are carried over to the new AWS Glue interactive session. Additionally,Studio and Studio Classic automatically add two AWS-generated internal tags ((`sagemaker:user-profile-arn` and `sagemaker:domain-arn`) or (`sagemaker:shared-space-arn` and `sagemaker:domain-arn`)) to new AWS Glue interactive sessions created from their UI. You can use these tags to aggregate costs across individual domains, user profiles, or spaces.

Enable tag propagation

To enable the automatic propagation of tags to new AWS Glue interactive sessions, set the following permissions for your SageMaker AI execution role and the IAM role associated with your AWS Glue session:

> **Note**
>
> By default, the role associated with the AWS Glue interactive session is the same as the SageMaker AI execution role. You can specify a different execution role for the AWS Glue interactive session by using the `%iam_role` magic command. For information on the available Jupyter magic commands to configure AWS Glue interactive sessions, see Configure your AWS Glue interactive session in Studio or Studio Classic.

- *On your SageMaker AI execution role*: Create a new inline policy, and paste the following JSON file. The policy grants the execution role permission to describe (`DescribeUserProfile`, `DescribeSpace`, `DescribeDomain`) and list the tags (`ListTag`) set on the user profiles, shared spaces, and SageMaker AI domain.

```
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:ListTags"
    ],
    "Resource": [
        "arn:aws:sagemaker:*:*:user-profile/*",
        "arn:aws:sagemaker:*:*:space/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeUserProfile"
    ],
    "Resource": [
        "arn:aws:sagemaker:*:*:user-profile/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeSpace"
    ],
    "Resource": [
        "arn:aws:sagemaker:*:*:space/*"
    ]
}
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeDomain"
    ],
    "Resource": [
        "arn:aws:sagemaker:*:*:domain/*"
    ]
}
```

- *On the IAM role of your AWS Glue session*: Create a new inline policy, and paste the following JSON file. The policy grants your role permission to attach tags (`TagResource`) to your session, or retrieve its list of tags (`GetTags`).

```
{
    "Effect": "Allow",
    "Action": [
        "glue:TagResource",
        "glue:GetTags"
    ],
    "Resource": [
        "arn:aws:glue:*:*:session/*"
    ]
}
```

Note

- Failures occurring while applying those permissions do not prevent the creation of AWS Glue interactive sessions. You can find details about the reason of the failure in Studio or Studio Classic CloudWatch logs.
- You must restart the kernel of your AWS Glue interactive session to propagate the update of a tag's value.

It is important to note the following points:

- Once a tag is attached to a session, it cannot be removed by propagation.

  You can remove tags from an AWS Glue interactive session directly through the AWS CLI, the AWS Glue API, or the https://console.aws.amazon.com/sagemaker/. For example, using the AWS CLI, you can remove a tag by providing the session's ARN and the tag keys you want to remove as follows:

  ```
  aws glue untag-resource \
  --resource-arn arn:aws:glue:region:account-id:session:session-name \
  --tags-to-remove tag-key1,tag-key2
  ```

- Studio and Studio Classic add two AWS-generated internal tags ((`sagemaker:user-profile-arn` and `sagemaker:domain-arn`) or (`sagemaker:shared-space-arn` and `sagemaker:domain-arn`)) to new AWS Glue interactive sessions created from their UI. Those tags count against the limit of 50 tags set on all AWS resources. Both `sagemaker:user-`

`profile-arn` and `sagemaker:shared-space-arn` contain the domain ID to which they belong.

- Tags keys starting with `aws:`, `AWS:`, or any combination of upper and lowercase letters as a prefix for keys are not propagated and are reserved for AWS use.

Additional information

For more information on tagging, refer to the following resources.

- To learn about adding metadata to your AWS resources with tagging, see Tagging AWS resources.
- For information on tracking costs using tags, see Cost analysis in Studio administration best practices.
- For information on controlling access to AWS Glue based on tag keys, see ABAC with AWS Glue.

Launch your AWS Glue interactive session on Studio or Studio Classic

After you create the roles, policies, and SageMaker AI domain, you can launch your AWS Glue interactive session in Studio or Studio Classic.

1. Sign in to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. From the left navigation pane, choose **Studio**.
3. From the Studio landing page, select the domain and user profile for launching Studio.
4. Choose **Open Studio** and start a JupyterLab or Studio Classic application.
5. In the Jupyter view, choose **File**, then **New**, then **Notebook**.
6. For Studio Classic users: In the **Image** dropdown menu, select **SparkAnalytics 1.0** or **SparkAnalytics 2.0**. In the **kernel** dropdown menu, select **Glue Spark** or **Glue Python [PySpark and Ray]**. Choose **Select**.

   For Studio users, select a **Glue Spark** or **Glue Python [PySpark and Ray]** kernel
7. (optional) Use Jupyter magics to customize your environment. For more information about Jupyter magics, see Configure your AWS Glue interactive session in Studio or Studio Classic.
8. Start writing your Spark data processing scripts. The following notebook showcases an end-to-end workflow for ETL on a large dataset using an AWS Glue interactive session, exploratory data analysis, data preprocessing, and finally training a model on the processed data with SageMaker AI.

Configure your AWS Glue interactive session in Studio or Studio Classic

Note

All magic configurations are carried over to subsequent sessions for the lifetime of the AWS Glue kernel.

You can use Jupyter magics in your AWS Glue interactive session to modify your session and configuration parameters. Magics are short commands prefixed with `%` at the start of Jupyter cells that provide a quick and easy way to help you control your environment. In your AWS Glue interactive session, the following magics are set for you by default:

Magic	Default value
`%glue_version`	3.0
`%iam_role`	*execution role attached to your SageMaker AI domain*
`%region`	your region

You can use magics to further customize your environment. For example, if you want to change the number of workers allocated to your job from the default five to 10, you can specify `%number_of_workers 10`. If you want to configure your session to stop after 10 minutes of idle time instead of the default 2880, you can specify `%idle_timeout 10`.

All of the Jupyter magics currently available in AWS Glue are also available in Studio or Studio Classic. For the complete list of AWS Glue magics available, see [Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks](#).

AWS Glue interactive session pricing

When you use AWS Glue interactive sessions on Studio or Studio Classic notebooks, you are charged separately for resource usage on AWS Glue and Studio notebooks.

AWS charges for AWS Glue interactive sessions based on how long the session is active and the number of Data Processing Units (DPU) used. You are charged an hourly rate for the number of DPUs used to run your workloads, billed in increments of one second. AWS Glue interactive sessions assigns a default of five DPUs and requires a minimum of two DPUs. There is also a one-minute minimum billing duration for each interactive session. To see the AWS Glue rates and pricing examples, or to estimate your costs using the AWS Pricing Calculator, see [AWS Glue pricing](#) .

Your Studio or Studio Classic notebook runs on an Amazon EC2 instance and you are charged for the instance type you choose, based on the duration of use. Studio Classic assign you a default EC2 instance type of `ml-t3-medium` when you select the `SparkAnalytics` image and associated kernel. You can change the instance type for of your Studio Classic notebook to suit your workload. For information about Studio and Studio Classic pricing, see [Amazon SageMaker Pricing](#).

Prepare ML Data with Amazon SageMaker Data Wrangler

> **Important**
>
> Amazon SageMaker Data Wrangler has been integrated into Amazon SageMaker Canvas. Within the new Data Wrangler experience in SageMaker Canvas, you can use a natural language interface to explore and transform your data in addition to the visual interface. For more information about Data Wrangler in SageMaker Canvas, see [Data preparation](#).

Amazon SageMaker Data Wrangler (Data Wrangler) is a feature of Amazon SageMaker Studio Classic that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. You can integrate a Data Wrangler data preparation flow into your machine learning (ML) workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize workflows.

Data Wrangler provides the following core functionalities to help you analyze and prepare data for machine learning applications.

- **Import** – Connect to and import data from Amazon Simple Storage Service (Amazon S3), Amazon Athena (Athena), Amazon Redshift, Snowflake, and Databricks.
- **Data Flow** – Create a data flow to define a series of ML data prep steps. You can use a flow to combine datasets from different data sources, identify the number and types of transformations you want to apply to datasets, and define a data prep workflow that can be integrated into an ML pipeline.

- **Transform** – Clean and transform your dataset using standard *transforms* like string, vector, and numeric data formatting tools. Featurize your data using transforms like text and date/time embedding and categorical encoding.
- **Generate Data Insights** – Automatically verify data quality and detect abnormalities in your data with Data Wrangler Data Insights and Quality Report.
- **Analyze** – Analyze features in your dataset at any point in your flow. Data Wrangler includes built-in data visualization tools like scatter plots and histograms, as well as data analysis tools like target leakage analysis and quick modeling to understand feature correlation.
- **Export** – Export your data preparation workflow to a different location. The following are example locations:
  - Amazon Simple Storage Service (Amazon S3) bucket
  - Amazon SageMaker Pipelines – Use Pipelines to automate model deployment. You can export the data that you've transformed directly to the pipelines.
  - Amazon SageMaker Feature Store – Store the features and their data in a centralized store.
  - Python script – Store the data and their transformations in a Python script for your custom workflows.

To start using Data Wrangler, see Get Started with Data Wrangler.

Important

Data Wrangler no longer supports Jupyter Lab Version 1 (JL1). To access the latest features and updates, update to Jupyter Lab Version 3. For more information about upgrading, see View and update the JupyterLab version of an application from the console.

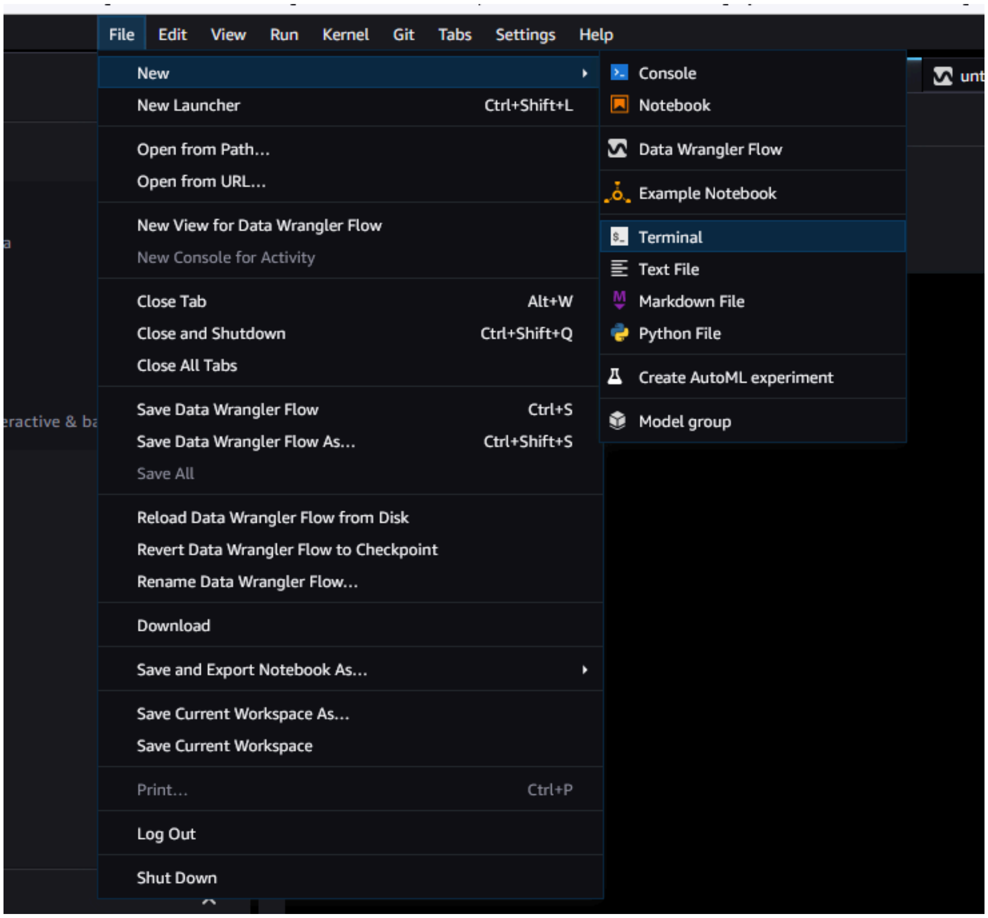
Important

The information and procedures in this guide use the latest version of Amazon SageMaker Studio Classic. For information about updating Studio Classic to the latest version, see Amazon SageMaker Studio Classic UI Overview.

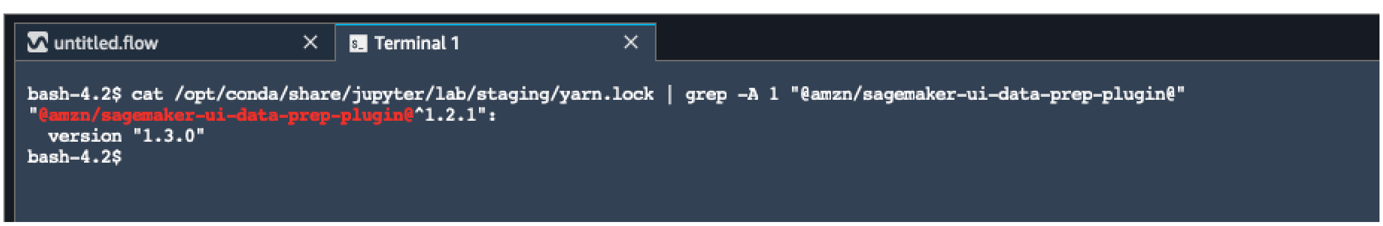
You must use Studio Classic version 1.3.0 or later. Use the following procedure to open Amazon SageMaker Studio Classic and see which version you're running.

To open Studio Classic and check its version, see the following procedure.

1. Use the steps in Prerequisites to access Data Wrangler through Amazon SageMaker Studio Classic.
2. Next to the user you want to use to launch Studio Classic, select **Launch app**.
3. Choose **Studio**.
4. After Studio Classic loads, select **File**, then **New**, and then **Terminal**.



5. Once you have launched Studio Classic, select **File**, then **New**, and then **Terminal**.
6. Enter `cat /opt/conda/share/jupyter/lab/staging/yarn.lock | grep -A 1 "@amzn/sagemaker-ui-data-prep-plugin@"` to print the version of your Studio Classic instance. You must have Studio Classic version 1.3.0 to use Snowflake.



You can update Amazon SageMaker Studio Classic from within the AWS Management Console. For more information about updating Studio Classic, see Amazon SageMaker Studio Classic UI Overview.

- Shut Down Data Wrangler

Get Started with Data Wrangler

Amazon SageMaker Data Wrangler is a feature in Amazon SageMaker Studio Classic. Use this section to learn how to access and get started using Data Wrangler. Do the following:

1. Complete each step in Prerequisites.
2. Follow the procedure in Access Data Wrangler to start using Data Wrangler.

Prerequisites

To use Data Wrangler, you must complete the following prerequisites.

1. To use Data Wrangler, you need access to an Amazon Elastic Compute Cloud (Amazon EC2) instance. For more information about the Amazon EC2 instances that you can use, see Instances. To learn how to view your quotas and, if necessary, request a quota increase, see AWS service quotas.
2. Configure the required permissions described in Security and Permissions.
3. If your organization is using a firewall that blocks internet traffic, you must have access to the following URLs:
   - `https://ui.prod-1.data-wrangler.sagemaker.aws/`
   - `https://ui.prod-2.data-wrangler.sagemaker.aws/`
   - `https://ui.prod-3.data-wrangler.sagemaker.aws/`
   - `https://ui.prod-4.data-wrangler.sagemaker.aws/`

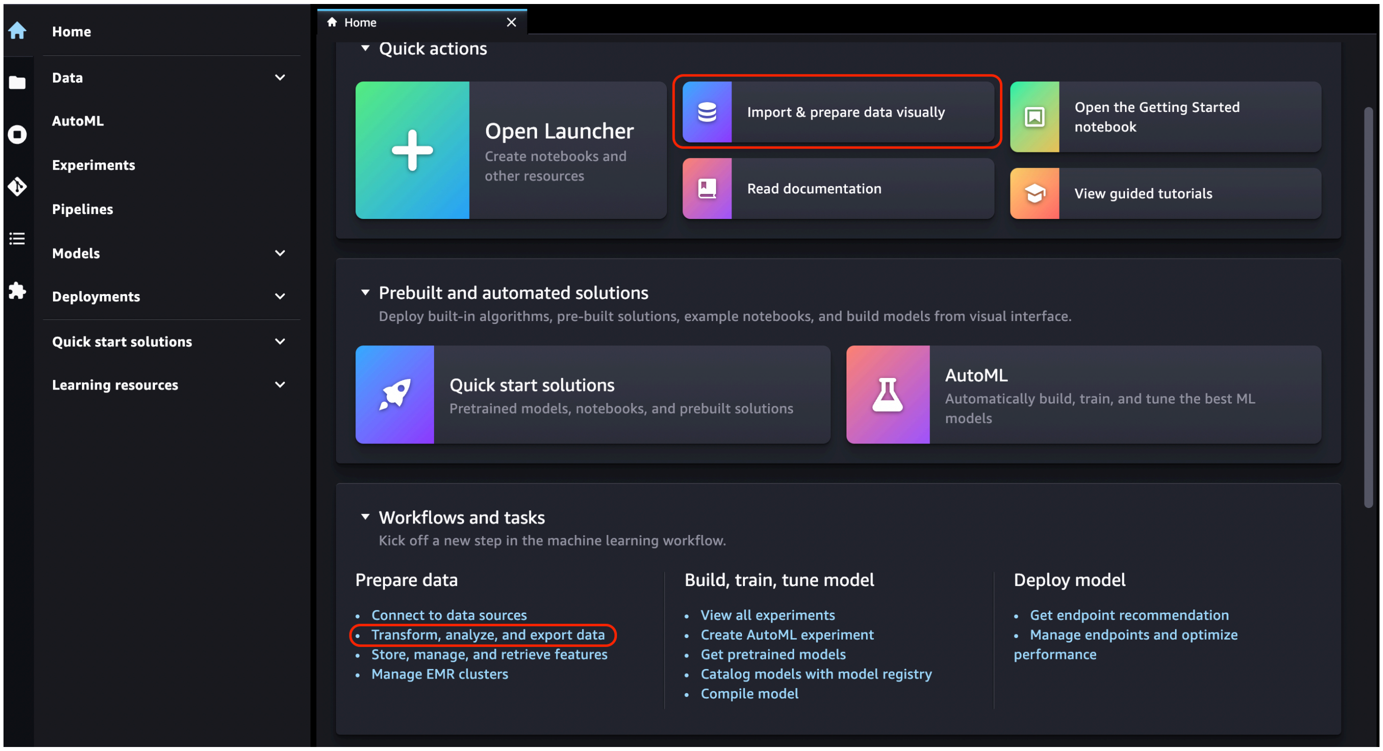
To use Data Wrangler, you need an active Studio Classic instance. To learn how to launch a new instance, see Amazon SageMaker AI domain overview. When your Studio Classic instance is **Ready**, use the instructions in Access Data Wrangler.

Access Data Wrangler

The following procedure assumes you have completed the Prerequisites.

To access Data Wrangler in Studio Classic, do the following.

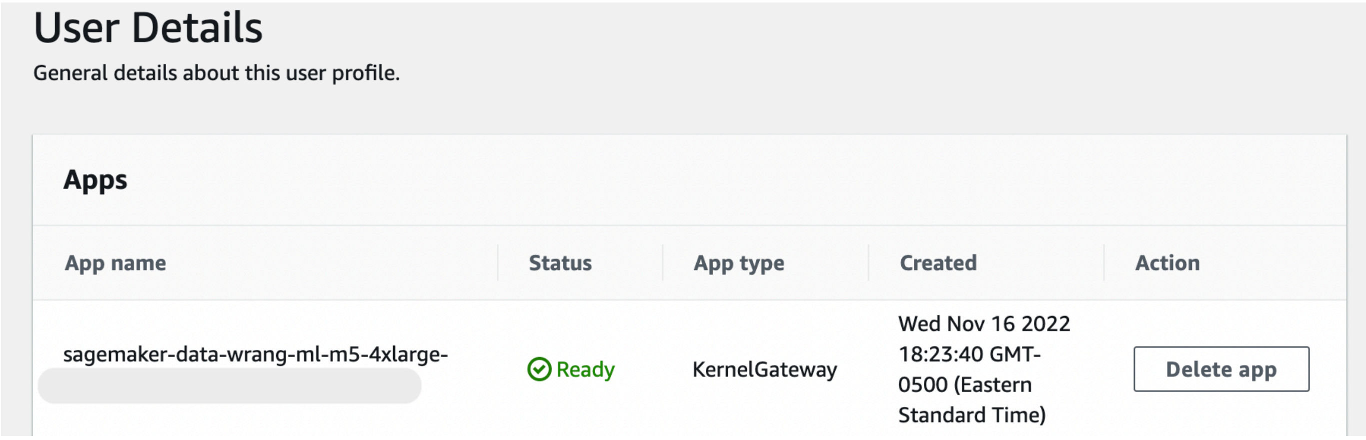
1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. You can also create a Data Wrangler flow by doing the following.
   a. In the top navigation bar, select **File**.
   b. Select **New**.
   c. Select **Data Wrangler Flow**.



9. (Optional) Rename the new directory and the .flow file.
10. When you create a new .flow file in Studio Classic, you might see a carousel that introduces you to Data Wrangler.

    This may take a few minutes.

    This messaging persists as long as the **KernelGateway** app on your **User Details** page is **Pending**. To see the status of this app, in the SageMaker AI console on the **Amazon SageMaker Studio Classic** page, select the name of the user you are using to access Studio Classic. On the **User Details** page, you see a **KernelGateway** app under **Apps**. Wait until this app status is **Ready** to start using Data Wrangler. This can take around 5 minutes the first time you launch Data Wrangler.



11. To get started, choose a data source and use it to import a dataset. See Import to learn more.

    When you import a dataset, it appears in your data flow. To learn more, see Create and Use a Data Wrangler Flow.

12. After you import a dataset, Data Wrangler automatically infers the type of data in each column. Choose **+** next to the **Data types** step and select **Edit data types**.

    > **Important**
    >
    > After you add transforms to the **Data types** step, you cannot bulk-update column types using **Update types**.

13. Use the data flow to add transforms and analyses. To learn more see Transform Data and Analyze and Visualize.

14. To export a complete data flow, choose **Export** and choose an export option. To learn more, see Export.

15. Finally, choose the **Components and registries** icon, and select **Data Wrangler** from the dropdown list to see all the .flow files that you've created. You can use this menu to find and move between data flows.

After you have launched Data Wrangler, you can use the following section to walk through how you might use Data Wrangler to create an ML data prep flow.

Update Data Wrangler

We recommend that you periodically update the Data Wrangler Studio Classic app to access the latest features and updates. The Data Wrangler app name starts with **sagemaker-data-wrang**. To learn how to update a Studio Classic app, see Shut down and Update Studio Classic Apps.

Demo: Data Wrangler Titanic Dataset Walkthrough

The following sections provide a walkthrough to help you get started using Data Wrangler. This walkthrough assumes that you have already followed the steps in Access Data Wrangler and have a new data flow file open that you intend to use for the demo. You may want to rename this .flow file to something similar to `titanic-demo.flow`.

This walkthrough uses the Titanic dataset. It's a modified version of the Titanic dataset that you can import into your Data Wrangler flow more easily. This data set contains the survival status, age, gender, and class (which serves as a proxy for economic status) of passengers aboard the maiden voyage of the *RMS Titanic* in 1912.

In this tutorial, you perform the following steps.

1. Do one of the following:
   - Open your Data Wrangler flow and choose **Use Sample Dataset**.
   - Upload the Titanic dataset to Amazon Simple Storage Service (Amazon S3), and then import this dataset into Data Wrangler.
2. Analyze this dataset using Data Wrangler analyses.
3. Define a data flow using Data Wrangler data transforms.
4. Export your flow to a Jupyter Notebook that you can use to create a Data Wrangler job.
5. Process your data, and kick off a SageMaker training job to train a XGBoost Binary Classifier.

Upload Dataset to S3 and Import

To get started, you can use one of the following methods to import the Titanic dataset into Data Wrangler:

- Importing the dataset directly from the Data Wrangler flow
- Uploading the dataset to Amazon S3 and then importing it into Data Wrangler

To import the dataset directly into Data Wrangler, open the flow and choose **Use Sample Dataset**.

Uploading the dataset to Amazon S3 and importing it into Data Wrangler is closer to the experience you have importing your own data. The following information tells you how to upload your dataset and import it.

Before you start importing the data into Data Wrangler, download the [Titanic dataset]() and upload it to an Amazon S3 (Amazon S3) bucket in the AWS Region in which you want to complete this demo.

If you are a new user of Amazon S3, you can do this using drag and drop in the Amazon S3 console. To learn how, see [Uploading Files and Folders by Using Drag and Drop]() in the Amazon Simple Storage Service User Guide.

> **Important**
>
> Upload your dataset to an S3 bucket in the same AWS Region you want to use to complete this demo.

When your dataset has been successfully uploaded to Amazon S3, you can import it into Data Wrangler.

Import the Titanic dataset to Data Wrangler

1. Choose the **Import data** button in your **Data flow** tab or choose the **Import** tab.
2. Select **Amazon S3**.
3. Use the **Import a dataset from S3** table to find the bucket to which you added the Titanic dataset. Choose the Titanic dataset CSV file to open the **Details** pane.
4. Under **Details**, the **File type** should be CSV. Check **First row is header** to specify that the first row of the dataset is a header. You can also name the dataset something more friendly, such as **`Titanic-train`**.
5. Choose the **Import** button.

When your dataset is imported into Data Wrangler, it appears in your **Data Flow** tab. You can double click on a node to enter the node detail view, which allows you to add transformations or analysis. You can use the plus icon for a quick access to the navigation. In the next section, you use this data flow to add analysis and transform steps.

Data Flow

In the data flow section, the only steps in the data flow are your recently imported dataset and a **Data type** step. After applying transformations, you can come back to this tab and see what the data flow looks like. Now, add some basic transformations under the **Prepare** and **Analyze** tabs.

Prepare and Visualize

Data Wrangler has built-in transformations and visualizations that you can use to analyze, clean, and transform your data.

The **Data** tab of the node detail view lists all built-in transformations in the right panel, which also contains an area in which you can add custom transformations. The following use case showcases how to use these transformations.

To get information that might help you with data exploration and feature engineering, create a data quality and insights report. The information from the report can help you clean and process your data. It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention. For more information about creating a report, see Get Insights On Data and Data Quality.

Data Exploration

First, create a table summary of the data using an analysis. Do the following:

1. Choose the **+** next to the **Data type** step in your data flow and select **Add analysis**.
2. In the **Analysis** area, select **Table summary** from the dropdown list.
3. Give the table summary a **Name**.
4. Select **Preview** to preview the table that will be created.
5. Choose **Save** to save it to your data flow. It appears under **All Analyses**.

Using the statistics you see, you can make observations similar to the following about this dataset:

- Fare average (mean) is around $33, while the max is over $500. This column likely has outliers.
- This dataset uses *?* to indicate missing values. A number of columns have missing values: *cabin*, *embarked*, and *home.dest*
- The age category is missing over 250 values.

Next, clean your data using the insights gained from these stats.

Drop Unused Columns

Using the analysis from the previous section, clean up the dataset to prepare it for training. To add a new transform to your data flow, choose **+** next to the **Data type** step in your data flow and choose **Add transform**.

First, drop columns that you don't want to use for training. You can use pandas data analysis library to do this, or you can use one of the built-in transforms.

Use the following procedure to drop the unused columns.

To drop the unused columns.

1. Open the Data Wrangler flow.
2. There are two nodes in your Data Wrangler flow. Choose the **+** to the right of the **Data types** node.
3. Choose **Add transform**.
4. In the **All steps** column, choose **Add step**.
5. In the **Standard** transform list, choose **Manage Columns**. The standard transformations are ready-made, built-in transformations. Make sure that **Drop column** is selected.
6. Under **Columns to drop**, check the following column names:
   - cabin
   - ticket
   - name
   - sibsp
   - parch
   - home.dest
   - boat
   - body
7. Choose **Preview**.
8. Verify that the columns have been dropped, then choose **Add**.

To do this using pandas, follow these steps.

1. In the **All steps** column, choose **Add step**.
2. In the **Custom** transform list, choose **Custom transform**.
3. Provide a name for your transformation, and choose **Python (Pandas)** from the dropdown list.
4. Enter the following Python script in the code box.

```
cols = ['name', 'ticket', 'cabin', 'sibsp', 'parch', 'home.dest','boat', 'body']
df = df.drop(cols, axis=1)
```

5. Choose **Preview** to preview the change, and then choose **Add** to add the transformation.

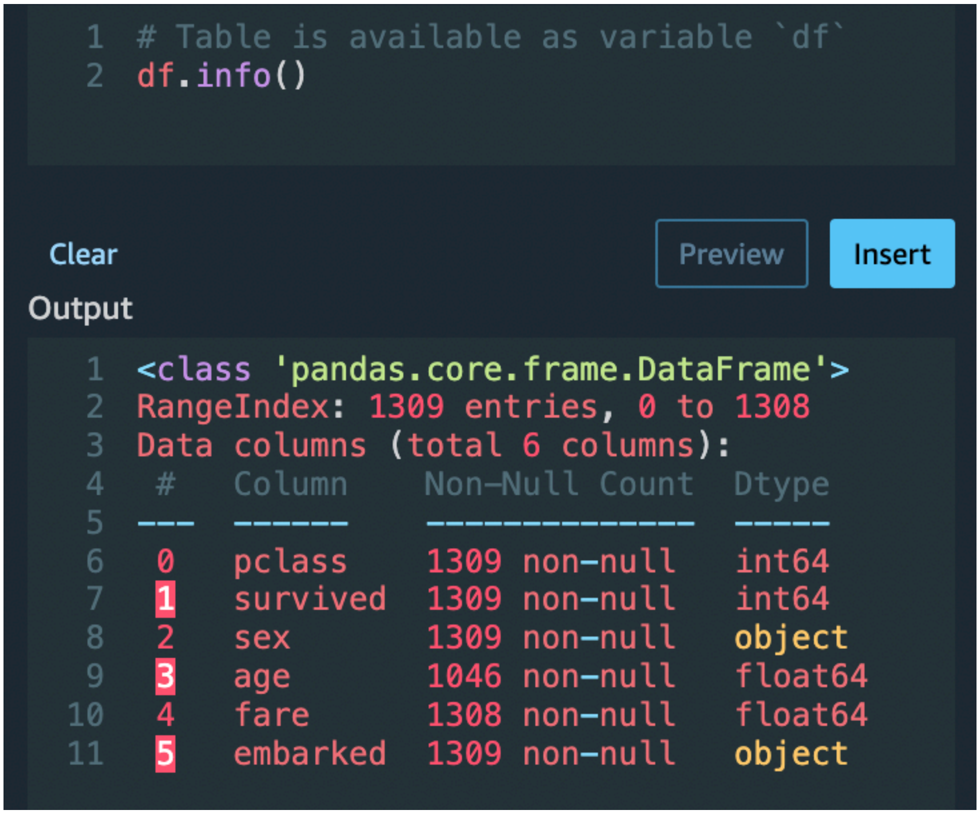
Clean up Missing Values

Now, clean up missing values. You can do this with the **Handling missing values** transform group.

A number of columns have missing values. Of the remaining columns, *age* and *fare* contain missing values. Inspect this using a **Custom Transform**.

Using the **Python (Pandas)** option, use the following to quickly review the number of entries in each column:

```
df.info()
```



To drop rows with missing values in the *age* category, do the following:

1. Choose **Handle missing**.
2. Choose **Drop missing** for the **Transformer**.
3. Choose *age* for the **Input column**.
4. Choose **Preview** to see the new data frame, and then choose **Add** to add the transform to your flow.
5. Repeat the same process for *fare*.

You can use `df.info()` in the **Custom transform** section to confirm that all rows now have 1,045 values.

Custom Pandas: Encode

Try flat encoding using Pandas. Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are `Dog` and `Cat`, you may encode this information into two vectors: `[1,0]` to represent `Dog`, and `[0,1]` to represent `Cat`.

1. In the **Custom Transform** section, choose **Python (Pandas)** from the dropdown list.

2. Enter the following in the code box.

```
import pandas as pd

dummies = []
cols = ['pclass','sex','embarked']
for col in cols:
    dummies.append(pd.get_dummies(df[col]))

encoded = pd.concat(dummies, axis=1)

df = pd.concat((df, encoded),axis=1)
```

3. Choose **Preview** to preview the change. The encoded version of each column is added to the dataset.
4. Choose **Add** to add the transformation.

Custom SQL: SELECT Columns

Now, select the columns you want to keep using SQL. For this demo, select the columns listed in the following SELECT statement. Because *survived* is your target column for training, put that column first.

1. In the **Custom Transform** section, select **SQL (PySpark SQL)** from the dropdown list.
2. Enter the following in the code box.

```
SELECT survived, age, fare, 1, 2, 3, female, male, C, Q, S FROM df;
```

3. Choose **Preview** to preview the change. The columns listed in your SELECT statement are the only remaining columns.
4. Choose **Add** to add the transformation.

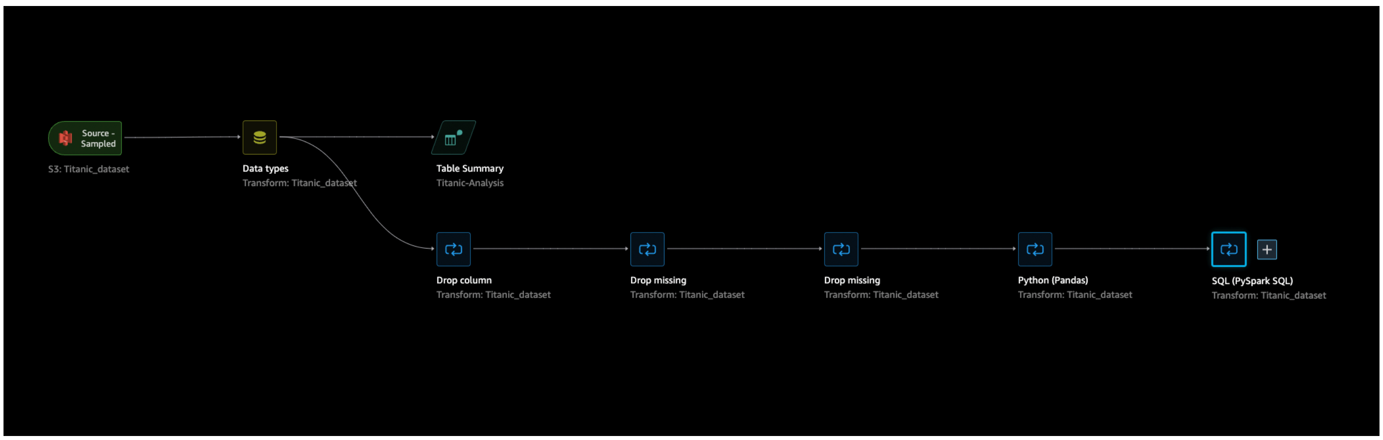
Export to a Data Wrangler Notebook

When you've finished creating a data flow, you have a number of export options. The following section explains how to export to a Data Wrangler job notebook. A Data Wrangler job is used to process your data using the steps defined in your data flow. To learn more about all export options, see Export.

Export to Data Wrangler Job Notebook

When you export your data flow using a **Data Wrangler job**, the process automatically creates a Jupyter Notebook. This notebook automatically opens in your Studio Classic instance and is configured to run a SageMaker Processing job to run your Data Wrangler data flow, which is referred to as a Data Wrangler job.

1. Save your data flow. Select **File** and then select **Save Data Wrangler Flow**.
2. Back to the **Data Flow** tab, select the last step in your data flow (SQL), then choose the **+** to open the navigation.
3. Choose **Export**, and **Amazon S3 (via Jupyter Notebook)**. This opens a Jupyter Notebook.



4. Choose any **Python 3 (Data Science)** kernel for the **Kernel**.
5. When the kernel starts, run the cells in the notebook book until **Kick off SageMaker Training Job (Optional)**.
6. Optionally, you can run the cells in **Kick off SageMaker Training Job (Optional)** if you want to create a SageMaker AI training job to train an XGBoost classifier. You can find the cost to run a SageMaker training job in Amazon SageMaker Pricing.

   Alternatively, you can add the code blocks found in Training XGBoost Classifier to the notebook and run them to use the XGBoost open source library to train an XGBoost classifier.
7. Uncomment and run the cell under **Cleanup** and run it to revert the SageMaker Python SDK to its original version.

You can monitor your Data Wrangler job status in the SageMaker AI console in the **Processing** tab. Additionally, you can monitor your Data Wrangler job using Amazon CloudWatch. For additional information, see Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics.

If you kicked off a training job, you can monitor its status using the SageMaker AI console under **Training jobs** in the **Training section**.

Training XGBoost Classifier

You can train an XGBoost Binary Classifier using either a Jupyter notebook or a Amazon SageMaker Autopilot. You can use Autopilot to automatically train and tune models on the data that you've transformed directly from your Data Wrangler flow. For information about Autopilot, see Automatically Train Models on Your Data Flow.

In the same notebook that kicked off the Data Wrangler job, you can pull the data and train an XGBoost Binary Classifier using the prepared data with minimal data preparation.

1. First, upgrade necessary modules using `pip` and remove the _SUCCESS file (this last file is problematic when using `awswrangler`).

```
! pip install --upgrade awscli awswrangler boto sklearn
! aws s3 rm {output_path} --recursive  --exclude "*" --include "*_SUCCESS*"
```

2. Read the data from Amazon S3. You can use `awswrangler` to recursively read all the CSV files in the S3 prefix. The data is then split into features and labels. The label is the first column of the dataframe.

```
import awswrangler as wr

df = wr.s3.read_csv(path=output_path, dataset=True)
X, y = df.iloc[:,:-1],df.iloc[:,-1]
```

- Finally, create DMatrices (the XGBoost primitive structure for data) and do cross-validation using the XGBoost binary classification.

```
import xgboost as xgb

dmatrix = xgb.DMatrix(data=X, label=y)

params = {"objective":"binary:logistic",'learning_rate': 0.1, 'max_depth': 5,
 'alpha': 10}

xgb.cv(
    dtrain=dmatrix,
    params=params,
```

```
    nfold=3,
    num_boost_round=50,
    early_stopping_rounds=10,
    metrics="rmse",
    as_pandas=True,
    seed=123)
```

Shut down Data Wrangler

When you are finished using Data Wrangler, we recommend that you shut down the instance it runs on to avoid incurring additional charges. To learn how to shut down the Data Wrangler app and associated instance, see Shut Down Data Wrangler.

Import

You can use Amazon SageMaker Data Wrangler to import data from the following *data sources*: Amazon Simple Storage Service (Amazon S3), Amazon Athena, Amazon Redshift, and Snowflake. The dataset that you import can include up to 1000 columns.

Topics

Some data sources allow you to add multiple *data connections*:

- You can connect to multiple Amazon Redshift clusters. Each cluster becomes a data source.
- You can query any Athena database in your account to import data from that database.

When you import a dataset from a data source, it appears in your data flow. Data Wrangler automatically infers the data type of each column in your dataset. To modify these types, select the **Data types** step and select **Edit data types**.

When you import data from Athena or Amazon Redshift, the imported data is automatically stored in the default SageMaker AI S3 bucket for the AWS Region in which you are using Studio Classic. Additionally, Athena stores data you preview in Data Wrangler in this bucket. To learn more, see Imported Data Storage.

> **Important**
>
> The default Amazon S3 bucket may not have the least permissive security settings, such as bucket policy and server-side encryption (SSE). We strongly recommend that you Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler.

> **Important**
>
> In addition, if you use the managed policy for SageMaker AI, we strongly recommend that you scope it down to the most restrictive policy that allows you to perform your use case. For more information, see Grant an IAM Role Permission to Use Data Wrangler.

All data sources except for Amazon Simple Storage Service (Amazon S3) require you to specify a SQL query to import your data. For each query, you must specify the following:

- **Data catalog**
- **Database**
- **Table**

You can specify the name of the database or the data catalog in either the drop down menus or within the query. The following are example queries:

- `select * from` *`example-data-catalog-name`*`.`*`example-database-name`*`.`*`example-table-name`* – The query doesn't use anything specified in the dropdown menus of the user-interface (UI) to run. It queries `example-table-name` within `example-database-name` within `example-data-catalog-name`.

- `select * from example-database-name.example-table-name` – The query uses the data catalog that you've specified in the **Data catalog** dropdown menu to run. It queries `example-table-name` within `example-database-name` within the data catalog that you've specified.
- `select * from example-table-name` – The query requires you to select fields for both the **Data catalog** and **Database name** dropdown menus. It queries `example-table-name` within the data catalog within the database and data catalog that you've specified.

The link between Data Wrangler and the data source is a *connection*. You use the connection to import data from your data source.

There are the following types of connections:

- Direct
- Cataloged

Data Wrangler always has access to the most recent data in a direct connection. If the data in the data source has been updated, you can use the connection to import the data. For example, if someone adds a file to one of your Amazon S3 buckets, you can import the file.

A cataloged connection is the result of a data transfer. The data in the cataloged connection doesn't necessarily have the most recent data. For example, you might set up a data transfer between Salesforce and Amazon S3. If there's an update to the Salesforce data, you must transfer the data again. You can automate the process of transferring data. For more information about data transfers, see Import Data From Software as a Service (SaaS) Platforms.

Import data from Amazon S3

You can use Amazon Simple Storage Service (Amazon S3) to store and retrieve any amount of data, at any time, from anywhere on the web. You can accomplish these tasks using the AWS Management Console, which is a simple and intuitive web interface, and the Amazon S3 API. If you've stored your dataset locally, we recommend that you add it to an S3 bucket for import into Data Wrangler. To learn how, see Uploading an object to a bucket in the Amazon Simple Storage Service User Guide.

Data Wrangler uses S3 Select to allow you to preview your Amazon S3 files in Data Wrangler. You incur standard charges for each file preview. To learn more about pricing, see the **Requests & data retrievals** tab on Amazon S3 pricing.

Important

If you plan to export a data flow and launch a Data Wrangler job, ingest data into a SageMaker AI feature store, or create a SageMaker AI pipeline, be aware that these integrations require Amazon S3 input data to be located in the same AWS region.

Important

If you're importing a CSV file, make sure it meets the following requirements:

- A record in your dataset can't be longer than one line.
- A backslash, \, is the only valid escape character.
- Your dataset must use one of the following delimiters:
  - Comma – `,`
  - Colon – `:`
  - Semicolon – `;`
  - Pipe – `|`
  - Tab – `[TAB]`

To save space, you can import compressed CSV files.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Amazon S3, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

After you've imported your data, you can also use the sampling transformer to take one or more samples from your entire dataset. For more information about the sampling transformer, see Sampling.

You can use one of the following resource identifiers to import your data:

- An Amazon S3 URI that uses an Amazon S3 bucket or Amazon S3 access point
- An Amazon S3 access point alias
- An Amazon Resource Name (ARN) that uses an Amazon S3 access point or Amazon S3 bucket

Amazon S3 access points are named network endpoints that are attached to the buckets. Each access point has distinct permissions and network controls that you can configure. For more information about access points, see [Managing data access with Amazon S3 access points](#).

> **Important**
>
> If you're using an Amazon Resource Name (ARN) to import your data, it must be for a resource located in the same AWS Region that you're using to access Amazon SageMaker Studio Classic.

You can import either a single file or multiple files as a dataset. You can use the multifile import operation when you have a dataset that is partitioned into separate files. It takes all of the files from an Amazon S3 directory and imports them as a single dataset. For information on the types of files that you can import and how to import them, see the following sections.

Single File Import

You can import single files in the following formats:

- Comma Separated Values (CSV)
- Parquet
- Javascript Object Notation (JSON)
- Optimized Row Columnar (ORC)
- Image – Data Wrangler uses OpenCV to import images. For more information about supported image formats, see [Image file reading and writing](#).

For files formatted in JSON, Data Wrangler supports both JSON lines (.jsonl) and JSON documents (.json). When you preview your data, it automatically shows the JSON in tabular format. For nested JSON documents that are larger than 5 MB, Data Wrangler shows the schema for the structure and the arrays as values in the dataset. Use the **Flatten structured** and

Explode array operators to display the nested values in tabular format. For more information, see Unnest JSON Data and Explode Array.

When you choose a dataset, you can rename it, specify the file type, and identify the first row as a header.

You can import a dataset that you've partitioned into multiple files in an Amazon S3 bucket in a single import step.

To import a dataset into Data Wrangler from a single file that you've stored in Amazon S3:

1. If you are not currently on the **Import** tab, choose **Import**.
2. Under **Available**, choose **Amazon S3**.
3. From the **Import tabular, image, or time-series data from S3**, do one of the following:
   - Choose an Amazon S3 bucket from the tabular view and navigate to the file that you're importing.
   - For **S3 source**, specify an Amazon S3 bucket or an Amazon S3 URI and select **Go**. The Amazon S3 URIs can be in one of the following formats:
     - `s3://amzn-s3-demo-bucket/example-prefix/example-file`
     - *example-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a*-s3alias/datasets/*example-file*
     - `s3://arn:aws:s3:AWS-Region:111122223333:accesspoint/example-prefix/example-file`
4. Choose the dataset to open the **Import settings** pane.
5. If your CSV file has a header, select the checkbox next to **Add header to table**.
6. Use the **Preview** table to preview your dataset. This table shows up to 100 rows.
7. In the **Details** pane, verify or change the **Name** and **File Type** for your dataset. If you add a **Name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
8. Specify the sampling configuration that you'd like to use.
9. Choose **Import**.

Multifile Import

The following are the requirements for importing multiple files:

- The files must be in the same folder of your Amazon S3 bucket.
- The files must either share the same header or have no header.

Each file must be in one of the following formats:

- CSV
- Parquet
- Optimized Row Columnar (ORC)
- Image – Data Wrangler uses OpenCV to import images. For more information about supported image formats, see Image file reading and writing.

Use the following procedure to import multiple files.

To import a dataset into Data Wrangler from multiple files that you've stored in an Amazon S3 directory

1. If you are not currently on the **Import** tab, choose **Import**.
2. Under **Available**, choose **Amazon S3**.
3. From the **Import tabular, image, or time-series data from S3**, do one of the following:
   - Choose an Amazon S3 bucket from the tabular view and navigate to the folder containing the files that you're importing.
   - For **S3 source**, specify the Amazon S3 bucket or an Amazon S3 URI with your files and select **Go**. The following are valid URIs:
     - `s3://amzn-s3-demo-bucket/example-prefix/example-prefix`
     - `example-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a-s3alias/example-prefix/`
     - `s3://arn:aws:s3:AWS-Region:111122223333:accesspoint/example-prefix`
4. Select the folder containing the files that you want to import. Each file must be in one of the supported formats. Your files must be the same data type.
5. If your folder contains CSV files with headers, select the checkbox next to **First row is header**.

6. If your files are nested within other folders, select the checkbox next to **Include nested directories**.
7. (Optional) Choose **Add filename column** add a column to the dataset that shows the filename for each observation.
8. (Optional) By default, Data Wrangler doesn't show you a preview of a folder. You can activate previewing by choosing the blue **Preview off** button. A preview shows the first 10 rows of the first 10 files in the folder.
9. In the **Details** pane, verify or change the **Name** and **File Type** for your dataset. If you add a **Name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
10. Specify the sampling configuration that you'd like to use.
11. Choose **Import dataset**.

You can also use parameters to import a subset of files that match a pattern. Parameters help you more selectively pick the files that you're importing. To start using parameters, edit the data source and apply them to the path that you're using to import the data. For more information, see Reusing Data Flows for Different Datasets.

Import data from Athena

Use Amazon Athena to import your data from Amazon Simple Storage Service (Amazon S3) into Data Wrangler. In Athena, you write standard SQL queries to select the data that you're importing from Amazon S3. For more information, see What is Amazon Athena?

You can use the AWS Management Console to set up Amazon Athena. You must create at least one database in Athena before you start running queries. For more information about getting started with Athena, see Getting started.

Athena is directly integrated with Data Wrangler. You can write Athena queries without having to leave the Data Wrangler UI.

In addition to writing simple Athena queries in Data Wrangler, you can also use:

- Athena workgroups for query result management. For more information about workgroups, see Managing query results.
- Lifecycle configurations for setting data retention periods. For more information about data retention, see Setting data retention periods.

Query Athena within Data Wrangler

> **Note**
>
> Data Wrangler does not support federated queries.

If you use AWS Lake Formation with Athena, make sure your Lake Formation IAM permissions do not override IAM permissions for the database `sagemaker_data_wrangler`.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Athena, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The following procedure shows how to import a dataset from Athena into Data Wrangler.

To import a dataset into Data Wrangler from Athena

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Amazon Athena**.
10. For **Data Catalog**, choose a data catalog.
11. Use the **Database** dropdown list to select the database that you want to query. When you select a database, you can preview all tables in your database using the **Tables** listed under **Details**.

12. (Optional) Choose **Advanced configuration**.

    a. Choose a **Workgroup**.

    b. If your workgroup hasn't enforced the Amazon S3 output location or if you don't use a workgroup, specify a value for **Amazon S3 location of query results**.

    c. (Optional) For **Data retention period**, select the checkbox to set a data retention period and specify the number of days to store the data before it's deleted.

    d. (Optional) By default, Data Wrangler saves the connection. You can choose to deselect the checkbox and not save the connection.

13. For **Sampling**, choose a sampling method. Choose **None** to turn off sampling.

14. Enter your query in the query editor and use the **Run** button to run the query. After a successful query, you can preview your result under the editor.

    Note

    Salesforce data uses the `timestamptz` type. If you're querying the timestamp column that you've imported to Athena from Salesforce, cast the data in the column to the `timestamp` type. The following query casts the timestamp column to the correct type.

    ```
    # cast column timestamptz_col as timestamp type, and name it as
     timestamp_col
    select cast(timestamptz_col as timestamp) as timestamp_col from table
    ```

15. To import the results of your query, select **Import**.

After you complete the preceding procedure, the dataset that you've queried and imported appears in the Data Wrangler flow.

By default, Data Wrangler saves the connection settings as a new connection. When you import your data, the query that you've already specified appears as a new connection. The saved connections store information about the Athena workgroups and Amazon S3 buckets that you're using. When you're connecting to the data source again, you can choose the saved connection.

Managing query results

Data Wrangler supports using Athena workgroups to manage the query results within an AWS account. You can specify an Amazon S3 output location for each workgroup. You can also specify whether the output of the query can go to different Amazon S3 locations. For more information, see Using Workgroups to Control Query Access and Costs.

Your workgroup might be configured to enforce the Amazon S3 query output location. You can't change the output location of the query results for those workgroups.

If you don't use a workgroup or specify an output location for your queries, Data Wrangler uses the default Amazon S3 bucket in the same AWS Region in which your Studio Classic instance is located to store Athena query results. It creates temporary tables in this database to move the query output to this Amazon S3 bucket. It deletes these tables after data has been imported; however the database, `sagemaker_data_wrangler`, persists. To learn more, see Imported Data Storage.

To use Athena workgroups, set up the IAM policy that gives access to workgroups. If you're using a `SageMaker AI-Execution-Role`, we recommend adding the policy to the role. For more information about IAM policies for workgroups, see IAM policies for accessing workgroups. For example workgroup policies, see Workgroup example policies.

Setting data retention periods

Data Wrangler automatically sets a data retention period for the query results. The results are deleted after the length of the retention period. For example, the default retention period is five days. The results of the query are deleted after five days. This configuration is designed to help you clean up data that you're no longer using. Cleaning up your data prevents unauthorized users from gaining access. It also helps control the costs of storing your data on Amazon S3.

If you don't set a retention period, the Amazon S3 lifecycle configuration determines the duration that the objects are stored. The data retention policy that you've specified for the lifecycle configuration removes any query results that are older than the lifecycle configuration that you've specified. For more information, see Setting lifecycle configuration on a bucket.

Data Wrangler uses Amazon S3 lifecycle configurations to manage data retention and expiration. You must give your Amazon SageMaker Studio Classic IAM execution role permissions to manage bucket lifecycle configurations. Use the following procedure to give permissions.

To give permissions to manage the lifecycle configuration do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles**.
3. In the search bar, specify the Amazon SageMaker AI execution role that Amazon SageMaker Studio Classic is using.
4. Choose the role.
5. Choose **Add permissions**.
6. Choose **Create inline policy**.
7. For **Service**, specify **S3** and choose it.
8. Under the **Read** section, choose **GetLifecycleConfiguration**.
9. Under the **Write** section, choose **PutLifecycleConfiguration**.
10. For **Resources**, choose **Specific**.
11. For **Actions**, select the arrow icon next to **Permissions management**.
12. Choose **PutResourcePolicy**.
13. For **Resources**, choose **Specific**.
14. Choose the checkbox next to **Any in this account**.
15. Choose **Review policy**.
16. For **Name**, specify a name.
17. Choose **Create policy**.

Import data from Amazon Redshift

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. The first step to create a data warehouse is to launch a set of nodes, called an Amazon Redshift cluster. After you provision your cluster, you can upload your dataset and then perform data analysis queries.

You can connect to and query one or more Amazon Redshift clusters in Data Wrangler. To use this import option, you must create at least one cluster in Amazon Redshift. To learn how, see Getting started with Amazon Redshift.

You can output the results of your Amazon Redshift query in one of the following locations:

- The default Amazon S3 bucket

- An Amazon S3 output location that you specify

You can either import the entire dataset or sample a portion of it. For Amazon Redshift, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The default Amazon S3 bucket is in the same AWS Region in which your Studio Classic instance is located to store Amazon Redshift query results. For more information, see Imported Data Storage.

For either the default Amazon S3 bucket or the bucket that you specify, you have the following encryption options:

- The default AWS service-side encryption with an Amazon S3 managed key (SSE-S3)
- An AWS Key Management Service (AWS KMS) key that you specify

An AWS KMS key is an encryption key that you create and manage. For more information on KMS keys, see AWS Key Management Service.

You can specify an AWS KMS key using either the key ARN or the ARN of your AWS account.

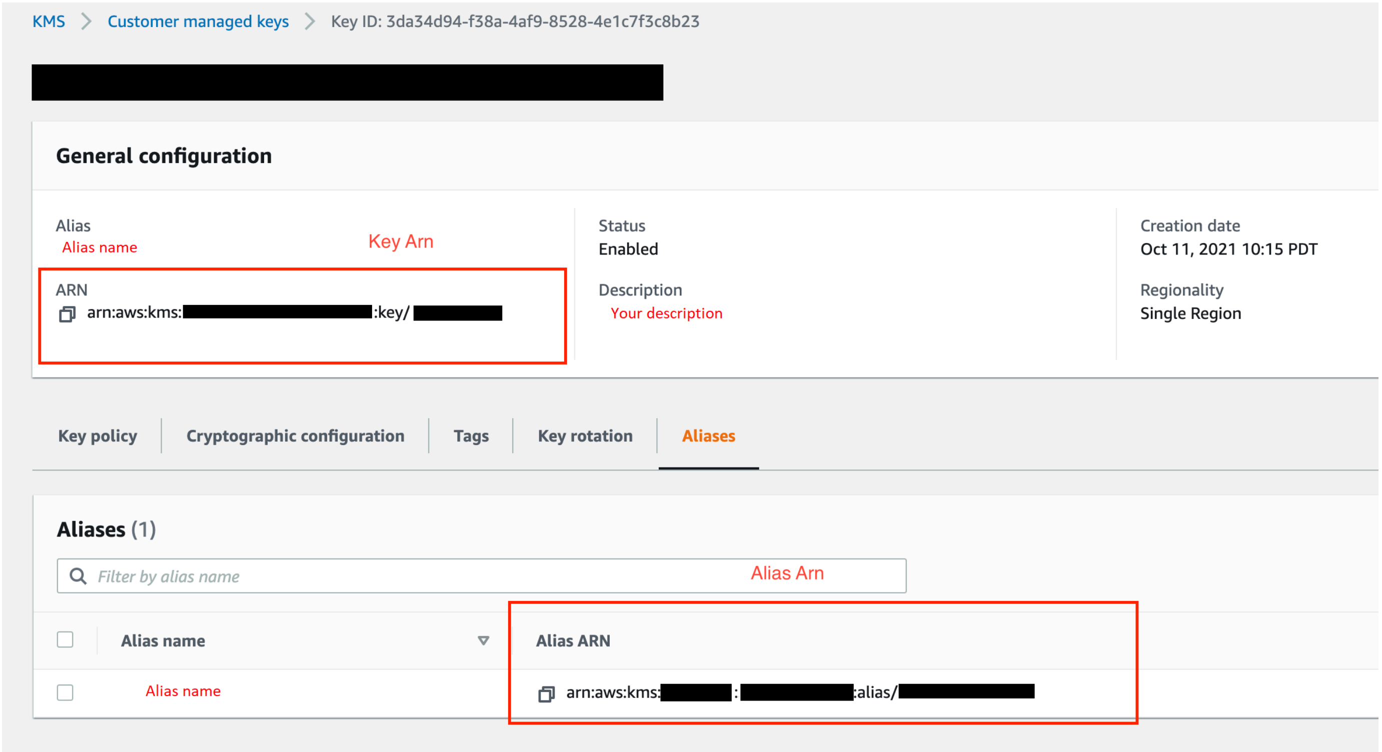
If you use the IAM managed policy, `AmazonSageMakerFullAccess`, to grant a role permission to use Data Wrangler in Studio Classic, your **Database User** name must have the prefix `sagemaker_access`.

Use the following procedures to learn how to add a new cluster.

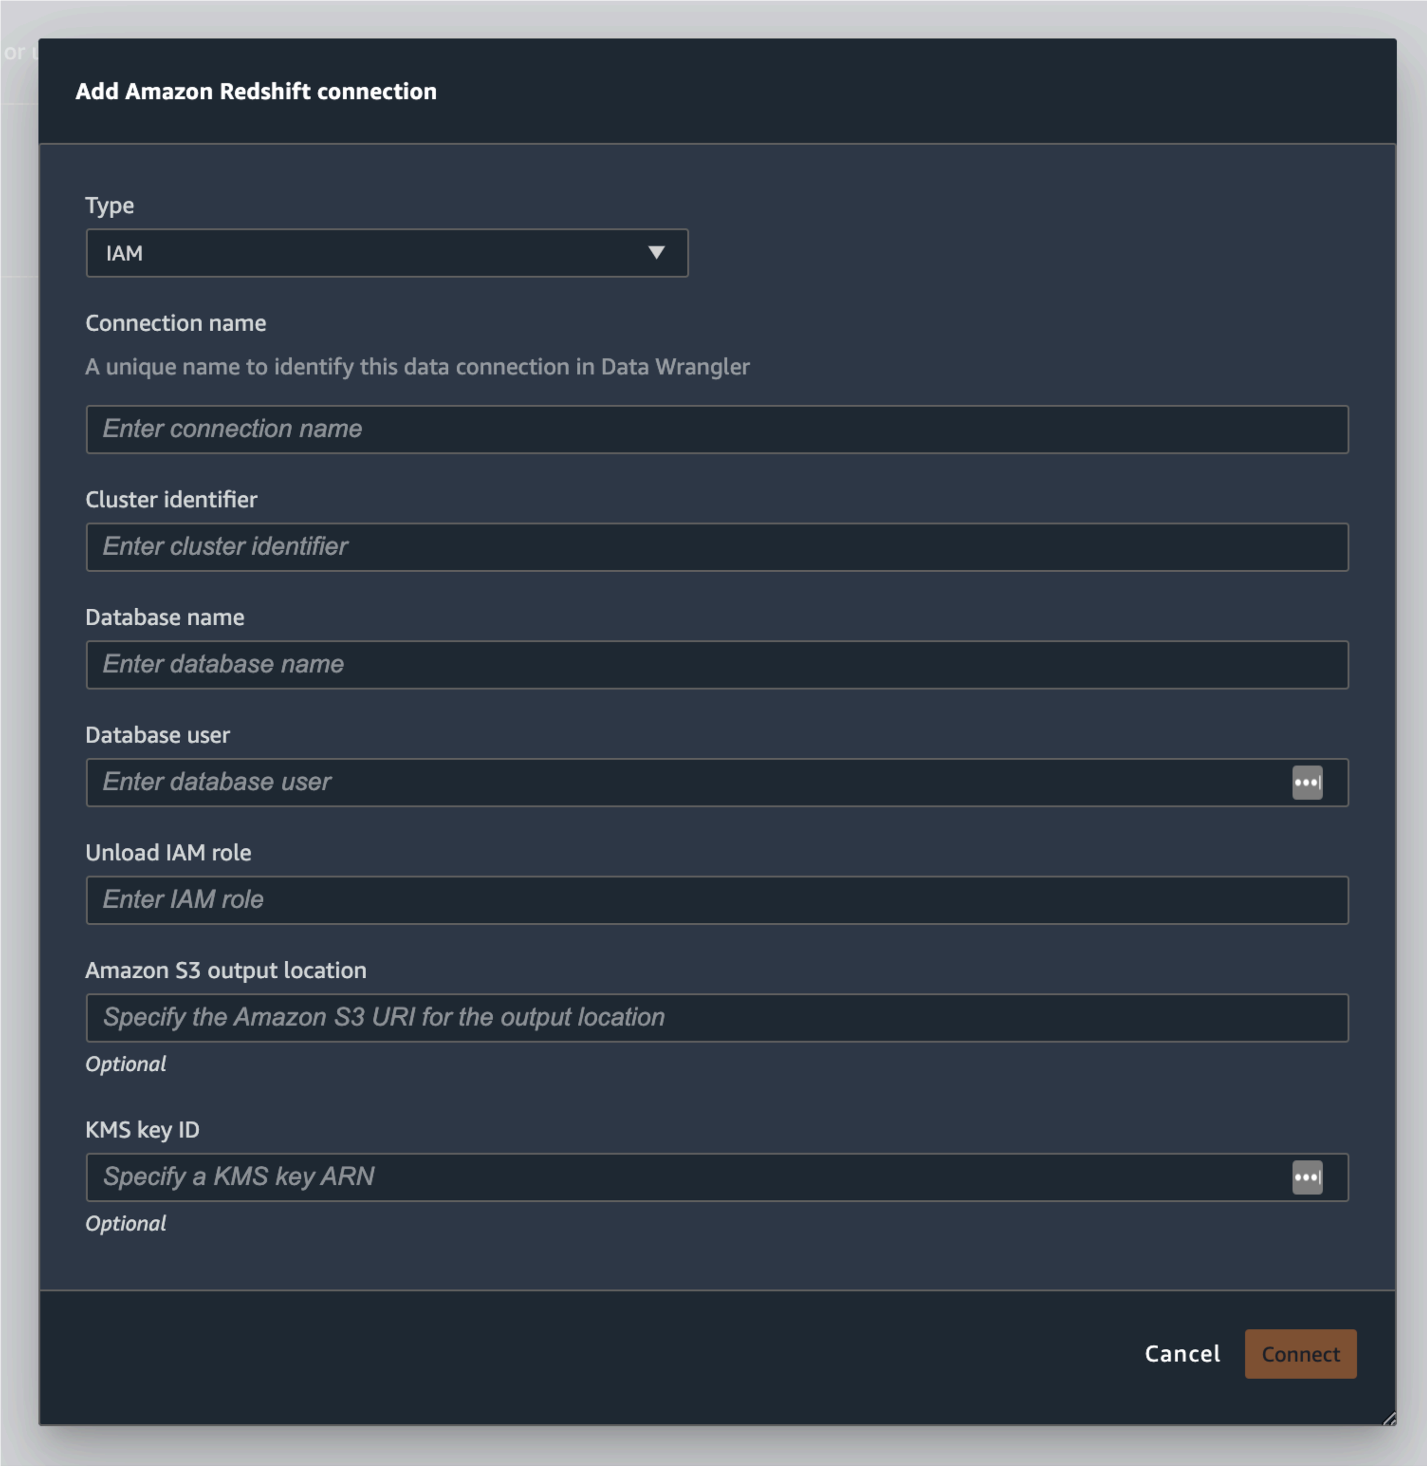
> **Note**
>
> Data Wrangler uses the Amazon Redshift Data API with temporary credentials. To learn more about this API, refer to Using the Amazon Redshift Data API in the Amazon Redshift Management Guide.

To connect to a Amazon Redshift cluster

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Amazon Athena**.
10. Choose **Amazon Redshift**.
11. Choose **Temporary credentials (IAM)** for **Type**.
12. Enter a **Connection Name**. This is a name used by Data Wrangler to identify this connection.
13. Enter the **Cluster Identifier** to specify to which cluster you want to connect. Note: Enter only the cluster identifier and not the full endpoint of the Amazon Redshift cluster.
14. Enter the **Database Name** of the database to which you want to connect.
15. Enter a **Database User** to identify the user you want to use to connect to the database.
16. For **UNLOAD IAM Role**, enter the IAM role ARN of the role that the Amazon Redshift cluster should assume to move and write data to Amazon S3. For more information about this role, see Authorizing Amazon Redshift to access other AWS services on your behalf in the Amazon Redshift Management Guide.
17. Choose **Connect**.
18. (Optional) For **Amazon S3 output location**, specify the S3 URI to store the query results.
19. (Optional) For **KMS key ID**, specify the ARN of the AWS KMS key or alias. The following image shows you where you can find either key in the AWS Management Console.



The following image shows all the fields from the preceding procedure.



After your connection is successfully established, it appears as a data source under **Data Import**. Select this data source to query your database and import data.

To query and import data from Amazon Redshift

1. Select the connection that you want to query from **Data Sources**.

2. Select a **Schema**. To learn more about Amazon Redshift Schemas, see Schemas in the Amazon Redshift Database Developer Guide.
3. (Optional) Under **Advanced configuration**, specify the **Sampling** method that you'd like to use.
4. Enter your query in the query editor and choose **Run** to run the query. After a successful query, you can preview your result under the editor.
5. Select **Import dataset** to import the dataset that has been queried.
6. Enter a **Dataset name**. If you add a **Dataset name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
7. Choose **Add**.

To edit a dataset, do the following.

1. Navigate to your Data Wrangler flow.
2. Choose the + next to **Source - Sampled**.
3. Change the data that you're importing.
4. Choose **Apply**

Import data from Amazon EMR

You can use Amazon EMR as a data source for your Amazon SageMaker Data Wrangler flow. Amazon EMR is a managed cluster platform that you can use process and analyze large amounts of data. For more information about Amazon EMR, see What is Amazon EMR?. To import a dataset from EMR, you connect to it and query it.

> **Important**
>
> You must meet the following prerequisites to connect to an Amazon EMR cluster:
>
> **Prerequisites**
>
> - **Network configurations**
>   - You have an Amazon VPC in the Region that you're using to launch Amazon SageMaker Studio Classic and Amazon EMR.

  - Both Amazon EMR and Amazon SageMaker Studio Classic must be launched in private subnets. They can be in the same subnet or in different ones.
  - Amazon SageMaker Studio Classic must be in VPC-only mode.

    For more information about creating a VPC, see Create a VPC.

    For more information about creating a VPC, see Connect SageMaker Studio Classic Notebooks in a VPC to External Resources.
  - The Amazon EMR clusters that you're running must be in the same Amazon VPC.
  - The Amazon EMR clusters and the Amazon VPC must be in the same AWS account.
  - Your Amazon EMR clusters are running Hive or Presto.
    - Hive clusters must allow inbound traffic from Studio Classic security groups on port 10000.
    - Presto clusters must allow inbound traffic from Studio Classic security groups on port 8889.

      Note

      The port number is different for Amazon EMR clusters using IAM roles. Navigate to the end of the prerequisites section for more information.

- **SageMaker Studio Classic**
  - Amazon SageMaker Studio Classic must run Jupyter Lab Version 3. For information about updating the Jupyter Lab Version, see View and update the JupyterLab version of an application from the console.
  - Amazon SageMaker Studio Classic has an IAM role that controls user access. The default IAM role that you're using to run Amazon SageMaker Studio Classic doesn't have policies that can give you access to Amazon EMR clusters. You must attach the policy granting permissions to the IAM role. For more information, see Configure listing Amazon EMR clusters.
  - The IAM role must also have the following policy attached `secretsmanager:PutResourcePolicy`.
  - If you're using a Studio Classic domain that you've already created, make sure that its `AppNetworkAccessType` is in VPC-only mode. For information about updating a domain to use VPC-only mode, see Shut down and Update SageMaker Studio Classic.

- **Amazon EMR clusters**
  - You must have Hive or Presto installed on your cluster.
  - The Amazon EMR release must be version 5.5.0 or later.

    Note

    Amazon EMR supports auto termination. Auto termination stops idle clusters from running and prevents you from incurring costs. The following are the releases that support auto termination:

    - For 6.x releases, version 6.1.0 or later.
    - For 5.x releases, version 5.30.0 or later.
- **Amazon EMR clusters using IAM runtime roles**
  - Use the following pages to set up IAM runtime roles for the Amazon EMR cluster. You must enable in-transit encryption when you're using runtime roles:
    - Prerequisites for launching an Amazon EMR cluster with a runtime role
    - Launch an Amazon EMR cluster with role-based access control
  - You must Lake Formation as a governance tool for the data within your databases. You must also use external data filtering for access control.
    - For more information about Lake Formation, see What is AWS Lake Formation?
    - For more information about integrating Lake Formation into Amazon EMR, see Integrating third-party services with Lake Formation.
  - The version of your cluster must be 6.9.0 or later.
  - Access to AWS Secrets Manager. For more information about Secrets Manager see What is AWS Secrets Manager?
  - Hive clusters must allow inbound traffic from Studio Classic security groups on port 10000.

An Amazon VPC is a virtual network that is logically isolated from other networks on the AWS cloud. Amazon SageMaker Studio Classic and your Amazon EMR cluster only exist within the Amazon VPC.

Use the following procedure to launch Amazon SageMaker Studio Classic in an Amazon VPC.

To launch Studio Classic within a VPC, do the following.

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Launch SageMaker Studio Classic**.
3. Choose **Standard setup**.
4. For **Default execution role**, choose the IAM role to set up Studio Classic.
5. Choose the VPC where you've launched the Amazon EMR clusters.
6. For **Subnet**, choose a private subnet.
7. For **Security group(s)**, specify the security groups that you're using to control between your VPC.
8. Choose **VPC Only**.
9. (Optional) AWS uses a default encryption key. You can specify an AWS Key Management Service key to encrypt your data.
10. Choose **Next**.
11. Under **Studio settings**, choose the configurations that are best suited to you.
12. Choose **Next** to skip the SageMaker Canvas settings.
13. Choose **Next** to skip the RStudio settings.

If you don't have an Amazon EMR cluster ready, you can use the following procedure to create one. For more information about Amazon EMR, see What is Amazon EMR?

To create a cluster, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify **`Amazon EMR`**.
3. Choose **Create cluster**.
4. For **Cluster name**, specify the name of your cluster.
5. For **Release**, select the release version of the cluster.

> **Note**
>
> Amazon EMR supports auto termination for the following releases:
>
> - For 6.x releases, releases 6.1.0 or later

- For 5.x releases, releases 5.30.0 or later

Auto termination stops idle clusters from running and prevents you from incurring costs.

6. (Optional) For **Applications**, choose **Presto**.
7. Choose the application that you're running on the cluster.
8. Under **Networking**, for **Hardware configuration**, specify the hardware configuration settings.

> **Important**
>
> For **Networking**, choose the VPC that is running Amazon SageMaker Studio Classic and choose a private subnet.

9. Under **Security and access**, specify the security settings.
10. Choose **Create**.

For a tutorial about creating an Amazon EMR cluster, see Getting started with Amazon EMR. For information about best practices for configuring a cluster, see Considerations and best practices.

> **Note**
>
> For security best practices, Data Wrangler can only connect to VPCs on private subnets. You can't connect to the master node unless you use AWS Systems Manager for your Amazon EMR instances. For more information, see Securing access to EMR clusters using AWS Systems Manager.

You can currently use the following methods to access an Amazon EMR cluster:

- No authentication
- Lightweight Directory Access Protocol (LDAP)
- IAM (Runtime role)

Not using authentication or using LDAP can require you to create multiple clusters and Amazon EC2 instance profiles. If you're an administrator, you might need to provide groups of users with different levels of access to the data. These methods can result in administrative overhead that makes it more difficult to manage your users.

We recommend using an IAM runtime role that gives multiple users the ability to connect to the same Amazon EMR cluster. A runtime role is an IAM role that you can assign to a user who is connecting to an Amazon EMR cluster. You can configure the runtime IAM role to have permissions that are specific to each group of users.

Use the following sections to create a Presto or Hive Amazon EMR cluster with LDAP activated.

Presto

> **Important**
>
> To use AWS Glue as a metastore for Presto tables, select **Use** for **Presto table metadata** to store the results of your Amazon EMR queries in a AWS Glue data catalog when you're launching an EMR cluster. Storing the query results in a AWS Glue data catalog can save you from incurring charges.
> To query large datasets on Amazon EMR clusters, you must add the following properties to the Presto configuration file on your Amazon EMR clusters:
>
> ```
> [{"classification":"presto-config","properties":{
> "http-server.max-request-header-size":"5MB",
> "http-server.max-response-header-size":"5MB"}}]
> ```
>
> You can also modify the configuration settings when you launch the Amazon EMR cluster.
> The configuration file for your Amazon EMR cluster is located under the following path: `/etc/presto/conf/config.properties`.

Use the following procedure to create a Presto cluster with LDAP activated.

To create a cluster, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify **`Amazon EMR`**.

3. Choose **Create cluster**.
4. For **Cluster name**, specify the name of your cluster.
5. For **Release**, select the release version of the cluster.

> **Note**
>
> Amazon EMR supports auto termination for the following releases:
>
> - For 6.x releases, releases 6.1.0 or later
> - For 5.x releases, releases 5.30.0 or later
>
> Auto termination stops idle clusters from running and prevent you from incurring costs.

6. Choose the application that you're running on the cluster.
7. Under **Networking**, for **Hardware configuration**, specify the hardware configuration settings.

> **Important**
>
> For **Networking**, choose the VPC that is running Amazon SageMaker Studio Classic and choose a private subnet.

8. Under **Security and access**, specify the security settings.
9. Choose **Create**.

Hive

> **Important**
>
> To use AWS Glue as a metastore for Hive tables, select **Use** for **Hive table metadata** to store the results of your Amazon EMR queries in a AWS Glue data catalog when you're launching an EMR cluster. Storing the query results in a AWS Glue data catalog can save you from incurring charges.
> To be able to query large datasets on Amazon EMR clusters, add the following properties to Hive configuration file on your Amazon EMR clusters:

```
[{"classification":"hive-site", "properties"
:{"hive.resultset.use.unique.column.names":"false"}}]
```

You can also modify the configuration settings when you launch the Amazon EMR cluster.
The configuration file for your Amazon EMR cluster is located under the following path: `/etc/hive/conf/hive-site.xml`. You can specify the following property and restart the cluster:

```
<property>
    <name>hive.resultset.use.unique.column.names</name>
    <value>false</value>
</property>
```

Use the following procedure to create a Hive cluster with LDAP activated.

To create a Hive cluster with LDAP activated, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify **`Amazon EMR`**.
3. Choose **Create cluster**.
4. Choose **Go to advanced options**.
5. For **Release**, select an Amazon EMR release version.
6. The **Hive** configuration option is selected by default. Make sure the **Hive** option has a checkbox next to it.
7. (Optional) You can also select **Presto** as a configuration option to activate both Hive and Presto on your cluster.
8. (Optional) Select **Use for Hive table metadata** to store the results of your Amazon EMR queries in a AWS Glue data catalog. Storing the query results in a AWS Glue catalog can save you from incurring charges. For more information, see Using the AWS Glue Data Catalog as the metastore for Hive.

> **Note**
>
> Storing the query results in a data catalog requires Amazon EMR version 5.8.0 or later.

9. Under **Enter configuration**, specify the following JSON:

```
[
  {
    "classification": "hive-site",
    "properties": {
      "hive.server2.authentication.ldap.baseDN": "dc=example,dc=org",
      "hive.server2.authentication": "LDAP",
      "hive.server2.authentication.ldap.url": "ldap://ldap-server-dns-name:389"
    }
  }
]
```

> **Note**
>
> As a security best practice, we recommend enabling SSL for HiveServer by adding a few properties in the preceding hive-site JSON. For more information, see [Enable SSL on HiveServer2](#).

10. Specify the remaining cluster settings and create a cluster.

Use the following sections to use LDAP authentication for Amazon EMR clusters that you've already created.

LDAP for Presto

Using LDAP on a cluster running Presto requires access to the Presto coordinator through HTTPS. Do the following to provide access:

- Activate access on port 636
- Enable SSL for the Presto coordinator

Use the following template to configure Presto:

```
- Classification: presto-config
    ConfigurationProperties:
      http-server.authentication.type: 'PASSWORD'
      http-server.https.enabled: 'true'
      http-server.https.port: '8889'
      http-server.http.port: '8899'
      node-scheduler.include-coordinator: 'true'
      http-server.https.keystore.path: '/path/to/keystore/path/for/presto'
      http-server.https.keystore.key: 'keystore-key-password'
      discovery.uri: 'http://master-node-dns-name:8899'
- Classification: presto-password-authenticator
    ConfigurationProperties:
      password-authenticator.name: 'ldap'
      ldap.url: !Sub 'ldaps://ldap-server-dns-name:636'
      ldap.user-bind-pattern: "uid=${USER},dc=example,dc=org"
      internal-communication.authentication.ldap.user: "ldap-user-name"
      internal-communication.authentication.ldap.password: "ldap-password"
```

For information about setting up LDAP in Presto, see the following resources:

- LDAP Authentication
- Using LDAP Authentication for Presto on Amazon EMR

Note

As a security best practice, we recommend enabling SSL for Presto. For more information, see Secure Internal Communication.

LDAP for Hive

To use LDAP for Hive for a cluster that you've created, use the following procedure Reconfigure an instance group in the console.

You're specifying the name of the cluster to which you're connecting.

```
[
  {
    "classification": "hive-site",
    "properties": {
      "hive.server2.authentication.ldap.baseDN": "dc=example,dc=org",
      "hive.server2.authentication": "LDAP",
      "hive.server2.authentication.ldap.url": "ldap://ldap-server-dns-name:389"
    }
  }
]
```

Use the following procedure to import data from a cluster.

To import data from a cluster, do the following.

1. Open a Data Wrangler flow.
2. Choose **Create Connection**.
3. Choose **Amazon EMR**.
4. Do one of the following.
   - (Optional) For **Secrets ARN**, specify the Amazon Resource Number (ARN) of the database within the cluster. Secrets provide additional security. For more information about secrets, see What is AWS Secrets Manager? For information about creating a secret for your cluster, see Creating a AWS Secrets Manager secret for your cluster.

     Important

     You must specify a secret if you're using an IAM runtime role for authentication.
   - From the dropdown table, choose a cluster.
5. Choose **Next**.
6. For **Select an endpoint for *example-cluster-name* cluster**, choose a query engine.
7. (Optional) Select **Save connection**.
8. Choose **Next, select login** and choose one of the following:
   - No authentication

    - LDAP
    - IAM

9. For **Login into *example-cluster-name* cluster**, specify the **Username** and **Password** for the cluster.
10. Choose **Connect**.
11. In the query editor specify a SQL query.
12. Choose **Run**.
13. Choose **Import**.

Creating a AWS Secrets Manager secret for your cluster

If you're using an IAM runtime role to access your Amazon EMR cluster, you must store the credentials that you're using to access the Amazon EMR as a Secrets Manager secret. You store all the credentials that you use to access the cluster within the secret.

You must store the following information in the secret:

- JDBC endpoint – `jdbc:hive2://`
- DNS name – The DNS name of your Amazon EMR cluster. It's either the endpoint for the primary node or the hostname.
- Port – `8446`

You can also store the following additional information within the secret:

- IAM role – The IAM role that you're using to access the cluster. Data Wrangler uses your SageMaker AI execution role by default.
- Truststore path – By default, Data Wrangler creates a truststore path for you. You can also use your own truststore path. For more information about truststore paths, see In-transit encryption in HiveServer2.
- Truststore password – By default, Data Wrangler creates a truststore password for you. You can also use your own truststore path. For more information about truststore paths, see In-transit encryption in HiveServer2.

Use the following procedure to store the credentials within a Secrets Manager secret.

To store your credentials as a secret, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify Secrets Manager.
3. Choose **AWS Secrets Manager**.
4. Choose **Store a new secret**.
5. For **Secret type**, choose **Other type of secret**.
6. Under **Key/value** pairs, select **Plaintext**.
7. For clusters running Hive, you can use the following template for IAM authentication.

```
{"jdbcURL": ""
 "iam_auth": {"endpoint": "jdbc:hive2://", #required
               "dns": "ip-xx-x-xxx-xxx.ec2.internal", #required
               "port": "10000", #required
             "cluster_id": "j-xxxxxxxxx", #required
             "iam_role": "arn:aws:iam::xxxxxxxx:role/xxxxxxxxxxxx", #optional
             "truststore_path": "/etc/alternatives/jre/lib/security/cacerts",
 #optional
             "truststore_password": "changeit" #optional

             }}
```

> **Note**
>
> After you import your data, you apply transformations to them. You then export the data that you've transformed to a specific location. If you're using a Jupyter notebook to export your transformed data to Amazon S3, you must use the truststore path specified in the preceding example.

A Secrets Manager secret stores the JDBC URL of the Amazon EMR cluster as a secret. Using a secret is more secure than directly entering in your credentials.

Use the following procedure to store the JDBC URL as a secret.

To store the JDBC URL as a secret, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify Secrets Manager.
3. Choose **AWS Secrets Manager**.
4. Choose **Store a new secret**.
5. For **Secret type**, choose **Other type of secret**.
6. For **Key/value pairs**, specify `jdbcURL` as the key and a valid JDBC URL as the value.

   The format of a valid JDBC URL depends on whether you use authentication and whether you use Hive or Presto as the query engine. The following list shows the valid JBDC URL formats for the different possible configurations.

   - Hive, no authentication – `jdbc:hive2://`*`emr-cluster-master-public`*`-dns:10000/;`
   - Hive, LDAP authentication – `jdbc:hive2://`*`emr-cluster-master-public-dns-name`*`:10000/;AuthMech=3;UID=david;PWD=welcome123;`
   - For Hive with SSL enabled, the JDBC URL format depends on whether you use a Java Keystore File for the TLS configuration. The Java Keystore File helps verify the identity of the master node of the Amazon EMR cluster. To use a Java Keystore File, generate it on an EMR cluster and upload it to Data Wrangler. To generate a file, use the following command on the Amazon EMR cluster, `keytool -genkey -alias hive -keyalg RSA -keysize 1024 -keystore hive.jks`. For information about running commands on an Amazon EMR cluster, see [Securing access to EMR clusters using AWS Systems Manager](). To upload a file, choose the upward arrow on the left-hand navigation of the Data Wrangler UI.

     The following are the valid JDBC URL formats for Hive with SSL enabled:

     - Without a Java Keystore File – `jdbc:hive2://`*`emr-cluster-master-public-dns`*`:10000/;AuthMech=3;UID=`*`user-name`*`;PWD=`*`password`*`;SSL=1;AllowSelfSignedCerts=1;`
     - With a Java Keystore File – `jdbc:hive2://`*`emr-cluster-master-public-dns`*`:10000/;AuthMech=3;UID=`*`user-name`*`;PWD=`*`password`*`;SSL=1;SSLKeyStore=/home/sagemaker-user/data/`*`Java-keystore-file-name`*`;SSLKeyStorePwd=`*`Java-keystore-file-passsword`*`;`
   - Presto, no authentication – jdbc:presto://*`emr-cluster-master-public-dns`*:8889/;
   - For Presto with LDAP authentication and SSL enabled, the JDBC URL format depends on whether you use a Java Keystore File for the TLS configuration. The Java Keystore File helps verify the identity of the master node of the Amazon EMR cluster. To use a Java Keystore

File, generate it on an EMR cluster and upload it to Data Wrangler. To upload a file, choose the upward arrow on the left-hand navigation of the Data Wrangler UI. For information about creating a Java Keystore File for Presto, see Java Keystore File for TLS. For information about running commands on an Amazon EMR cluster, see Securing access to EMR clusters using AWS Systems Manager.

- Without a Java Keystore File – `jdbc:presto://emr-cluster-master-public-dns:8889/;SSL=1;AuthenticationType=LDAP Authentication;UID=user-name;PWD=password;AllowSelfSignedServerCert=1;AllowHostNameCNMismatch=1;`
- With a Java Keystore File – `jdbc:presto://emr-cluster-master-public-dns:8889/;SSL=1;AuthenticationType=LDAP Authentication;SSLTrustStorePath=/home/sagemaker-user/data/Java-keystore-file-name;SSLTrustStorePwd=Java-keystore-file-passsword;UID=user-name;PWD=password;`

Throughout the process of importing data from an Amazon EMR cluster, you might run into issues. For information about troubleshooting them, see Troubleshooting issues with Amazon EMR.

Import data from Databricks (JDBC)

You can use Databricks as a data source for your Amazon SageMaker Data Wrangler flow. To import a dataset from Databricks, use the JDBC (Java Database Connectivity) import functionality to access to your Databricks database. After you access the database, specify a SQL query to get the data and import it.

We assume that you have a running Databricks cluster and that you've configured your JDBC driver to it. For more information, see the following Databricks documentation pages:

- JDBC driver
- JDBC configuration and connection parameters
- Authentication parameters

Data Wrangler stores your JDBC URL in AWS Secrets Manager. You must give your Amazon SageMaker Studio Classic IAM execution role permissions to use Secrets Manager. Use the following procedure to give permissions.

To give permissions to Secrets Manager, do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles**.
3. In the search bar, specify the Amazon SageMaker AI execution role that Amazon SageMaker Studio Classic is using.
4. Choose the role.
5. Choose **Add permissions**.
6. Choose **Create inline policy**.
7. For **Service**, specify **Secrets Manager** and choose it.
8. For **Actions**, select the arrow icon next to **Permissions management**.
9. Choose **PutResourcePolicy**.
10. For **Resources**, choose **Specific**.
11. Choose the checkbox next to **Any in this account**.
12. Choose **Review policy**.
13. For **Name**, specify a name.
14. Choose **Create policy**.

You can use partitions to import your data more quickly. Partitions give Data Wrangler the ability to process the data in parallel. By default, Data Wrangler uses 2 partitions. For most use cases, 2 partitions give you near-optimal data processing speeds.

If you choose to specify more than 2 partitions, you can also specify a column to partition the data. The type of the values in the column must be numeric or date.

We recommend using partitions only if you understand the structure of the data and how it's processed.

You can either import the entire dataset or sample a portion of it. For a Databricks database, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

Use the following procedure to import your data from a Databricks database.

To import data from Databricks, do the following.

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. From the **Import data** tab of your Data Wrangler flow, choose **Databricks**.
6. Specify the following fields:

   - **Dataset name** – A name that you want to use for the dataset in your Data Wrangler flow.
   - **Driver** – **com.simba.spark.jdbc.Driver**.
   - **JDBC URL** – The URL of the Databricks database. The URL formatting can vary between Databricks instances. For information about finding the URL and the specifying the parameters within it, see JDBC configuration and connection parameters. The following is an example of how a URL can be formatted: jdbc:spark://aws-sagemaker-datawrangler.cloud.databricks.com:443/default;transportMode=http;ssl=1;httpPath=sql/protocolv1/o/3122619508517275/0909-200301-cut318;AuthMech=3;UID=*token*;PWD=*personal-access-token*.

   > **Note**
   >
   > You can specify a secret ARN that contains the JDBC URL instead of specifying the JDBC URL itself. The secret must contain a key-value pair with the following format: `jdbcURL:JDBC-URL`. For more information, see What is Secrets Manager?.

7. Specify a SQL SELECT statement.

   > **Note**
   >
   > Data Wrangler doesn't support Common Table Expressions (CTE) or temporary tables within a query.

8. For **Sampling**, choose a sampling method.
9. Choose **Run**.

10. (Optional) For the **PREVIEW**, choose the gear to open the **Partition settings**.

    - Specify the number of partitions. You can partition by column if you specify the number of partitions:

        - **Enter number of partitions –** Specify a value greater than 2.
        - (Optional) **Partition by column –** Specify the following fields. You can only partition by a column if you've specified a value for **Enter number of partitions**.
            - **Select column –** Select the column that you're using for the data partition. The data type of the column must be numeric or date.
            - **Upper bound –** From the values in the column that you've specified, the upper bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify an upper bound that's close to the column's maximum.
            - **Lower bound –** From the values in the column that you've specified, the lower bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify a lower bound that's close to the column's minimum.

11. Choose **Import**.

Import data from Salesforce Data Cloud

You can use Salesforce Data Cloud as a data source in Amazon SageMaker Data Wrangler to prepare the data in your Salesforce Data Cloud for machine learning.

With Salesforce Data Cloud as a data source in Data Wrangler, you can quickly connect to your Salesforce data without writing a single line of code. You can join your Salesforce data with data from any other data source in Data Wrangler.

After you connect to the data cloud, you can do the following:

- Visualize your data with built-in visualizations
- Understand data and identify potential errors and extreme values
- Transform data with more than 300 built-in transformations
- Export the data that you've transformed

Topics

- Administrator setup
- Data Scientist Guide

Administrator setup

> **Important**
>
> Before you get started, make sure that your users are running Amazon SageMaker Studio Classic version 1.3.0 or later. For information about checking the version of Studio Classic and updating it, see Prepare ML Data with Amazon SageMaker Data Wrangler.

When you're setting up access to Salesforce Data Cloud, you must complete the following tasks:

- Getting your Salesforce Domain URL. Salesforce also refers to the Domain URL as your org's URL.
- Getting OAuth credentials from Salesforce.
- Getting the authorization URL and token URL for your Salesforce Domain.
- Creating a AWS Secrets Manager secret with the OAuth configuration.
- Creating a lifecycle configuration that Data Wrangler uses to read the credentials from the secret.
- Giving Data Wrangler permissions to read the secret.

After you perform the preceding tasks, your users can log into the Salesforce Data Cloud using OAuth.

> **Note**
>
> Your users might run into issues after you've set everything up. For information about troubleshooting, see Troubleshooting with Salesforce.

Use the following procedure to get the Domain URL.

1. Navigate to the Salesforce login page.

2. For **Quick find**, specify **My Domain**.
3. Copy the value of **Current My Domain URL** to a text file.
4. Add `https://` to the beginning of the URL.

After you get the Salesforce Domain URL, you can use the following procedure to get the login credentials from Salesforce and allow Data Wrangler to access your Salesforce data.

To get the log in credentials from Salesforce and provide access to Data Wrangler, do the following.

1. Navigate to your Salesforce Domain URL and log into your account.
2. Choose the gear icon.
3. In the search bar that appears, specify **App Manager**.
4. Select **New Connected App**.
5. Specify the following fields:
   - Connected App Name – You can specify any name, but we recommend choosing a name that includes Data Wrangler. For example, you can specify **Salesforce Data Cloud Data Wrangler Integration**.
   - API name – Use the default value.
   - Contact Email – Specify your email address.
   - Under **API heading (Enable OAuth Settings)**, select the checkbox to activate OAuth settings.
   - For **Callback URL** specify the Amazon SageMaker Studio Classic URL. To get the URL for Studio Classic, access it from the AWS Management Console and copy the URL.
6. Under **Selected OAuth Scopes**, move the following from the **Available OAuth Scopes** to **Selected OAuth Scopes**:
   - Manage user data via APIs (`api`)
   - Perform requests at any time (`refresh_token`, `offline_access`)
   - Perform ANSI SQL queries on Salesforce Data Cloud data (`cdp_query_api`)
   - Manage Salesforce Customer Data Platform profile data (`cdp_profile_api`)
7. Choose **Save**. After you save your changes, Salesforce opens a new page.
8. Choose **Continue**
9. Navigate to **Consumer Key and Secret**.

10. Choose **Manage Consumer Details**. Salesforce redirects you to a new page where you might have to pass two-factor authentication.
11. **Important**

    Copy the Consumer Key and Consumer Secret to a text editor. You need this information to connect the data cloud to Data Wrangler.
12. Navigate back to **Manage Connected Apps**.
13. Navigate to **Connected App Name** and the name of your application.
14. Choose **Manage**.

    a. Select **Edit Policies**.

    b. Change **IP Relaxation** to **Relax IP restrictions**.

    c. Choose **Save**.

After you provide access to your Salesforce Data Cloud, you need to provide permissions for your users. Use the following procedure to provide them with permissions.

To provide your users with permissions, do the following.

1. Navigate to the setup home page.
2. On the left-hand navigation, search for **Users** and choose the **Users** menu item.
3. Choose the hyperlink with your user name.
4. Navigate to **Permission Set Assignments**.
5. Choose **Edit Assignments**.
6. Add the following permissions:
   - **Customer Data Platform Admin**
   - **Customer Data Platform Data Aware Specialist**
7. Choose **Save**.

After you get the information for your Salesforce Domain, you must get the authorization URL and the token URL for the AWS Secrets Manager secret that you're creating.

Use the following procedure to get the authorization URL and the token URL.

To get the authorization URL and token URL

1. Navigate to your Salesforce Domain URL.
2. Use one of the following methods to get the URLs. If you are on a Linux distribution with `curl` and `jq` installed, we recommend using the method that only works on Linux.

   - (Linux only) Specify the following command in your terminal.

     ```
     curl salesforce-domain-URL/.well-known/openid-configuration | \
     jq '. | { authorization_url: .authorization_endpoint,
      token_url: .token_endpoint }' | \
     jq '.  += { identity_provider: "SALESFORCE", client_id: "example-client-id",
      client_secret: "example-client-secret" }'
     ```

   - a. Navigate to *`example-org-URL/.well-known/openid-configuration`* in your browser.

     b. Copy the `authorization_endpoint` and `token_endpoint` to a text editor.

     c. Create the following JSON object:

     ```
     {
       "identity_provider": "SALESFORCE",
       "authorization_url": "example-authorization-endpoint",
       "token_url": "example-token-endpoint",
       "client_id": "example-consumer-key",
       "client_secret": "example-consumer-secret"
     }
     ```

After you create the OAuth configuration object, you can create a AWS Secrets Manager secret that stores it. Use the following procedure to create the secret.

To create a secret, do the following.

1. Navigate to the AWS Secrets Manager console.
2. Choose **Store a secret**.
3. Select **Other type of secret**.
4. Under **Key/value** pairs select **Plaintext**.

5. Replace the empty JSON with the following configuration settings.

```
{
  "identity_provider": "SALESFORCE",
  "authorization_url": "example-authorization-endpoint",
  "token_url": "example-token-endpoint",
  "client_id": "example-consumer-key",
  "client_secret": "example-consumer-secret"
}
```

6. Choose **Next**.
7. For **Secret Name**, specify the name of the secret.
8. Under **Tags**, choose **Add**.
   - For the **Key**, specify **sagemaker:partner**. For **Value**, we recommend specifying a value that might be useful for your use case. However, you can specify anything.

   > **Important**
   >
   > You must create the key. You can't import your data from Salesforce if you don't create it.

9. Choose **Next**.
10. Choose **Store**.
11. Choose the secret you've created.
12. Make a note of the following fields:
    - The Amazon Resource Number (ARN) of the secret
    - The name of the secret

After you've created the secret, you must add permissions for Data Wrangler to read the secret. Use the following procedure to add permissions.

To add read permissions for Data Wrangler, do the following.

1. Navigate to the Amazon SageMaker AI console.
2. Choose **domains**.

3. Choose the domain that you're using to access Data Wrangler.
4. Choose your **User Profile**.
5. Under **Details**, find the **Execution role**. Its ARN is in the following format: `arn:aws:iam::111122223333:role/example-role`. Make a note of the SageMaker AI execution role. Within the ARN, it's everything after `role/`.
6. Navigate to the IAM console.
7. In the **Search IAM** search bar, specify the name of the SageMaker AI execution role.
8. Choose the role.
9. Choose **Add permissions**.
10. Choose **Create inline policy**.
11. Choose the JSON tab.
12. Specify the following policy within the editor.

JSON

```
{
 "Version": "2012-10-17",
 "Statement": [
     {
         "Effect": "Allow",
         "Action": [
             "secretsmanager:GetSecretValue",
             "secretsmanager:PutSecretValue"
         ],
         "Resource": "arn:aws:secretsmanager:*:*:secret:*",
         "Condition": {
             "ForAnyValue:StringLike": {
                 "aws:ResourceTag/sagemaker:partner": "*"
             }
         }
     },
     {
         "Effect": "Allow",
         "Action": [
             "secretsmanager:UpdateSecret"
         ],
         "Resource": "arn:aws:secretsmanager:*:*:secret:AmazonSageMaker-*"
```

```
        }
    ]
}
```

13. Choose **Review Policy**.
14. For **Name**, specify a name.
15. Choose **Create policy**.

After you've given Data Wrangler permissions to read the secret, you must add a Lifecycle Configuration that uses your Secrets Manager secret to your Amazon SageMaker Studio Classic user profile.

Use the following procedure to create a lifecycle configuration and add it to the Studio Classic profile.

To create a lifecycle configuration and add it to the Studio Classic profile, do the following.

1. Navigate to the [Amazon SageMaker AI console](https://console.aws.amazon.com/sagemaker/).
2. Choose **domains**.
3. Choose the domain that you're using to access Data Wrangler.
4. Choose your **User Profile**.
5. If you see the following applications, delete them:
   - KernelGateway
   - JupyterKernel

   > **Note**
   >
   > Deleting the applications updates Studio Classic. It can take a while for the updates to happen.
6. While you're waiting for updates to happen, choose **Lifecycle configurations**.
7. Make sure the page you're on says **Studio Classic Lifecycle configurations**.
8. Choose **Create configuration**.
9. Make sure **Jupyter server app** has been selected.

10. Choose **Next**.
11. For **Name**, specify a name for the configuration.
12. For **Scripts**, specify the following script:

```
#!/bin/bash
set -eux

cat > ~/.sfgenie_identity_provider_oauth_config <<EOL
{
    "secret_arn": "secrets-arn-containing-salesforce-credentials"
}
EOL
```

13. Choose **Submit**.
14. On the left hand navigation, choose **domains**.
15. Choose your domain.
16. Choose **Environment**.
17. Under **Lifecycle configurations for personal Studio Classic apps**, choose **Attach**.
18. Select **Existing configuration**.
19. Under **Studio Classic Lifecycle configurations** select the lifecycle configuration that you've created.
20. Choose **Attach to domain**.
21. Select the checkbox next to the lifecycle configuration that you've attached.
22. Select **Set as default**.

You might run into issues when you set up your lifecycle configuration. For information about debugging them, see [Debug lifecycle configurations](#).

Data Scientist Guide

Use the following to connect Salesforce Data Cloud and access your data in Data Wrangler.

Important

Your administrator needs to use the information in the preceding sections to set up Salesforce Data Cloud. If you're running into issues, contact them for troubleshooting help.

To open Studio Classic and check its version, see the following procedure.

1. Use the steps in Prerequisites to access Data Wrangler through Amazon SageMaker Studio Classic.
2. Next to the user you want to use to launch Studio Classic, select **Launch app**.
3. Choose **Studio**.

To create a dataset in Data Wrangler with data from the Salesforce Data Cloud

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Salesforce Data Cloud**.
10. For **Connection name**, specify a name for your connection to the Salesforce Data Cloud.
11. For **Org URL**, specify the organization URL in your Salesforce account. You can get the URL from your administrator.s
12. Choose **Connect**.
13. Specify your credentials to log into Salesforce.

You can begin creating a dataset using data from Salesforce Data Cloud after you've connected to it.

After you select a table, you can write queries and run them. The output of your query shows under **Query results**.

After you have settled on the output of your query, you can then import the output of your query into a Data Wrangler flow to perform data transformations.

After you've created a dataset, navigate to the **Data flow** screen to start transforming your data.

Import data from Snowflake

You can use Snowflake as a data source in SageMaker Data Wrangler to prepare data in Snowflake for machine learning.

With Snowflake as a data source in Data Wrangler, you can quickly connect to Snowflake without writing a single line of code. You can join your data in Snowflake with data from any other data source in Data Wrangler.

Once connected, you can interactively query data stored in Snowflake, transform data with more than 300 preconfigured data transformations, understand data and identify potential errors and extreme values with a set of robust preconfigured visualization templates, quickly identify inconsistencies in your data preparation workflow, and diagnose issues before models are deployed into production. Finally, you can export your data preparation workflow to Amazon S3 for use with other SageMaker AI features such as Amazon SageMaker Autopilot, Amazon SageMaker Feature Store and Amazon SageMaker Pipelines.

You can encrypt the output of your queries using an AWS Key Management Service key that you've created. For more information about AWS KMS, see [AWS Key Management Service](#).

Topics

- [Administrator Guide](#)
- [Data Scientist Guide](#)

Administrator Guide

> **Important**
>
> To learn more about granular access control and best practices, see [Security Access Control](#).

This section is for Snowflake administrators who are setting up access to Snowflake from within SageMaker Data Wrangler.

> **Important**
>
> You are responsible for managing and monitoring the access control within Snowflake. Data Wrangler does not add a layer of access control with respect to Snowflake. Access control includes the following:
>
> - The data that a user accesses
> - (Optional) The storage integration that provides Snowflake the ability to write query results to an Amazon S3 bucket
> - The queries that a user can run

(Optional) Configure Snowflake Data Import Permissions

By default, Data Wrangler queries the data in Snowflake without creating a copy of it in an Amazon S3 location. Use the following information if you're configuring a storage integration with Snowflake. Your users can use a storage integration to store their query results in an Amazon S3 location.

Your users might have different levels of access of sensitive data. For optimal data security, provide each user with their own storage integration. Each storage integration should have its own data governance policy.

This feature is currently not available in the opt-in Regions.

Snowflake requires the following permissions on an S3 bucket and directory to be able to access files in the directory:

- `s3:GetObject`
- `s3:GetObjectVersion`
- `s3:ListBucket`
- `s3:ListObjects`
- `s3:GetBucketLocation`

Create an IAM policy

You must create an IAM policy to configure access permissions for Snowflake to load and unload data from an Amazon S3 bucket.

The following is the JSON policy document that you use to create the policy:

```
# Example policy for S3 write access
# This needs to be updated
{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:GetObjectVersion",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion"
    ],
    "Resource": "arn:aws:s3:::bucket/prefix/*"
  },
  {
    "Effect": "Allow",
    "Action": [
        "s3:ListBucket"
    ],
    "Resource": "arn:aws:s3:::bucket/",
    "Condition": {
        "StringLike": {
            "s3:prefix": ["prefix/*"]
        }
    }
  }
 ]
}
```

For information and procedures about creating policies with policy documents, see Creating IAM policies.

For documentation that provides an overview of using IAM permissions with Snowflake, see the following resources:

- What is IAM?

- Create the IAM Role in AWS
- Create a Cloud Storage Integration in Snowflake
- Retrieve the AWS IAM User for your Snowflake Account
- Grant the IAM User Permissions to Access Bucket.

To grant the data scientist's Snowflake role usage permission to the storage integration, you must run `GRANT USAGE ON INTEGRATION integration_name TO snowflake_role;`.

- `integration_name` is the name of your storage integration.
- `snowflake_role` is the name of the default Snowflake role given to the data scientist user.

Setting up Snowflake OAuth Access

Instead of having your users directly enter their credentials into Data Wrangler, you can have them use an identity provider to access Snowflake. The following are links to the Snowflake documentation for the identity providers that Data Wrangler supports.

- Azure AD
- Okta
- Ping Federate

Use the documentation from the preceding links to set up access to your identity provider. The information and procedures in this section help you understand how to properly use the documentation to access Snowflake within Data Wrangler.

Your identity provider needs to recognize Data Wrangler as an application. Use the following procedure to register Data Wrangler as an application within the identity provider:

1. Select the configuration that starts the process of registering Data Wrangler as an application.
2. Provide the users within the identity provider access to Data Wrangler.
3. Turn on OAuth client authentication by storing the client credentials as an AWS Secrets Manager secret.
4. Specify a redirect URL using the following format: https://*domain-ID*.studio.*AWS Region*.sagemaker.aws/jupyter/default/lab

> **Important**
>
> You're specifying the Amazon SageMaker AI domain ID and AWS Region that you're using to run Data Wrangler.

> **Important**
>
> You must register a URL for each Amazon SageMaker AI domain and AWS Region where you're running Data Wrangler. Users from a domain and AWS Region that don't have redirect URLs set up for them won't be able to authenticate with the identity provider to access the Snowflake connection.

5. Make sure that the authorization code and refresh token grant types are allowed for the Data Wrangler application.

Within your identity provider, you must set up a server that sends OAuth tokens to Data Wrangler at the user level. The server sends the tokens with Snowflake as the audience.

Snowflake uses the concept of roles that are distinct role the IAM roles used in AWS. You must configure the identity provider to use any role to use the default role associated with the Snowflake account. For example, if a user has `systems administrator` as the default role in their Snowflake profile, the connection from Data Wrangler to Snowflake uses `systems administrator` as the role.

Use the following procedure to set up the server.

To set up the server, do the following. You're working within Snowflake for all steps except the last one.

1. Start setting up the server or API.
2. Configure the authorization server to use the authorization code and refresh token grant types.
3. Specify the lifetime of the access token.
4. Set the refresh token idle timeout. The idle timeout is the time that the refresh token expires if it's not used.

> **Note**
>
> If you're scheduling jobs in Data Wrangler, we recommend making the idle timeout time greater than the frequency of the processing job. Otherwise, some processing jobs might fail because the refresh token expired before they could run. When the refresh token expires, the user must re-authenticate by accessing the connection that they've made to Snowflake through Data Wrangler.

5. Specify `session:role-any` as the new scope.

   > **Note**
   >
   > For Azure AD, copy the unique identifier for the scope. Data Wrangler requires you to provide it with the identifier.

6. > **Important**
   >
   > Within the External OAuth Security Integration for Snowflake, enable `external_oauth_any_role_mode`.

> **Important**
>
> Data Wrangler doesn't support rotating refresh tokens. Using rotating refresh tokens might result in access failures or users needing to log in frequently.

> **Important**
>
> If the refresh token expires, your users must reauthenticate by accessing the connection that they've made to Snowflake through Data Wrangler.

After you've set up the OAuth provider, you provide Data Wrangler with the information it needs to connect to the provider. You can use the documentation from your identity provider to get values for the following fields:

- Token URL – The URL of the token that the identity provider sends to Data Wrangler.
- Authorization URL – The URL of the authorization server of the identity provider.
- Client ID – The ID of the identity provider.
- Client secret – The secret that only the authorization server or API recognizes.
- (Azure AD only) The OAuth scope credentials that you've copied.

You store the fields and values in a AWS Secrets Manager secret and add it to the Amazon SageMaker Studio Classic lifecycle configuration that you're using for Data Wrangler. A Lifecycle Configuration is a shell script. Use it to make the Amazon Resource Name (ARN) of the secret accessible to Data Wrangler. For information about creating secrets see Move hardcoded secrets to AWS Secrets Manager. For information about using lifecycle configurations in Studio Classic, see Use lifecycle configurations to customize Studio Classic.

Important

Before you create a Secrets Manager secret, make sure that the SageMaker AI execution role that you're using for Amazon SageMaker Studio Classic has permissions to create and update secrets in Secrets Manager. For more information about adding permissions, see Example: Permission to create secrets.

For Okta and Ping Federate, the following is the format of the secret:

```
{
    "token_url":"https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/token",
    "client_id":"example-client-id",
    "client_secret":"example-client-secret",
    "identity_provider":"OKTA"|"PING_FEDERATE",
    "authorization_url":"https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/authorize"
}
```

For Azure AD, the following is the format of the secret:

```
{
    "token_url":"https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/
token",
    "client_id":"example-client-id",
    "client_secret":"example-client-secret",
    "identity_provider":"AZURE_AD",
    "authorization_url":"https://identityprovider.com/oauth2/example-portion-of-URL-
path/v2/authorize",
    "datasource_oauth_scope":"api://appuri/session:role-any)"
}
```

You must have a lifecycle configuration that uses the Secrets Manager secret that you've created. You can either create the lifecycle configuration or modify one that has already been created. The configuration must use the following script.

```
#!/bin/bash

set -eux

## Script Body

cat > ~/.snowflake_identity_provider_oauth_config <<EOL
{
    "secret_arn": "example-secret-arn"
}
EOL
```

For information about setting up lifecycle configurations, see [Create and associate a lifecycle configuration](). When you're going through the process of setting up, do the following:

- Set the application type of the configuration to `Jupyter Server`.
- Attach the configuration to the Amazon SageMaker AI domain that has your users.
- Have the configuration run by default. It must run every time a user logs into Studio Classic. Otherwise, the credentials saved in the configuration won't be available to your users when they're using Data Wrangler.
- The lifecycle configuration creates a file with the name, `snowflake_identity_provider_oauth_config` in the user's home folder. The file contains

the Secrets Manager secret. Make sure that it's in the user's home folder every time the Jupyter Server's instance is initialized.

Private Connectivity between Data Wrangler and Snowflake via AWS PrivateLink

This section explains how to use AWS PrivateLink to establish a private connection between Data Wrangler and Snowflake. The steps are explained in the following sections.

Create a VPC

If you do not have a VPC set up, then follow the Create a new VPC instructions to create one.

Once you have a chosen VPC you would like to use for establishing a private connection, provide the following credentials to your Snowflake Administrator to enable AWS PrivateLink:

- VPC ID
- AWS Account ID
- Your corresponding account URL you use to access Snowflake

> **Important**
>
> As described in Snowflake's documentation, enabling your Snowflake account can take up to two business days.

Set up Snowflake AWS PrivateLink Integration

After AWS PrivateLink is activated, retrieve the AWS PrivateLink configuration for your Region by running the following command in a Snowflake worksheet. Log into your Snowflake console and enter the following under **Worksheets**: `select SYSTEM$GET_PRIVATELINK_CONFIG();`

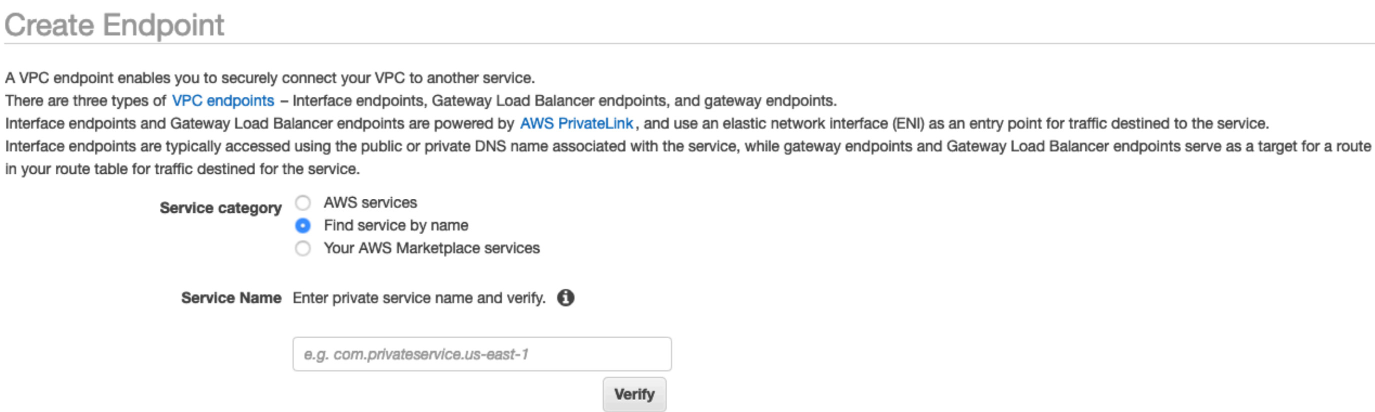
1. Retrieve the values for the following: `privatelink-account-name`, `privatelink_ocsp-url`, `privatelink-account-url`, and `privatelink_ocsp-url` from the resulting JSON object. Examples of each value are shown in the following snippet. Store these values for later use.

```
privatelink-account-name: xxxxxxxx.region.privatelink
privatelink-vpce-id: com.amazonaws.vpce.region.vpce-svc-xxxxxxxxxxxxxxxxx
```

```
privatelink-account-url: xxxxxxxx.region.privatelink.snowflakecomputing.com
privatelink_ocsp-url: ocsp.xxxxxxxx.region.privatelink.snowflakecomputing.com
```

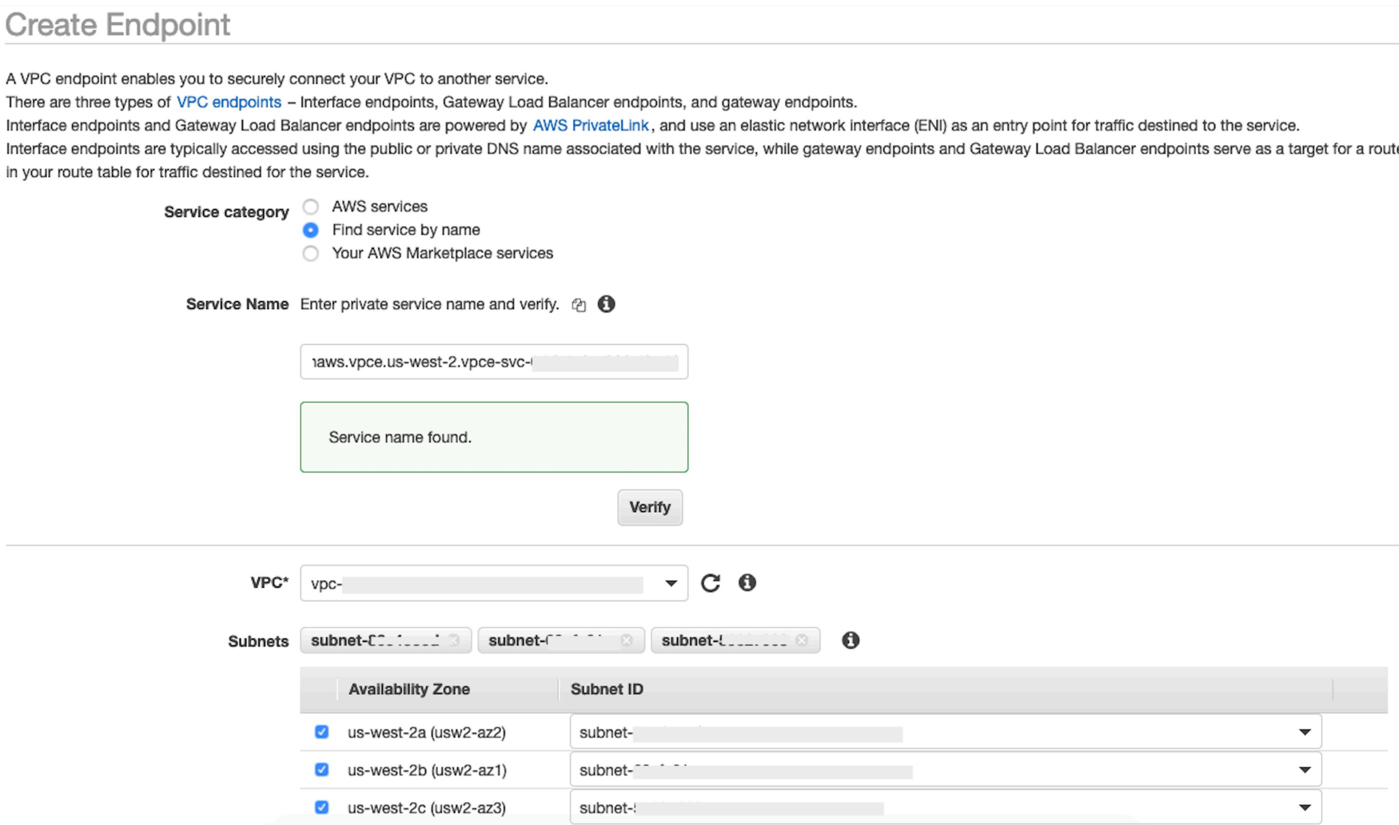
2. Switch to your AWS Console and navigate to the VPC menu.
3. From the left side panel, choose the **Endpoints** link to navigate to the **VPC Endpoints** setup.

   Once there, choose **Create Endpoint**.
4. Select the radio button for **Find service by name**, as shown in the following screenshot.



5. In the **Service Name** field, paste in the value for `privatelink-vpce-id` that you retrieved in the preceding step and choose **Verify**.

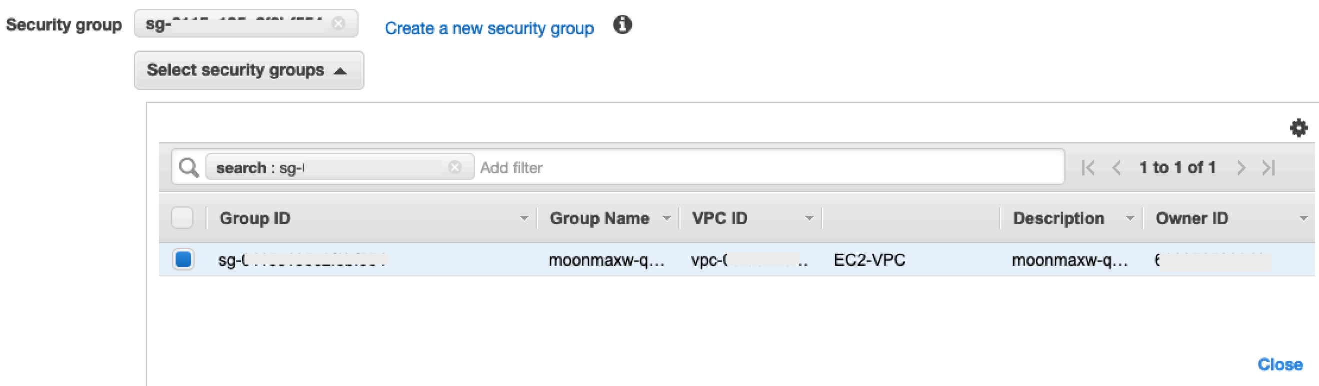
   If the connection is successful, a green alert saying **Service name found** appears on your screen and the **VPC** and **Subnet** options automatically expand, as shown in the following screenshot. Depending on your targeted Region, your resulting screen may show another AWS Region name.



6. Select the same VPC ID that you sent to Snowflake from the **VPC** dropdown list.
7. If you have not yet created a subnet, then perform the following set of instructions on creating a subnet.
8. Select **Subnets** from the **VPC** dropdown list. Then select **Create subnet** and follow the prompts to create a subset in your VPC. Ensure you select the VPC ID you sent Snowflake.
9. Under **Security Group Configuration**, select **Create New Security Group** to open the default **Security Group** screen in a new tab. In this new tab, select t**Create Security Group**.
10. Provide a name for the new security group (such as `datawrangler-doc-snowflake-privatelink-connection`) and a description. Be sure to select the VPC ID you have used in previous steps.
11. Add two rules to allow traffic from within your VPC to this VPC endpoint.

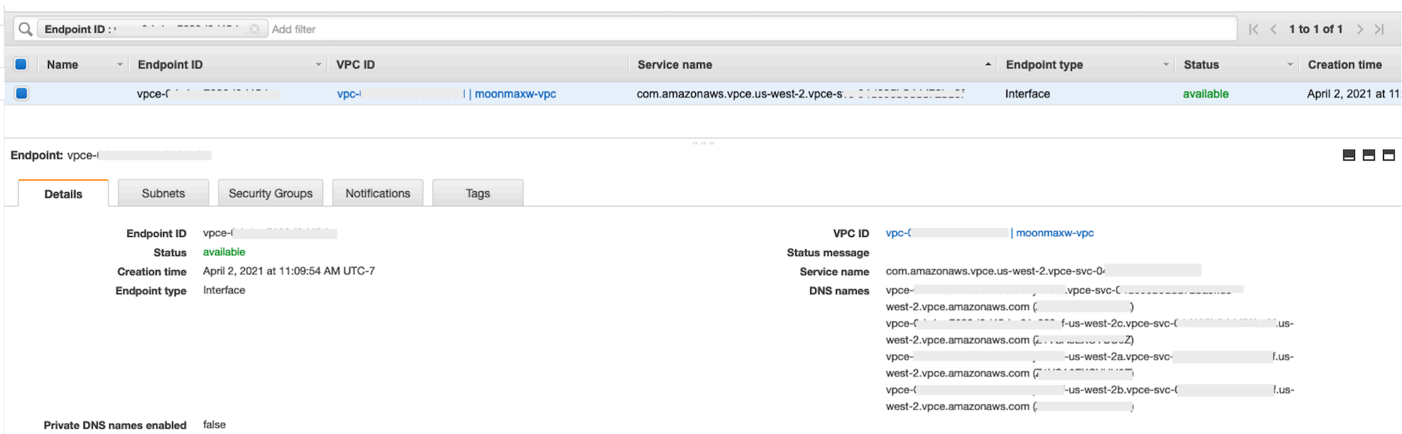
    Navigate to your VPC under **Your VPCs** in a separate tab, and retrieve your CIDR block for your VPC. Then choose **Add Rule** in the **Inbound Rules** section. Select HTTPS for the type, leave the **Source** as **Custom** in the form, and paste in the value retrieved from the preceding `describe-vpcs` call (such as `10.0.0.0/16`).
12. Choose **Create Security Group**. Retrieve the **Security Group ID** from the newly created security group (such as `sg-xxxxxxxxxxxxxxxxx`).

13. In the **VPC Endpoint** configuration screen, remove the default security group. Paste in the security group ID in the search field and select the checkbox.



14. Select **Create Endpoint**.

15. If the endpoint creation is successful, you see a page that has a link to your VPC endpoint configuration, specified by the VPC ID. Select the link to view the configuration in full.



Retrieve the topmost record in the DNS names list. This can be differentiated from other DNS names because it only includes the Region name (such as `us-west-2`), and no Availability Zone letter notation (such as `us-west-2a`). Store this information for later use.

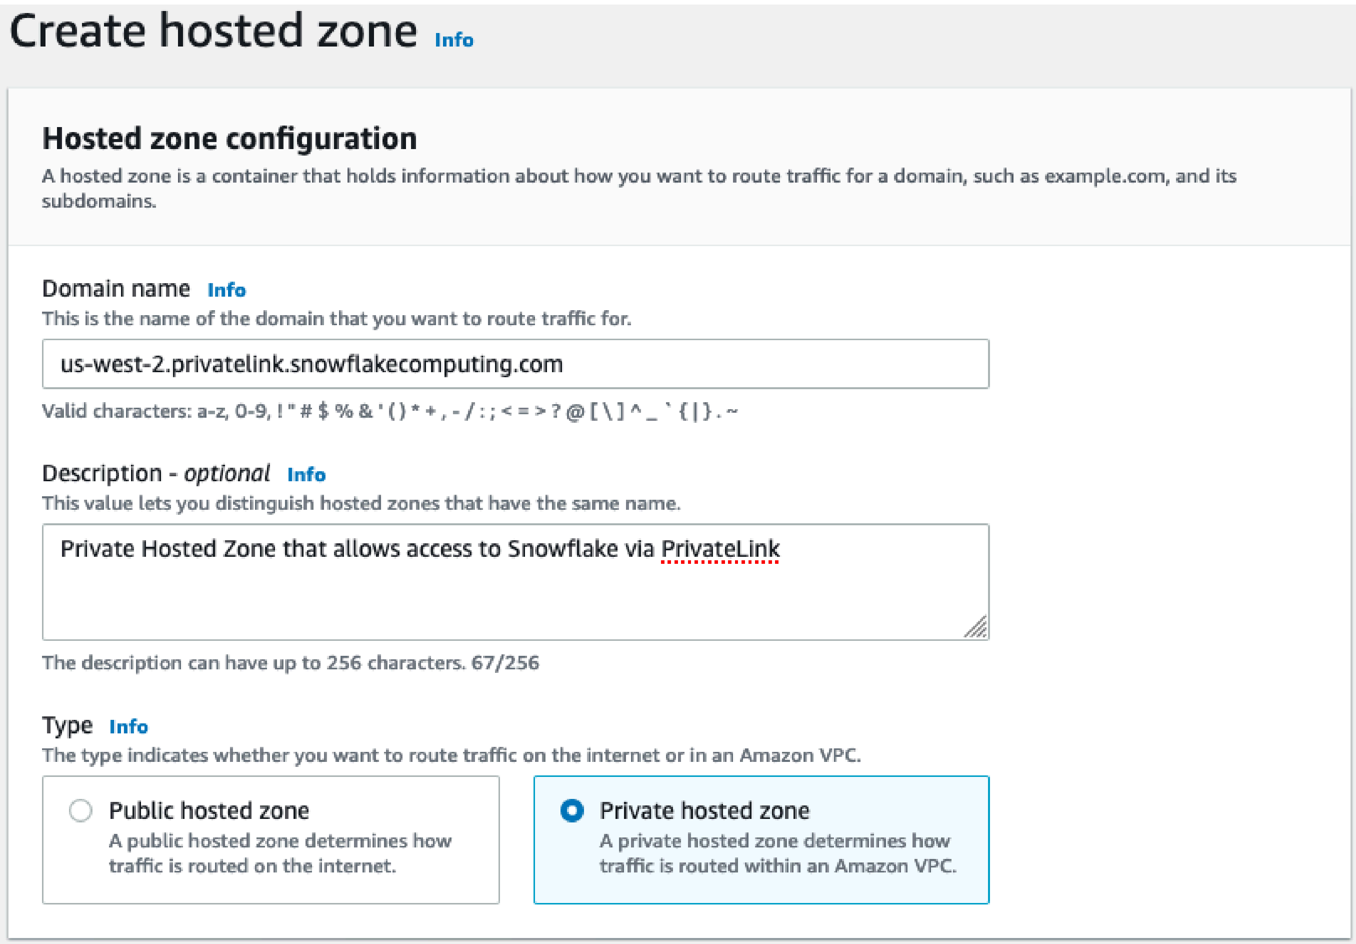
Configure DNS for Snowflake Endpoints in your VPC

This section explains how to configure DNS for Snowflake endpoints in your VPC. This allows your VPC to resolve requests to the Snowflake AWS PrivateLink endpoint.

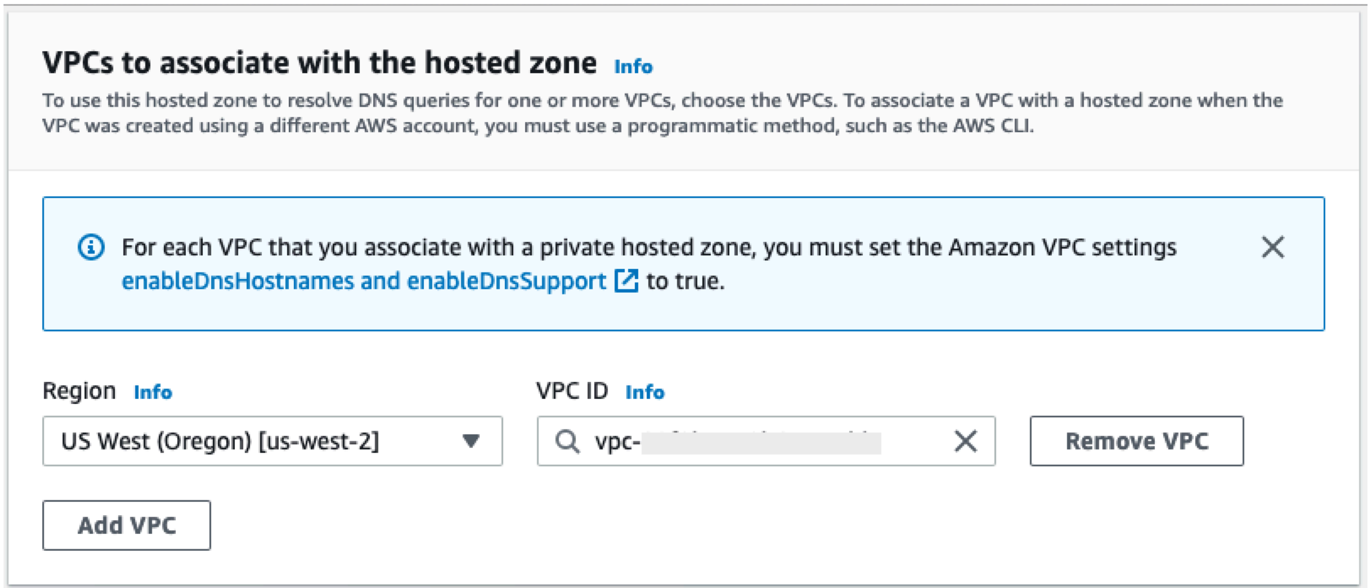
1. Navigate to the Route 53 menu within your AWS console.
2. Select the **Hosted Zones** option (if necessary, expand the left-hand menu to find this option).
3. Choose **Create Hosted Zone**.

a. In the **Domain name** field, reference the value that was stored for `privatelink-account-url` in the preceding steps. In this field, your Snowflake account ID is removed from the DNS name and only uses the value starting with the Region identifier. A **Resource Record Set** is also created later for the subdomain, such as, `region.privatelink.snowflakecomputing.com`.

b. Select the radio button for **Private Hosted Zone** in the **Type** section. Your Region code may not be `us-west-2`. Reference the DNS name returned to you by Snowflake.



c. In the **VPCs to associate with the hosted zone** section, select the Region in which your VPC is located and the VPC ID used in previous steps.



d. Choose **Create hosted zone**.

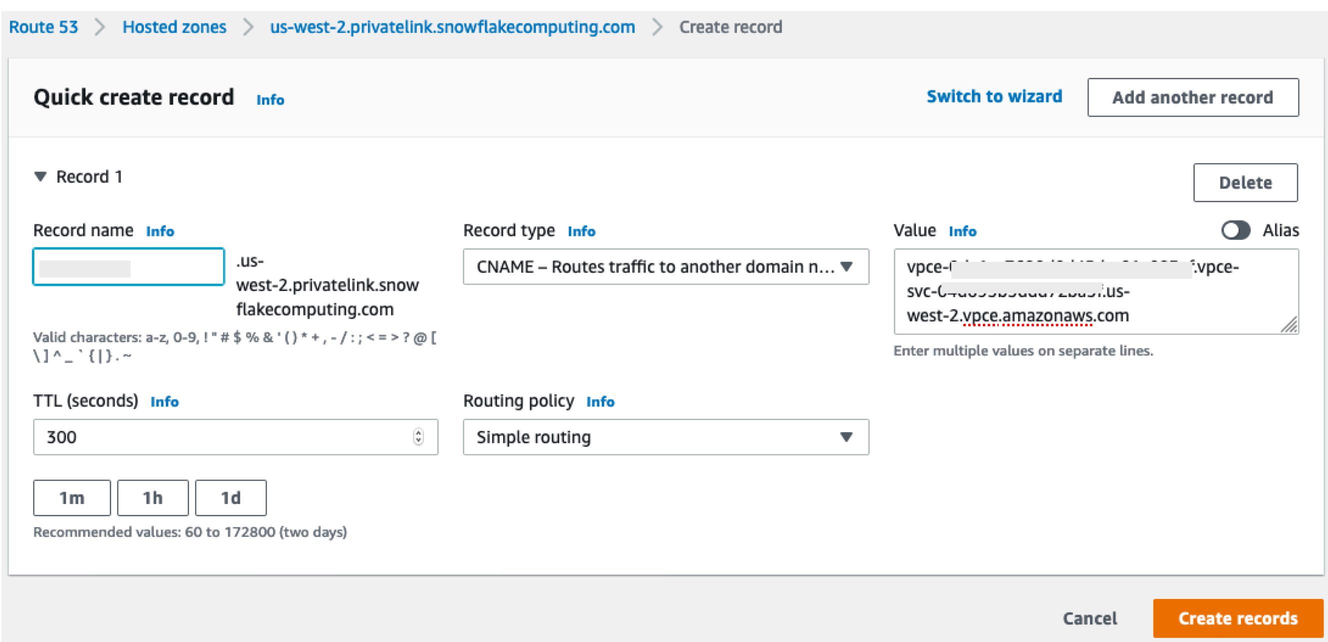
4. Next, create two records, one for `privatelink-account-url` and one for `privatelink_ocsp-url`.

- In the **Hosted Zone** menu, choose **Create Record Set**.

  a. Under **Record name**, enter your Snowflake Account ID only (the first 8 characters in `privatelink-account-url`).

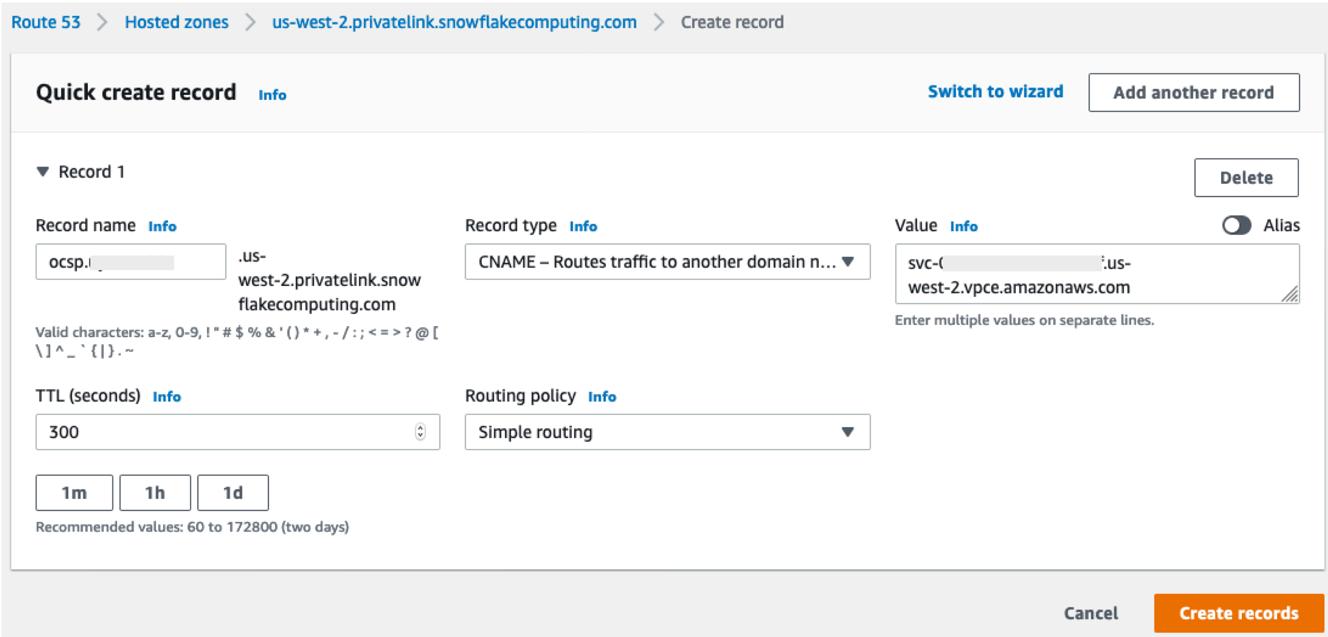
  b. Under **Record type**, select **CNAME**.

  c. Under **Value**, enter the DNS name for the regional VPC endpoint you retrieved in the last step of the *Set up the Snowflake AWS PrivateLink Integration* section.



d. Choose **Create records**.

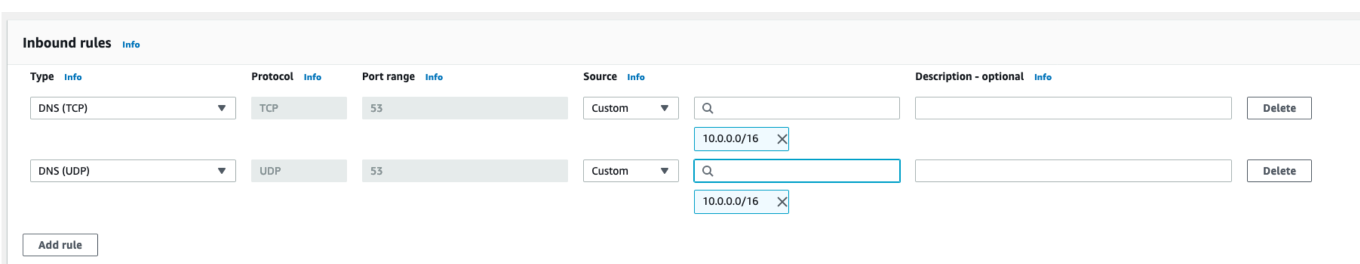
e. Repeat the preceding steps for the OCSP record we notated as `privatelink-ocsp-url`, starting with `ocsp` through the 8-character Snowflake ID for the record name (such as `ocsp.xxxxxxxx`).



Configure Route 53 Resolver Inbound Endpoint for your VPC

This section explains how to configure Route 53 resolvers inbound endpoints for your VPC.

1. Navigate to the Route 53 menu within your AWS console.
   - In the left hand panel in the **Security** section, select the **Security Groups** option.
2. Choose **Create Security Group**.
   - Provide a name for your security group (such as `datawranger-doc-route53-resolver-sg`) and a description.
   - Select the VPC ID used in previous steps.
   - Create rules that allow for DNS over UDP and TCP from within the VPC CIDR block.



- Choose **Create Security Group**. Note the **Security Group ID** because adds a rule to allow traffic to the VPC endpoint security group.

3. Navigate to the [Route 53 menu](#) within your AWS console.

   - In the **Resolver** section, select the **Inbound Endpoint** option.

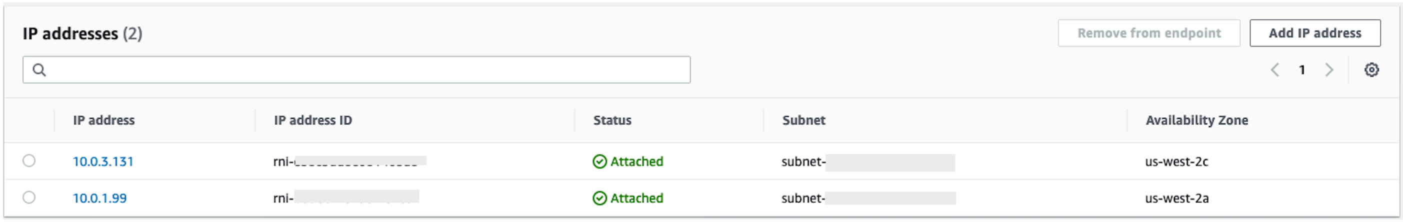
4. Choose **Create Inbound Endpoint**.

   - Provide an endpoint name.
   - From the **VPC in the Region** dropdown list, select the VPC ID you have used in all previous steps.
   - In the **Security group for this endpoint** dropdown list, select the security group ID from Step 2 in this section.

   - In the **IP Address** section, select an Availability Zones, select a subnet, and leave the radio selector for **Use an IP address that is selected automatically** selected for each IP address.

- Choose **Submit**.

5. Select the **Inbound endpoint** after it has been created.
6. Once the inbound endpoint is created, note the two IP addresses for the resolvers.



SageMaker AI VPC Endpoints

This section explains how to create VPC endpoints for the following: Amazon SageMaker Studio Classic, SageMaker Notebooks, the SageMaker API, SageMaker Runtime Runtime, and Amazon SageMaker Feature Store Runtime.

Create a security group that is applied to all endpoints.

1. Navigate to the EC2 menu in the AWS Console.
2. In the **Network & Security** section, select the **Security groups** option.
3. Choose **Create security group**.
4. Provide a security group name and description (such as `datawrangler-doc-sagemaker-vpce-sg`). A rule is added later to allow traffic over HTTPS from SageMaker AI to this group.

Creating the endpoints

1. Navigate to the VPC menu in the AWS console.
2. Select the **Endpoints** option.
3. Choose **Create Endpoint**.
4. Search for the service by entering its name in the **Search** field.
5. From the **VPC** dropdown list, select the VPC in which your Snowflake AWS PrivateLink connection exists.
6. In the **Subnets** section, select the subnets which have access to the Snowflake PrivateLink connection.
7. Leave the **Enable DNS Name** checkbox selected.
8. In the **Security Groups** section, select the security group you created in the preceding section.
9. Choose **Create Endpoint**.

Configure Studio Classic and Data Wrangler

This section explains how to configure Studio Classic and Data Wrangler.

1. Configure the security group.
   a. Navigate to the Amazon EC2 menu in the AWS Console.
   b. Select the **Security Groups** option in the **Network & Security** section.
   c. Choose **Create Security Group**.
   d. Provide a name and description for your security group (such as `datawrangler-doc-sagemaker-studio`).
   e. Create the following inbound rules.
      - The HTTPS connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the *Set up the Snowflake PrivateLink Integration* step.
      - The HTTP connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the *Set up the Snowflake PrivateLink Integration step*.
      - The UDP and TCP for DNS (port 53) to Route 53 Resolver Inbound Endpoint security group you create in step 2 of *Configure Route 53 Resolver Inbound Endpoint for your VPC*.
   f. Choose **Create Security Group** button in the lower right hand corner.
2. Configure Studio Classic.
   - Navigate to the SageMaker AI menu in the AWS console.
   - From the left hand console, Select the **SageMaker AI Studio Classic** option.
   - If you do not have any domains configured, the **Get Started** menu is present.
   - Select the **Standard Setup** option from the **Get Started** menu.
   - Under **Authentication method**, select **AWS Identity and Access Management (IAM)**.
   - From the **Permissions** menu, you can create a new role or use a pre-existing role, depending on your use case.
     - If you choose **Create a new role**, you are presented the option to provide an S3 bucket name, and a policy is generated for you.
     - If you already have a role created with permissions for the S3 buckets to which you require access, select the role from the dropdown list. This role should have the `AmazonSageMakerFullAccess` policy attached to it.
   - Select the **Network and Storage** dropdown list to configure the VPC, security, and subnets SageMaker AI uses.

    - Under **VPC**, select the VPC in which your Snowflake PrivateLink connection exists.
    - Under **Subnet(s)**, select the subnets which have access to the Snowflake PrivateLink connection.
    - Under **Network Access for Studio Classic**, select **VPC Only**.
    - Under **Security Group(s)**, select the security group you created in step 1.
  - Choose **Submit**.

3. Edit the SageMaker AI security group.
  - Create the following inbound rules:
    - Port 2049 to the inbound and outbound NFS Security Groups created automatically by SageMaker AI in step 2 (the security group names contain the Studio Classic domain ID).
    - Access to all TCP ports to itself (required for SageMaker AI for VPC Only).
4. Edit the VPC Endpoint Security Groups:
  - Navigate to the Amazon EC2 menu in the AWS console.
  - Locate the security group you created in a preceding step.
  - Add an inbound rule allowing for HTTPS traffic from the security group created in step 1.
5. Create a user profile.
  - From the **SageMaker Studio Classic Control Panel** , choose **Add User**.
  - Provide a user name.
  - For the **Execution Role**, choose to create a new role or to use a pre-existing role.
    - If you choose **Create a new role**, you are presented the option to provide an Amazon S3 bucket name, and a policy is generated for you.
    - If you already have a role created with permissions to the Amazon S3 buckets to which you require access, select the role from the dropdown list. This role should have the `AmazonSageMakerFullAccess` policy attached to it.
  - Choose **Submit**.
6. Create a data flow (follow the data scientist guide outlined in a preceding section).
  - When adding a Snowflake connection, enter the value of `privatelink-account-name` (from the *Set up Snowflake PrivateLink Integration* step) into the **Snowflake account name (alphanumeric)** field, instead of the plain Snowflake account name. Everything else is left unchanged.

Provide information to the data scientist

Provide the data scientist with the information that they need to access Snowflake from Amazon SageMaker AI Data Wrangler.

> **Important**
>
> Your users need to run Amazon SageMaker Studio Classic version 1.3.0 or later. For information about checking the version of Studio Classic and updating it, see Prepare ML Data with Amazon SageMaker Data Wrangler.

1. To allow your data scientist to access Snowflake from SageMaker Data Wrangler, provide them with one of the following:

   - For Basic Authentication, a Snowflake account name, user name, and password.
   - For OAuth, a user name and password in the identity provider.
   - For ARN, the Secrets Manager secret Amazon Resource Name (ARN).
   - A secret created with AWS Secrets Manager and the ARN of the secret. Use the following procedure below to create the secret for Snowflake if you choose this option.

   > **Important**
   >
   > If your data scientists use the **Snowflake Credentials (User name and Password)** option to connect to Snowflake, you can use Secrets Manager to store the credentials in a secret. Secrets Manager rotates secrets as part of a best practice security plan. The secret created in Secrets Manager is only accessible with the Studio Classic role configured when you set up a Studio Classic user profile. This requires you to add this permission, `secretsmanager:PutResourcePolicy`, to the policy that is attached to your Studio Classic role.
   > We strongly recommend that you scope the role policy to use different roles for different groups of Studio Classic users. You can add additional resource-based permissions for the Secrets Manager secrets. See Manage Secret Policy for condition keys you can use.
   > For information about creating a secret, see Create a secret. You're charged for the secrets that you create.

2. (Optional) Provide the data scientist with the name of the storage integration that you created using the following procedure [Create a Cloud Storage Integration in Snowflake](). This is the name of the new integration and is called `integration_name` in the `CREATE INTEGRATION` SQL command you ran, which is shown in the following snippet:

```
CREATE STORAGE INTEGRATION integration_name
TYPE = EXTERNAL_STAGE
STORAGE_PROVIDER = S3
ENABLED = TRUE
STORAGE_AWS_ROLE_ARN = 'iam_role'
[ STORAGE_AWS_OBJECT_ACL = 'bucket-owner-full-control' ]
STORAGE_ALLOWED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/')
[ STORAGE_BLOCKED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/') ]
```

Data Scientist Guide

Use the following to connect Snowflake and access your data in Data Wrangler.

> **Important**
>
> Your administrator needs to use the information in the preceding sections to set up Snowflake. If you're running into issues, contact them for troubleshooting help.

You can connect to Snowflake in one of the following ways:

- Specifying your Snowflake credentials (account name, user name, and password) in Data Wrangler.
- Providing an Amazon Resource Name (ARN) of a secret containing the credentials.
- Using an open standard for access delegation (OAuth) provider that connects to Snowflake. Your administrator can give you access to one of the following OAuth providers:
  - Azure AD
  - Okta
  - Ping Federate

Talk to your administrator about the method that you need to use to connect to Snowflake.

The following sections have information about how you can connect to Snowflake using the preceding methods.

Specifying your Snowflake Credentials

To import a dataset into Data Wrangler from Snowflake using your credentials

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Snowflake**.
10. For **Connection name**, specify a name that uniquely identifies the connection.
11. For **Authentication method**, choose **Basic Username-Password**.
12. For **Snowflake account name (alphanumeric)**, specify the full name of the Snowflake account.
13. For **Username**, specify the username that you use to access the Snowflake account.
14. For **Password**, specify the password associated with the username.
15. (Optional) For **Advanced settings**. specify the following:
    - **Role** – A role within Snowflake. Some roles have access to different datasets. If you don't specify a role, Data Wrangler uses the default role in your Snowflake account.
    - **Storage integration** – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.
    - **KMS key ID** – A KMS key that you've created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.
16. Choose **Connect**.

Providing an Amazon Resource Name (ARN)

To import a dataset into Data Wrangler from Snowflake using an ARN

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Snowflake**.
10. For **Connection name**, specify a name that uniquely identifies the connection.
11. For **Authentication method**, choose **ARN**.
12. **Secrets Manager ARN** – The ARN of the AWS Secrets Manager secret used to store the credentials used to connect to Snowflake.
13. (Optional) For **Advanced settings**. specify the following:
    - **Role** – A role within Snowflake. Some roles have access to different datasets. If you don't specify a role, Data Wrangler uses the default role in your Snowflake account.
    - **Storage integration** – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.
    - **KMS key ID** – A KMS key that you've created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.
14. Choose **Connect**.

Using an OAuth Connection

> **Important**
>
> Your administrator customized your Studio Classic environment to provide the functionality you're using to use an OAuth connection. You might need to restart the Jupyter server application to use the functionality.
> Use the following procedure to update the Jupyter server application.
>
> 1. Within Studio Classic, choose **File**
> 2. Choose **Shut down**.
> 3. Choose **Shut down server**.
> 4. Close the tab or window that you're using to access Studio Classic.
> 5. From the Amazon SageMaker AI console, open Studio Classic.

To import a dataset into Data Wrangler from Snowflake using your credentials

1. Sign into [Amazon SageMaker AI Console](https://console.aws.amazon.com/sagemaker/).
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Snowflake**.
10. For **Connection name**, specify a name that uniquely identifies the connection.
11. For **Authentication method**, choose **OAuth**.
12. (Optional) For **Advanced settings**. specify the following:

    - **Role** – A role within Snowflake. Some roles have access to different datasets. If you don't specify a role, Data Wrangler uses the default role in your Snowflake account.
    - **Storage integration** – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query

results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.

- **KMS key ID** – A KMS key that you've created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.

13. Choose **Connect**.

You can begin the process of importing your data from Snowflake after you've connected to it.

Within Data Wrangler, you can view your data warehouses, databases, and schemas, along with the eye icon with which you can preview your table. After you select the **Preview Table** icon, the schema preview of that table is generated. You must select a warehouse before you can preview a table.

> **Important**
>
> If you're importing a dataset with columns of type `TIMESTAMP_TZ` or `TIMESTAMP_LTZ`, add `::string` to the column names of your query. For more information, see How To: Unload TIMESTAMP_TZ and TIMESTAMP_LTZ data to a Parquet file.

After you select a data warehouse, database and schema, you can now write queries and run them. The output of your query shows under **Query results**.

After you have settled on the output of your query, you can then import the output of your query into a Data Wrangler flow to perform data transformations.

After you've imported your data, navigate to your Data Wrangler flow and start adding transformations to it. For a list of available transforms, see Transform Data.

Import Data From Software as a Service (SaaS) Platforms

You can use Data Wrangler to import data from more than forty software as a service (SaaS) platforms. To import your data from your SaaS platform, you or your administrator must use Amazon AppFlow to transfer the data from the platform to Amazon S3 or Amazon Redshift. For more information about Amazon AppFlow, see What is Amazon AppFlow? If you don't need to use Amazon Redshift, we recommend transferring the data to Amazon S3 for a simpler process.

Data Wrangler supports transferring data from the following SaaS platforms:

- Amplitude
- Asana
- Braintree
- CircleCI
- DocuSign Monitor
- Delighted
- Domo
- Datadog
- Dynatrace
- Facebook Ads
- Facebook Page Insights
- Google Ads
- Google Analytics 4
- Google Calendar
- Google Search Console
- GitHub
- GitLab
- Infor Nexus
- Instagram Ads
- Intercom
- JDBC (Sync)
- Jira Cloud
- LinkedIn Ads
- Mailchimp
- Marketo
- Microsoft Dynamics 365
- Microsoft Teams
- Mixpanel
- Okta
- Oracle HCM

- Paypal Checkout
- Pendo
- Salesforce
- Salesforce Marketing Cloud
- Salesforce Pardot
- SAP OData
- SendGrid
- ServiceNow
- Singular
- Slack
- Smartsheet
- Snapchat Ads
- Stripe
- Trend Micro
- Typeform
- Veeva
- WooCommerce
- Zendesk
- Zendesk Chat
- Zendesk Sell
- Zendesk Sunshine
- Zoho CRM
- Zoom Meetings

The preceding list has links to more information about setting up your data source. You or your administrator can refer to the preceding links after you've read the following information.

When you navigate to the **Import** tab of your Data Wrangler flow, you see data sources under the following sections:

- **Available**

- **Set up data sources**

You can connect to data sources under **Available** without needing additional configuration. You can choose the data source and import your data.

Data sources under **Set up data sources**, require you or your administrator to use Amazon AppFlow to transfer the data from the SaaS platform to Amazon S3 or Amazon Redshift. For information about performing a transfer, see Using Amazon AppFlow to transfer your data.

After you perform the data transfer, the SaaS platform appears as a data source under **Available**. You can choose it and import the data that you've transferred into Data Wrangler. The data that you've transferred appears as tables that you can query.

Using Amazon AppFlow to transfer your data

Amazon AppFlow is a platform that you can use to transfer data from your SaaS platform to Amazon S3 or Amazon Redshift without having to write any code. To perform a data transfer, you use the AWS Management Console.

> **Important**
>
> You must make sure you've set up the permissions to perform a data transfer. For more information, see Amazon AppFlow Permissions.

After you've added permissions, you can transfer the data. Within Amazon AppFlow, you create a *flow* to transfer the data. A flow is a series of configurations. You can use it to specify whether you're running the data transfer on a schedule or whether you're partitioning the data into separate files. After you've configured the flow, you run it to transfer the data.

For information about creating a flow, see Creating flows in Amazon AppFlow. For information about running a flow, see Activate an Amazon AppFlow flow.

After the data has been transferred, use the following procedure to access the data in Data Wrangler.

> **Important**
>
> Before you try to access your data, make sure your IAM role has the following policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "glue:SearchTables",
            "Resource": [
                "arn:aws:glue:*:*:table/*/*",
                "arn:aws:glue:*:*:database/*",
                "arn:aws:glue:*:*:catalog"
            ]
        }
    ]
}
```

By default, the IAM role that you use to access Data Wrangler is the `SageMakerExecutionRole`. For more information about adding policies, see Adding IAM identity permissions (console).

To connect to a data source, do the following.

1. Sign into Amazon SageMaker AI Console.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose the data source.

10. For the **Name** field, specify the name of the connection.
11. (Optional) Choose **Advanced configuration**.

    a. Choose a **Workgroup**.

    b. If your workgroup hasn't enforced the Amazon S3 output location or if you don't use a workgroup, specify a value for **Amazon S3 location of query results**.

    c. (Optional) For **Data retention period**, select the checkbox to set a data retention period and specify the number of days to store the data before it's deleted.

    d. (Optional) By default, Data Wrangler saves the connection. You can choose to deselect the checkbox and not save the connection.
12. Choose **Connect**.
13. Specify a query.

    Note

    To help you specify a query, you can choose a table on the left-hand navigation panel. Data Wrangler shows the table name and a preview of the table. Choose the icon next to the table name to copy the name. You can use the table name in the query.
14. Choose **Run**.
15. Choose **Import query**.
16. For **Dataset name**, specify the name of the dataset.
17. Choose **Add**.

When you navigate to the **Import data** screen, you can see the connection that you've created. You can use the connection to import more data.

Imported Data Storage

Important

We strongly recommend that you follow the best practices around protecting your Amazon S3 bucket by following Security best practices.

When you query data from Amazon Athena or Amazon Redshift, the queried dataset is automatically stored in Amazon S3. Data is stored in the default SageMaker AI S3 bucket for the AWS Region in which you are using Studio Classic.

Default S3 buckets have the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio Classic in `us-east-1`, your imported datasets are stored in `sagemaker-us-east-1-111122223333`.

Data Wrangler flows depend on this Amazon S3 dataset location, so you should not modify this dataset in Amazon S3 while you are using a dependent flow. If you do modify this S3 location, and you want to continue using your data flow, you must remove all objects in `trained_parameters` in your .flow file. To do this, download the .flow file from Studio Classic and for each instance of `trained_parameters`, delete all entries. When you are done, `trained_parameters` should be an empty JSON object:

```
"trained_parameters": {}
```

When you export and use your data flow to process your data, the .flow file you export refers to this dataset in Amazon S3. Use the following sections to learn more.

Amazon Redshift Import Storage

Data Wrangler stores the datasets that result from your query in a Parquet file in your default SageMaker AI S3 bucket.

This file is stored under the following prefix (directory): redshift/*uuid*/data/, where *uuid* is a unique identifier that gets created for each query.

For example, if your default bucket is `sagemaker-us-east-1-111122223333`, a single dataset queried from Amazon Redshift is located in s3://sagemaker-us-east-1-111122223333/redshift/*uuid*/data/.

Amazon Athena Import Storage

When you query an Athena database and import a dataset, Data Wrangler stores the dataset, as well as a subset of that dataset, or *preview files*, in Amazon S3.

The dataset you import by selecting **Import dataset** is stored in Parquet format in Amazon S3.

Preview files are written in CSV format when you select **Run** on the Athena import screen, and contain up to 100 rows from your queried dataset.

The dataset you query is located under the prefix (directory): athena/*uuid*/data/, where *uuid* is a unique identifier that gets created for each query.

For example, if your default bucket is `sagemaker-us-east-1-111122223333`, a single dataset queried from Athena is located in `s3://sagemaker-us-east-1-111122223333`/athena/*uuid*/data/*example_dataset.parquet*.

The subset of the dataset that is stored to preview dataframes in Data Wrangler is stored under the prefix: athena/.

Create and Use a Data Wrangler Flow

Use an Amazon SageMaker Data Wrangler flow, or a *data flow*, to create and modify a data preparation pipeline. The data flow connects the datasets, transformations, and analyses, or *steps*, you create and can be used to define your pipeline.

Instances

When you create a Data Wrangler flow in Amazon SageMaker Studio Classic, Data Wrangler uses an Amazon EC2 instance to run the analyses and transformations in your flow. By default, Data Wrangler uses the m5.4xlarge instance. m5 instances are general purpose instances that provide a balance between compute and memory. You can use m5 instances for a variety of compute workloads.

Data Wrangler also gives you the option of using r5 instances. r5 instances are designed to deliver fast performance that processes large datasets in memory.

We recommend that you choose an instance that is best optimized around your workloads. For example, the r5.8xlarge might have a higher price than the m5.4xlarge, but the r5.8xlarge might be better optimized for your workloads. With better optimized instances, you can run your data flows in less time at lower cost.

The following table shows the instances that you can use to run your Data Wrangler flow.

Standard Instances	vCPU	Memory
ml.m5.4xlarge	16	64 GiB
ml.m5.8xlarge	32	128 GiB

Standard Instances	vCPU	Memory
ml.m5.16xlarge	64	256 GiB
ml.m5.24xlarge	96	384 GiB
r5.4xlarge	16	128 GiB
r5.8xlarge	32	256 GiB
r5.24xlarge	96	768 GiB

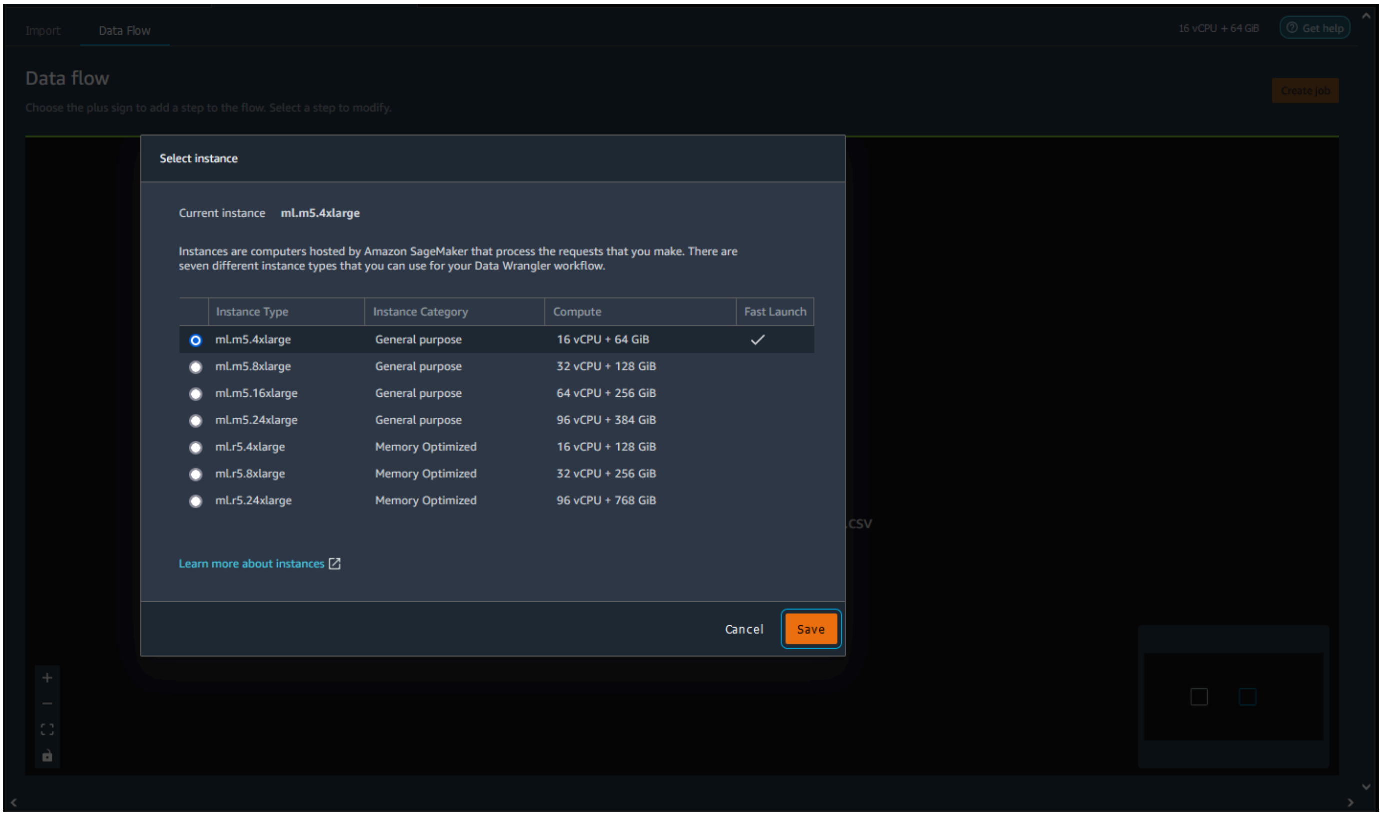
For more information about r5 instances, see Amazon EC2 R5 Instances. For more information about m5 instances, see Amazon EC2 M5 Instances.

Each Data Wrangler flow has an Amazon EC2 instance associated with it. You might have multiple flows that are associated with a single instance.

For each flow file, you can seamlessly switch the instance type. If you switch the instance type, the instance that you used to run the flow continues to run.

To switch the instance type of your flow, do the following.

1. Choose the **Running Terminals and Kernels** icon ().
2. Navigate to the instance that you're using and choose it.
3. Choose the instance type that you want to use.

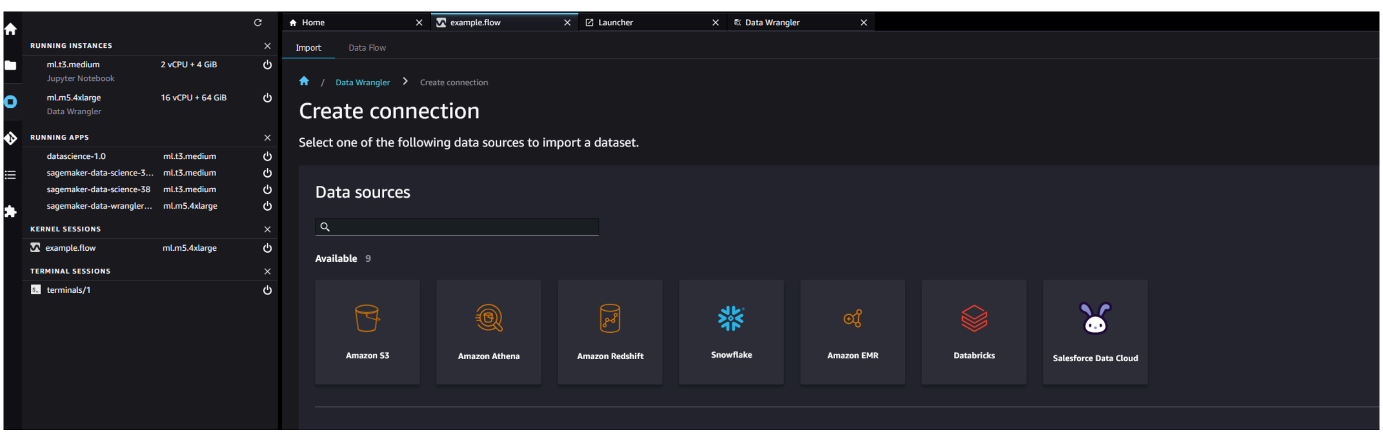


4. Choose **Save**.

You are charged for all running instances. To avoid incurring additional charges, shut down the instances that you aren't using manually. To shut down an instance that is running, use the following procedure.

To shut down a running instance.

1. Choose the instance icon. The following image shows you where to select the **RUNNING INSTANCES** icon.



2. Choose **Shut down** next to the instance that you want to shut down.

If you shut down an instance used to run a flow, you temporarily can't access the flow. If you get an error while attempting to open the flow running an instance you previously shut down, wait for 5 minutes and try opening it again.

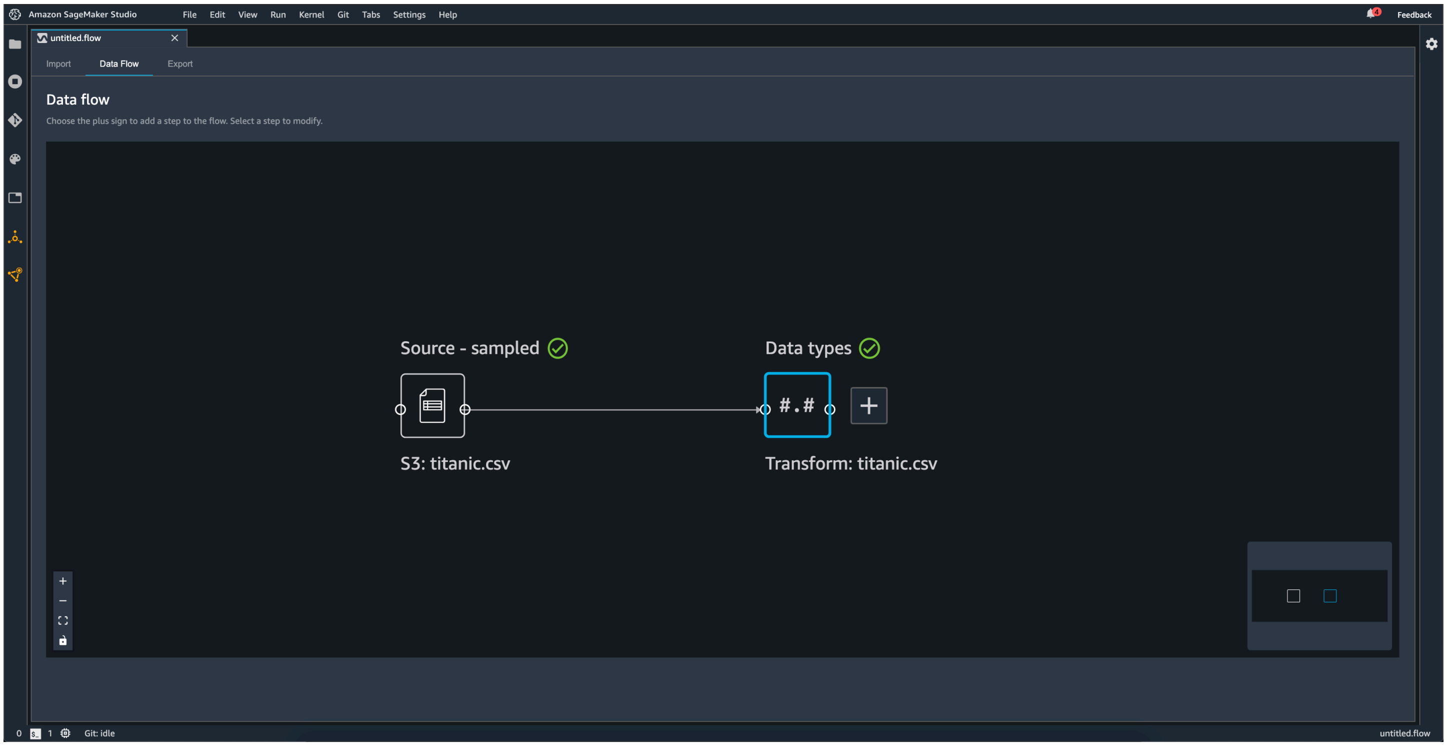
When you export your data flow to a location such as Amazon Simple Storage Service or Amazon SageMaker Feature Store, Data Wrangler runs an Amazon SageMaker processing job. You can use one of the following instances for the processing job. For more information on exporting your data, see Export.

Standard Instances	vCPU	Memory
ml.m5.4xlarge	16	64 GiB
ml.m5.12xlarge	48	192 GiB
ml.m5.24xlarge	96	384 GiB

For more information about the cost per hour for using the available instance types, see SageMaker Pricing.

The Data Flow UI

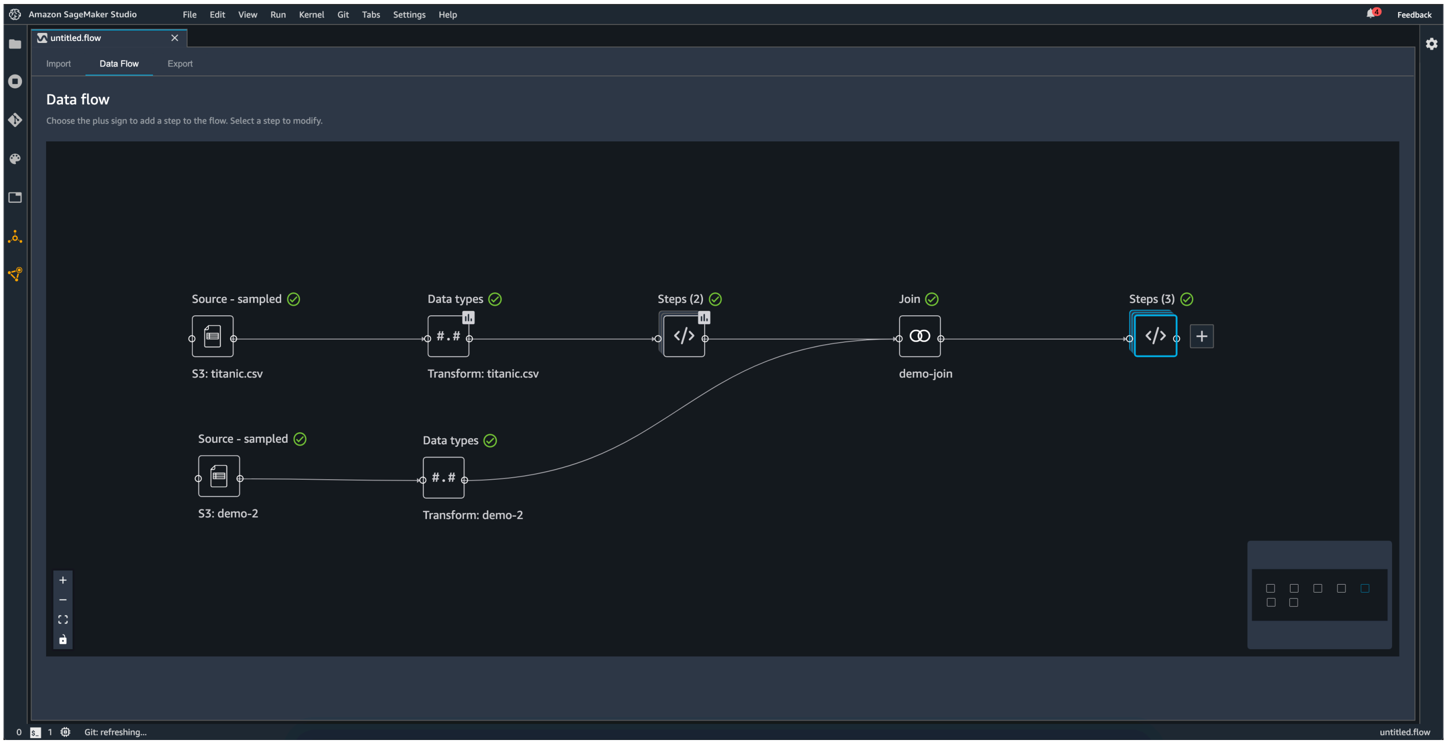
When you import a dataset, the original dataset appears on the data flow and is named **Source**. If you turned on sampling when you imported your data, this dataset is named **Source - sampled**. Data Wrangler automatically infers the types of each column in your dataset and creates a new dataframe named **Data types**. You can select this frame to update the inferred data types. You see results similar to those shown in the following image after you upload a single dataset:



Each time you add a transform step, you create a new dataframe. When multiple transform steps (other than **Join** or **Concatenate**) are added to the same dataset, they are stacked.

Join and **Concatenate** create standalone steps that contain the new joined or concatenated dataset.

The following diagram shows a data flow with a join between two datasets, as well as two stacks of steps. The first stack (**Steps (2)**) adds two transforms to the type inferred in the **Data types** dataset. The *downstream* stack, or the stack to the right, adds transforms to the dataset resulting from a join named **demo-join**.



The small, gray box in the bottom right corner of the data flow provides an overview of number of stacks and steps in the flow and the layout of the flow. The lighter box inside the gray box indicates the steps that are within the UI view. You can use this box to see sections of your data flow that fall outside of the UI view. Use the fit screen icon ( ) to fit all steps and datasets into your UI view.

The bottom left navigation bar includes icons that you can use to zoom in ( ) and zoom out ( ) of your data flow and resize the data flow to fit the screen ( ). Use the lock icon ( ) to lock and unlock the location of each step on the screen.

Add a Step to Your Data Flow

Select **+** next to any dataset or previously added step and then select one of the following options:

- **Edit data types** (For a **Data types** step only): If you have not added any transforms to a **Data types** step, you can select **Edit data types** to update the data types Data Wrangler inferred when importing your dataset.
- **Add transform**: Adds a new transform step. See Transform Data to learn more about the data transformations you can add.
- **Add analysis**: Adds an analysis. You can use this option to analyze your data at any point in the data flow. When you add one or more analyses to a step, an analysis icon () appears on that step. See Analyze and Visualize to learn more about the analyses you can add.
- **Join**: Joins two datasets and adds the resulting dataset to the data flow. To learn more, see Join Datasets.
- **Concatenate**: Concatenates two datasets and adds the resulting dataset to the data flow. To learn more, see Concatenate Datasets.

Delete a Step from Your Data Flow

To delete a step, select the step and select **Delete**. If the node is a node that has a single input, you delete only the step that you select. Deleting a step that has a single input doesn't delete the steps that follow it. If you're deleting a step for a source, join, or concatenate node, all the steps that follow it are also deleted.

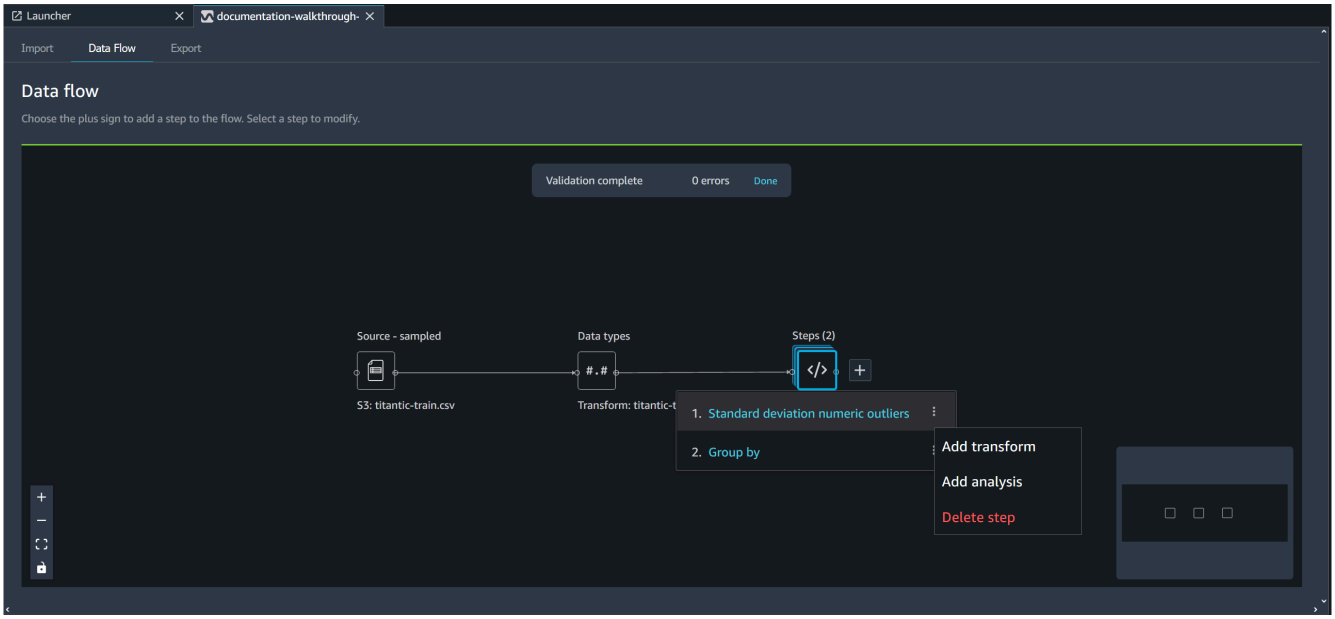
To delete a step from a stack of steps, select the stack and then select the step you want to delete.

You can use one of the following procedures to delete a step without deleting the downstream steps.

Delete a step in the Data Wrangler flow

> You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.
>
> Use the following procedure to delete a step in the Data Wrangler flow.

1. Choose the group of steps that has the step that you're deleting.
2. Choose the icon next to the step.
3. Choose **Delete step**.

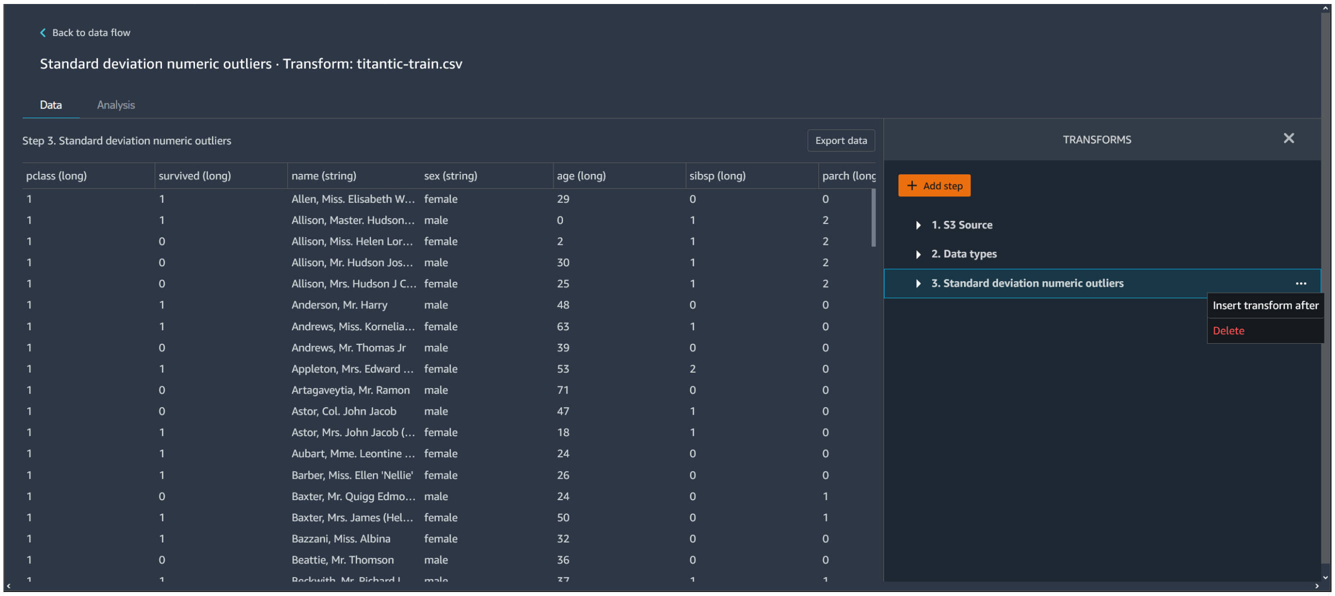


Delete a step in the table view

Use the following procedure to delete a step in the table view.

You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.

1. Choose the step and open the table view for the step.
2. Move your cursor over the step so the ellipsis icon appears.
3. Choose the icon next to the step.
4. Choose **Delete**.



Edit a Step in Your Data Wrangler Flow

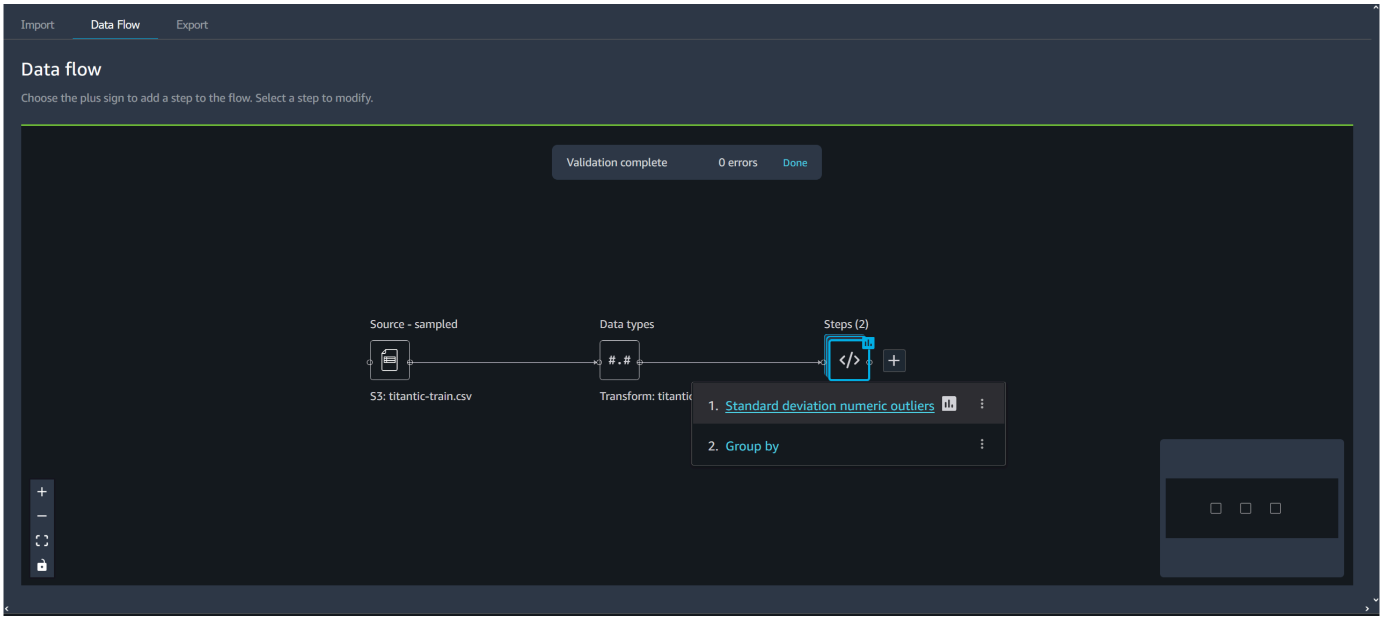
You can edit each step that you've added in your Data Wrangler flow. By editing steps, you can change the transformations or the data types of the columns. You can edit the steps to make changes with which you can perform better analyses.

There are many ways that you can edit a step. Some examples include changing the imputation method or changing the threshold for considering a value to be an outlier.

Use the following procedure to edit a step.

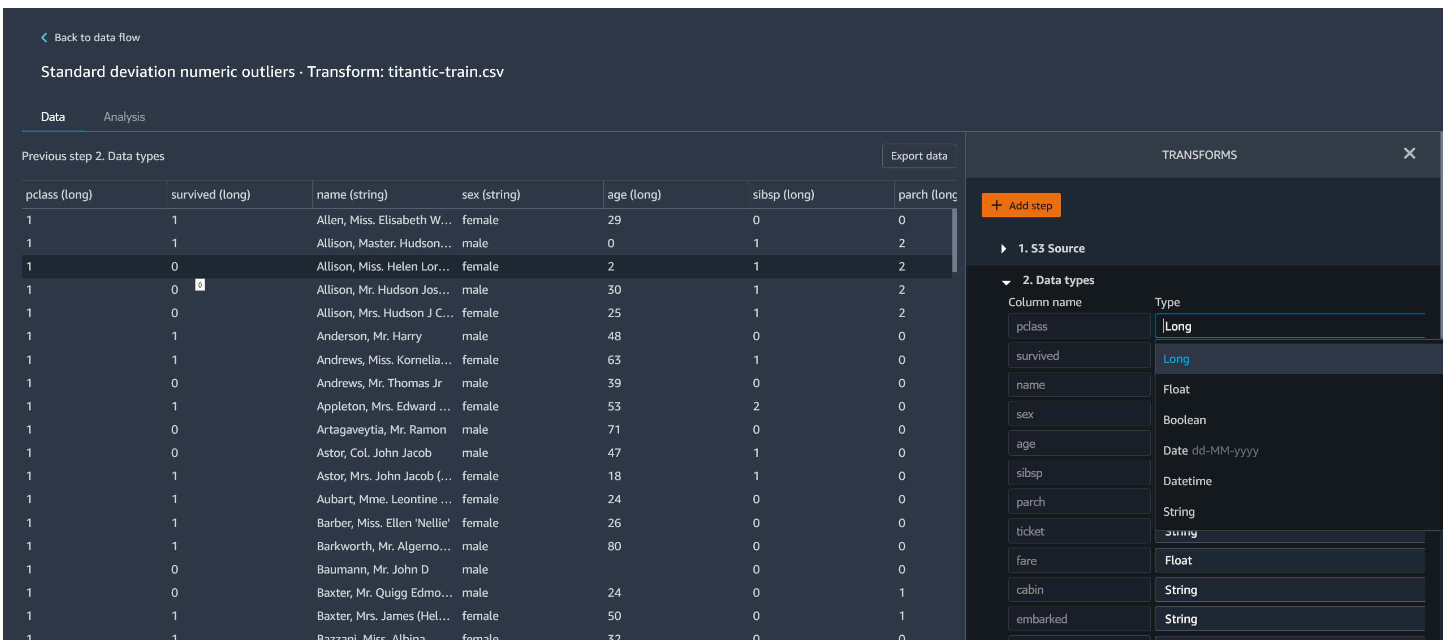
To edit a step, do the following.

1. Choose a step in the Data Wrangler flow to open the table view.



2. Choose a step in the data flow.
3. Edit the step.

The following image shows an example of editing a step.



> **Note**
>
> You can use the shared spaces within your Amazon SageMaker AI domain to work collaboratively on your Data Wrangler flows. Within a shared space, you and your

collaborators can edit a flow file in real-time. However, neither you nor your collaborators can see the changes in real-time. When anyone makes a change to the Data Wrangler flow, they must save it immediately. When someone saves a file, a collaborator won't be able to see it unless the close the file and reopen it. Any changes that aren't saved by one person are overwritten by the person who saved their changes.

Get Insights On Data and Data Quality

Use the **Data Quality and Insights Report** to perform an analysis of the data that you've imported into Data Wrangler. We recommend that you create the report after you import your dataset. You can use the report to help you clean and process your data. It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention.

Use the following procedure to create a Data Quality and Insights report. It assumes that you've already imported a dataset into your Data Wrangler flow.

To create a Data Quality and Insights report

1. Choose a **+** next to a node in your Data Wrangler flow.
2. Select **Get data insights**.
3. For **Analysis name**, specify a name for the insights report.
4. (Optional) For **Target column**, specify the target column.
5. For **Problem type**, specify **Regression** or **Classification**.
6. For **Data size**, specify one of the following:

   - **50 K** – Uses the first 50000 rows of the dataset that you've imported to create the report.
   - **Entire dataset** – Uses the entire dataset that you've imported to create the report.

> **Note**
>
> Creating a Data Quality and Insights report on the entire dataset uses an Amazon SageMaker processing job. A SageMaker Processing job provisions the additional compute resources required to get insights for all of your data. For more information

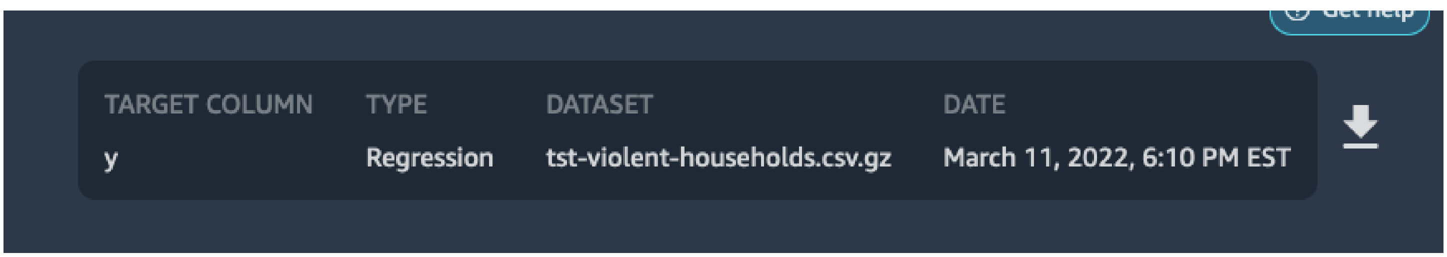
about SageMaker Processing jobs, see Data transformation workloads with SageMaker Processing.

7. Choose **Create**.

The following topics show the sections of the report:

Topics

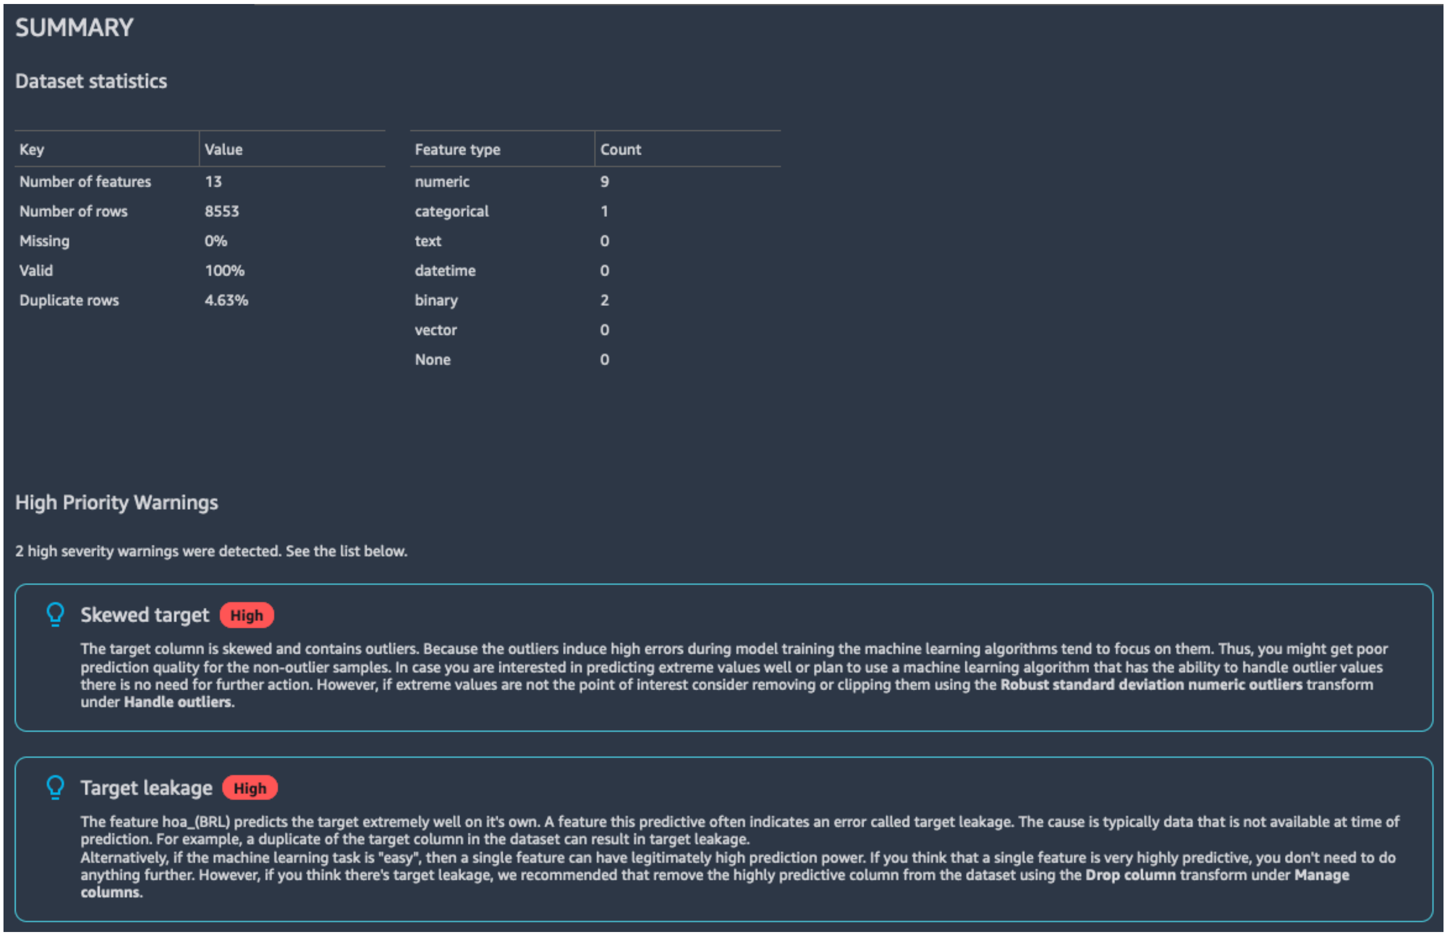
You can either download the report or view it online. To download the report, choose the download button at the top right corner of the screen. The following image shows the button.



Summary

The insights report has a brief summary of the data that includes general information such as missing values, invalid values, feature types, outlier counts, and more. It can also include high severity warnings that point to probable issues with the data. We recommend that you investigate the warnings.

The following is an example of a report summary.

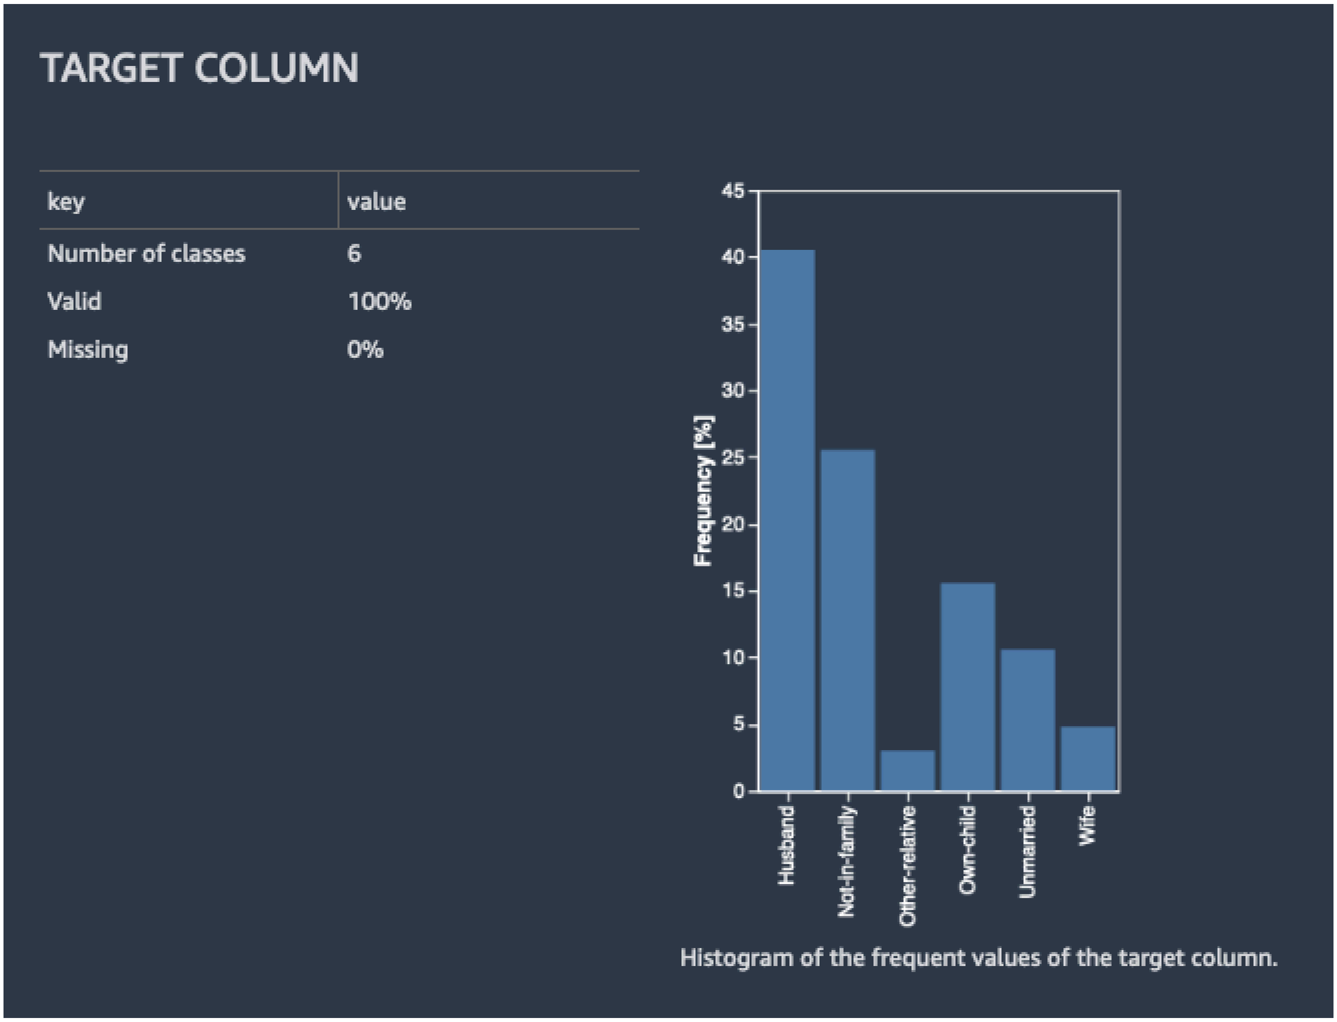


Target column

When you create the data quality and insights report, Data Wrangler gives you the option to select a target column. A target column is a column that you're trying to predict. When you choose a target column, Data Wrangler automatically creates a target column analysis. It also ranks the features in the order of their predictive power. When you select a target column, you must specify whether you're trying to solve a regression or a classification problem.

For classification, Data Wrangler shows a table and a histogram of the most common classes. A class is a category. It also presents observations, or rows, with a missing or invalid target value.

The following image shows an example target column analysis for a classification problem.

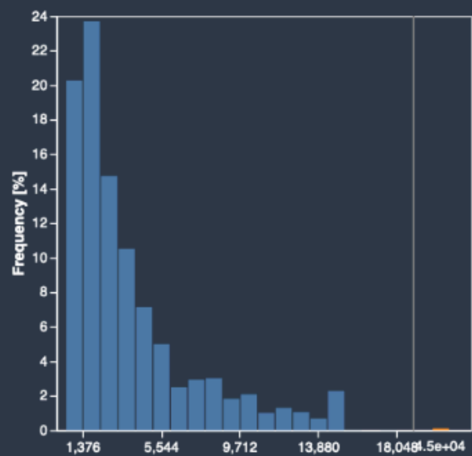


For regression, Data Wrangler shows a histogram of all the values in the target column. It also presents observations, or rows, with a missing, invalid, or outlier target value.

The following image shows an example target column analysis for a regression problem.

TARGET COLUMN

key	value
Valid	100%
Missing	0%
Outliers	0.103%
Min	450
Max	4.5e+04
Mean	3.9e+03
Median	2.66e+03
Skew	1.84
Kurtosis	4.62
Number of unique	1195



Histogram of the target column. The orange bars contain outliers and the value below them is the outliers average.

See below several samples with outlier target values.

city	area	rooms	bathroom	parking spaces	floor	animal	furniture	hoa (R$)	rent amount (R$)	property tax (R$)	fire insurance (R$)	total (R$)
São Paulo	700	4	7	8	-	acept	not furnished	0	45000	8750	677	54430
São Paulo	350	3	3	3	-	acept	not furnished	0	30000	560	451	31010
São Paulo	486	8	4	6	-	acept	not furnished	0	25000	2200	376	27580
São Paulo	80	2	1	1	1	acept	not furnished	875	24000	0	305	25180
São Paulo	900	3	4	8	-	acept	not furnished	0	20000	3813	301	24110

Quick model

The **Quick model** provides an estimate of the expected predicted quality of a model that you train on your data.

Data Wrangler splits your data into training and validation folds. It uses 80% of the samples for training and 20% of the values for validation. For classification, the sample is stratified split. For a stratified split, each data partition has the same ratio of labels. For classification problems, it's important to have the same ratio of labels between the training and classification folds. Data Wrangler trains the XGBoost model with the default hyperparameters. It applies early stopping on the validation data and performs minimal feature preprocessing.

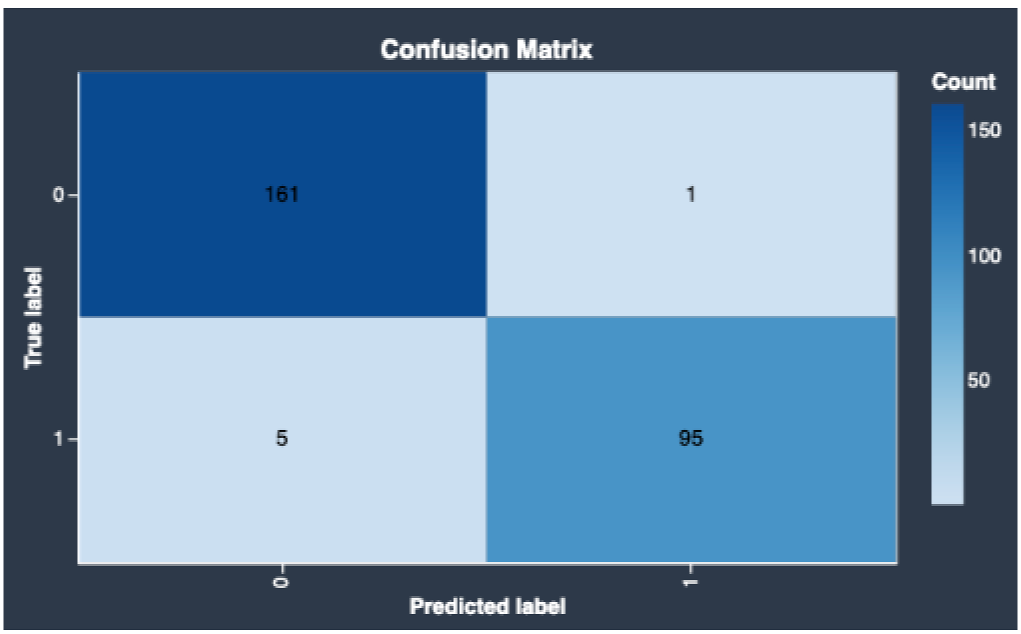
For classification models, Data Wrangler returns both a model summary and a confusion matrix.

The following is an example of a classification model summary. To learn more about the information that it returns, see Definitions.

Metric	Validation scores	Train scores
Accuracy	0.977	0.992
Balanced accuracy	0.972	0.99
ROC-AUC	0.995	1
F1	0.969	0.99
Precision	0.99	0.997
Recall	0.95	0.983

class	precision	recall	f1-score	support
0	0.9698795180722891	0.9938271604938271	0.9817073170731707	162.0
1	0.9895833333333334	0.95	0.9693877551020408	100.0

The following is an example of a confusion matrix that the quick model returns.



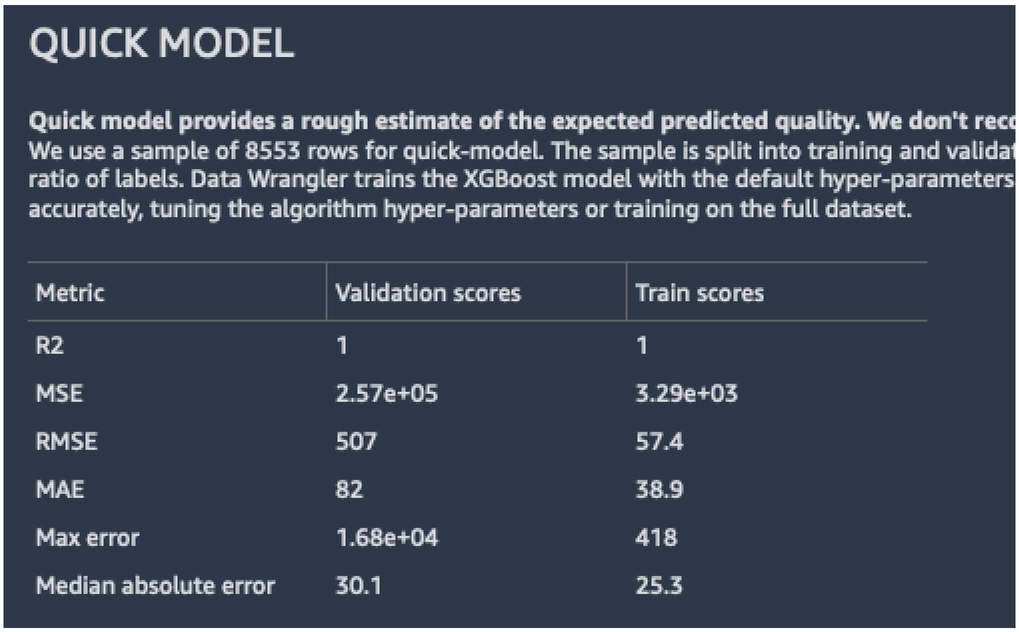
A confusion matrix gives you the following information:

- The number of times the predicted label matches the true label.
- The number of times the predicted label doesn't match the true label.

The true label represents an actual observation in your data. For example, if you're using a model to detect fraudulent transactions, the true label represents a transaction that is actually fraudulent or non-fraudulent. The predicted label represents the label that your model assigns to the data.

You can use the confusion matrix to see how well the model predicts the presence or the absence of a condition. If you're predicting fraudulent transactions, you can use the confusion matrix to get a sense of both the sensitivity and the specificity of the model. The sensitivity refers to the model's ability to detect fraudulent transactions. The specificity refers to the model's ability to avoid detecting non-fraudulent transactions as fraudulent.

The following is an example of the quick model outputs for a regression problem.



Feature summary

When you specify a target column, Data Wrangler orders the features by their prediction power. Prediction power is measured on the data after it was split into 80% training and 20% validation folds. Data Wrangler fits a model for each feature separately on the training fold. It applies minimal feature preprocessing and measures prediction performance on the validation data.

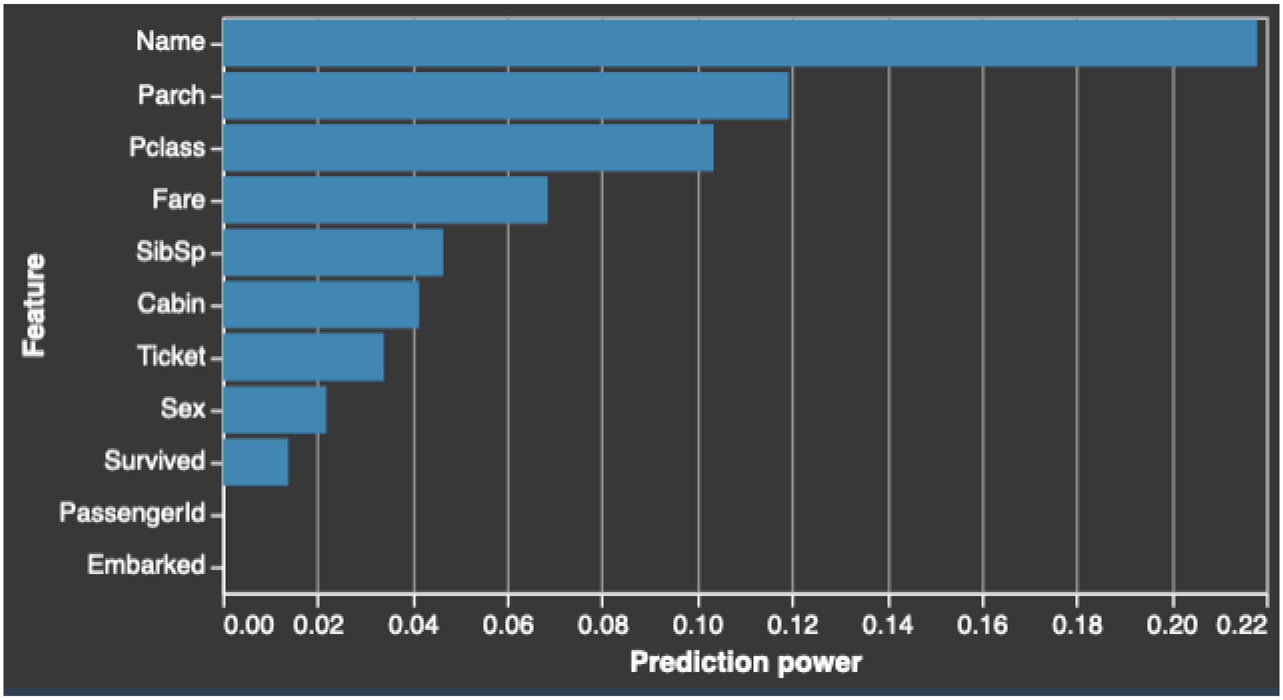
It normalizes the scores to the range [0,1]. Higher prediction scores indicate columns that are more useful for predicting the target on their own. Lower scores point to columns that aren't predictive of the target column.

It's uncommon for a column that isn't predictive on its own to be predictive when it's used in tandem with other columns. You can confidently use the prediction scores to determine whether a feature in your dataset is predictive.

A low score usually indicates the feature is redundant. A score of 1 implies perfect predictive abilities, which often indicates target leakage. Target leakage usually happens when the dataset contains a column that isn't available at the prediction time. For example, it could be a duplicate of the target column.

The following are examples of the table and the histogram that show the prediction value of each feature.

Feature	Prediction power	Type	Valid	Missing	Outliers	#Warnings
Name	0.274276	text	100.0%	0.0%		0
Pclass	0.154638	numeric	100.0%	0.0%	0.0%	0
SibSp	0.141675	numeric	100.0%	0.0%	3.22%	0
Parch	0.127353	numeric	100.0%	0.0%	1.4%	0
Cabin	0.112283	text	25.91%	74.09%		0
Ticket	0.0869433	numeric	72.97%	0.0%	3.07%	0
Fare	0.0625847	numeric	100.0%	0.0%	2.52%	0
Embarked	0.00600914	categorical	99.72%	0.28%		0
Survived	0.00434197	binary	100.0%	0.0%		0
PassengerId	0	numeric	100.0%	0.0%	0.0%	0
Sex	0	binary	100.0%	0.0%		0



Samples

Data Wrangler provides information about whether your samples are anomalous or if there are duplicates in your dataset.

Data Wrangler detects anomalous samples using the *isolation forest algorithm*. The isolation forest associates an anomaly score with each sample (row) of the dataset. Low anomaly scores indicate anomalous samples. High scores are associated with non-anomalous samples. Samples with a negative anomaly score are usually considered anomalous and samples with positive anomaly score are considered non-anomalous.

When you look at a sample that might be anomalous, we recommend that you pay attention to unusual values. For example, you might have anomalous values that result from errors in gathering and processing the data. We recommend using domain knowledge and business logic when you examine anomalous samples.

Data Wrangler detects duplicate rows and calculates the ratio of duplicate rows in your data. Some data sources could include valid duplicates. Other data sources could have duplicates that point to problems in data collection. Duplicate samples that result from faulty data collection could interfere with machine learning processes that rely on splitting the data into independent training and validation folds.

The following are elements of the insights report that can be impacted by duplicated samples:

- Quick model
- Prediction power estimation
- Automatic hyperparameter tuning

You can remove duplicate samples from the dataset using the **Drop duplicates** transform under **Manage rows**. Data Wrangler shows you the most frequently duplicated rows.

Definitions

The following are definitions for the technical terms that are used in the data insights report.

Feature types

The following are the definitions for each of the feature types:

- **Numeric –** Numeric values can be either floats or integers, such as age or income. The machine learning models assume that numeric values are ordered and a distance is defined over them. For example, 3 is closer to 4 than to 10 and 3 < 4 < 10.
- Categorical – The column entries belong to a set of unique values, which is usually much smaller than the number of entries in the column. For example, a column of length 100 could contain the unique values `Dog`, `Cat`, and `Mouse`. The values could be numeric, text, or a combination of both. `Horse`, `House`, `8`, `Love`, and `3.1` would all be valid values and could be found in the same categorical column. The machine learning model does not assume order or distance on the values of categorical features, as opposed to numeric features, even when all the values are numbers.
- **Binary –** Binary features are a special categorical feature type in which the cardinality of the set of unique values is 2.
- **Text –** A text column contains many non-numeric unique values. In extreme cases, all the elements of the column are unique. In an extreme case, no two entries are the same.
- **Datetime –** A datetime column contains information about the date or time. It can have information about both the date and time.

Feature statistics

The following are definitions for each of the feature statistics:

- **Prediction power –** Prediction power measures how useful the column is in predicting the target.
- **Outliers** (in numeric columns) **–** Data Wrangler detects outliers using two statistics that are robust to outliers: median and robust standard deviation (RSTD). RSTD is derived by clipping the feature values to the range [5 percentile, 95 percentile] and calculating the standard deviation of the clipped vector. All values larger than median + 5 * RSTD or smaller than median - 5 * RSTD are considered to be outliers.
- **Skew** (in numeric columns) **–** Skew measures the symmetry of the distribution and is defined as the third moment of the distribution divided by the third power of the standard deviation. The skewness of the normal distribution or any other symmetric distribution is zero. Positive values imply that the right tail of the distribution is longer than the left tail. Negative values imply that the left tail of the distribution is longer than the right tail. As a rule of thumb, a distribution is considered skewed when the absolute value of the skew is larger than 3.
- **Kurtosis** (in numeric columns) **–** Pearson's kurtosis measures the heaviness of the tail of the distribution. It's defined as the fourth moment of the distribution divided by the square of the second moment. The kurtosis of the normal distribution is 3. Kurtosis values lower than 3 imply that the distribution is concentrated around the mean and the tails are lighter than the tails of the normal distribution. Kurtosis values higher than 3 imply heavier tails or outliers.
- **Missing values –** Null-like objects, empty strings and strings composed of only white spaces are considered missing.
- **Valid values for numeric features or regression target –** All values that you can cast to finite floats are valid. Missing values are not valid.
- **Valid values for categorical, binary, or text features, or for classification target –** All values that are not missing are valid.
- **Datetime features –** All values that you can cast to a datetime object are valid. Missing values are not valid.
- **Invalid values –** Values that are either missing or you can't properly cast. For example, in a numeric column, you can't cast the string `"six"` or a null value.

Quick model metrics for regression

The following are the definitions for the quick model metrics:

- R2 or coefficient of determination) **–** R2 is the proportion of the variation in the target that is predicted by the model. R2 is in the range of [-infty, 1]. 1 is the score of the model that predicts the target perfectly and 0 is the score of the trivial model that always predicts the target mean.

- MSE or mean squared error – MSE is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.
- MAE or mean absolute error – MAE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.
- RMSE or root mean square error – RMSE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.
- Max error – The maximum absolute value of the error over the dataset. Max error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.
- Median absolute error – Median absolute error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

Quick model metrics for classification

The following are the definitions for the quick model metrics:

- **Accuracy** – Accuracy is the ratio of samples that are predicted accurately. Accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples incorrectly and 1 is the score of the perfect model.
- **Balanced accuracy** – Balanced accuracy is the ratio of samples that are predicted accurately when the class weights are adjusted to balance the data. All classes are given the same importance, regardless of their frequency. Balanced accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples wrong. 1 is the score of the perfect model.
- **AUC (binary classification)** – This is the area under the receiver operating characteristic curve. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.
- **AUC (OVR)** – For multiclass classification, this is the area under the receiver operating characteristic curve calculated separately for each label using one versus rest. Data Wrangler reports the average of the areas. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.
- **Precision** – Precision is defined for a specific class. Precision is the fraction of true positives out of all the instances that the model classified as that class. Precision is in the range [0, 1]. 1 is the score of the model that has no false positives for the class. For binary classification, Data Wrangler reports the precision of the positive class.

- **Recall –** Recall is defined for a specific class. Recall is the fraction of the relevant class instances that are successfully retrieved. Recall is in the range [0, 1]. 1 is the score of the model that classifies all the instances of the class correctly. For binary classification, Data Wrangler reports the recall of the positive class.
- **F1 –** F1 is defined for a specific class. It's the harmonic mean of the precision and recall. F1 is in the range [0, 1]. 1 is the score of the perfect model. For binary classification, Data Wrangler reports the F1 for classes with positive values.

Textual patterns

Patterns describe the textual format of a string using an easy to read format. The following are examples of textual patterns:

- "{digits:4-7}" describes a sequence of digits that have a length between 4 and 7.
- "{alnum:5}" describes an alpha-numeric string with a length of exactly 5.

Data Wrangler infers the patterns by looking at samples of non-empty strings from your data. It can describe many of the commonly used patterns. The **confidence** expressed as a percentage indicates how much of the data is estimated to match the pattern. Using the textual pattern, you can see which rows in your data you need to correct or drop.

The following describes the patterns that Data Wrangler can recognize:

Pattern	Textual Format
{alnum}	Alphanumeric strings
{any}	Any string of word characters
{digits}	A sequence of digits
{lower}	A lowercase word
{mixed}	A mixed-case word
{name}	A word beginning with a capital letter
{upper}	An uppercase word

Pattern	Textual Format
{whitespace}	whitespace characters

A word character is either an underscore or a character that might appear in a word in any language. For example, the strings 'Hello_word' and 'écoute' both consist of word characters. 'H' and 'é' are both examples of word characters.

Automatically Train Models on Your Data Flow

You can use Amazon SageMaker Autopilot to automatically train, tune, and deploy models on the data that you've transformed in your data flow. Amazon SageMaker Autopilot can go through several algorithms and use the one that works best with your data. For more information about Amazon SageMaker Autopilot, see SageMaker Autopilot.

When you train and tune a model, Data Wrangler exports your data to an Amazon S3 location where Amazon SageMaker Autopilot can access it.

You can prepare and deploy a model by choosing a node in your Data Wrangler flow and choosing **Export and Train** in the data preview. You can use this method to view your dataset before you choose to train a model on it.

You can also train and deploy a model directly from your data flow.

The following procedure prepares and deploys a model from the data flow. For Data Wrangler flows with multi-row transforms, you can't use the transforms from the Data Wrangler flow when you're deploying the model. You can use the following procedure to process the data before you use it to perform inference.

To train and deploy a model directly from your data flow, do the following.

1. Choose the **+** next to the node containing the training data.
2. Choose **Train model**.
3. (Optional) Specify a AWS KMS key or ID. For more information about creating and controlling cryptographic keys to protect your data, see AWS Key Management Service.
4. Choose **Export and train**.

5. After Amazon SageMaker Autopilot trains the model on the data that Data Wrangler exported, specify a name for **Experiment name**.
6. Under **Input data**, choose **Preview** to verify that Data Wrangler properly exported your data to Amazon SageMaker Autopilot.
7. For **Target**, choose the target column.
8. (Optional) For **S3 location** under **Output data**, specify an Amazon S3 location other than the default location.
9. Choose **Next: Training method**.
10. Choose a training method. For more information, see Training modes.
11. (Optional) For **Auto deploy endpoint**, specify a name for the endpoint.
12. For **Deployment option**, choose a deployment method. You can choose to deploy with or without the transformations that you've made to your data.

> **Important**
>
> You can't deploy an Amazon SageMaker Autopilot model with the transformations that you've made in your Data Wrangler flow. For more information about those transformations, see Export to an Inference Endpoint.

13. Choose **Next: Review and create**.
14. Choose **Create experiment**.

For more information about model training and deployment, see Create Regression or Classification Jobs for Tabular Data Using the AutoML API. Autopilot shows you analyses about the best model's performance. For more information about model performance, see View an Autopilot model performance report.

Transform Data

Amazon SageMaker Data Wrangler provides numerous ML data transforms to streamline cleaning, transforming, and featurizing your data. When you add a transform, it adds a step to the data flow. Each transform you add modifies your dataset and produces a new dataframe. All subsequent transforms apply to the resulting dataframe.

Data Wrangler includes built-in transforms, which you can use to transform columns without any code. You can also add custom transformations using PySpark, Python (User-Defined Function), pandas, and PySpark SQL. Some transforms operate in place, while others create a new output column in your dataset.

You can apply transforms to multiple columns at once. For example, you can delete multiple columns in a single step.

You can apply the **Process numeric** and **Handle missing** transforms only to a single column.

Use this page to learn more about these built-in and custom transforms.

Transform UI

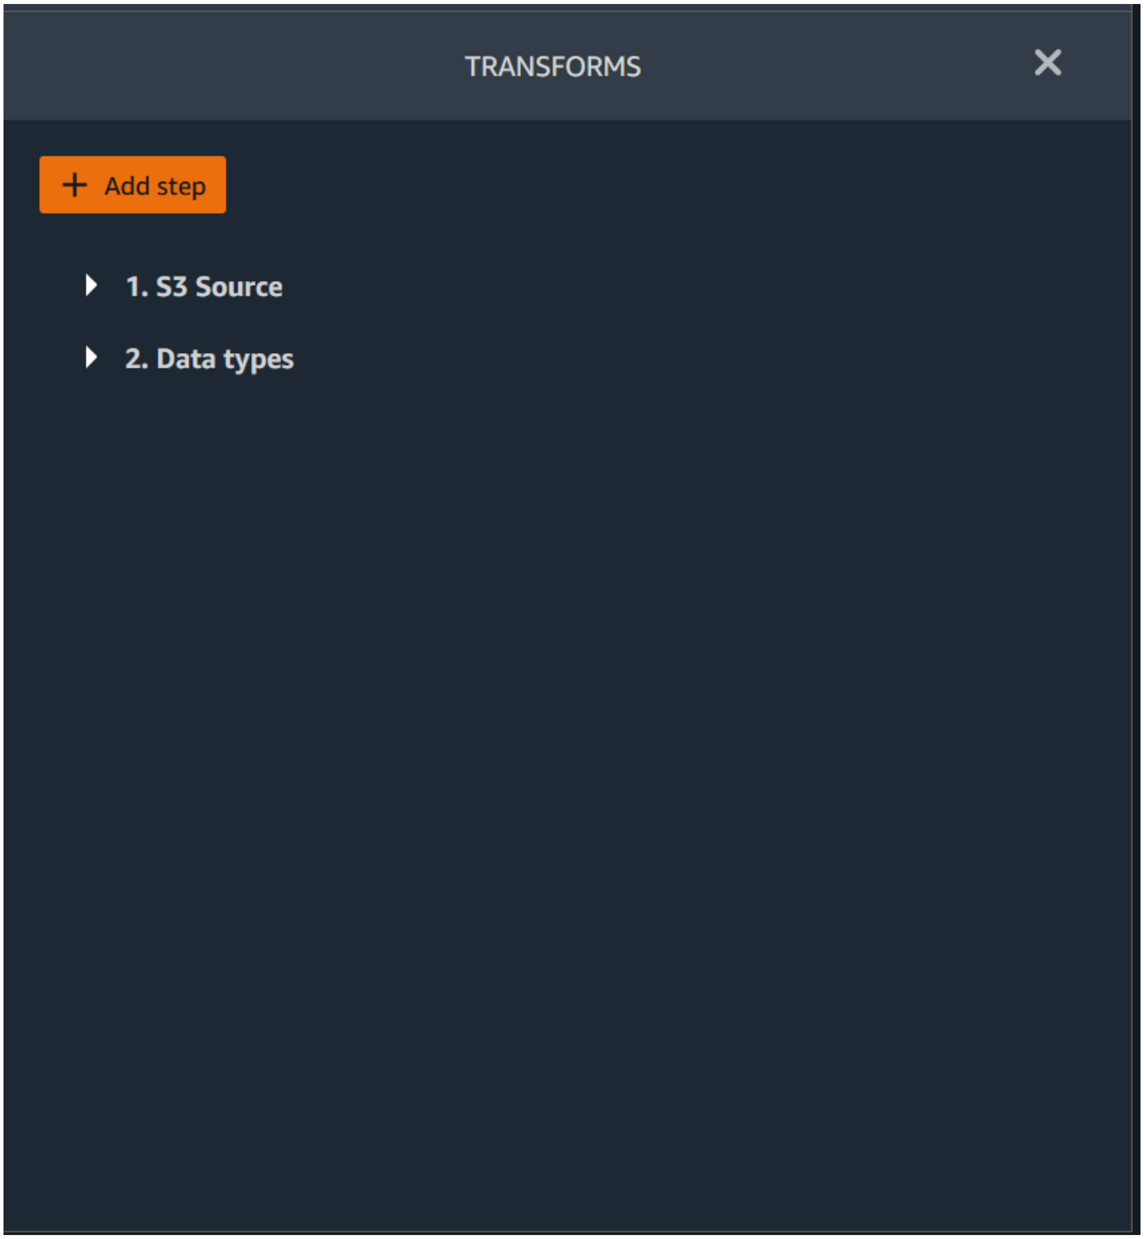
Most of the built-in transforms are located in the **Prepare** tab of the Data Wrangler UI. You can access the join and concatenate transforms through the data flow view. Use the following table to preview these two views.

Transform

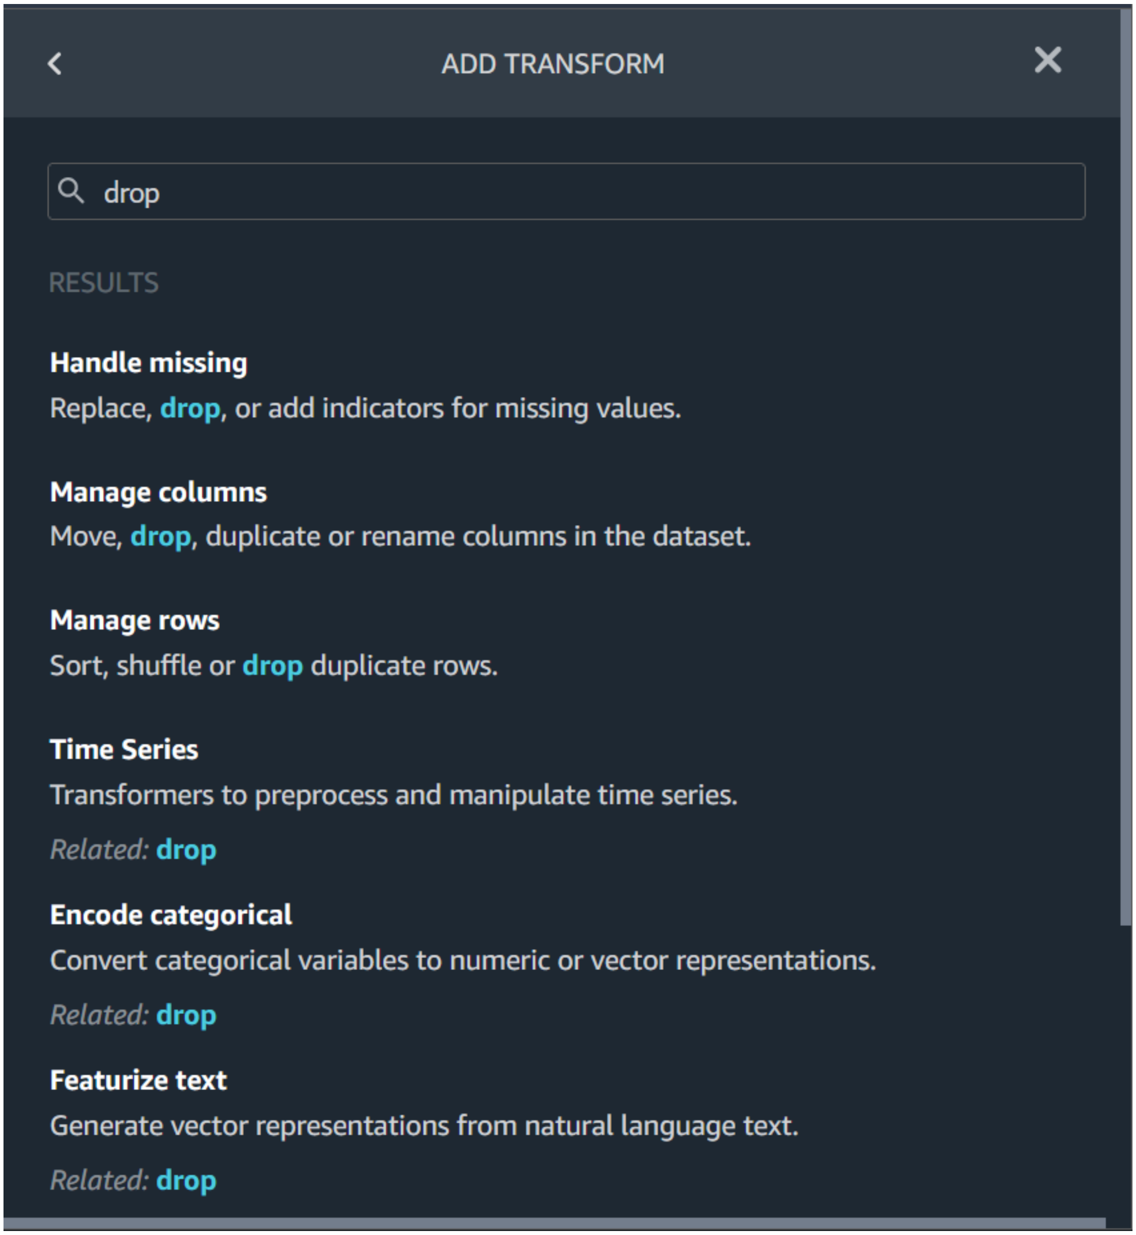
You can add a transform to any step in your data flow. Use the following procedure to add a transform to your data flow.

To add a step to your data flow, do the following.

1. Choose the **+** next to the step in the data flow.
2. Choose **Add transform**.
3. Choose **Add step**.

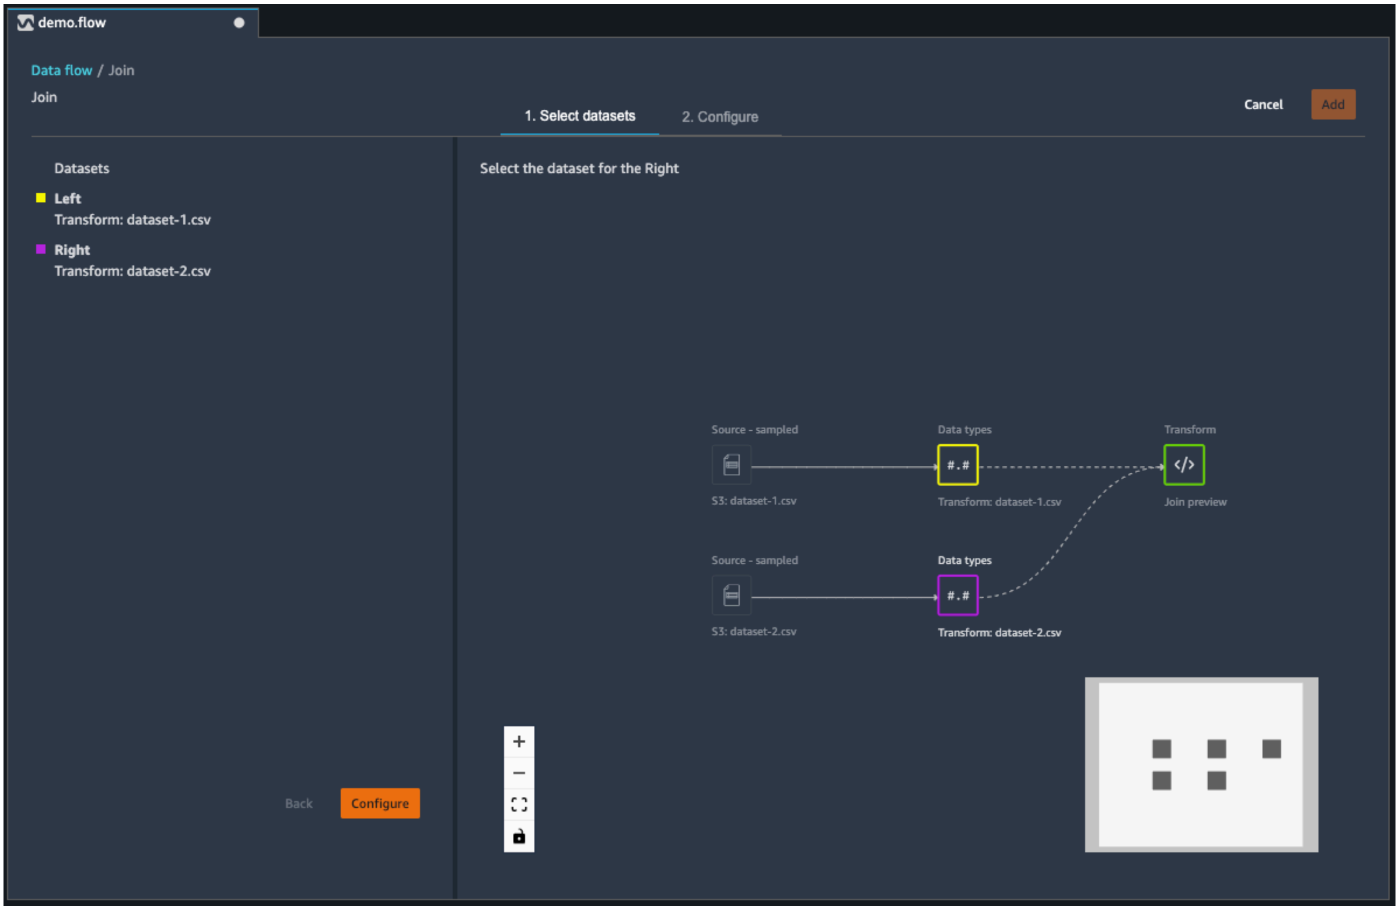


4. Choose a transform.
5. (Optional) You can search for the transform that you want to use. Data Wrangler highlights the query in the results.

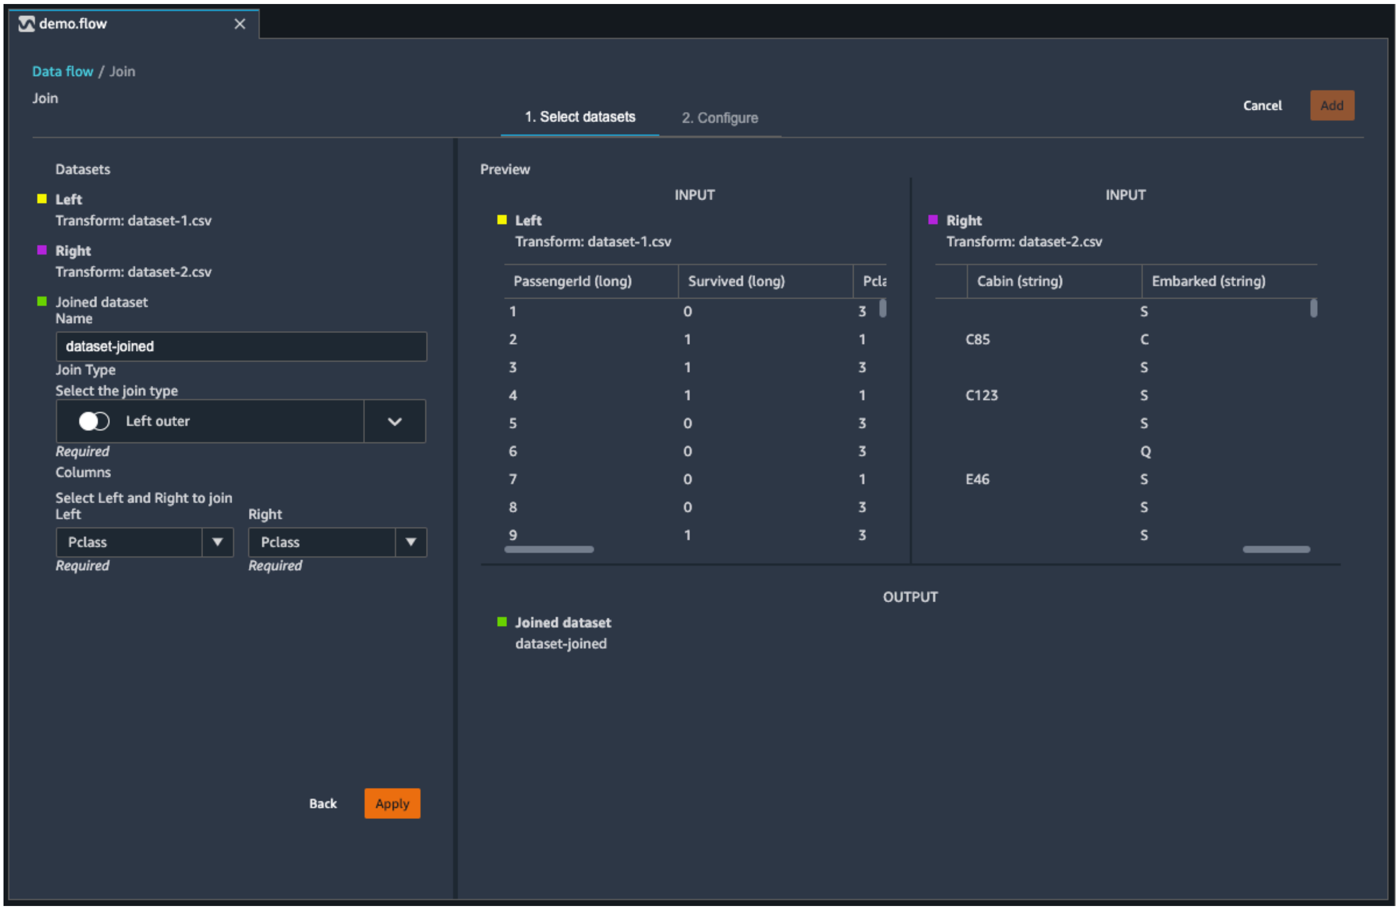


Join View

To join two datasets, select the first dataset in your data flow and choose **Join**. When you choose **Join**, you see results similar to those shown in the following image. Your left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly joined dataset added.



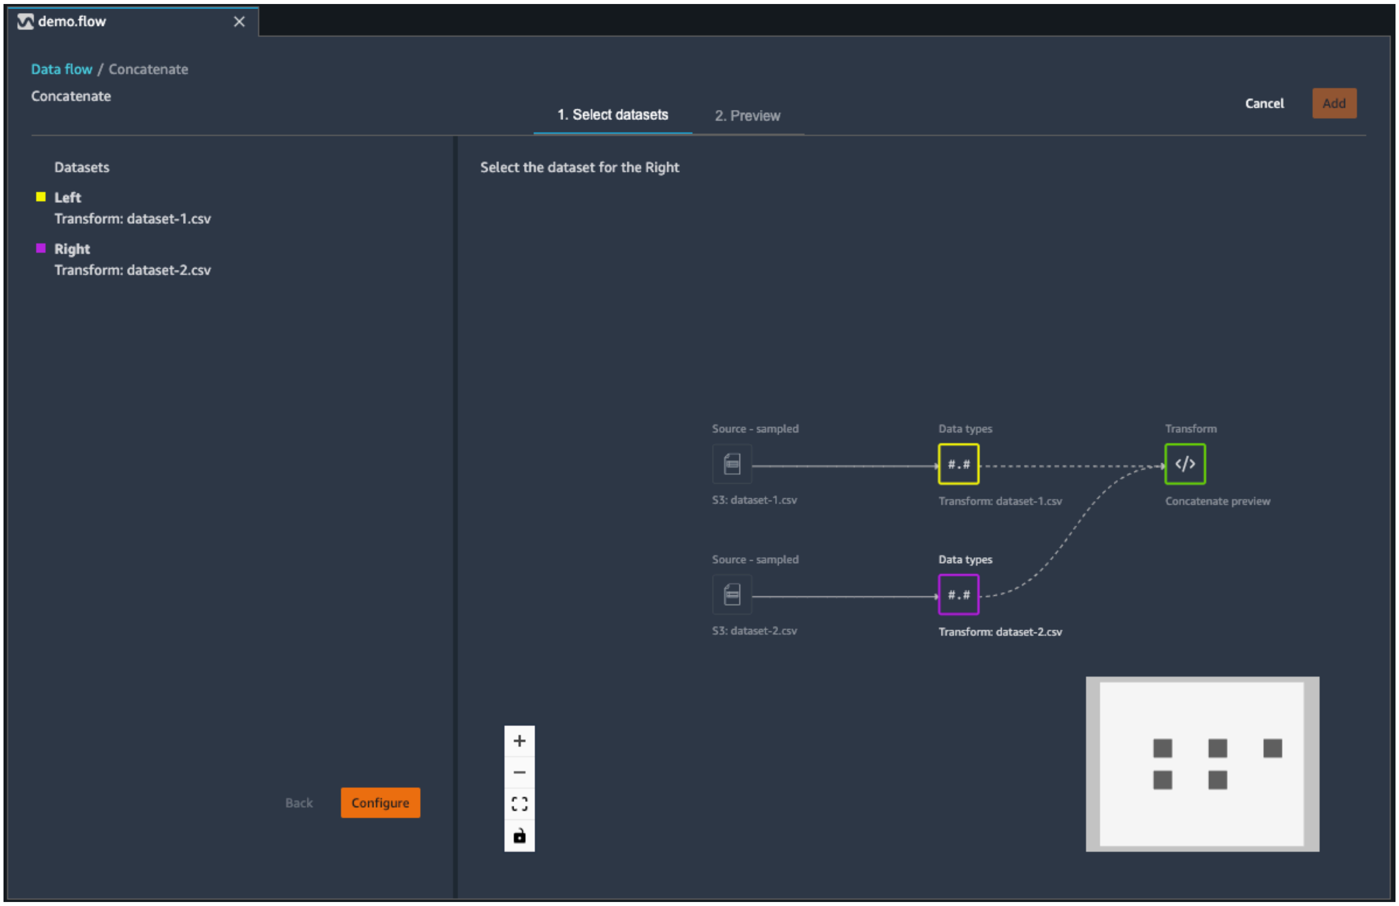
When you choose **Configure** to configure your join, you see results similar to those shown in the following image. Your join configuration is displayed in the left panel. You can use this panel to choose the joined dataset name, join type, and columns to join. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the joined dataset.



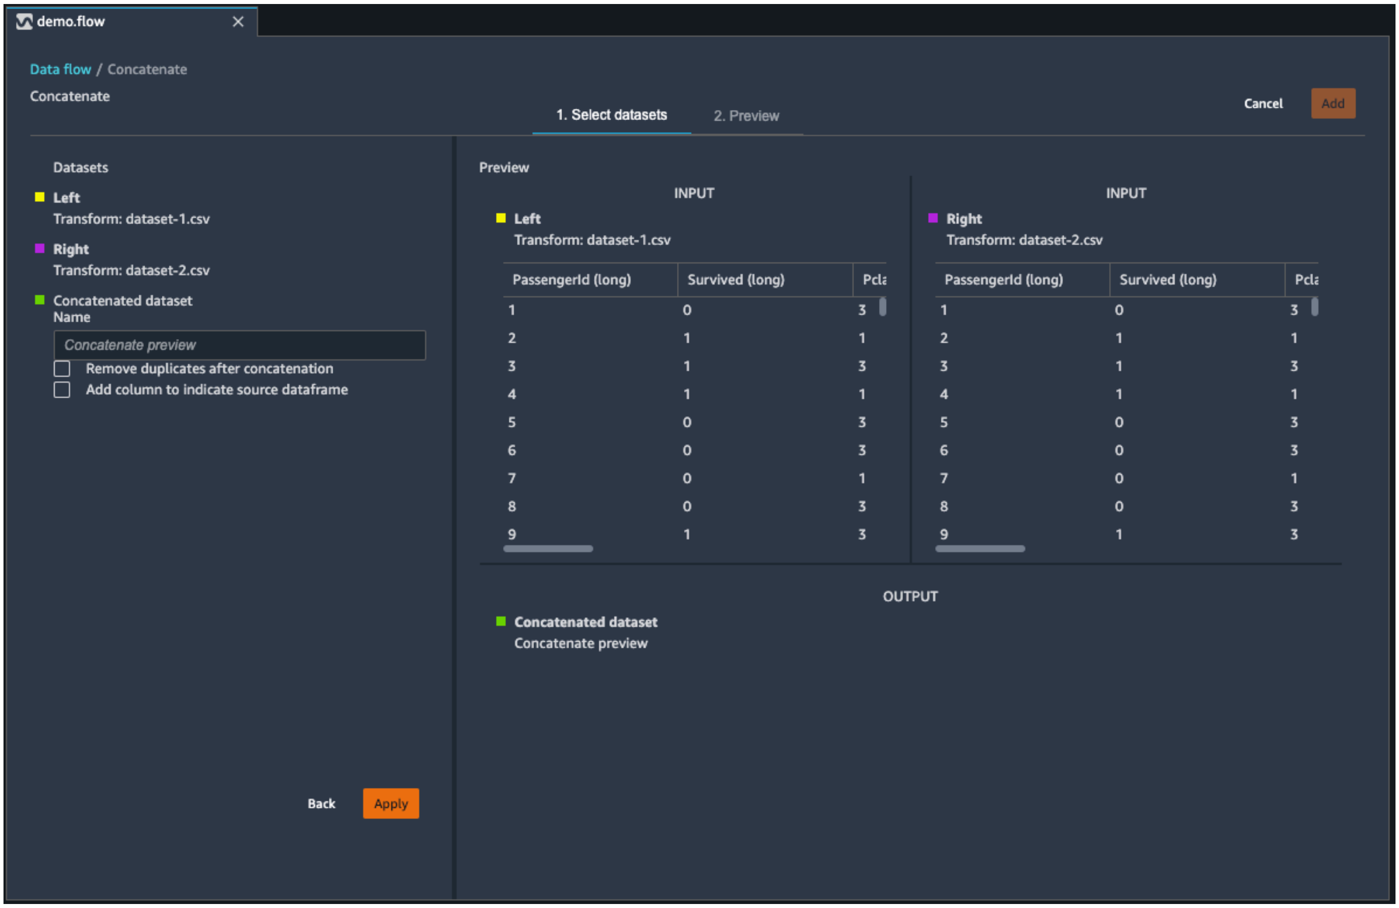
See Join Datasets to learn more.

Concatenate View

To concatenate two datasets, you select the first dataset in your data flow and choose **Concatenate**. When you select **Concatenate**, you see results similar to those shown in the following image. Your left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly concatenated dataset added.



When you choose **Configure** to configure your concatenation, you see results similar to those shown in the following image. Your concatenate configuration displays in the left panel. You can use this panel to choose the concatenated dataset's name, and choose to remove duplicates after concatenation and add columns to indicate the source dataframe. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the concatenated dataset.



See Concatenate Datasets to learn more.

Join Datasets

You join dataframes directly in your data flow. When you join two datasets, the resulting joined dataset appears in your flow. The following join types are supported by Data Wrangler.

- **Left Outer –** Include all rows from the left table. If the value for the column joined on a left table row does not match any right table row values, that row contains null values for all right table columns in the joined table.
- **Left Anti –** Include rows from the left table that do not contain values in the right table for the joined column.
- **Left semi –** Include a single row from the left table for all identical rows that satisfy the criteria in the join statement. This excludes duplicate rows from the left table that match the criteria of the join.

- **Right Outer –** Include all rows from the right table. If the value for the joined column in a right table row does not match any left table row values, that row contains null values for all left table columns in the joined table.
- **Inner –** Include rows from left and right tables that contain matching values in the joined column.
- **Full Outer –** Include all rows from the left and right tables. If the row value for the joined column in either table does not match, separate rows are created in the joined table. If a row doesn't contain a value for a column in the joined table, null is inserted for that column.
- **Cartesian Cross –** Include rows which combine each row from the first table with each row from the second table. This is a Cartesian product of rows from tables in the join. The result of this product is the size of the left table times the size of the right table. Therefore, we recommend caution in using this join between very large datasets.

Use the following procedure to join two dataframes.

1. Select **+** next to the left dataframe that you want to join. The first dataframe you select is always the left table in your join.
2. Choose **Join**.
3. Select the right dataframe. The second dataframe you select is always the right table in your join.
4. Choose **Configure** to configure your join.
5. Give your joined dataset a name using the **Name** field.
6. Select a **Join type**.
7. Select a column from the left and right tables to join.
8. Choose **Apply** to preview the joined dataset on the right.
9. To add the joined table to your data flow, choose **Add**.

Concatenate Datasets

Concatenate two datasets:

1. Choose **+** next to the left dataframe that you want to concatenate. The first dataframe you select is always the left table in your concatenate.
2. Choose **Concatenate**.

3. Select the right dataframe. The second dataframe you select is always the right table in your concatenate.
4. Choose **Configure** to configure your concatenate.
5. Give your concatenated dataset a name using the **Name** field.
6. (Optional) Select the checkbox next to **Remove duplicates after concatenation** to remove duplicate columns.
7. (Optional) Select the checkbox next to **Add column to indicate source dataframe** if, for each column in the new dataset, you want to add an indicator of the column's source.
8. Choose **Apply** to preview the new dataset.
9. Choose **Add** to add the new dataset to your data flow.

Balance Data

You can balance the data for datasets with an underrepresented category. Balancing a dataset can help you create better models for binary classification.

> **Note**
>
> You can't balance datasets containing column vectors.

You can use the **Balance data** operation to balance your data using one of the following operators:

- *Random oversampling* – Randomly duplicates samples in the minority category. For example, if you're trying to detect fraud, you might only have cases of fraud in 10% of your data. For an equal proportion of fraudulent and non-fraudulent cases, this operator randomly duplicates fraud cases within the dataset 8 times.
- *Random undersampling* – Roughly equivalent to random oversampling. Randomly removes samples from the overrepresented category to get the proportion of samples that you desire.
- *Synthetic Minority Oversampling Technique (SMOTE)* – Uses samples from the underrepresented category to interpolate new synthetic minority samples. For more information about SMOTE, see the following description.

You can use all transforms for datasets containing both numeric and non-numeric features. SMOTE interpolates values by using neighboring samples. Data Wrangler uses the R-squared distance to determine the neighborhood to interpolate the additional samples. Data Wrangler only uses numeric features to calculate the distances between samples in the underrepresented group.

For two real samples in the underrepresented group, Data Wrangler interpolates the numeric features by using a weighted average. It randomly assigns weights to those samples in the range of [0, 1]. For numeric features, Data Wrangler interpolates samples using a weighted average of the samples. For samples A and B, Data Wrangler could randomly assign a weight of 0.7 to A and 0.3 to B. The interpolated sample has a value of 0.7A + 0.3B.

Data Wrangler interpolates non-numeric features by copying from either of the interpolated real samples. It copies the samples with a probability that it randomly assigns to each sample. For samples A and B, it can assign probabilities 0.8 to A and 0.2 to B. For the probabilities it assigned, it copies A 80% of the time.

Custom Transforms

The **Custom Transforms** group allows you to use Python (User-Defined Function), PySpark, pandas, or PySpark (SQL) to define custom transformations. For all three options, you use the variable `df` to access the dataframe to which you want to apply the transform. To apply your custom code to your dataframe, assign the dataframe with the transformations that you've made to the `df` variable. If you're not using Python (User-Defined Function), you don't need to include a return statement. Choose **Preview** to preview the result of the custom transform. Choose **Add** to add the custom transform to your list of **Previous steps**.

You can import the popular libraries with an `import` statement in the custom transform code block, such as the following:

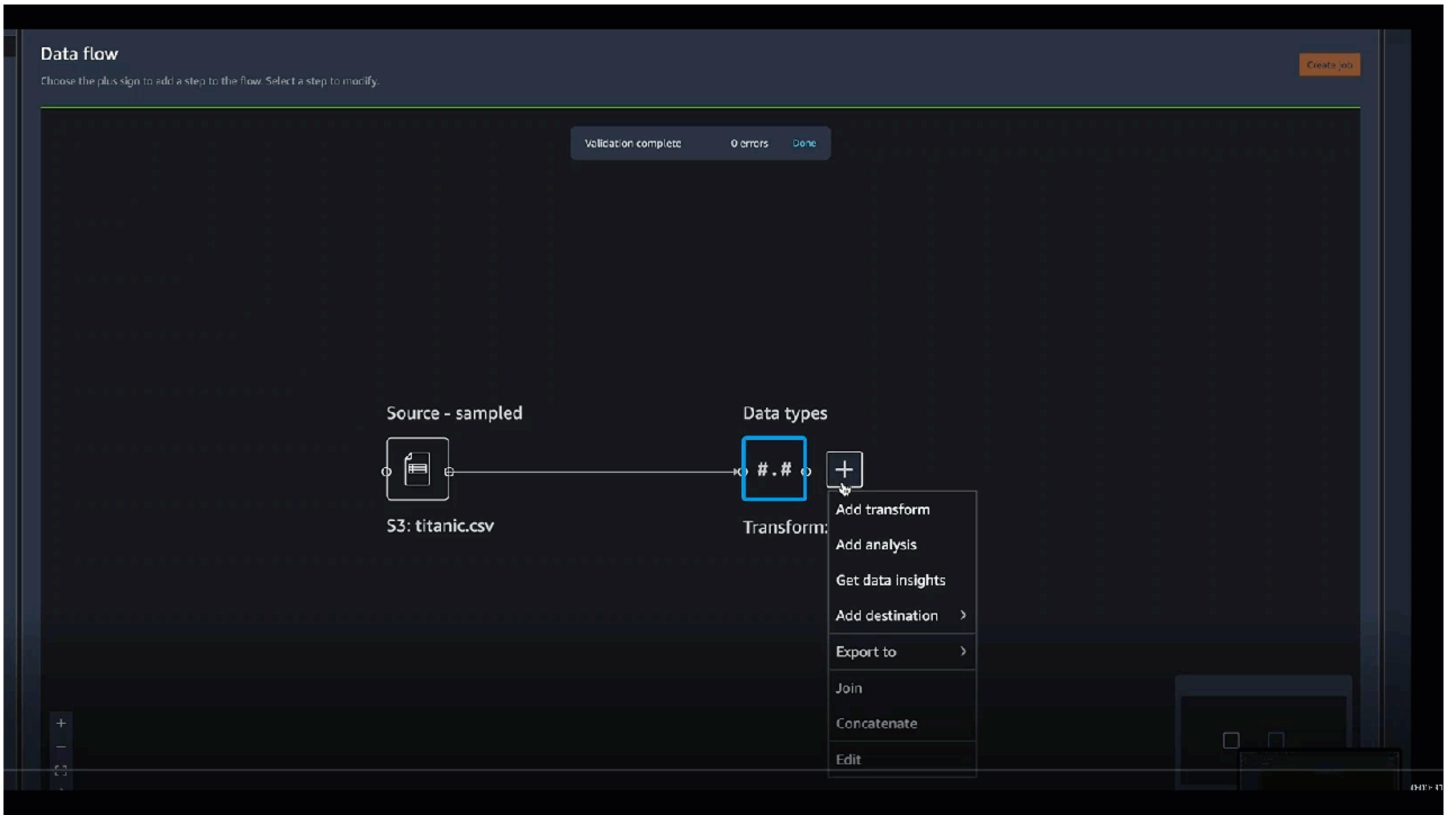
- NumPy version 1.19.0
- scikit-learn version 0.23.2
- SciPy version 1.5.4
- pandas version 1.0.3
- PySpark version 3.0.0

> **Important**
>
> **Custom transform** doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the **Rename column** transform in the **Manage columns**

transform group to remove spaces from a column's name. You can also add a **Python (Pandas) Custom transform** similar to the following to remove spaces from multiple columns in a single step. This example changes columns named `A column` and `B column` to `A_column` and `B_column` respectively.

```
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

If you include print statements in the code block, the result appears when you select **Preview**. You can resize the custom code transformer panel. Resizing the panel provides more space to write code. The following image shows the resizing of the panel.



The following sections provide additional context and examples for writing custom transform code.

Python (User-Defined Function)

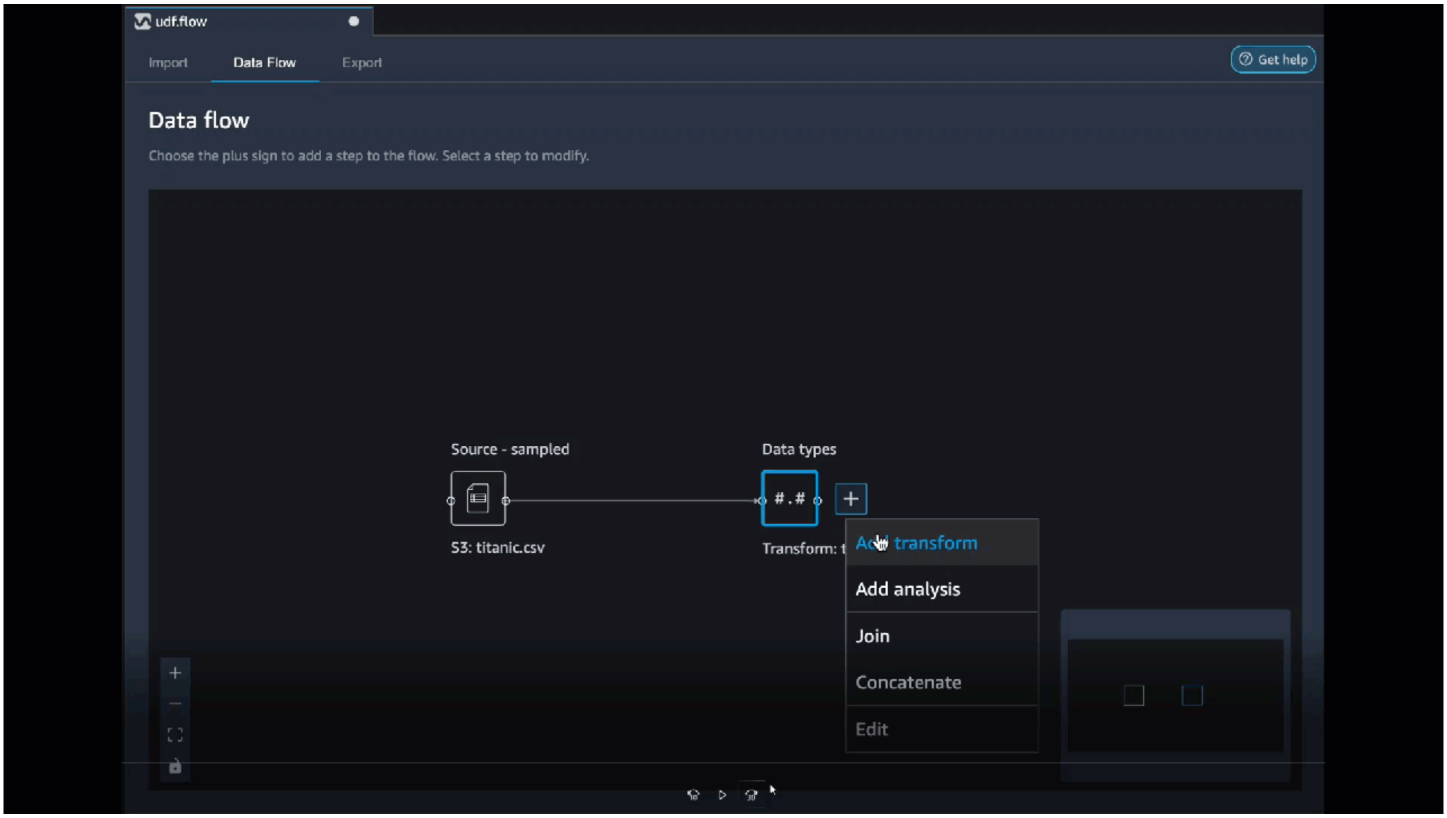
The Python function gives you the ability to write custom transformations without needing to know Apache Spark or pandas. Data Wrangler is optimized to run your custom code quickly. You get similar performance using custom Python code and an Apache Spark plugin.

To use the Python (User-Defined Function) code block, you specify the following:

- **Input column** – The input column where you're applying the transform.
- **Mode** – The scripting mode, either pandas or Python.
- **Return type** – The data type of the value that you're returning.

Using the pandas mode gives better performance. The Python mode makes it easier for you to write transformations by using pure Python functions.

The following video shows an example of how to use custom code to create a transformation. It uses the Titanic dataset to create a column with the person's salutation.



PySpark

The following example extracts date and time from a timestamp.

```
from pyspark.sql.functions import from_unixtime, to_date, date_format
df = df.withColumn('DATE_TIME', from_unixtime('TIMESTAMP'))
df = df.withColumn( 'EVENT_DATE', to_date('DATE_TIME')).withColumn(
'EVENT_TIME', date_format('DATE_TIME', 'HH:mm:ss'))
```

pandas

The following example provides an overview of the dataframe to which you are adding transforms.

```
df.info()
```

PySpark (SQL)

The following example creates a new dataframe with four columns: *name*, *fare*, *pclass*, *survived*.

```
SELECT name, fare, pclass, survived FROM df
```

If you don’t know how to use PySpark, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of code snippets. You can use to code snippets to perform tasks such as dropping columns, grouping by columns, or modelling.

To use a code snippet, choose **Search example snippets** and specify a query in the search bar. The text you specify in the query doesn’t have to match the name of the code snippet exactly.

The following example shows a **Drop duplicate rows** code snippet that can delete rows with similar data in your dataset. You can find the code snippet by searching for one of the following:

- Duplicates
- Identical
- Remove

The following snippet has comments to help you understand the changes that you need to make. For most snippets, you must specify the column names of your dataset in the code.

```
# Specify the subset of columns
# all rows having identical values in these columns will be dropped

subset = ["col1", "col2", "col3"]
df = df.dropDuplicates(subset)

# to drop the full-duplicate rows run
# df = df.dropDuplicates()
```

To use a snippet, copy and paste its content into the **Custom transform** field. You can copy and paste multiple code snippets into the custom transform field.

Custom Formula

Use **Custom formula** to define a new column using a Spark SQL expression to query data in the current dataframe. The query must use the conventions of Spark SQL expressions.

> **Important**
>
> **Custom formula** doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the **Rename column** transform in the **Manage columns** transform group to remove spaces from a column's name. You can also add a **Python (Pandas) Custom transform** similar to the following to remove spaces from multiple columns in a single step. This example changes columns named `A column` and `B column` to `A_column` and `B_column` respectively.
>
> ```
> df.rename(columns={"A column": "A_column", "B column": "B_column"})
> ```

You can use this transform to perform operations on columns, referencing the columns by name. For example, assuming the current dataframe contains columns named *col_a* and *col_b*, you can use the following operation to produce an **Output column** that is the product of these two columns with the following code:

```
col_a * col_b
```

Other common operations include the following, assuming a dataframe contains `col_a` and `col_b` columns:

- Concatenate two columns: `concat(col_a, col_b)`
- Add two columns: `col_a + col_b`
- Subtract two columns: `col_a - col_b`
- Divide two columns: `col_a / col_b`
- Take the absolute value of a column: `abs(col_a)`

For more information, see the Spark documentation on selecting data.

Reduce Dimensionality within a Dataset

Reduce the dimensionality in your data by using Principal Component Analysis (PCA). The dimensionality of your dataset corresponds to the number of features. When you use dimensionality reduction in Data Wrangler, you get a new set of features called components. Each component accounts for some variability in the data.

The first component accounts for the largest amount of variation in the data. The second component accounts for the second largest amount of variation in the data, and so on.

You can use dimensionality reduction to reduce the size of the data sets that you use to train models. Instead of using the features in your dataset, you can use the principal components instead.

To perform PCA, Data Wrangler creates axes for your data. An axis is an affine combination of columns in your dataset. The first principal component is the value on the axis that has the largest amount of variance. The second principal component is the value on the axis that has the second largest amount of variance. The nth principal component is the value on the axis that has the nth largest amount of variance.

You can configure the number of principal components that Data Wrangler returns. You can either specify the number of principal components directly or you can specify the variance threshold percentage. Each principal component explains an amount of variance in the data. For example, you might have a principal component with a value of 0.5. The component would explain 50% of the variation in the data. When you specify a variance threshold percentage, Data Wrangler returns the smallest number of components that meet the percentage that you specify.

The following are example principal components with the amount of variance that they explain in the data.

- Component 1 – 0.5
- Component 2 – 0.45
- Component 3 – 0.05

If you specify a variance threshold percentage of 94 or 95, Data Wrangler returns Component 1 and Component 2. If you specify a variance threshold percentage of 96, Data Wrangler returns all three principal components.

You can use the following procedure to run PCA on your dataset.

To run PCA on your dataset, do the following.

1. Open your Data Wrangler data flow.
2. Choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Dimensionality Reduction**.
5. For **Input Columns**, choose the features that you're reducing into the principal components.
6. (Optional) For **Number of principal components**, choose the number of principal components that Data Wrangler returns in your dataset. If specify a value for the field, you can't specify a value for **Variance threshold percentage**.
7. (Optional) For **Variance threshold percentage**, specify the percentage of variation in the data that you want explained by the principal components. Data Wrangler uses the default value of 95 if you don't specify a value for the variance threshold. You can't specify a variance threshold percentage if you've specified a value for **Number of principal components**.
8. (Optional) Deselect **Center** to not use the mean of the columns as the center of the data. By default, Data Wrangler centers the data with the mean before scaling.
9. (Optional) Deselect **Scale** to not scale the data with the unit standard deviation.
10. (Optional) Choose **Columns** to output the components to separate columns. Choose **Vector** to output the components as a single vector.
11. (Optional) For **Output column**, specify a name for an output column. If you're outputting the components to separate columns, the name that you specify is a prefix. If you're outputting the components to a vector, the name that you specify is the name of the vector column.
12. (Optional) Select **Keep input columns**. We don't recommend selecting this option if you plan on only using the principal components to train your model.
13. Choose **Preview**.
14. Choose **Add**.

Encode Categorical

Categorical data is usually composed of a finite number of categories, where each category is represented with a string. For example, if you have a table of customer data, a column that indicates the country a person lives in is categorical. The categories would be *Afghanistan*, *Albania*, *Algeria*, and so on. Categorical data can be *nominal* or *ordinal*. Ordinal categories have an inherent order, and nominal categories do not. The highest degree obtained (*High school*, *Bachelors*, *Masters*, and so on) is an example of ordinal categories.

Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are *Dog* and *Cat*, you may encode this information into two vectors, `[1,0]` to represent *Dog*, and `[0,1]` to represent *Cat*.

When you encode ordinal categories, you may need to translate the natural order of categories into your encoding. For example, you can represent the highest degree obtained with the following map: `{"High school": 1, "Bachelors": 2, "Masters":3}`.

Use categorical encoding to encode categorical data that is in string format into arrays of integers.

The Data Wrangler categorical encoders create encodings for all categories that exist in a column at the time the step is defined. If new categories have been added to a column when you start a Data Wrangler job to process your dataset at time *t*, and this column was the input for a Data Wrangler categorical encoding transform at time *t*-1, these new categories are considered *missing* in the Data Wrangler job. The option you select for **Invalid handling strategy** is applied to these missing values. Examples of when this can occur are:

- When you use a .flow file to create a Data Wrangler job to process a dataset that was updated after the creation of the data flow. For example, you may use a data flow to regularly process sales data each month. If that sales data is updated weekly, new categories may be introduced into columns for which an encode categorical step is defined.
- When you select **Sampling** when you import your dataset, some categories may be left out of the sample.

In these situations, these new categories are considered missing values in the Data Wrangler job.

You can choose from and configure an *ordinal* and a *one-hot encode*. Use the following sections to learn more about these options.

Both transforms create a new column named **Output column name**. You specify the output format of this column with **Output style**:

- Select **Vector** to produce a single column with a sparse vector.
- Select **Columns** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category.

Ordinal Encode

Select **Ordinal encode** to encode categories into an integer between 0 and the total number of categories in the **Input column** you select.

Invalid handing strategy: Select a method to handle invalid or missing values.

- Choose **Skip** if you want to omit the rows with missing values.
- Choose **Keep** to retain missing values as the last category.
- Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the **Input column**.
- Choose **Replace with NaN** to replace missing with NaN. This option is recommended if your ML algorithm can handle missing values. Otherwise, the first three options in this list may produce better results.

One-Hot Encode

Select **One-hot encode** for **Transform** to use one-hot encoding. Configure this transform using the following:

- **Drop last category**: If `True`, the last category does not have a corresponding index in the one-hot encoding. When missing values are possible, a missing category is always the last one and setting this to `True` means that a missing value results in an all zero vector.
- **Invalid handing strategy**: Select a method to handle invalid or missing values.
  - Choose **Skip** if you want to omit the rows with missing values.
  - Choose **Keep** to retain missing values as the last category.
  - Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the **Input column**.
- **Is input ordinal encoded**: Select this option if the input vector contains ordinal encoded data. This option requires that input data contain non-negative integers. If **True**, input *i* is encoded as a vector with a non-zero in the *i*th location.

Similarity encode

Use similarity encoding when you have the following:

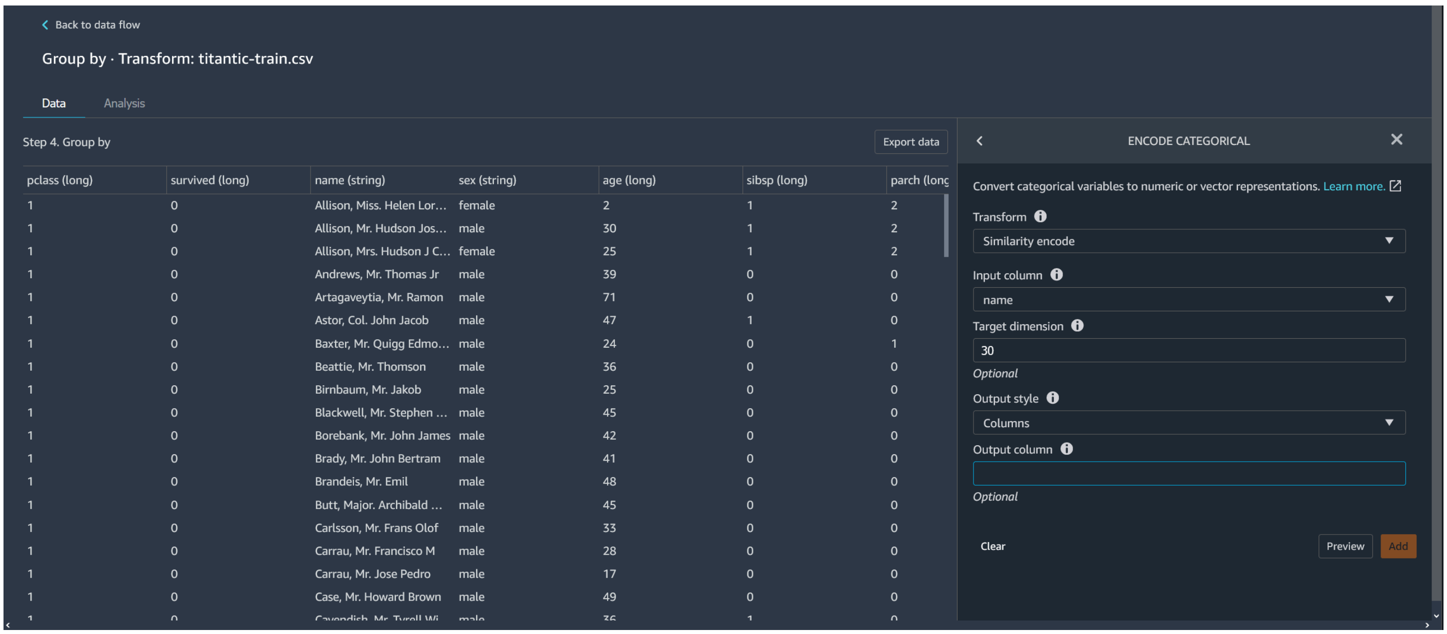
- A large number of categorical variables

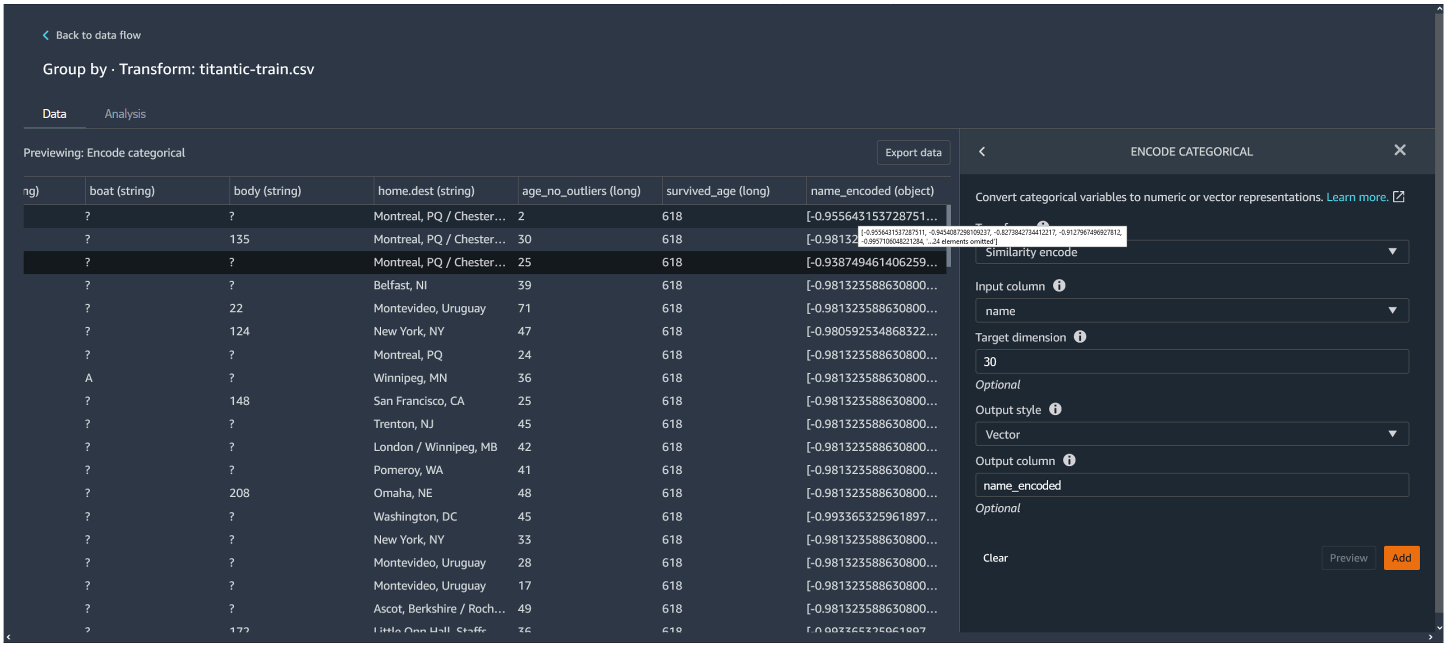
- Noisy data

The similarity encoder creates embeddings for columns with categorical data. An embedding is a mapping of discrete objects, such as words, to vectors of real numbers. It encodes similar strings to vectors containing similar values. For example, it creates very similar encodings for "California" and "Calfornia".

Data Wrangler converts each category in your dataset into a set of tokens using a 3-gram tokenizer. It converts the tokens into an embedding using min-hash encoding.

The following example shows how the similarity encoder creates vectors from strings.





The similarity encodings that Data Wrangler creates:

- Have low dimensionality
- Are scalable to a large number of categories
- Are robust and resistant to noise

For the preceding reasons, similarity encoding is more versatile than one-hot encoding.

To add the similarity encoding transform to your dataset, use the following procedure.

To use similarity encoding, do the following.

1. Sign in to the [Amazon SageMaker AI Console](https://console.aws.amazon.com/sagemaker/).
2. Choose **Open Studio Classic**.
3. Choose **Launch app**.
4. Choose **Studio**.
5. Specify your data flow.
6. Choose a step with a transformation.
7. Choose **Add step**.
8. Choose **Encode categorical**.
9. Specify the following:

- **Transform – Similarity encode**
- **Input column –** The column containing the categorical data that you're encoding.
- **Target dimension –** (Optional) The dimension of the categorical embedding vector. The default value is 30. We recommend using a larger target dimension if you have a large dataset with many categories.
- **Output style –** Choose **Vector** for a single vector with all of the encoded values. Choose **Column** to have the encoded values in separate columns.
- **Output column –** (Optional) The name of the output column for a vector encoded output. For a column-encoded output, this is the prefix of the column names followed by listed number.

Featurize Text

Use the **Featurize Text** transform group to inspect string-typed columns and use text embedding to featurize these columns.

This feature group contains two features, *Character statistics* and *Vectorize*. Use the following sections to learn more about these transforms. For both options, the **Input column** must contain text data (string type).

Character Statistics

Use **Character statistics** to generate statistics for each row in a column containing text data.

This transform computes the following ratios and counts for each row, and creates a new column to report the result. The new column is named using the input column name as a prefix and a suffix that is specific to the ratio or count.

- **Number of words**: The total number of words in that row. The suffix for this output column is `-stats_word_count`.
- **Number of characters**: The total number of characters in that row. The suffix for this output column is `-stats_char_count`.
- **Ratio of upper**: The number of uppercase characters, from A to Z, divided by all characters in the column. The suffix for this output column is `-stats_capital_ratio`.
- **Ratio of lower**: The number of lowercase characters, from a to z, divided by all characters in the column. The suffix for this output column is `-stats_lower_ratio`.

- **Ratio of digits**: The ratio of digits in a single row over the sum of digits in the input column. The suffix for this output column is `-stats_digit_ratio`.
- **Special characters ratio**: The ratio of non-alphanumeric (characters like #$&%:@) characters to over the sum of all characters in the input column. The suffix for this output column is `-stats_special_ratio`.

Vectorize

Text embedding involves mapping words or phrases from a vocabulary to vectors of real numbers. Use the Data Wrangler text embedding transform to tokenize and vectorize text data into term frequency–inverse document frequency (TF-IDF) vectors.

When TF-IDF is calculated for a column of text data, each word in each sentence is converted to a real number that represents its semantic importance. Higher numbers are associated with less frequent words, which tend to be more meaningful.

When you define a **Vectorize** transform step, Data Wrangler uses the data in your dataset to define the count vectorizer and TF-IDF methods . Running a Data Wrangler job uses these same methods.

You configure this transform using the following:

- **Output column name**: This transform creates a new column with the text embedding. Use this field to specify a name for this output column.
- **Tokenizer**: A tokenizer converts the sentence into a list of words, or *tokens*.

  Choose **Standard** to use a tokenizer that splits by white space and converts each word to lowercase. For example, `"Good dog"` is tokenized to `["good","dog"]`.

  Choose **Custom** to use a customized tokenizer. If you choose **Custom**, you can use the following fields to configure the tokenizer:

  - **Minimum token length**: The minimum length, in characters, for a token to be valid. Defaults to `1`. For example, if you specify `3` for minimum token length, words like `a, at, in` are dropped from the tokenized sentence.
  - **Should regex split on gaps**: If selected, **regex** splits on gaps. Otherwise, it matches tokens. Defaults to `True`.
  - **Regex pattern**: Regex pattern that defines the tokenization process. Defaults to `' \\ s+'`.
  - **To lowercase**: If chosen, Data Wrangler converts all characters to lowercase before tokenization. Defaults to `True`.

To learn more, see the Spark documentation on Tokenizer.

- **Vectorizer**: The vectorizer converts the list of tokens into a sparse numeric vector. Each token corresponds to an index in the vector and a non-zero indicates the existence of the token in the input sentence. You can choose from two vectorizer options, *Count* and *Hashing*.
  - **Count vectorize** allows customizations that filter infrequent or too common tokens. **Count vectorize parameters** include the following:
    - **Minimum term frequency**: In each row, terms (tokens) with smaller frequency are filtered. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to `1`.
    - **Minimum document frequency**: Minimum number of rows in which a term (token) must appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to `1`.
    - **Maximum document frequency**: Maximum number of documents (rows) in which a term (token) can appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to `0.999`.
    - **Maximum vocabulary size**: Maximum size of the vocabulary. The vocabulary is made up of all terms (tokens) in all rows of the column. Defaults to `262144`.
    - **Binary outputs**: If selected, the vector outputs do not include the number of appearances of a term in a document, but rather are a binary indicator of its appearance. Defaults to `False`.

    To learn more about this option, see the Spark documentation on CountVectorizer.
  - **Hashing** is computationally faster. **Hash vectorize parameters** includes the following:
    - **Number of features during hashing**: A hash vectorizer maps tokens to a vector index according to their hash value. This feature determines the number of possible hash values. Large values result in fewer collisions between hash values but a higher dimension output vector.

    To learn more about this option, see the Spark documentation on FeatureHasher
- **Apply IDF** applies an IDF transformation, which multiplies the term frequency with the standard inverse document frequency used for TF-IDF embedding. **IDF parameters** include the following:
  - **Minimum document frequency** : Minimum number of documents (rows) in which a term (token) must appear to be included. If **count_vectorize** is the chosen vectorizer, we

recommend that you keep the default value and only modify the **min_doc_freq** field in **Count vectorize parameters**. Defaults to 5.

- **Output format**:The output format of each row.
  - Select **Vector** to produce a single column with a sparse vector.
  - Select **Flattened** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category. You can only choose flattened when **Vectorizer** is set as **Count vectorizer**.

Transform Time Series

In Data Wrangler, you can transform time series data. The values in a time series dataset are indexed to specific time. For example, a dataset that shows the number of customers in a store for each hour in a day is a time series dataset. The following table shows an example of a time series dataset.

Hourly number of customers in a store

Number of customers	Time (hour)
4	09:00
10	10:00
14	11:00
25	12:00
20	13:00
18	14:00

For the preceding table, the **Number of Customers** column contains the time series data. The time series data is indexed on the hourly data in the **Time (hour)** column.

You might need to perform a series of transformations on your data to get it in a format that you can use for your analysis. Use the **Time series** transform group to transform your time series data. For more information about the transformations that you can perform, see the following sections.

Topics

Group by a Time Series

You can use the group by operation to group time series data for specific values in a column.

For example, you have the following table that tracks the average daily electricity usage in a household.

Average daily household electricity usage

Household ID	Daily timestamp	Electricity usage (kWh)	Number of household occupants
household_0	1/1/2020	30	2
household_0	1/2/2020	40	2
household_0	1/4/2020	35	3
household_1	1/2/2020	45	3
household_1	1/3/2020	55	4

If you choose to group by ID, you get the following table.

Electricity usage grouped by household ID

Household ID	Electricity usage series (kWh)	Number of household occupants series
household_0	[30, 40, 35]	[2, 2, 3]
household_1	[45, 55]	[3, 4]

Each entry in the time series sequence is ordered by the corresponding timestamp. The first element of the sequence corresponds to the first timestamp of the series. For `household_0`, `30` is the first value of the **Electricity Usage Series**. The value of `30` corresponds to the first timestamp of `1/1/2020`.

You can include the starting timestamp and ending timestamp. The following table shows how that information appears.

Electricity usage grouped by household ID

Household ID	Electricity usage series (kWh)	Number of household occupants series	Start_time	End_time
household_0	[30, 40, 35]	[2, 2, 3]	1/1/2020	1/4/2020
household_1	[45, 55]	[3, 4]	1/2/2020	1/3/2020

You can use the following procedure to group by a time series column.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Time Series**.
6. Under **Transform**, choose **Group by**.
7. Specify a column in **Group by this column**.
8. For **Apply to columns**, specify a value.

9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

Resample Time Series Data

Time series data usually has observations that aren't taken at regular intervals. For example, a dataset could have some observations that are recorded hourly and other observations that are recorded every two hours.

Many analyses, such as forecasting algorithms, require the observations to be taken at regular intervals. Resampling gives you the ability to establish regular intervals for the observations in your dataset.

You can either upsample or downsample a time series. Downsampling increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The hourly observations are aggregated into a single value using an aggregation method such as the mean or median.

Upsampling reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, you can use an interpolation method to infer hourly observations from the ones that have been taken every two hours. For information on interpolation methods, see [pandas.DataFrame.interpolate](https://pandas.pydata.org/docs/reference/api/pandas.DataFrame.interpolate.html).

You can resample both numeric and non-numeric data.

Use the **Resample** operation to resample your time series data. If you have multiple time series in your dataset, Data Wrangler standardizes the time interval for each time series.

The following table shows an example of downsampling time series data by using the mean as the aggregation method. The data is downsampled from every two hours to every hour.

Hourly temperature readings over a day before downsampling

Timestamp	Temperature (Celsius)
12:00	30
1:00	32

Timestamp	Temperature (Celsius)
2:00	35
3:00	32
4:00	30

Temperature readings downsampled to every two hours

Timestamp	Temperature (Celsius)
12:00	30
2:00	33.5
4:00	35

You can use the following procedure to resample time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Resample**.
6. For **Timestamp**, choose the timestamp column.
7. For **Frequency unit**, specify the frequency that you're resampling.
8. (Optional) Specify a value for **Frequency quantity**.
9. Configure the transform by specifying the remaining fields.
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

Handle Missing Time Series Data

If you have missing values in your dataset, you can do one of the following:

- For datasets that have multiple time series, drop the time series that have missing values that are greater than a threshold that you specify.
- Impute the missing values in a time series by using other values in the time series.

Imputing a missing value involves replacing the data by either specifying a value or by using an inferential method. The following are the methods that you can use for imputation:

- Constant value – Replace all the missing data in your dataset with a value that you specify.
- Most common value – Replace all the missing data with the value that has the highest frequency in the dataset.
- Forward fill – Use a forward fill to replace the missing values with the non-missing value that precedes the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 7. The sequence that results from using a forward fill is [2, 4, 7, 7, 7, 7, 8].
- Backward fill – Use a backward fill to replace the missing values with the non-missing value that follows the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 8. The sequence that results from using a backward fill is [2, 4, 7, 8, 8, 8, 8].
- Interpolate – Uses an interpolation function to impute the missing values. For more information on the functions that you can use for interpolation, see pandas.DataFrame.interpolate.

Some of the imputation methods might not be able to impute of all the missing value in your dataset. For example, a **Forward fill** can't impute a missing value that appears at the beginning of the time series. You can impute the values by using either a forward fill or a backward fill.

You can either impute missing values within a cell or within a column.

The following example shows how values are imputed within a cell.

Electricity usage with missing values

Household ID	Electricity usage series (kWh)
household_0	[30, 40, 35, NaN, NaN]
household_1	[45, NaN, 55]

Electricity usage with values imputed using a forward fill

Household ID	Electricity usage series (kWh)
household_0	[30, 40, 35, 35, 35]
household_1	[45, 45, 55]

The following example shows how values are imputed within a column.

Average daily household electricity usage with missing values

Household ID	Electricity usage (kWh)
household_0	30
household_0	40
household_0	NaN
household_1	NaN
household_1	NaN

Average daily household electricity usage with values imputed using a forward fill

Household ID	Electricity usage (kWh)
household_0	30
household_0	40
household_0	40
household_1	40
household_1	40

You can use the following procedure to handle missing values.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Handle missing**.
6. For **Time series input type**, choose whether you want to handle missing values inside of a cell or along a column.
7. For **Impute missing values for this column**, specify the column that has the missing values.
8. For **Method for imputing values**, select a method.
9. Configure the transform by specifying the remaining fields.
10. Choose **Preview** to generate a preview of the transform.
11. If you have missing values, you can specify a method for imputing them under **Method for imputing values**.
12. Choose **Add** to add the transform to the Data Wrangler data flow.

Validate the Timestamp of Your Time Series Data

You might have time stamp data that is invalid. You can use the **Validate time stamp** function to determine whether the timestamps in your dataset are valid. Your timestamp can be invalid for one or more of the following reasons:

- Your timestamp column has missing values.
- The values in your timestamp column are not formatted correctly.

If you have invalid timestamps in your dataset, you can't perform your analysis successfully. You can use Data Wrangler to identify invalid timestamps and understand where you need to clean your data.

The time series validation works in one of the two ways:

You can configure Data Wrangler to do one of the following if it encounters missing values in your dataset:

- Drop the rows that have the missing or invalid values.
- Identify the rows that have the missing or invalid values.
- Throw an error if it finds any missing or invalid values in your dataset.

You can validate the timestamps on columns that either have the `timestamp` type or the `string` type. If the column has the `string` type, Data Wrangler converts the type of the column to `timestamp` and performs the validation.

You can use the following procedure to validate the timestamps in your dataset.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Validate timestamps**.
6. For **Timestamp Column**, choose the timestamp column.
7. For **Policy**, choose whether you want to handle missing timestamps.
8. (Optional) For **Output column**, specify a name for the output column.
9. If the date time column is formatted for the string type, choose **Cast to datetime**.
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

Standardizing the Length of the Time Series

If you have time series data stored as arrays, you can standardize each time series to the same length. Standardizing the length of the time series array might make it easier for you to perform your analysis on the data.

You can standardize your time series for data transformations that require the length of your data to be fixed.

Many ML algorithms require you to flatten your time series data before you use them. Flattening time series data is separating each value of the time series into its own column in a dataset. The number of columns in a dataset can't change, so the lengths of the time series need to be standardized between you flatten each array into a set of features.

Each time series is set to the length that you specify as a quantile or percentile of the time series set. For example, you can have three sequences that have the following lengths:

- 3
- 4
- 5

You can set the length of all of the sequences as the length of the sequence that has the 50th percentile length.

Time series arrays that are shorter than the length you've specified have missing values added. The following is an example format of standardizing the time series to a longer length: [2, 4, 5, NaN, NaN, NaN].

You can use different approaches to handle the missing values. For information on those approaches, see Handle Missing Time Series Data.

The time series arrays that are longer than the length that you specify are truncated.

You can use the following procedure to standardize the length of the time series.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Standardize length**.
6. For **Standardize the time series length for the column**, choose a column.
7. (Optional) For **Output column**, specify a name for the output column. If you don't specify a name, the transform is done in place.
8. If the datetime column is formatted for the string type, choose **Cast to datetime**.
9. Choose **Cutoff quantile** and specify a quantile to set the length of the sequence.
10. Choose **Flatten the output** to output the values of the time series into separate columns.
11. Choose **Preview** to generate a preview of the transform.
12. Choose **Add** to add the transform to the Data Wrangler data flow.

Extract Features from Your Time Series Data

If you're running a classification or a regression algorithm on your time series data, we recommend extracting features from the time series before running the algorithm. Extracting features might improve the performance of your algorithm.

Use the following options to choose how you want to extract features from your data:

- Use **Minimal subset** to specify extracting 8 features that you know are useful in downstream analyses. You can use a minimal subset when you need to perform computations quickly. You can also use it when your ML algorithm has a high risk of overfitting and you want to provide it with fewer features.
- Use **Efficient subset** to specify extracting the most features possible without extracting features that are computationally intensive in your analyses.
- Use **All features** to specify extracting all features from the tune series.
- Use **Manual subset** to choose a list of features that you think explain the variation in your data well.

Use the following the procedure to extract features from your time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Extract features**.
6. For **Extract features for this column**, choose a column.
7. (Optional) Select **Flatten** to output the features into separate columns.
8. For **Strategy**, choose a strategy to extract the features.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

Use Lagged Features from Your Time Series Data

For many use cases, the best way to predict the future behavior of your time series is to use its most recent behavior.

The most common uses of lagged features are the following:

- Collecting a handful of past values. For example, for time, t + 1, you collect t, t - 1, t - 2, and t - 3.
- Collecting values that correspond to seasonal behavior in the data. For example, to predict the occupancy in a restaurant at 1:00 PM, you might want to use the features from 1:00 PM on the previous day. Using the features from 12:00 PM or 11:00 AM on the same day might not be as predictive as using the features from previous days.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Lag features**.
6. For **Generate lag features for this column**, choose a column.
7. For **Timestamp Column**, choose the column containing the timestamps.
8. For **Lag**, specify the duration of the lag.
9. (Optional) Configure the output using one of the following options:
   - **Include the entire lag window**
   - **Flatten the output**
   - **Drop rows without history**
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

Create a Datetime Range In Your Time Series

You might have time series data that don't have timestamps. If you know that the observations were taken at regular intervals, you can generate timestamps for the time series in a separate column. To generate timestamps, you specify the value for the start timestamp and the frequency of the timestamps.

For example, you might have the following time series data for the number of customers at a restaurant.

Time series data on the number of customers at a restaurant

Number of customers
10
14
24
40
30
20

If you know that the restaurant opened at 5:00 PM and that the observations are taken hourly, you can add a timestamp column that corresponds to the time series data. You can see the timestamp column in the following table.

Time series data on the number of customers at a restaurant

Number of customers	Timestamp
10	1:00 PM
14	2:00 PM
24	3:00 PM
40	4:00 PM
30	5:00 PM
20	6:00 PM

Use the following procedure to add a datetime range to your data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.

3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Datetime range**.
6. For **Frequency type**, choose the unit used to measure the frequency of the timestamps.
7. For **Starting timestamp**, specify the start timestamp.
8. For **Output column**, specify a name for the output column.
9. (Optional) Configure the output using the remaining fields.
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

Use a Rolling Window In Your Time Series

You can extract features over a time period. For example, for time, *t*, and a time window length of 3, and for the row that indicates the *t*th timestamp, we append the features that are extracted from the time series at times *t* - 3, *t* -2, and *t* - 1. For information on extracting features, see Extract Features from Your Time Series Data.

You can use the following procedure to extract features over a time period.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Rolling window features**.
6. For **Generate rolling window features for this column**, choose a column.
7. For **Timestamp Column**, choose the column containing the timestamps.
8. (Optional) For **Output Column**, specify the name of the output column.
9. For **Window size**, specify the window size.
10. For **Strategy**, choose the extraction strategy.
11. Choose **Preview** to generate a preview of the transform.
12. Choose **Add** to add the transform to the Data Wrangler data flow.

Featurize Datetime

Use **Featurize date/time** to create a vector embedding representing a datetime field. To use this transform, your datetime data must be in one of the following formats:

- Strings describing datetime: For example, `"January 1st, 2020, 12:44pm"`.
- A Unix timestamp: A Unix timestamp describes the number of seconds, milliseconds, microseconds, or nanoseconds from 1/1/1970.

You can choose to **Infer datetime format** and provide a **Datetime format**. If you provide a datetime format, you must use the codes described in the Python documentation. The options you select for these two configurations have implications for the speed of the operation and the final results.

- The most manual and computationally fastest option is to specify a **Datetime format** and select **No** for **Infer datetime format**.
- To reduce manual labor, you can choose **Infer datetime format** and not specify a datetime format. It is also a computationally fast operation; however, the first datetime format encountered in the input column is assumed to be the format for the entire column. If there are other formats in the column, these values are NaN in the final output. Inferring the datetime format can give you unparsed strings.
- If you don't specify a format and select **No** for **Infer datetime format**, you get the most robust results. All the valid datetime strings are parsed. However, this operation can be an order of magnitude slower than the first two options in this list.

When you use this transform, you specify an **Input column** which contains datetime data in one of the formats listed above. The transform creates an output column named **Output column name**. The format of the output column depends on your configuration using the following:

- **Vector**: Outputs a single column as a vector.
- **Columns**: Creates a new column for every feature. For example, if the output contains a year, month, and day, three separate columns are created for year, month, and day.

Additionally, you must choose an **Embedding mode**. For linear models and deep networks, we recommend choosing **cyclic**. For tree-based algorithms, we recommend choosing **ordinal**.

Format String

The **Format string** transforms contain standard string formatting operations. For example, you can use these operations to remove special characters, normalize string lengths, and update string casing.

This feature group contains the following transforms. All transforms return copies of the strings in the **Input column** and add the result to a new, output column.

Name	Function
Left pad	Left-pad the string with a given **Fill character** to the given **width**. If the string is longer than **width**, the return value is shortened to **width** characters.
Right pad	Right-pad the string with a given **Fill character** to the given **width**. If the string is longer than **width**, the return value is shortened to **width** characters.
Center (pad on either side)	Center-pad the string (add padding on both sides of the string) with a given **Fill character** to the given **width**. If the string is longer than **width**, the return value is shortened to **width** characters.
Prepend zeros	Left-fill a numeric string with zeros, up to a given **width**. If the string is longer than **width**, the return value is shortened to **width** characters.
Strip left and right	Returns a copy of the string with the leading and trailing characters removed.
Strip characters from left	Returns a copy of the string with leading characters removed.

Name	Function
Strip characters from right	Returns a copy of the string with trailing characters removed.
Lower case	Convert all letters in text to lowercase.
Upper case	Convert all letters in text to uppercase.
Capitalize	Capitalize the first letter in each sentence.
Swap case	Converts all uppercase characters to lowercase and all lowercase characters to uppercase characters of the given string, and returns it.
Add prefix or suffix	Adds a prefix and a suffix the string column. You must specify at least one of **Prefix** and **Suffix**.
Remove symbols	Removes given symbols from a string. All listed characters are removed. Defaults to white space.

Handle Outliers

Machine learning models are sensitive to the distribution and range of your feature values. Outliers, or rare values, can negatively impact model accuracy and lead to longer training times. Use this feature group to detect and update outliers in your dataset.

When you define a **Handle outliers** transform step, the statistics used to detect outliers are generated on the data available in Data Wrangler when defining this step. These same statistics are used when running a Data Wrangler job.

Use the following sections to learn more about the transforms this group contains. You specify an **Output name** and each of these transforms produces an output column with the resulting data.

Robust standard deviation numeric outliers

This transform detects and fixes outliers in numeric features using statistics that are robust to outliers.

You must define an **Upper quantile** and a **Lower quantile** for the statistics used to calculate outliers. You must also specify the number of **Standard deviations** from which a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Standard Deviation Numeric Outliers

This transform detects and fixes outliers in numeric features using the mean and standard deviation.

You specify the number of **Standard deviations** a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Quantile Numeric Outliers

Use this transform to detect and fix outliers in numeric features using quantiles. You can define an **Upper quantile** and a **Lower quantile**. All values that fall above the upper quantile or below the lower quantile are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.

- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Min-Max Numeric Outliers

This transform detects and fixes outliers in numeric features using upper and lower thresholds. Use this method if you know threshold values that demark outliers.

You specify a **Upper threshold** and a **Lower threshold**, and if values fall above or below those thresholds respectively, they are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Replace Rare

When you use the **Replace rare** transform, you specify a threshold and Data Wrangler finds all values that meet that threshold and replaces them with a string that you specify. For example, you may want to use this transform to categorize all outliers in a column into an "Others" category.

- **Replacement string**: The string with which to replace outliers.
- **Absolute threshold**: A category is rare if the number of instances is less than or equal to this absolute threshold.
- **Fraction threshold**: A category is rare if the number of instances is less than or equal to this fraction threshold multiplied by the number of rows.
- **Max common categories**: Maximum not-rare categories that remain after the operation. If the threshold does not filter enough categories, those with the top number of appearances are classified as not rare. If set to 0 (default), there is no hard limit to the number of categories.

Handle Missing Values

Missing values are a common occurrence in machine learning datasets. In some situations, it is appropriate to impute missing data with a calculated value, such as an average or categorically common value. You can process missing values using the **Handle missing values** transform group. This group contains the following transforms.

Fill Missing

Use the **Fill missing** transform to replace missing values with a **Fill value** you define.

Impute Missing

Use the **Impute missing** transform to create a new column that contains imputed values where missing values were found in input categorical and numerical data. The configuration depends on your data type.

For numeric data, choose an imputing strategy, the strategy used to determine the new value to impute. You can choose to impute the mean or the median over the values that are present in your dataset. Data Wrangler uses the value that it computes to impute the missing values.

For categorical data, Data Wrangler imputes missing values using the most frequent value in the column. To impute a custom string, use the **Fill missing** transform instead.

Add Indicator for Missing

Use the **Add indicator for missing** transform to create a new indicator column, which contains a Boolean `"false"` if a row contains a value, and `"true"` if a row contains a missing value.

Drop Missing

Use the **Drop missing** option to drop rows that contain missing values from the **Input column**.

Manage Columns

You can use the following transforms to quickly update and manage columns in your dataset:

Name	Function
Drop Column	Delete a column.
Duplicate Column	Duplicate a column.
Rename Column	Rename a column.
Move Column	Move a column's location in the dataset. Choose to move your column to the start or

Name	Function
	end of the dataset, before or after a reference column, or to a specific index.

Manage Rows

Use this transform group to quickly perform sort and shuffle operations on rows. This group contains the following:

- **Sort**: Sort the entire dataframe by a given column. Select the check box next to **Ascending order** for this option; otherwise, deselect the check box and descending order is used for the sort.
- **Shuffle**: Randomly shuffle all rows in the dataset.

Manage Vectors

Use this transform group to combine or flatten vector columns. This group contains the following transforms.

- **Assemble**: Use this transform to combine Spark vectors and numeric data into a single column. For example, you can combine three columns: two containing numeric data and one containing vectors. Add all the columns you want to combine in **Input columns** and specify a **Output column name** for the combined data.
- **Flatten**: Use this transform to flatten a single column containing vector data. The input column must contain PySpark vectors or array-like objects. You can control the number of columns created by specifying a **Method to detect number of outputs**. For example, if you select **Length of first vector**, the number of elements in the first valid vector or array found in the column determines the number of output columns that are created. All other input vectors with too many items are truncated. Inputs with too few items are filled with NaNs.

  You also specify an **Output prefix**, which is used as the prefix for each output column.

Process Numeric

Use the **Process Numeric** feature group to process numeric data. Each scalar in this group is defined using the Spark library. The following scalars are supported:

- **Standard Scaler**: Standardize the input column by subtracting the mean from each value and scaling to unit variance. To learn more, see the Spark documentation for StandardScaler.
- **Robust Scaler**: Scale the input column using statistics that are robust to outliers. To learn more, see the Spark documentation for RobustScaler.
- **Min Max Scaler**: Transform the input column by scaling each feature to a given range. To learn more, see the Spark documentation for MinMaxScaler.
- **Max Absolute Scaler**: Scale the input column by dividing each value by the maximum absolute value. To learn more, see the Spark documentation for MaxAbsScaler.

Sampling

After you've imported your data, you can use the **Sampling** transformer to take one or more samples of it. When you use the sampling transformer, Data Wrangler samples your original dataset.

You can choose one of the following sample methods:

- **Limit**: Samples the dataset starting from the first row up to the limit that you specify.
- **Randomized**: Takes a random sample of a size that you specify.
- **Stratified**: Takes a stratified random sample.

You can stratify a randomized sample to make sure that it represents the original distribution of the dataset.

You might be performing data preparation for multiple use cases. For each use case, you can take a different sample and apply a different set of transformations.

The following procedure describes the process of creating a random sample.

To take a random sample from your data.

1. Choose the **+** to the right of the dataset that you've imported. The name of your dataset is located below the **+**.
2. Choose **Add transform**.
3. Choose **Sampling**.
4. For **Sampling method**, choose the sampling method.

5. For **Approximate sample size**, choose the approximate number of observations that you want in your sample.
6. (Optional) Specify an integer for **Random seed** to create a reproducible sample.

The following procedure describes the process of creating a stratified sample.

To take a stratified sample from your data.

1. Choose the **+** to the right of the dataset that you've imported. The name of your dataset is located below the **+**.
2. Choose **Add transform**.
3. Choose **Sampling**.
4. For **Sampling method**, choose the sampling method.
5. For **Approximate sample size**, choose the approximate number of observations that you want in your sample.
6. For **Stratify column**, specify the name of the column that you want to stratify on.
7. (Optional) Specify an integer for **Random seed** to create a reproducible sample.

Search and Edit

Use this section to search for and edit specific patterns within strings. For example, you can find and update strings within sentences or documents, split strings by delimiters, and find occurrences of specific strings.

The following transforms are supported under **Search and edit**. All transforms return copies of the strings in the **Input column** and add the result to a new output column.

Name	Function
Find substring	Returns the index of the first occurrence of the **Substring** for which you searched , You can start and end the search at **Start** and **End** respectively.
Find substring (from right)	Returns the index of the last occurrence of the **Substring** for which you searched. You

Name	Function
	can start and end the search at **Start** and **End** respectively.
Matches prefix	Returns a Boolean value if the string contains a given **Pattern**. A pattern can be a character sequence or regular expression. Optionally, you can make the pattern case sensitive.
Find all occurrences	Returns an array with all occurrences of a given pattern. A pattern can be a character sequence or regular expression.
Extract using regex	Returns a string that matches a given Regex pattern.
Extract between delimiters	Returns a string with all characters found between **Left delimiter** and **Right delimiter**.
Extract from position	Returns a string, starting from **Start position** in the input string, that contains all characters up to the start position plus **Length**.
Find and replace substring	Returns a string with all matches of a given **Pattern** (regular expression) replaced by **Replacement string**.
Replace between delimiters	Returns a string with the substring found between the first appearance of a **Left delimiter** and the last appearance of a **Right delimiter** replaced by **Replacement string**. If no match is found, nothing is replaced.

Name	Function
Replace from position	Returns a string with the substring between **Start position** and **Start position** plus **Length** replaced by **Replacement string**. If **Start position** plus **Length** is greater than the length of the replacement string, the output contains **...**.
Convert regex to missing	Converts a string to None if invalid and returns the result. Validity is defined with a regular expression in **Pattern**.
Split string by delimiter	Returns an array of strings from the input string, split by **Delimiter**, with up to **Max number of splits** (optional). The delimiter defaults to white space.

Split data

Use the **Split data** transform to split your dataset into two or three datasets. For example, you can split your dataset into a dataset used to train your model and a dataset used to test it. You can determine the proportion of the dataset that goes into each split. For example, if you're splitting one dataset into two datasets, the training dataset can have 80% of the data while the testing dataset has 20%.

Splitting your data into three datasets gives you the ability to create training, validation, and test datasets. You can see how well the model performs on the test dataset by dropping the target column.

Your use case determines how much of the original dataset each of your datasets get and the method you use to split the data. For example, you might want to use a stratified split to make sure that the distribution of the observations in the target column are the same across datasets. You can use the following split transforms:

- Randomized split — Each split is a random, non-overlapping sample of the original dataset. For larger datasets, using a randomized split might be computationally expensive and take longer than an ordered split.

- Ordered split – Splits the dataset based on the sequential order of the observations. For example, for an 80/20 train-test split, the first observations that make up 80% of the dataset go to the training dataset. The last 20% of the observations go to the testing dataset. Ordered splits are effective in keeping the existing order of the data between splits.
- Stratified split – Splits the dataset to make sure that the number of observations in the input column have proportional representation. For an input column that has the observations 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, an 80/20 split on the column would mean that approximately 80% of the 1s, 80% of the 2s, and 80% of the 3s go to the training set. About 20% of each type of observation go to the testing set.
- Split by key – Avoids data with the same key occurring in more than one split. For example, if you have a dataset with the column 'customer_id' and you're using it as a key, no customer id is in more than one split.

After you split the data, you can apply additional transformations to each dataset. For most use cases, they aren't necessary.

Data Wrangler calculates the proportions of the splits for performance. You can choose an error threshold to set the accuracy of the splits. Lower error thresholds more accurately reflect the proportions that you specify for the splits. If you set a higher error threshold, you get better performance, but lower accuracy.

For perfectly split data, set the error threshold to 0. You can specify a threshold between 0 and 1 for better performance. If you specify a value greater than 1, Data Wrangler interprets that value as 1.

If you have 10000 rows in your dataset and you specify an 80/20 split with an error of 0.001, you would get observations approximating one of the following results:

- 8010 observations in the training set and 1990 in the testing set
- 7990 observations in the training set and 2010 in the testing set

The number of observations for the testing set in the preceding example is in the interval between 8010 and 7990.

By default, Data Wrangler uses a random seed to make the splits reproducible. You can specify a different value for the seed to create a different reproducible split.

Randomized split

Use the following procedure to perform a randomized split on your dataset.

To split your dataset randomly, do the following

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
5. (Optional) Choose the **+** to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
6. (Optional) Specify a value for **Error threshold** other than the default value.
7. (Optional) Specify a value for **Random seed**.
8. Choose **Preview**.
9. Choose **Add**.

Ordered split

Use the following procedure to perform an ordered split on your dataset.

To make an ordered split in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. For **Transform**, choose **Ordered split**.
4. Choose **Split data**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. (Optional) Specify a value for **Error threshold** other than the default value.

8. (Optional) For **Input column**, specify a column with numeric values. Uses the values of the columns to infer which records are in each split. The smaller values are in one split with the larger values in the other splits.
9. (Optional) Select **Handle duplicates** to add noise to duplicate values and create a dataset of entirely unique values.
10. (Optional) Specify a value for **Random seed**.
11. Choose **Preview**.
12. Choose **Add**.

Stratified split

Use the following procedure to perform a stratified split on your dataset.

To make a stratified split in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Stratified split**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Input column**, specify a column with up to 100 unique values. Data Wrangler can't stratify a column with more than 100 unique values.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. (Optional) Specify a value for **Random seed** to specify a different seed.
10. Choose **Preview**.
11. Choose **Add**.

Split by column keys

Use the following procedure to split by the column keys in your dataset.

To split by the column keys in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Split by key**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Key columns**, specify the columns with values that you don't want to appear in both datasets.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. Choose **Preview**.
10. Choose **Add**.

Parse Value as Type

Use this transform to cast a column to a new type. The supported Data Wrangler data types are:

- Long
- Float
- Boolean
- Date, in the format dd-MM-yyyy, representing day, month, and year respectively.
- String

Validate String

Use the **Validate string** transforms to create a new column that indicates that a row of text data meets a specified condition. For example, you can use a **Validate string** transform to verify that a string only contains lowercase characters. The following transforms are supported under **Validate string**.

The following transforms are included in this transform group. If a transform outputs a Boolean value, `True` is represented with a 1 and `False` is represented with a `0`.

Name	Function
String length	Returns `True` if a string length equals specified length. Otherwise, returns `False`.
Starts with	Returns `True` if a string starts will a specified prefix. Otherwise, returns `False`.
Ends with	Returns `True` if a string length equals specified length. Otherwise, returns `False`.
Is alphanumeric	Returns `True` if a string only contains numbers and letters. Otherwise, returns `False`.
Is alpha (letters)	Returns `True` if a string only contains letters. Otherwise, returns `False`.
Is digit	Returns `True` if a string only contains digits. Otherwise, returns `False`.
Is space	Returns `True` if a string only contains numbers and letters. Otherwise, returns `False`.
Is title	Returns `True` if a string contains any white spaces. Otherwise, returns `False`.
Is lowercase	Returns `True` if a string only contains lower case letters. Otherwise, returns `False`.
Is uppercase	Returns `True` if a string only contains upper case letters. Otherwise, returns `False`.
Is numeric	Returns `True` if a string only contains numbers. Otherwise, returns `False`.

Name	Function
Is decimal	Returns `True` if a string only contains decimal numbers. Otherwise, returns `False`.

Unnest JSON Data

If you have a .csv file, you might have values in your dataset that are JSON strings. Similarly, you might have nested data in columns of either a Parquet file or a JSON document.

Use the **Flatten structured** operator to separate the first level keys into separate columns. A first level key is a key that isn't nested within a value.

For example, you might have a dataset that has a *person* column with demographic information on each person stored as JSON strings. A JSON string might look like the following.

```
"{"seq": 1,"name": {"first": "Nathaniel","last": "Ferguson"},"age": 59,"city":
"Posbotno","state": "WV"}"
```

The **Flatten structured** operator converts the following first level keys into additional columns in your dataset:

- seq
- name
- age
- city
- state

Data Wrangler puts the values of the keys as values under the columns. The following shows the column names and values of the JSON.

```
seq, name,                                    age, city, state
1, {"first": "Nathaniel","last": "Ferguson"}, 59, Posbotno, WV
```

For each value in your dataset containing JSON, the **Flatten structured** operator creates columns for the first-level keys. To create columns for nested keys, call the operator again. For the preceding example, calling the operator creates the columns:

- name_first
- name_last

The following example shows the dataset that results from calling the operation again.

```
seq, name,                                    age, city, state, name_first, name_last
1, {"first": "Nathaniel","last": "Ferguson"}, 59, Posbotno, WV, Nathaniel, Ferguson
```

Choose **Keys to flatten on** to specify the first-level keys that want to extract as separate columns. If you don't specify any keys, Data Wrangler extracts all the keys by default.

Explode Array

Use **Explode array** to expand the values of the array into separate output rows. For example, the operation can take each value in the array, [[1, 2, 3,], [4, 5, 6], [7, 8, 9]] and create a new column with the following rows:

```
                [1, 2, 3]
                [4, 5, 6]
                [7, 8, 9]
```

Data Wrangler names the new column, input_column_name_flatten.

You can call the **Explode array** operation multiple times to get the nested values of the array into separate output columns. The following example shows the result of calling the operation multiple times on a dataset with a nested array.

Putting the values of a nested array into separate columns

id	array	id	array_items	id	array_items_items
1	[[cat, dog], [bat, frog]]	1	[cat, dog]	1	cat
2	[[rose, petunia], [lily, daisy]]	1	[bat, frog]	1	dog
		2	[rose, petunia]	1	bat
		2	[lily, daisy]	1	frog
			2	2	rose
			2	2	petunia
			2	2	lily
			2	2	daisy

Transform Image Data

Use Data Wrangler to import and transform the images that you're using for your machine learning (ML) pipelines. After you've prepared your image data, you can export it from your Data Wrangler flow to your ML pipeline.

You can use the information provided here to familiarize yourself with importing and transforming image data in Data Wrangler. Data Wrangler uses OpenCV to import images. For more information about supported image formats, see Image file reading and writing.

After you've familiarized yourself with the concepts of transforming your image data, go through the following tutorial, Prepare image data with Amazon SageMaker Data Wrangler.

The following industries and use cases are examples where applying machine learning to transformed image data can be useful:

- Manufacturing – Identifying defects in items from the assembly line

- Food – Identifying spoiled or rotten food
- Medicine – Identifying lesions in tissues

When you work with image data in Data Wrangler, you go through the following process:

1. Import – Select the images by choosing the directory containing them in your Amazon S3 bucket.
2. Transform – Use the built-in transformations to prepare the images for your machine learning pipeline.
3. Export – Export the images that you've transformed to a location that can be accessed from the pipeline.

Use the following procedure to import your image data.

To import your image data

1. Navigate to the **Create connection** page.
2. Choose **Amazon S3**.
3. Specify the Amazon S3 file path that contains the image data.
4. For **File type**, choose **Image**.
5. (Optional) Choose **Import nested directories** to import images from multiple Amazon S3 paths.
6. Choose **Import**.

Data Wrangler uses the open-source [imgaug](https://imgaug.readthedocs.io/en/latest/) library for its built-in image transformations. You can use the following built-in transformations:

- **ResizeImage**
- **EnhanceImage**
- **CorruptImage**
- **SplitImage**
- **DropCorruptedImages**
- **DropImageDuplicates**

- **Brightness**
- **ColorChannels**
- **Grayscale**
- **Rotate**

Use the following procedure to transform your images without writing code.

To transform the image data without writing code

1. From your Data Wrangler flow, choose the **+** next to the node representing the images that you've imported.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose the transform and configure it.
5. Choose **Preview**.
6. Choose **Add**.

In addition to using the transformations that Data Wrangler provides, you can also use your own custom code snippets. For more information about using custom code snippets, see Custom Transforms. You can import the OpenCV and imgaug libraries within your code snippets and use the transforms associated with them. The following is an example of a code snippet that detects edges within the images.

```
# A table with your image data is stored in the `df` variable
import cv2
import numpy as np
from pyspark.sql.functions import column

from sagemaker_dataprep.compute.operators.transforms.image.constants import
 DEFAULT_IMAGE_COLUMN, IMAGE_COLUMN_TYPE
from sagemaker_dataprep.compute.operators.transforms.image.decorators import
 BasicImageOperationDecorator, PandasUDFOperationDecorator

@BasicImageOperationDecorator
def my_transform(image: np.ndarray) -> np.ndarray:
```

```
 # To use the code snippet on your image data, modify the following lines within the
 function
    HYST_THRLD_1, HYST_THRLD_2 = 100, 200
    edges = cv2.Canny(image,HYST_THRLD_1,HYST_THRLD_2)
    return edges

@PandasUDFOperationDecorator(IMAGE_COLUMN_TYPE)
def custom_image_udf(image_row):
    return my_transform(image_row)

df = df.withColumn(DEFAULT_IMAGE_COLUMN,
 custom_image_udf(column(DEFAULT_IMAGE_COLUMN)))
```

When apply transformations in your Data Wrangler flow, Data Wrangler only applies them to a sample of the images in your dataset. To optimize your experience with the application, Data Wrangler doesn't apply the transforms to all of your images.

To apply the transformations to all of your images, export your Data Wrangler flow to an Amazon S3 location. You can use the images that you've exported in your training or inference pipelines. Use a destination node or a Jupyter Notebook to export your data. You can access either method for exporting your data from the Data Wrangler flow. For information about using these methods, see [Export to Amazon S3](#).

Filter data

Use Data Wrangler to filter the data in your columns. When you filter the data in a column, you specify the following fields:

- **Column name** – The name of the column that you're using to filter the data.
- **Condition** – The type of filter that you're applying to values in the column.
- **Value** – The value or category in the column to which you're applying the filter.

You can filter on the following conditions:

- **=** – Returns values that match the value or category that you specify.
- **!=** – Returns values that don't match the value or category that you specify.

- **>=** – For **Long** or **Float** data, filters for values that are greater than or equal to the value that you specify.
- **<=** – For **Long** or **Float** data, filters for values that are less than or equal to the value that you specify.
- **>** – For **Long** or **Float** data, filters for values that are greater than the value that you specify.
- **<** – For **Long** or **Float** data, filters for values that are less than the value that you specify.

For a column that has the categories, `male` and `female`, you can filter out all the `male` values. You could also filter for all the `female` values. Because there are only `male` and `female` values in the column, the filter returns a column that only has `female` values.

You can also add multiple filters. The filters can be applied across multiple columns or the same column. For example, if you're creating a column that only has values within a certain range, you add two different filters. One filter specifies that the column must have values greater than the value that you provide. The other filter specifies that the column must have values less than the value that you provide.

Use the following procedure to add the filter transform to your data.

To filter your data

1. From your Data Wrangler flow, choose the **+** next to the node with the data that you're filtering.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose **Filter data**.
5. Specify the following fields:
   - **Column name –** The column that you're filtering.
   - **Condition –** The condition of the filter.
   - **Value –** The value or category in the column to which you're applying the filter.
6. (Optional) Choose **+** following the filter that you've created.
7. Configure the filter.
8. Choose **Preview**.
9. Choose **Add**.

Map Columns for Amazon Personalize

Data Wrangler integrates with Amazon Personalize, a fully managed machine learning service that generates item recommendations and user segments. You can use the **Map columns for Amazon Personalize** transform to get your data into a format that Amazon Personalize can interpret. For more information about the transforms specific to Amazon Personalize, see Importing data using Amazon SageMaker Data Wrangler. For more information about Amazon Personalize see What is Amazon Personalize?

Analyze and Visualize

Amazon SageMaker Data Wrangler includes built-in analyses that help you generate visualizations and data analyses in a few clicks. You can also create custom analyses using your own code.

You add an analysis to a dataframe by selecting a step in your data flow, and then choosing **Add analysis**. To access an analysis you've created, select the step that contains the analysis, and select the analysis.

All analyses are generated using 100,000 rows of your dataset.

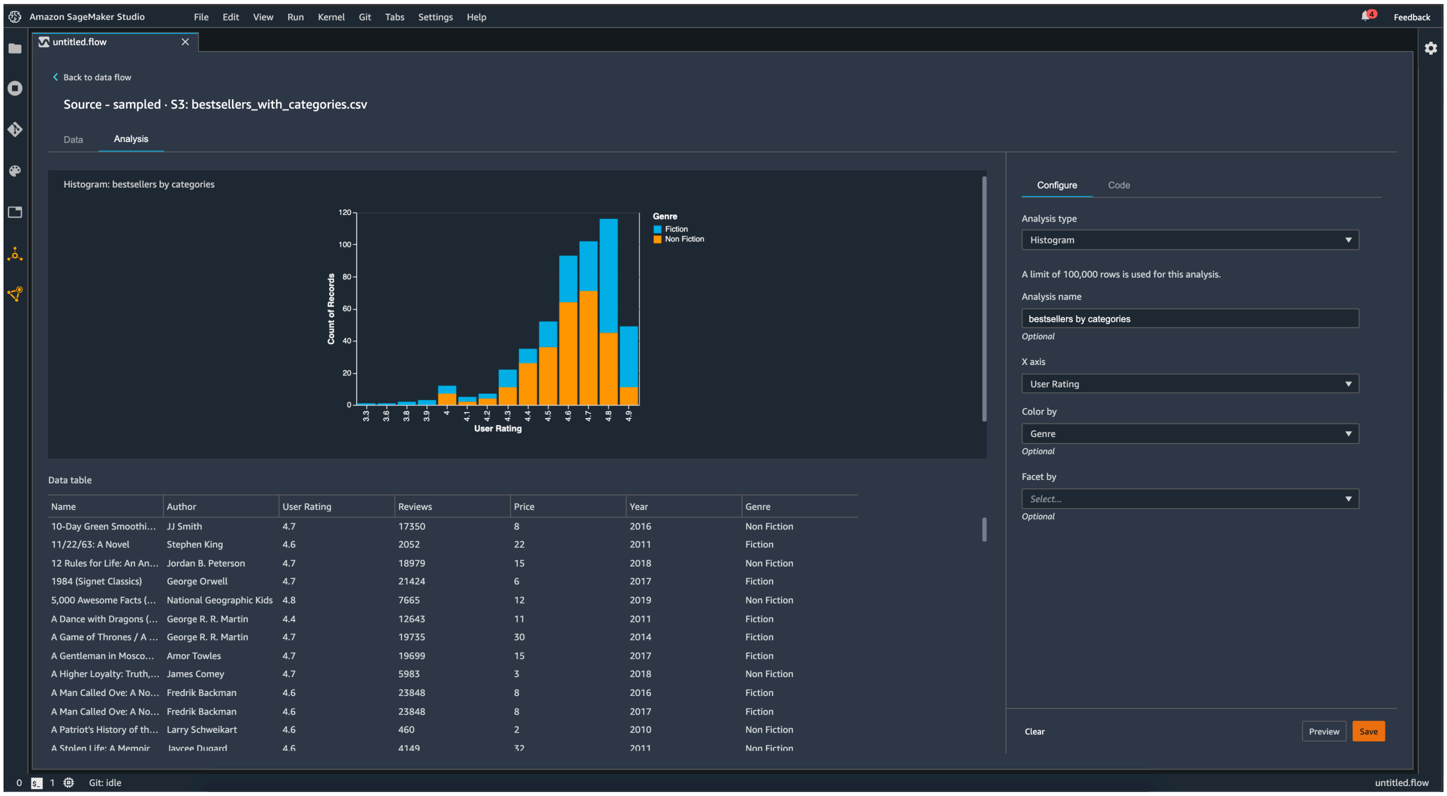
You can add the following analysis to a dataframe:

- Data visualizations, including histograms and scatter plots.
- A quick summary of your dataset, including number of entries, minimum and maximum values (for numeric data), and most and least frequent categories (for categorical data).
- A quick model of the dataset, which can be used to generate an importance score for each feature.
- A target leakage report, which you can use to determine if one or more features are strongly correlated with your target feature.
- A custom visualization using your own code.

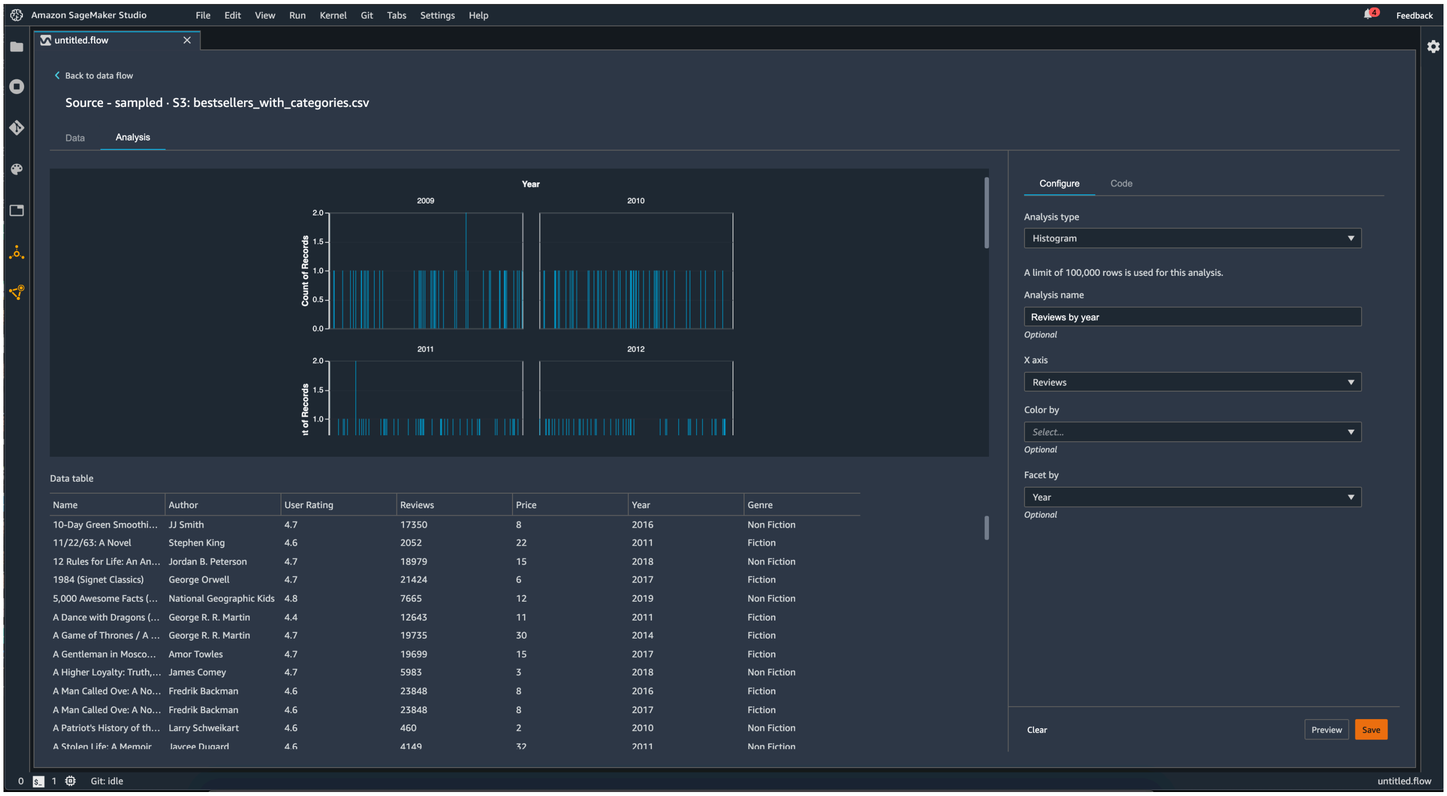
Use the following sections to learn more about these options.

Histogram

Use histograms to see the counts of feature values for a specific feature. You can inspect the relationships between features using the **Color by** option. For example, the following histogram charts the distribution of user ratings of the best-selling books on Amazon from 2009–2019, colored by genre.



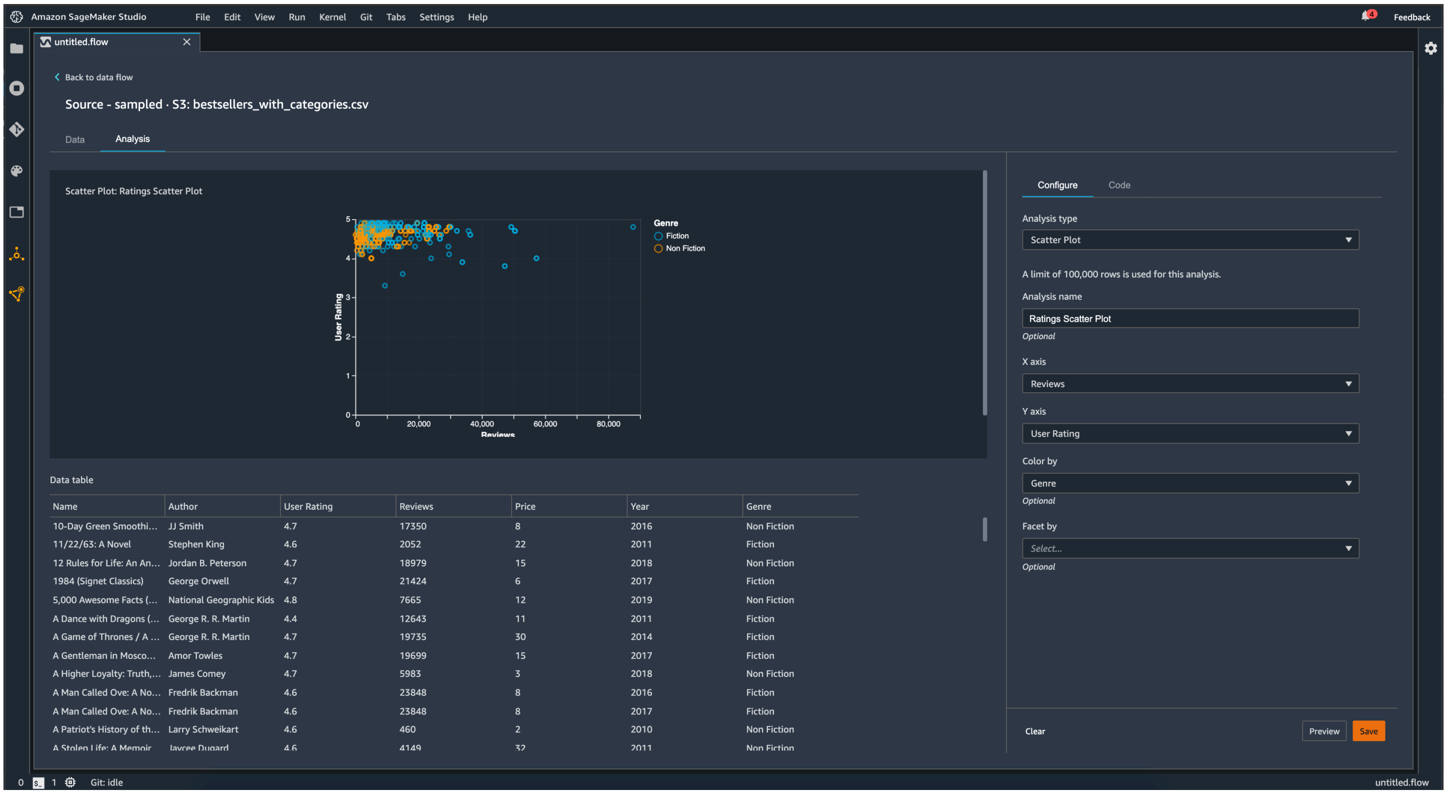
You can use the **Facet by** feature to create histograms of one column, for each value in another column. For example, the following diagram shows histograms of user reviews of best-selling books on Amazon if faceted by year.



Scatter Plot

Use the **Scatter Plot** feature to inspect the relationship between features. To create a scatter plot, select a feature to plot on the **X axis** and the **Y axis**. Both of these columns must be numeric typed columns.

You can color scatter plots by an additional column. For example, the following example shows a scatter plot comparing the number of reviews against user ratings of top-selling books on Amazon between 2009 and 2019. The scatter plot is colored by book genre.



Additionally, you can facet scatter plots by features. For example, the following image shows an example of the same review versus user rating scatter plot, faceted by year.

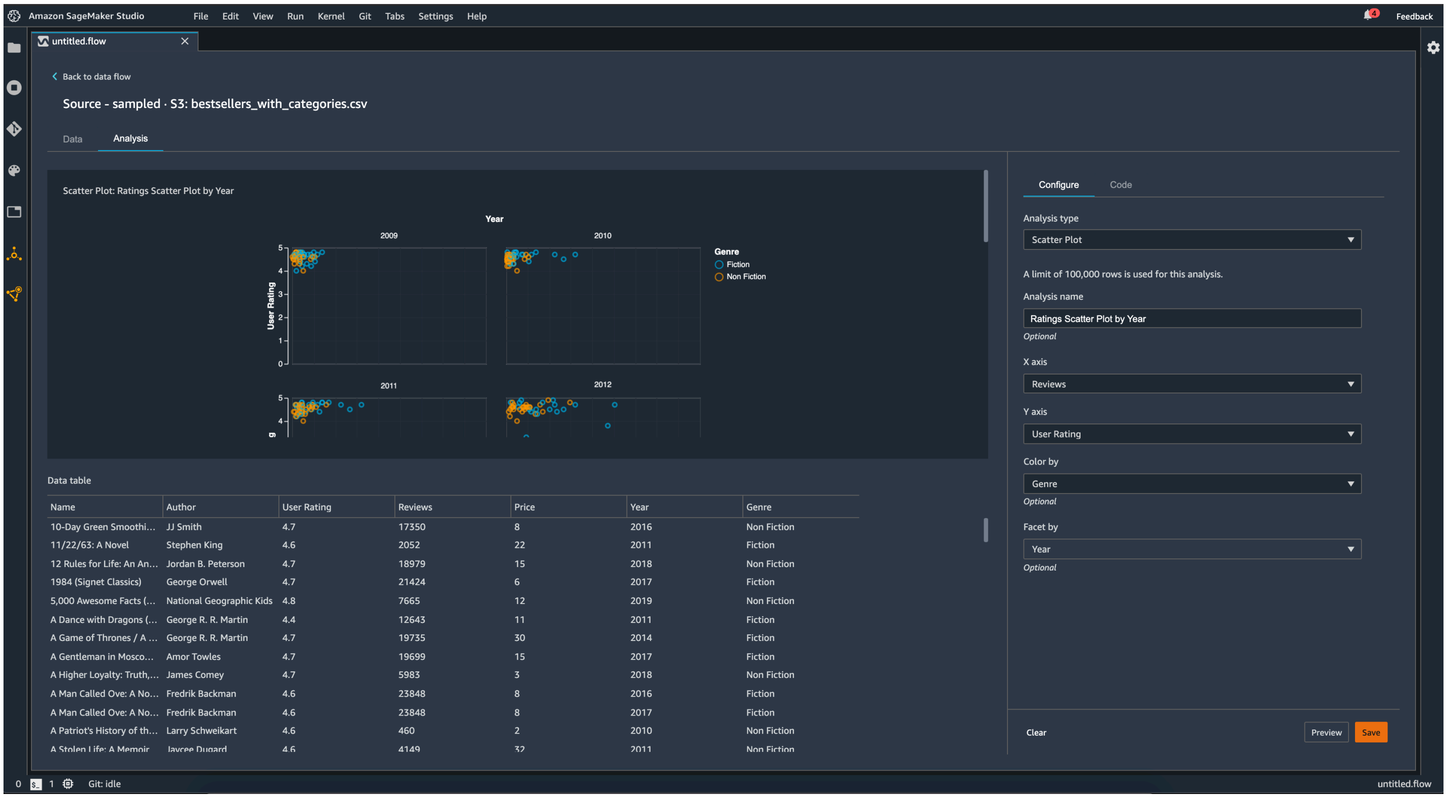


Table Summary

Use the **Table Summary** analysis to quickly summarize your data.

For columns with numerical data, including log and float data, a table summary reports the number of entries (count), minimum (min), maximum (max), mean, and standard deviation (stddev) for each column.

For columns with non-numerical data, including columns with string, Boolean, or date/time data, a table summary reports the number of entries (count), least frequent value (min), and most frequent value (max).

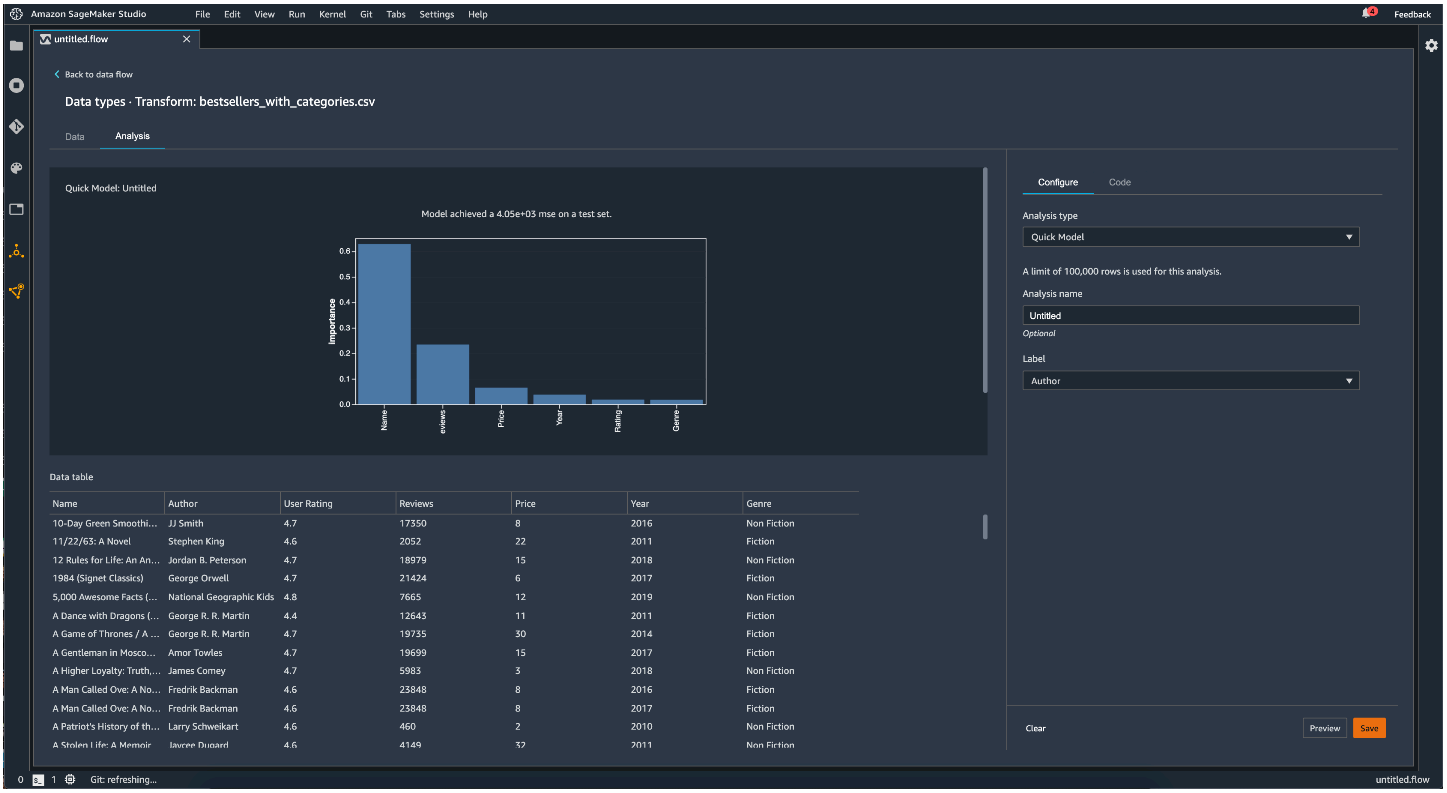
Quick Model

Use the **Quick Model** visualization to quickly evaluate your data and produce importance scores for each feature. A feature importance score score indicates how useful a feature is at predicting a target label. The feature importance score is between [0, 1] and a higher number indicates that the feature is more important to the whole dataset. On the top of the quick model chart, there is a model score. A classification problem shows an F1 score. A regression problem has a mean squared error (MSE) score.

When you create a quick model chart, you select a dataset you want evaluated, and a target label against which you want feature importance to be compared. Data Wrangler does the following:

- Infers the data types for the target label and each feature in the dataset selected.
- Determines the problem type. Based on the number of distinct values in the label column, Data Wrangler determines if this is a regression or classification problem type. Data Wrangler sets a categorical threshold to 100. If there are more than 100 distinct values in the label column, Data Wrangler classifies it as a regression problem; otherwise, it is classified as a classification problem.
- Pre-processes features and label data for training. The algorithm used requires encoding features to vector type and encoding labels to double type.
- Trains a random forest algorithm with 70% of data. Spark's RandomForestRegressor is used to train a model for regression problems. The RandomForestClassifier is used to train a model for classification problems.
- Evaluates a random forest model with the remaining 30% of data. Data Wrangler evaluates classification models using an F1 score and evaluates regression models using an MSE score.
- Calculates feature importance for each feature using the Gini importance method.

The following image shows the user interface for the quick model feature.



Target Leakage

Target leakage occurs when there is data in a machine learning training dataset that is strongly correlated with the target label, but is not available in real-world data. For example, you may have a column in your dataset that serves as a proxy for the column you want to predict with your model.

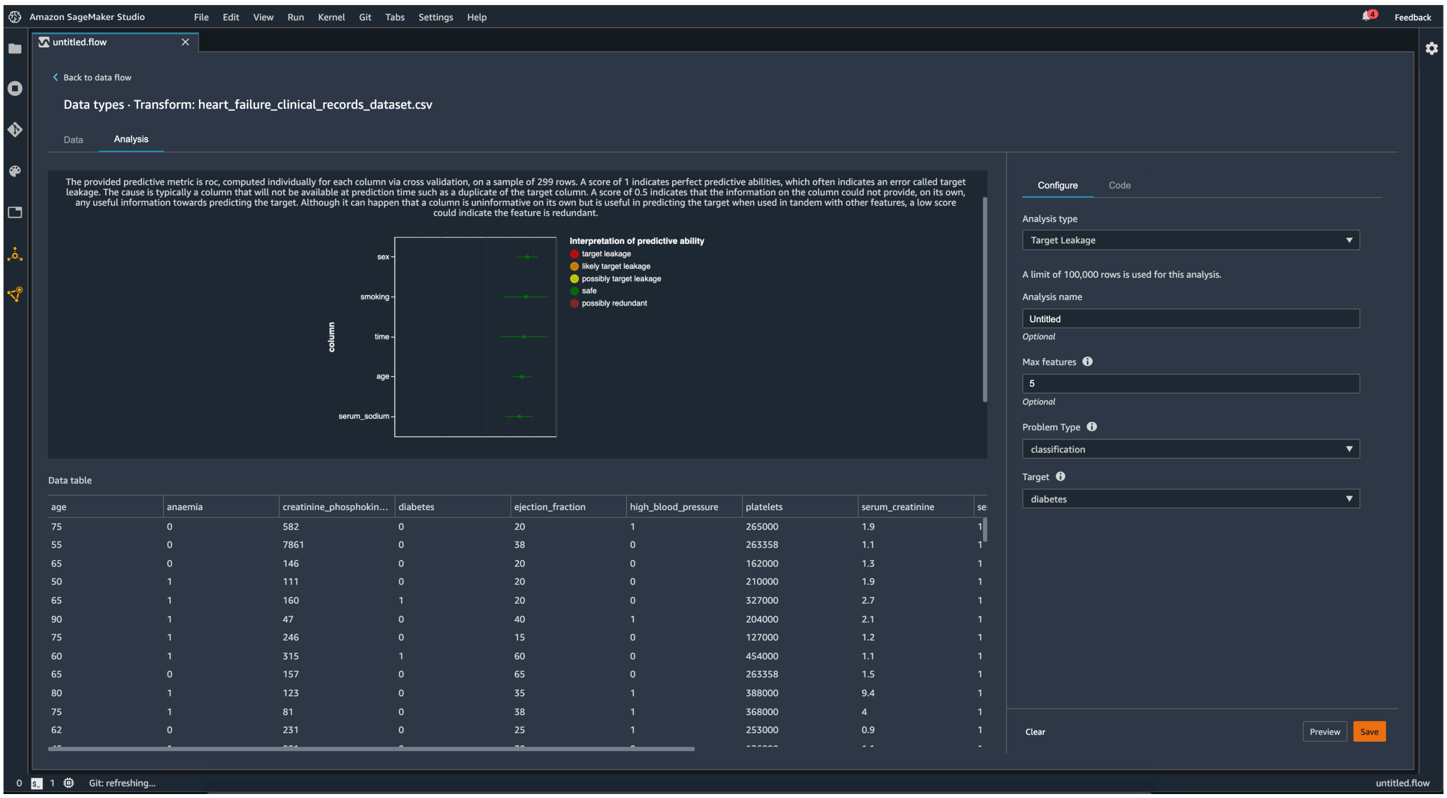
When you use the **Target Leakage** analysis, you specify the following:

- **Target**: This is the feature about which you want your ML model to be able to make predictions.
- **Problem type**: This is the ML problem type on which you are working. Problem type can either be **classification** or **regression**.
- (Optional) **Max features**: This is the maximum number of features to present in the visualization, which shows features ranked by their risk of being target leakage.

For classification, the target leakage analysis uses the area under the receiver operating characteristic, or AUC - ROC curve for each column, up to **Max features**. For regression, it uses a coefficient of determination, or R2 metric.

The AUC - ROC curve provides a predictive metric, computed individually for each column using cross-validation, on a sample of up to around 1000 rows. A score of 1 indicates perfect predictive abilities, which often indicates target leakage. A score of 0.5 or lower indicates that the information on the column could not provide, on its own, any useful information towards predicting the target. Although it can happen that a column is uninformative on its own but is useful in predicting the target when used in tandem with other features, a low score could indicate the feature is redundant.

For example, the following image shows a target leakage report for a diabetes classification problem, that is, predicting if a person has diabetes or not. An AUC - ROC curve is used to calculate the predictive ability of five features, and all are determined to be safe from target leakage.



Multicollinearity

Multicollinearity is a circumstance where two or more predictor variables are related to each other. The predictor variables are the features in your dataset that you're using to predict a target variable. When you have multicollinearity, the predictor variables are not only predictive of the target variable, but also predictive of each other.

You can use the **Variance Inflation Factor (VIF)**, **Principal Component Analysis (PCA)**, or **Lasso feature selection** as measures for the multicollinearity in your data. For more information, see the following.

Variance Inflation Factor (VIF)

The Variance Inflation Factor (VIF) is a measure of collinearity among variable pairs. Data Wrangler returns a VIF score as a measure of how closely the variables are related to each other. A VIF score is a positive number that is greater than or equal to 1.

A score of 1 means that the variable is uncorrelated with the other variables. Scores greater than 1 indicate higher correlation.

Theoretically, you can have a VIF score with a value of infinity. Data Wrangler clips high scores to 50. If you have a VIF score greater than 50, Data Wrangler sets the score to 50.

You can use the following guidelines to interpret your VIF scores:

- A VIF score less than or equal to 5 indicates that the variables are moderately correlated with the other variables.
- A VIF score greater than or equal to 5 indicates that the variables are highly correlated with the other variables.

Principle Component Analysis (PCA)

Principal Component Analysis (PCA) measures the variance of the data along different directions in the feature space. The feature space consists of all the predictor variables that you use to predict the target variable in your dataset.

For example, if you're trying to predict who survived on the *RMS Titanic* after it hit an iceberg, your feature space can include the passengers' age, gender, and the fare that they paid.

From the feature space, PCA generates an ordered list of variances. These variances are also known as singular values. The values in the list of variances are greater than or equal to 0. We can use them to determine how much multicollinearity there is in our data.

When the numbers are roughly uniform, the data has very few instances of multicollinearity. When there is a lot of variability among the values, we have many instances of multicollinearity. Before it performs PCA, Data Wrangler normalizes each feature to have a mean of 0 and a standard deviation of 1.

> **Note**
>
> PCA in this circumstance can also be referred to as Singular Value Decomposition (SVD).

Lasso feature selection

Lasso feature selection uses the L1 regularization technique to only include the most predictive features in your dataset.

For both classification and regression, the regularization technique generates a coefficient for each feature. The absolute value of the coefficient provides an importance score for the feature. A higher importance score indicates that it is more predictive of the target variable. A common feature selection method is to use all the features that have a non-zero lasso coefficient.

Detect Anomalies In Time Series Data

You can use the anomaly detection visualization to see outliers in your time series data. To understand what determines an anomaly, you need to understand that we decompose the time series into a predicted term and an error term. We treat the seasonality and trend of the time series as the predicted term. We treat the residuals as the error term.

For the error term, you specify a threshold as the number of standard of deviations the residual can be away from the mean for it to be considered an anomaly. For example, you can specify a threshold as being 3 standard deviations. Any residual greater than 3 standard deviations away from the mean is an anomaly.

You can use the following procedure to perform an **Anomaly detection** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Anomaly detection**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

Seasonal Trend Decomposition In Time Series Data

You can determine whether there's seasonality in your time series data by using the Seasonal Trend Decomposition visualization. We use the STL (Seasonal Trend decomposition using LOESS) method to perform the decomposition. We decompose the time series into its seasonal, trend, and residual components. The trend reflects the long term progression of the series. The seasonal component is a signal that recurs in a time period. After removing the trend and the seasonal components from the time series, you have the residual.

You can use the following procedure to perform a **Seasonal-Trend decomposition** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Seasonal-Trend decomposition**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

Bias Report

You can use the bias report in Data Wrangler to uncover potential biases in your data. To generate a bias report, you must specify the target column, or **Label**, that you want to predict and a **Facet**, or the column that you want to inspect for biases.

Label: The feature about which you want a model to make predictions. For example, if you are predicting customer conversion, you may select a column containing data on whether or not a customer has placed an order. You must also specify whether this feature is a label or a threshold. If you specify a label, you must specify what a *positive outcome* looks like in your data. In the customer conversion example, a positive outcome may be a 1 in the orders column, representing the positive outcome of a customer placing an order within the last three months. If you specify a threshold, you must specify a lower bound defining a positive outcome. For example, if your customer orders columns contains the number of orders placed in the last year, you may want to specify 1.

Facet: The column that you want to inspect for biases. For example, if you are trying to predict customer conversion, your facet may be the age of the customer. You may choose this facet because you believe that your data is biased toward a certain age group. You must identify whether the facet is measured as a value or threshold. For example, if you wanted to inspect one or more specific ages, you select **Value** and specify those ages. If you want to look at an age group, you select **Threshold** and specify the threshold of ages you want to inspect.

After you select your feature and label, you select the types of bias metrics you want to calculate.

To learn more, see [Generate reports for bias in pre-training data](#).

Create Custom Visualizations

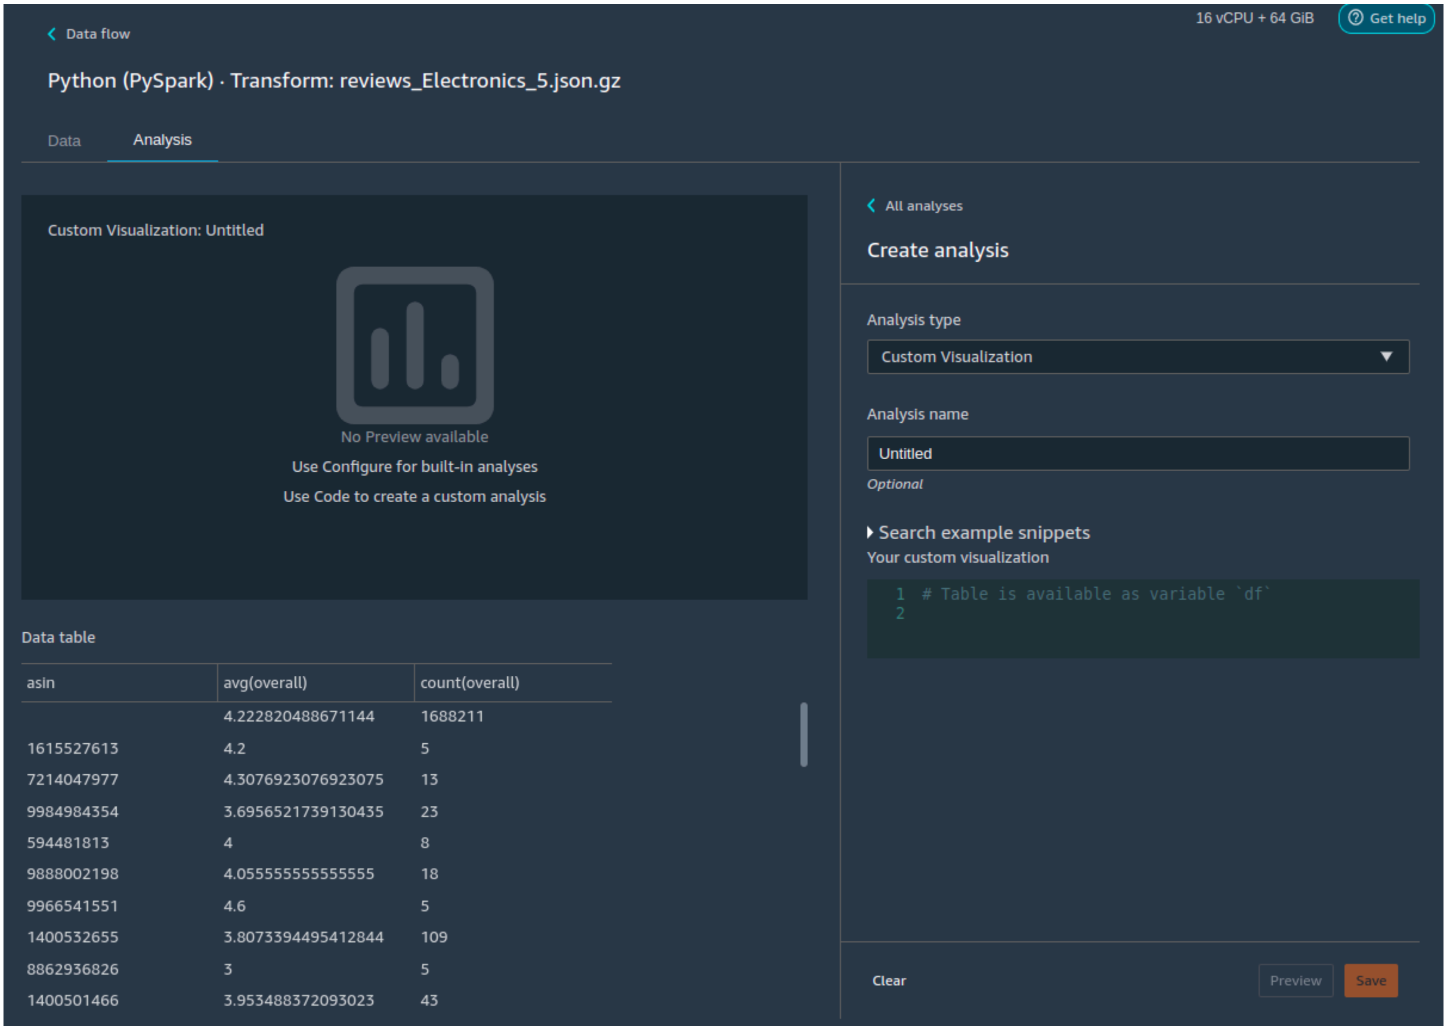
You can add an analysis to your Data Wrangler flow to create a custom visualization. Your dataset, with all the transformations you've applied, is available as a [Pandas DataFrame](#). Data Wrangler uses the `df` variable to store the dataframe. You access the dataframe by calling the variable.

You must provide the output variable, `chart`, to store an [Altair](#) output chart. For example, you can use the following code block to create a custom histogram using the Titanic dataset.

```
import altair as alt
df = df.iloc[:30]
df = df.rename(columns={"Age": "value"})
df = df.assign(count=df.groupby('value').value.transform('count'))
df = df[["value", "count"]]
base = alt.Chart(df)
bar = base.mark_bar().encode(x=alt.X('value', bin=True, axis=None), y=alt.Y('count'))
rule = base.mark_rule(color='red').encode(
    x='mean(value):Q',
    size=alt.value(5))
chart = bar + rule
```

To create a custom visualization:

1. Next to the node containing the transformation that you'd like to visualize, choose the **+**.
2. Choose **Add analysis**.
3. For **Analysis type**, choose **Custom Visualization**.
4. For **Analysis name**, specify a name.
5. Enter your code in the code box.
6. Choose **Preview** to preview your visualization.
7. Choose **Save** to add your visualization.



If you don't know how to use the Altair visualization package in Python, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of visualization snippets. To use a visualization snippet, choose **Search example snippets** and specify a query in the search bar.

The following example uses the **Binned scatterplot** code snippet. It plots a histogram for 2 dimensions.

The snippets have comments to help you understand the changes that you need to make to the code. You usually need to specify the column names of your dataset in the code.

```
import altair as alt

# Specify the number of top rows for plotting
```

```
rows_number = 1000
df = df.head(rows_number)
# You can also choose bottom rows or randomly sampled rows
# df = df.tail(rows_number)
# df = df.sample(rows_number)

chart = (
    alt.Chart(df)
    .mark_circle()
    .encode(
        # Specify the column names for binning and number of bins for X and Y axis
        x=alt.X("col1:Q", bin=alt.Bin(maxbins=20)),
        y=alt.Y("col2:Q", bin=alt.Bin(maxbins=20)),
        size="count()",
    )
)

# :Q specifies that label column has quantitative type.
# For more details on Altair typing refer to
# https://altair-viz.github.io/user_guide/encoding.html#encoding-data-types
```

Reusing Data Flows for Different Datasets

For Amazon Simple Storage Service (Amazon S3) data sources, you can create and use parameters. A parameter is a variable that you've saved in your Data Wrangler flow. Its value can be any portion of the data source's Amazon S3 path. Use parameters to quickly change the data that you're importing into a Data Wrangler flow or exporting to a processing job. You can also use parameters to select and import a specific subset of your data.

After you created a Data Wrangler flow, you might have trained a model on the data that you've transformed. For datasets that have the same schema, you can use parameters to apply the same transformations on a different dataset and train a different model. You can use the new datasets to perform inference with your model or you could be using them to retrain your model.

In general, parameters have the following attributes:

- Name – The name you specify for the parameter
- Type – The type of value that the parameter represents
- Default value – The value of the parameter when you don't specify a new value

Note

Datetime parameters have a time range attribute that they use as the default value.

Data Wrangler uses curly braces, `{{}}`, to indicate that a parameter is being used in the Amazon S3 path. For example, you can have a URL such as `s3://amzn-s3-demo-bucket1/{{example_parameter_name}}/example-dataset.csv`.

You create a parameter when you're editing the Amazon S3 data source that you've imported. You can set any portion of the file path to a parameter value. You can set the parameter value to either a value or a pattern. The following are the available parameter value types in the Data Wrangler flow:

- Number
- String
- Pattern
- Datetime

Note

You can't create a pattern parameter or a datetime parameter for the name of the bucket in the Amazon S3 path.

You must set a number as the default value of a number parameter. You can change the value of the parameter to a different number when you're editing a parameter or when you're launching a processing job. For example, in the S3 path, `s3://amzn-s3-demo-bucket/example-prefix/example-file-1.csv`, you can create a number parameter named `number_parameter` in the place of `1`. Your S3 path now appears as `s3://amzn-s3-demo-bucket/example-prefix/example-file-{{number_parameter}}.csv`. The path continues to point to the `example-file-1.csv` dataset until you change the value of the parameter. If you change the value of `number_parameter` to `2` the path is now `s3://amzn-s3-demo-bucket/example-prefix/example-file-2.csv`. You can import `example-file-2.csv` into Data Wrangler if you've uploaded the file to that Amazon S3 location.

A string parameter stores a string as its default value. For example, in the S3 path, `s3://amzn-s3-demo-bucket/example-prefix/example-file-1.csv`, you can create a string parameter named `string_parameter` in the place of the filename, `example-file-1.csv`. The path now appears as `s3://amzn-s3-demo-bucket/example-prefix/{{string_parameter}}`. It continues to match `s3://amzn-s3-demo-bucket/example-prefix/example-file-1.csv`, until you change the value of the parameter.

Instead of specifying the filename as a string parameter, you can create a string parameter using the entire Amazon S3 path. You can specify a dataset from any Amazon S3 location in the string parameter.

A pattern parameter stores a regular expression (Python REGEX) string as its default value. You can use a pattern parameter to import multiple data files at the same time. To import more than one object at a time, specify a parameter value that matches the Amazon S3 objects that you're importing.

You can also create a pattern parameter for the following datasets:

- s3://amzn-s3-demo-bucket1/example-prefix/example-file-1.csv
- s3://amzn-s3-demo-bucket1/example-prefix/example-file-2.csv
- s3://amzn-s3-demo-bucket1/example-prefix/example-file-10.csv
- s3://amzn-s3-demo-bucket/example-prefix/example-file-0123.csv

For `s3://amzn-s3-demo-bucket1/example-prefix/example-file-1.csv`, you can create a pattern parameter in the place of 1, and set the default value of the parameter to `\d+`. The `\d+` REGEX string matches any one or more decimal digits. If you create a pattern parameter named `pattern_parameter`, your S3 path appears as `s3://amzn-s3-demo-bucket1/example-prefix/example-file-{{pattern_parameter}}.csv`.

You can also use pattern parameters to match all CSV objects within your bucket. To match all objects in a bucket, create a pattern parameter with the default value of `.*` and set the path to `s3://amzn-s3-demo-bucket/{{pattern_parameter}}.csv`. The `.*` character matches any string character in the path.

The `s3://amzn-s3-demo-bucket/{{pattern_parameter}}.csv` path can match the following datasets.

- `example-file-1.csv`

- `other-example-file.csv`
- `example-file-a.csv`

A datetime parameter stores the format with the following information:

- A format for parsing strings inside an Amazon S3 path.
- A relative time range to limit the datetime values that match

For example, in the Amazon S3 file path, `s3://amzn-s3-demo-bucket/2020/01/01/example-dataset.csv`, 2020/01/01 represents a datetime in the format of `year/month/day`. You can set the parameter's time range to an interval such as `1 years` or `24 hours`. An interval of `1 years` matches all S3 paths with datetimes that fall between the current time and the time exactly a year before the current time. The current time is the time when you start exporting the transformations that you've made to the data. For more information about exporting data, see [Export](). If the current date is 2022/01/01 and the time range is `1 years`, the S3 path matches datasets such as the following:

- s3://amzn-s3-demo-bucket/2021/01/01/example-dataset.csv
- s3://amzn-s3-demo-bucket/2021/06/30/example-dataset.csv
- s3://amzn-s3-demo-bucket/2021/12/31/example-dataset.csv

The datetime values within a relative time range change as time passes. The S3 paths that fall within the relative time range might also differ.

For the Amazon S3 file path, `s3://`*`amzn-s3-demo-bucket1`*`/`*`20200101`*`/example-dataset.csv`, `20220101` is an example of a path that can become a datetime parameter.

To view a table of all parameters that you've created in Data Wrangler flow, choose the `{{}}` to the right of the text box containing the Amazon S3 path. If you no longer need a parameter that you've created, you can edit or delete. To edit or delete a parameter, choose icons to the right of the parameter.

Important

Before you delete a parameter, make sure that you haven't used it anywhere in your Data Wrangler flow. Deleted parameters that are still within the flow cause errors.

You can create parameters for any step of your Data Wrangler flow. You can edit or delete any parameter that you create. If you're applying transformations to data that is no longer relevant to your use case, you can modify the values of parameters. Modifying the values of the parameters changes the data that you're importing.

The following sections provide additional examples and general guidance on using parameters. You can use the sections to understand the parameters that work best for you.

> **Note**
>
> The following sections contain procedures that use the Data Wrangler interface to override the parameters and create a processing job.
> You can also override the parameters by using the following procedures.
>
> To export your Data Wrangler flow and override the value of a parameter, do the following.
>
> 1. Choose the **+** next to the node that you want to export.
> 2. Choose **Export to**.
> 3. Choose the location where you're exporting the data.
> 4. Under `parameter_overrides`, specify different values for the parameters that you've created.
> 5. Run the Jupyter Notebook.

Applying a Data Wrangler flow to files using patterns

You can use parameters to apply transformations in your Data Wrangler flow to different files that match a pattern in the Amazon S3 URI path. This helps you specify the files in your S3 bucket that you want to transform with high specificity. For example, you might have a dataset with the path `s3://amzn-s3-demo-bucket1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`. Different datasets named `example-dataset.csv` are stored under many different example prefixes. The prefixes might also be numbered sequentially. You can create patterns for the numbers in the Amazon S3 URI. Pattern parameters use REGEX to select any number of files that match the pattern of the expression. The following are REGEX patterns that might be useful:

- `.*` – Matches zero or more of any character, except newline characters
- `.+` – Matches one or more of any character, excluding newline characters

- \d+ – Matches one or more of any decimal digit
- \w+ – Matches one or more of any alphanumeric character
- [abc-_]{2,4} – Matches a string two, three, or four characters composed of the set of characters provided within a set of brackets
- abc|def – Matches one string or another. For example, the operation matches either abc or def

You can replace each number in the following paths with a single parameter that has a value of \d+.

- s3://amzn-s3-demo-bucket1/example-prefix-3/example-prefix-4/example-prefix-5/example-dataset.csv
- s3://amzn-s3-demo-bucket1/example-prefix-8/example-prefix-12/example-prefix-13/example-dataset.csv
- s3://amzn-s3-demo-bucket1/example-prefix-4/example-prefix-9/example-prefix-137/example-dataset.csv

The following procedure creates a pattern parameter for a dataset with the path s3://amzn-s3-demo-bucket1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv.

To create a pattern parameter, do the following.

1. Next to the dataset that you've imported, choose **Edit dataset**.
2. Highlight the 0 in example-prefix-0.
3. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – **Pattern**
   - **Value** – **\d+** a regular expression that corresponds to one or more digits
4. Choose **Create**.
5. Replace the 1 and the 2 in S3 URI path with the parameter. The path should have the following format: s3://amzn-s3-demo-bucket1/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-dataset.csv

The following is a general procedure for creating a pattern parameter.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the portion of the URI that you're using as the value of the pattern parameter.
4. Choose **Create custom parameter**.
5. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – **Pattern**
   - **Value** – A regular expression containing the pattern that you'd like to store.
6. Choose **Create**.

Applying a Data Wrangler flow to files using numeric values

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://amzn-s3-demo-bucket1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

You might have the transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix-1`. You might want to apply the same transformations to `example-dataset.csv` that falls under `example-prefix-10` or `example-prefix-20`.

You can create a parameter that stores the value `1`. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create numeric parameters for `s3://amzn-s3-demo-bucket1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create parameters for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.

3. Highlight the number in an example prefix of `example-prefix-number`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **Integer**.
7. For **Value**, specify the number.
8. Create parameters for the remaining numbers by repeating the procedure.

After you've created the parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export.

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following.

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.
8. Choose **Run**.

Applying a Data Wrangler flow to files using strings

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://amzn-s3-demo-bucket1/example-prefix/example-dataset.csv`.

You might have transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix`. You might want to apply the same transformations to `example-dataset.csv` under `another-example-prefix` or `example-prefix-20`.

You can create a parameter that stores the value `example-prefix`. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create a string parameter for `s3://amzn-s3-demo-bucket1/example-prefix/example-dataset.csv`.

To create a parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the example prefix, `example-prefix`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **String**.
7. For **Value**, specify the prefix.

After you've created the parameter, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export.

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.

7. Repeat the procedure for the other parameters.
8. Choose **Run**.

Applying a Data Wrangler flow to different datetime ranges

Use datetime parameters to apply transformations in your Data Wrangler flow to different time ranges. Highlight the portion of the Amazon S3 URI that has a timestamp and create a parameter for it. When you create a parameter, you specify a time range from the current time to a time in the past. For example, you might have an Amazon S3 URI that looks like the following: `s3://amzn-s3-demo-bucket1/example-prefix/2022/05/15/example-dataset.csv`. You can save `2022/05/15` as a datetime parameter. If you specify a year as the time range, the time range includes the moment that you run the processing job containing the datetime parameter and the time exactly one year ago. If the moment you're running the processing job is September 6th, 2022 or `2022/09/06`, the time ranges can include the following:

- `s3://amzn-s3-demo-bucket1/example-prefix/2022/03/15/example-dataset.csv`
- `s3://amzn-s3-demo-bucket1/example-prefix/2022/01/08/example-dataset.csv`
- `s3://amzn-s3-demo-bucket1/example-prefix/2022/07/31/example-dataset.csv`
- `s3://amzn-s3-demo-bucket1/example-prefix/2021/09/07/example-dataset.csv`

The transformations in the Data Wrangler flow apply to all of the preceding prefixes. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow. To apply the transformations to datasets within a different time range, do the following:

1. Create a destination node containing all the transformations that you'd like to use.
2. Create a Data Wrangler job.
3. Configure the job to use a different time range for the parameter. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow.

For more information about destination nodes and Data Wrangler jobs, see [Export](#).

The following procedure creates a datetime parameter for the Amazon S3 path: `s3://amzn-s3-demo-bucket1/example-prefix/2022/05/15/example-dataset.csv`.

To create a datetime parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the portion of the URI that you're using as the value of the datetime parameter.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **Datetime**.

   > **Note**
   >
   > By default, Data Wrangler selects **Predefined**, which provides a dropdown menu for you to select a date format. However, the timestamp format that you're using might not be available. Instead of using **Predefined** as the default option, you can choose **Custom** and specify the timestamp format manually.

7. For **Date format**, open the dropdown menu following **Predefined** and choose **yyyy/MM/dd**. The format, **yyyy/MM/dd,** corresponds to the year/month/day of the timestamp.
8. For **Timezone**, choose a time zone.

   > **Note**
   >
   > The data that you're analyzing might have time stamps taken in a different time zone from your time zone. Make sure that the time zone that you select matches the time zone of the data.

9. For **Time range**, specify the time range for the parameter.
10. (Optional) Enter a description to describe how you're using the parameter.
11. Choose **Create**.

After you've created the datetime parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export.

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

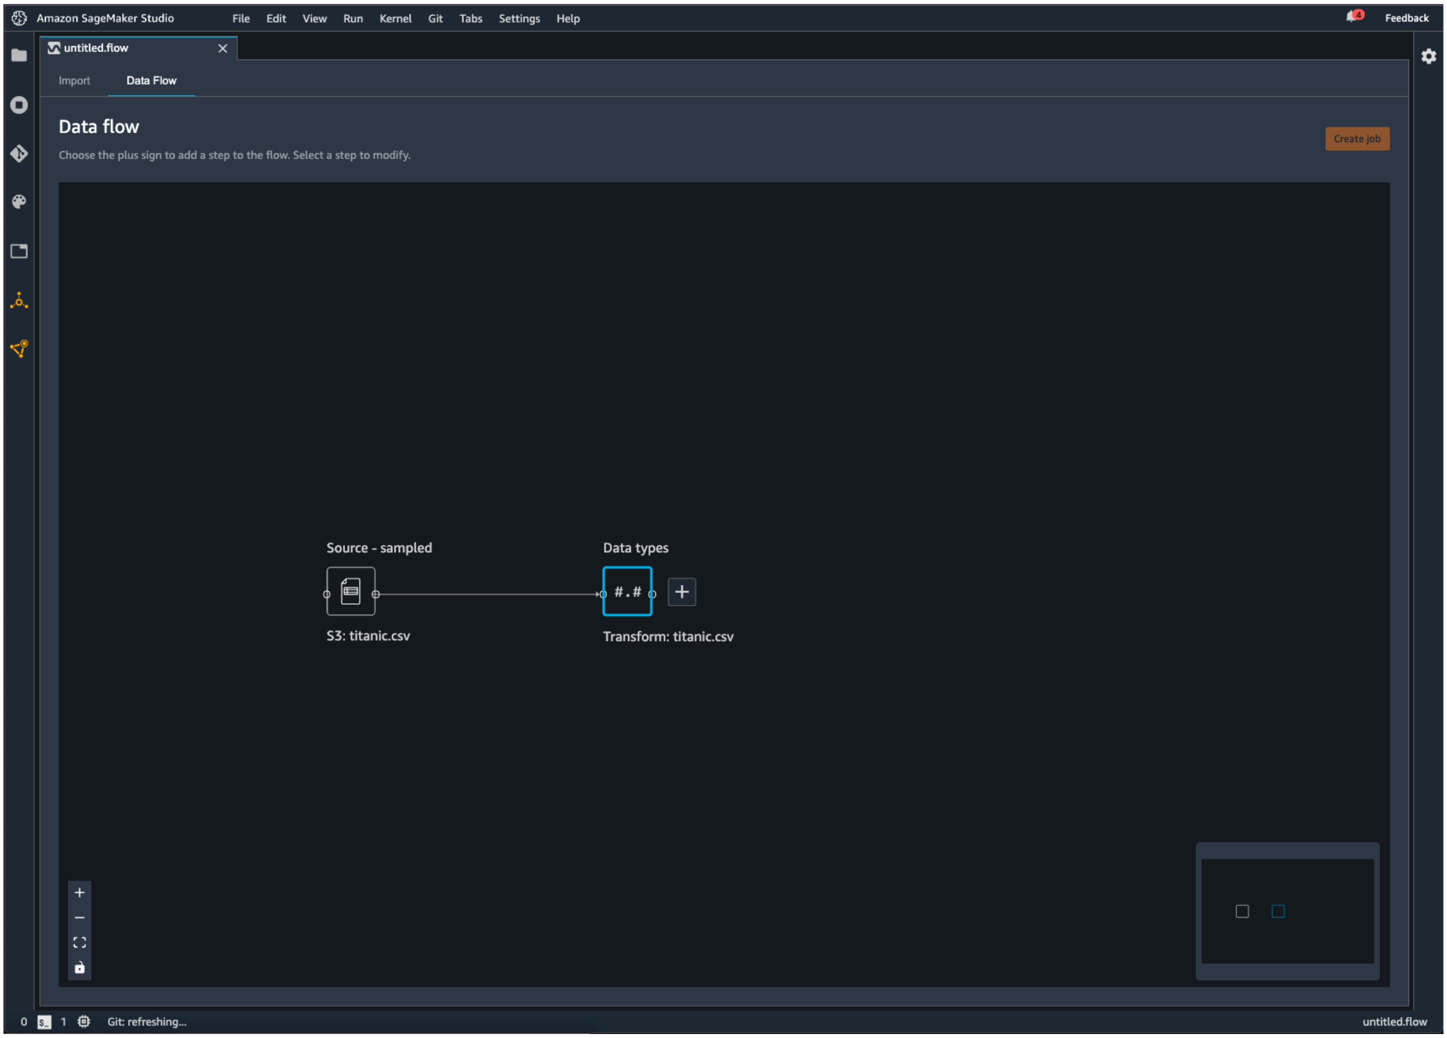
To change the value of a datetime parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of the datetime parameter that you've created.
6. For **Time range**, change the time range for the datasets.
7. Choose **Run**.

Export

In your Data Wrangler flow, you can export some or all of the transformations that you've made to your data processing pipelines.

A *Data Wrangler flow* is the series of data preparation steps that you've performed on your data. In your data preparation, you perform one or more transformations to your data. Each transformation is done using a transform step. The flow has a series of nodes that represent the import of your data and the transformations that you've performed. For an example of nodes, see the following image.



The preceding image shows a Data Wrangler flow with two nodes. The **Source - sampled** node shows the data source from which you've imported your data. The **Data types** node indicates that Data Wrangler has performed a transformation to convert the dataset into a usable format.

Each transformation that you add to the Data Wrangler flow appears as an additional node. For information on the transforms that you can add, see [Transform Data](). The following image shows a Data Wrangler flow that has a **Rename-column** node to change the name of a column in a dataset.

You can export your data transformations to the following:

- Amazon S3
- Pipelines
- Amazon SageMaker Feature Store
- Python Code

> **Important**
>
> We recommend that you use the IAM `AmazonSageMakerFullAccess` managed policy to grant AWS permission to use Data Wrangler. If you don't use the managed policy, you can use an IAM policy that gives Data Wrangler access to an Amazon S3 bucket. For more information on the policy, see Security and Permissions.

When you export your data flow, you're charged for the AWS resources that you use. You can use cost allocation tags to organize and manage the costs of those resources. You create these tags for your user-profile and Data Wrangler automatically applies them to the resources used to export the data flow. For more information, see Using Cost Allocation Tags.

Export to Amazon S3

Data Wrangler gives you the ability to export your data to a location within an Amazon S3 bucket. You can specify the location using one of the following methods:

- Destination node – Where Data Wrangler stores the data after it has processed it.
- Export to – Exports the data resulting from a transformation to Amazon S3.
- Export data – For small datasets, can quickly export the data that you've transformed.

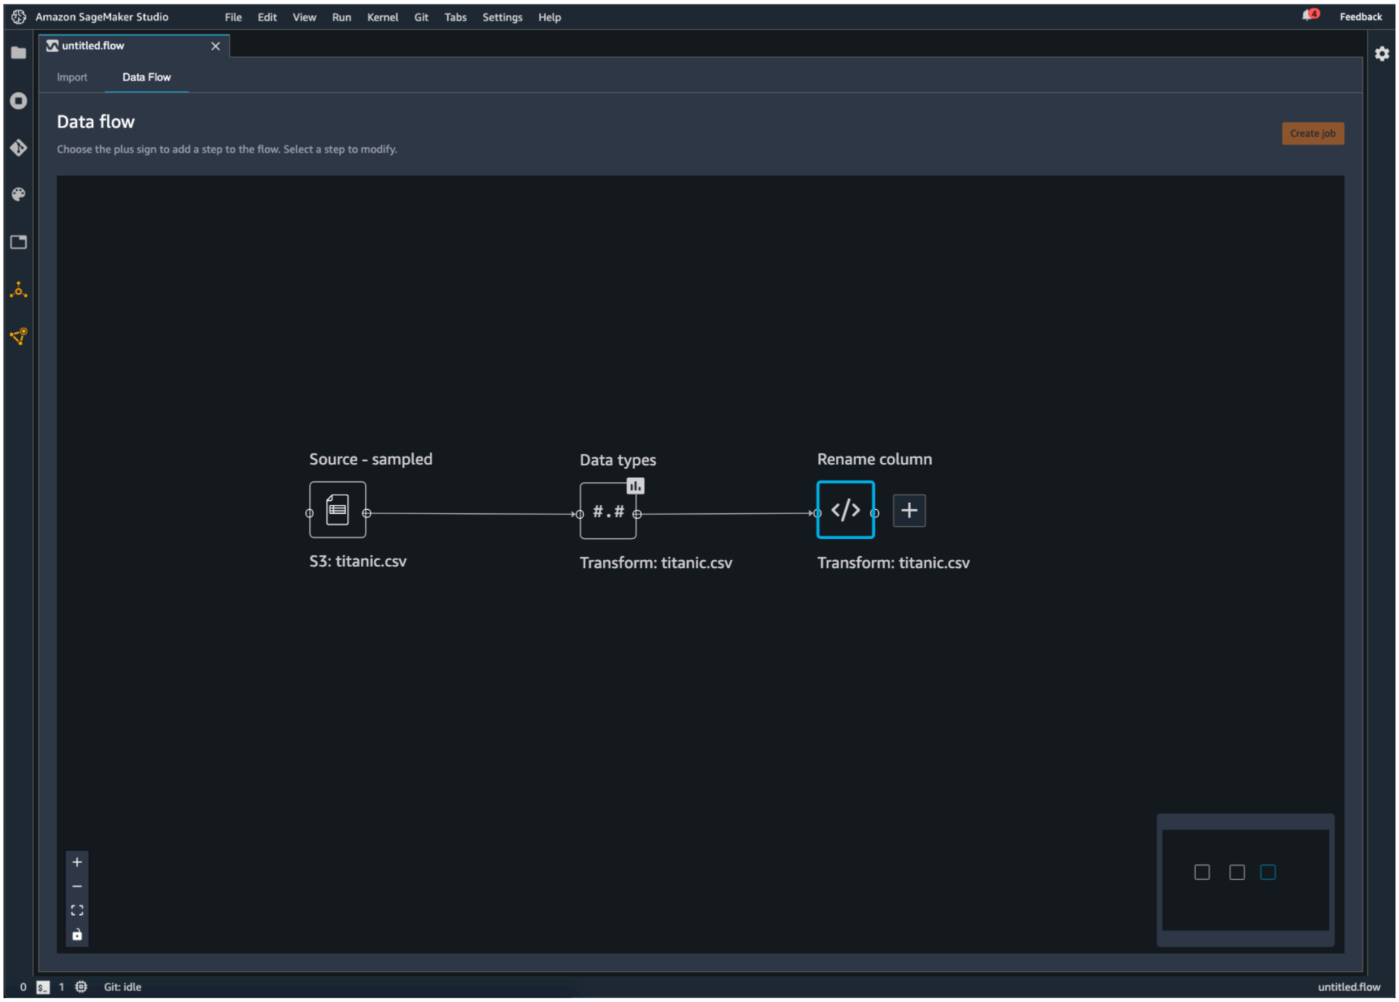
Use the following sections to learn more about each of these methods.

Destination Node

If you want to output a series of data processing steps that you've performed to Amazon S3, you create a destination node. A *destination node* tells Data Wrangler where to store the data after you've processed it. After you create a destination node, you create a processing job to output the data. A *processing job* is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to Amazon S3.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

You can use multiple destination nodes to export different transformations or sets of transformations. The following example shows two destination nodes in a single Data Wrangler flow.



You can use the following procedure to create destination nodes and export them to an Amazon S3 bucket.

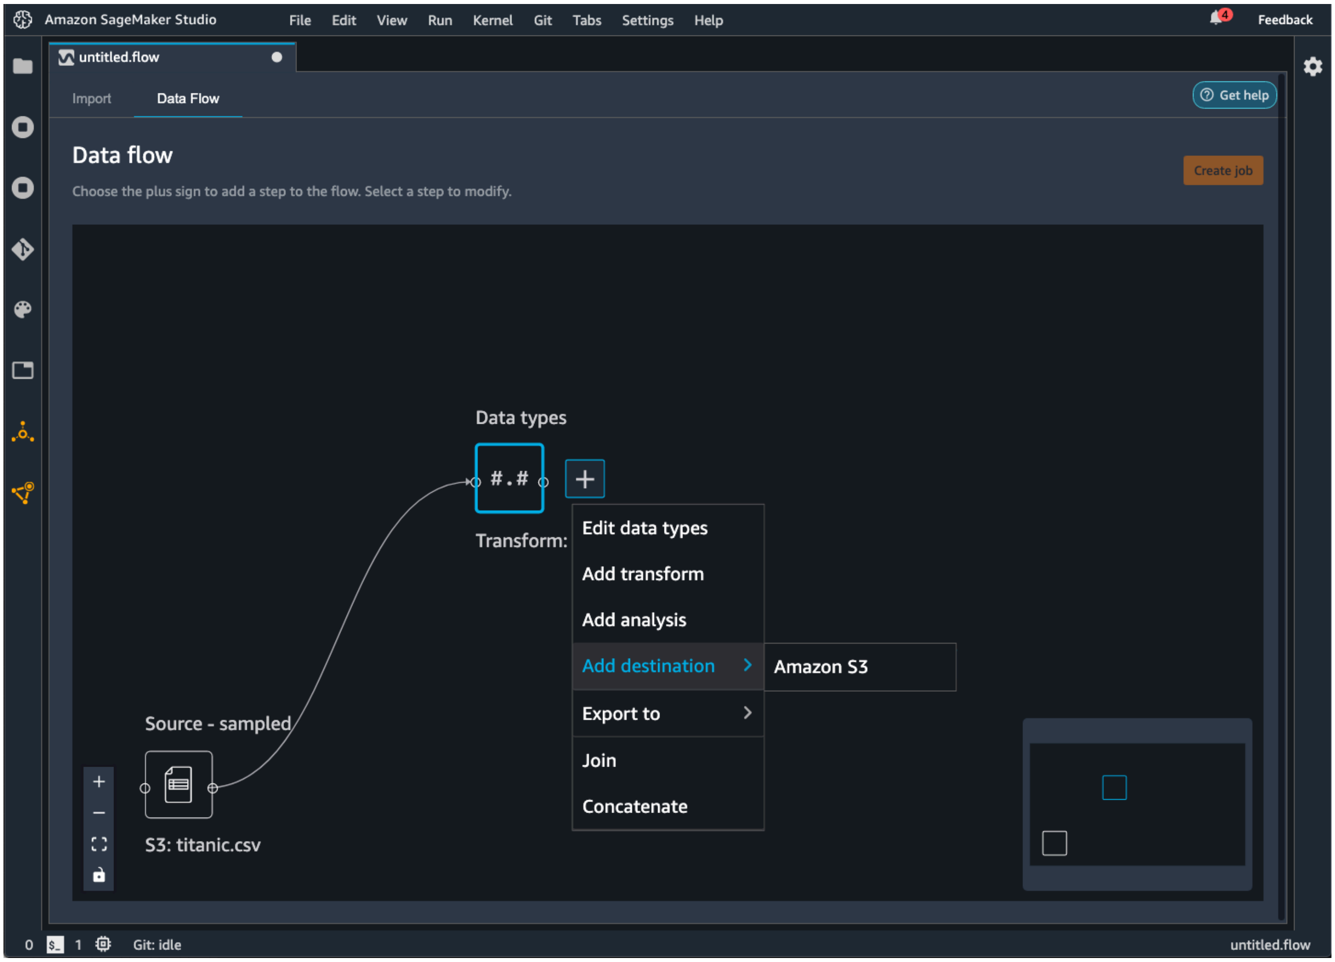
To export your data flow, you create destination nodes and a Data Wrangler job to export the data. Creating a Data Wrangler job starts a SageMaker Processing job to export your flow. You can choose the destination nodes that you want to export after you've created them.

> **Note**
>
> You can choose **Create job** in the Data Wrangler flow to view the instructions to use a processing job.

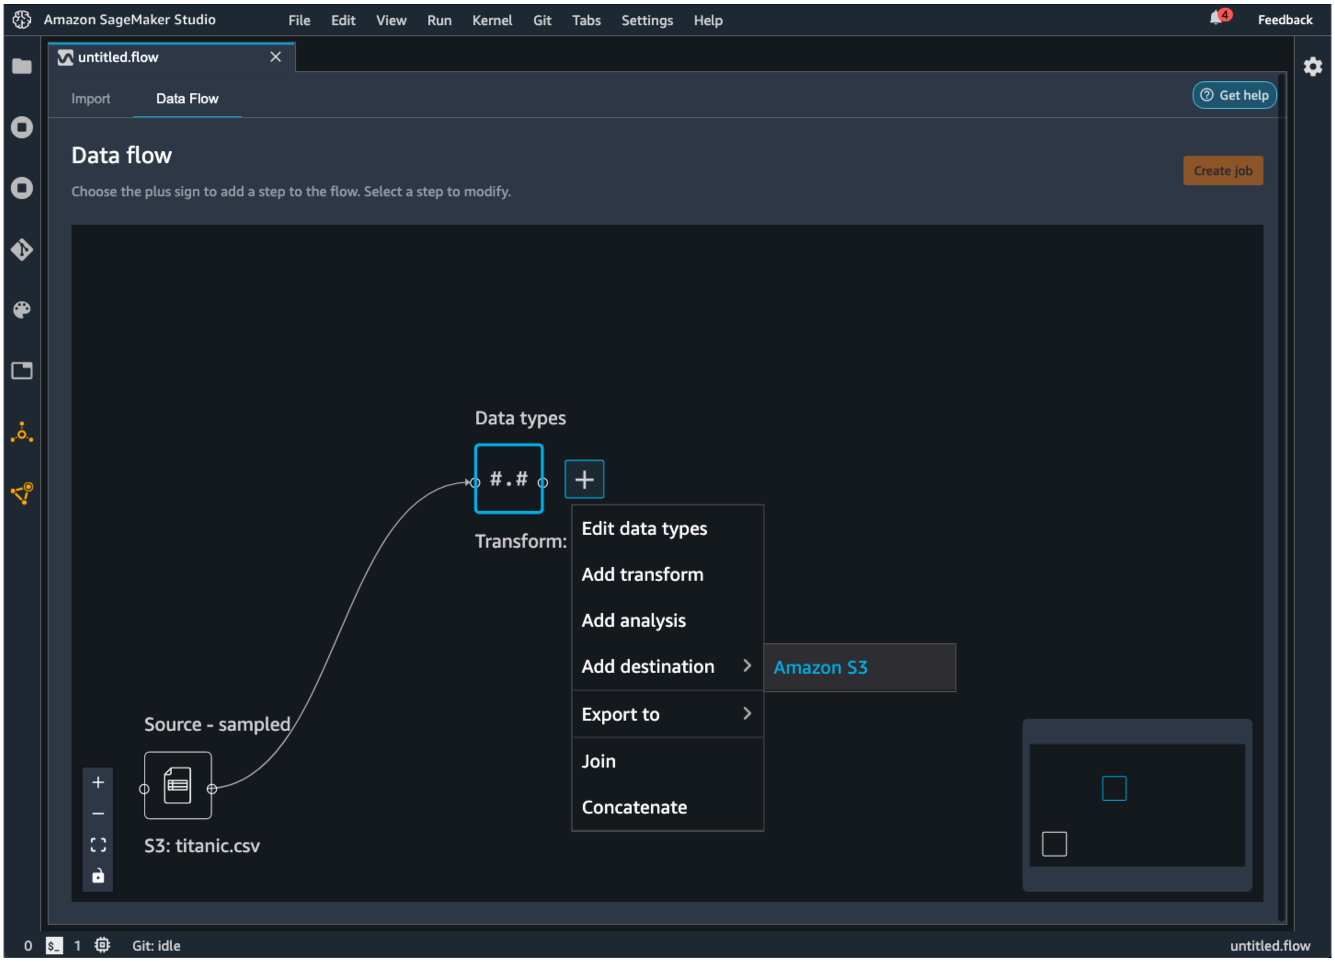
Use the following procedure to create destination nodes.

1. Choose the **+** next to the nodes that represent the transformations that you want to export.

2. Choose **Add destination**.



3. Choose **Amazon S3**.



4. Specify the following fields.

- **Dataset name** – The name that you specify for the dataset that you're exporting.
- **File type** – The format of the file that you're exporting.
- **Delimiter** (CSV and Parquet files only) – The value used to separate other values.
- **Compression** (CSV and Parquet files only) – The compression method used to reduce the file size. You can use the following compression methods:
  - bzip2
  - deflate
  - gzip
- (Optional) **Amazon S3 location** – The S3 location that you're using to output the files.
- (Optional) **Number of partitions** – The number of datasets that you're writing as the output of the processing job.

- (Optional) **Partition by column** – Writes all data with the same unique value from the column.
- (Optional) **Inference Parameters** – Selecting **Generate inference artifact** applies all of the transformations you've used in the Data Wrangler flow to data coming into your inference pipeline. The model in your pipeline makes predictions on the transformed data.

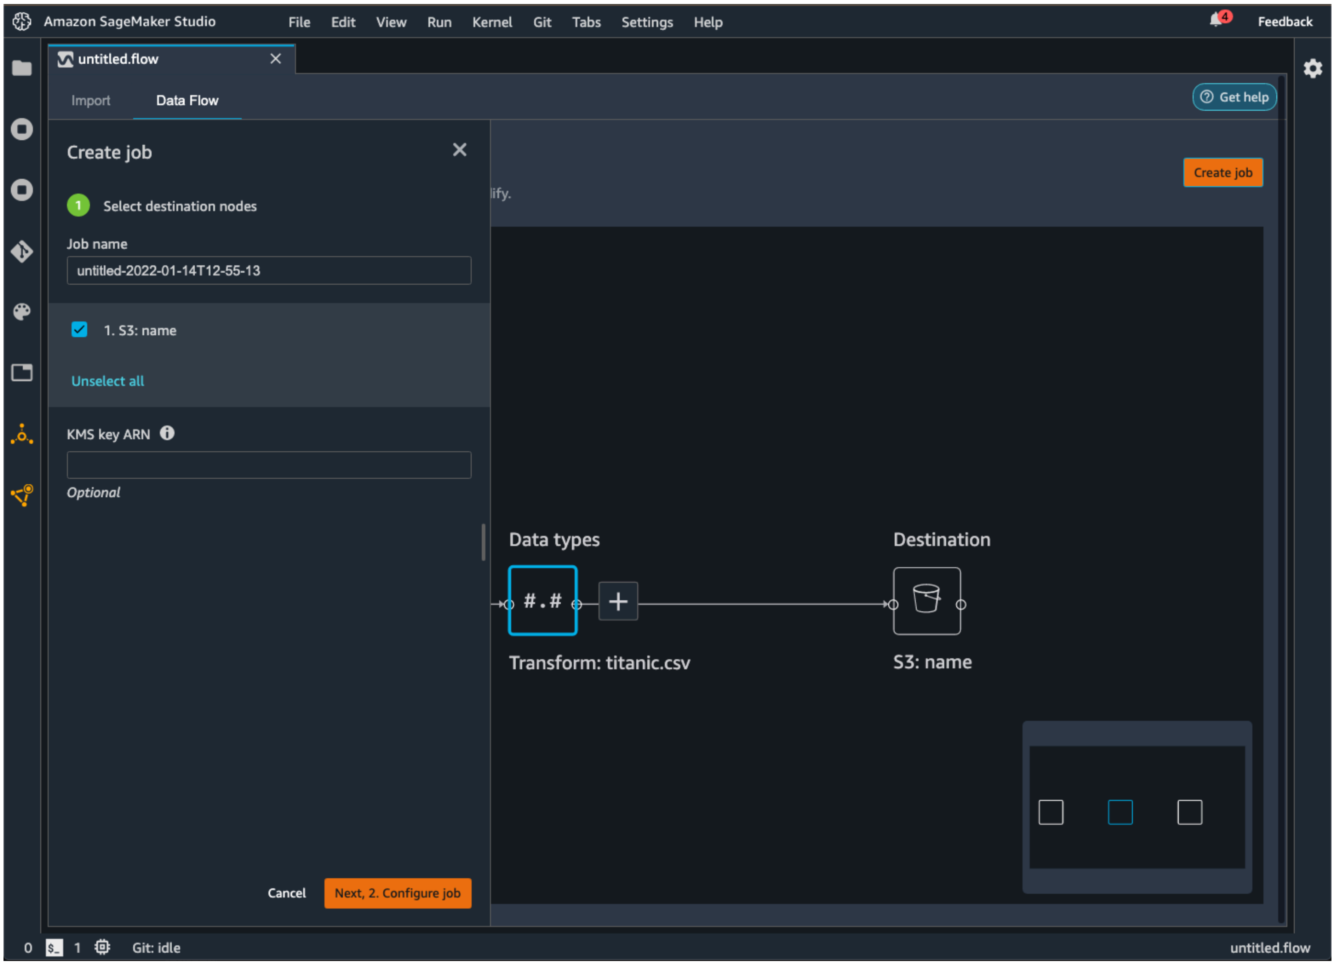
5. Choose **Add destination**.

Use the following procedure to create a processing job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

> **Note**
>
> You can choose **Create job** in the Data Wrangler flow to view the instructions for creating a processing job.

1. Choose **Create job**. The following image shows the pane that appears after you select **Create job**.



2. For **Job name**, specify the name of the export job.

3. Choose the destination nodes that you want to export.

4. (Optional) Specify a AWS KMS key ARN. A AWS KMS key is a cryptographic key that you can use to protect your data. For more information about AWS KMS keys, see AWS Key Management Service.

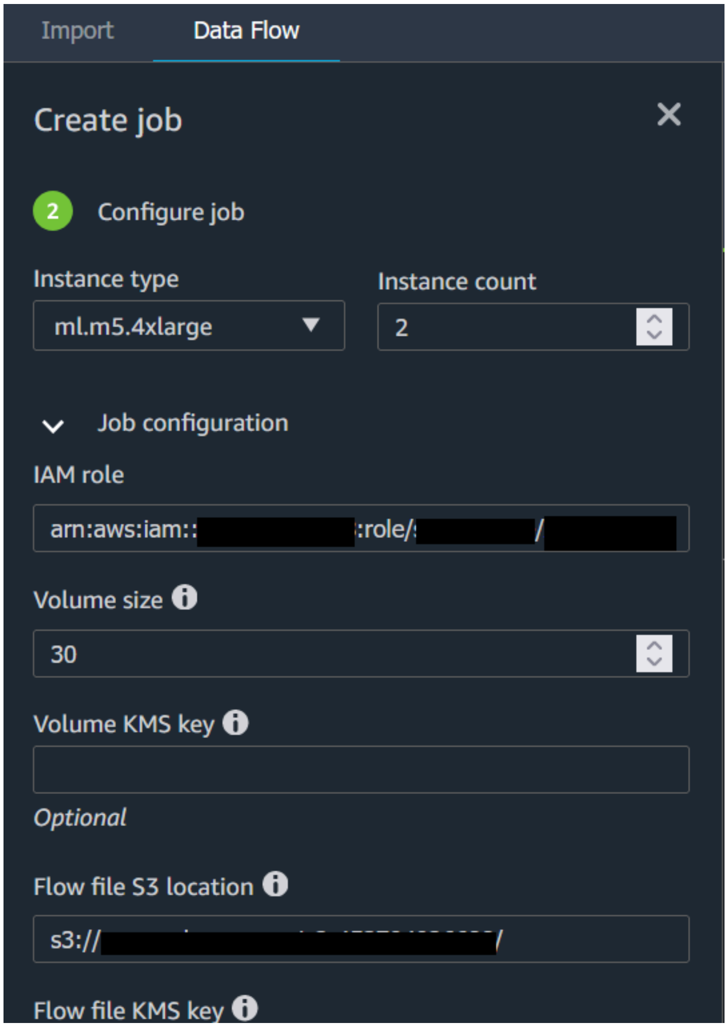
5. (Optional) Under **Trained parameters**. choose **Refit** if you've done the following:

   - Sampled your dataset
   - Applied a transform that uses your data to create a new column in the dataset

   For more information about refitting the transformations you've made to an entire dataset, see Refit Transforms to The Entire Dataset and Export Them.

> **Note**
>
> For image data, Data Wrangler exports the transformations that you've made to all of the images. Refitting the transformations isn't applicable to your use case.

6. Choose **Configure job**. The following image shows the **Configure job** page.



7. (Optional) Configure the Data Wrangler job. You can make the following configurations:

   - **Job configuration**
   - **Spark memory configuration**
   - **Network configuration**
   - **Tags**
   - **Parameters**

- **Associate Schedules**

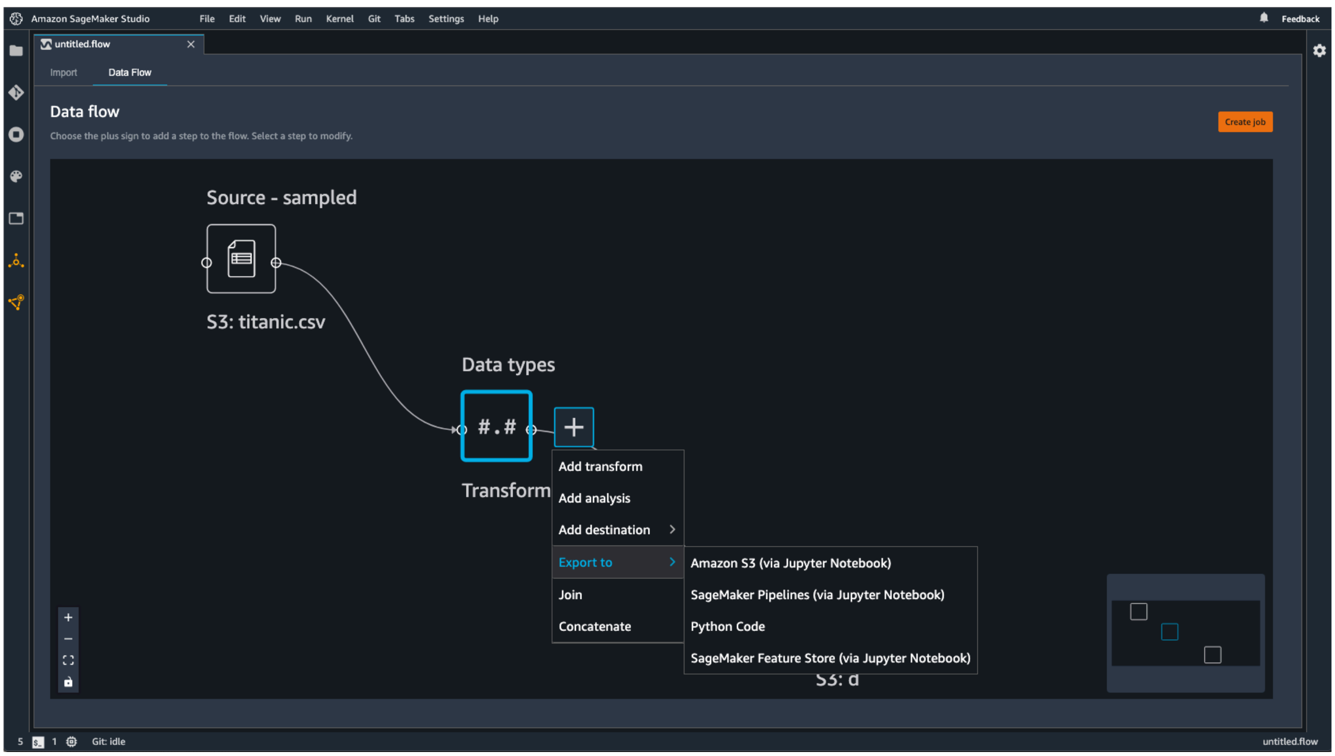
8. Choose **Run**.

Export to

As an alternative to using a destination node, you can use the **Export to** option to export your Data Wrangler flow to Amazon S3 using a Jupyter notebook. You can choose any data node in your Data Wrangler flow and export it. Exporting the data node exports the transformation that the node represents and the transformations that precede it.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Amazon S3.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Amazon S3 (via Jupyter Notebook)**.
4. Run the Jupyter notebook.



When you run the notebook, it exports your data flow (.flow file) in the same AWS Region as the Data Wrangler flow.

The notebook provides options that you can use to configure the processing job and the data that it outputs.

> **Important**
>
> We provide you with job configurations to configure the output of your data. For the partitioning and driver memory options, we strongly recommend that you don't specify a configuration unless you already have knowledge about them.

Under **Job Configurations**, you can configure the following:

- `output_content_type` – The content type of the output file. Uses `CSV` as the default format, but you can specify `Parquet`.
- `delimiter` – The character used to separate values in the dataset when writing to a CSV file.
- `compression` – If set, compresses the output file. Uses gzip as the default compression format.
- `num_partitions` – The number of partitions or files that Data Wrangler writes as the output.
- `partition_by` – The names of the columns that you use to partition the output.

To change the output file format from CSV to Parquet, change the value from `"CSV"` to `"Parquet"`. For the rest of the preceding fields, uncomment the lines containing the fields that you want to specify.

Under **(Optional) Configure Spark Cluster Driver Memory** you can configure Spark properties for the job, such as the Spark driver memory, in the `config` dictionary.

The following shows the `config` dictionary.

```
config = json.dumps({
    "Classification": "spark-defaults",
    "Properties": {
        "spark.driver.memory": f"{driver_memory_in_mb}m",
    }
})
```

To apply the configuration to the processing job, uncomment the following lines:

```
# data_sources.append(ProcessingInput(
#     source=config_s3_uri,
#     destination="/opt/ml/processing/input/conf",
#     input_name="spark-config",
#     s3_data_type="S3Prefix",
#     s3_input_mode="File",
#     s3_data_distribution_type="FullyReplicated"
# ))
```

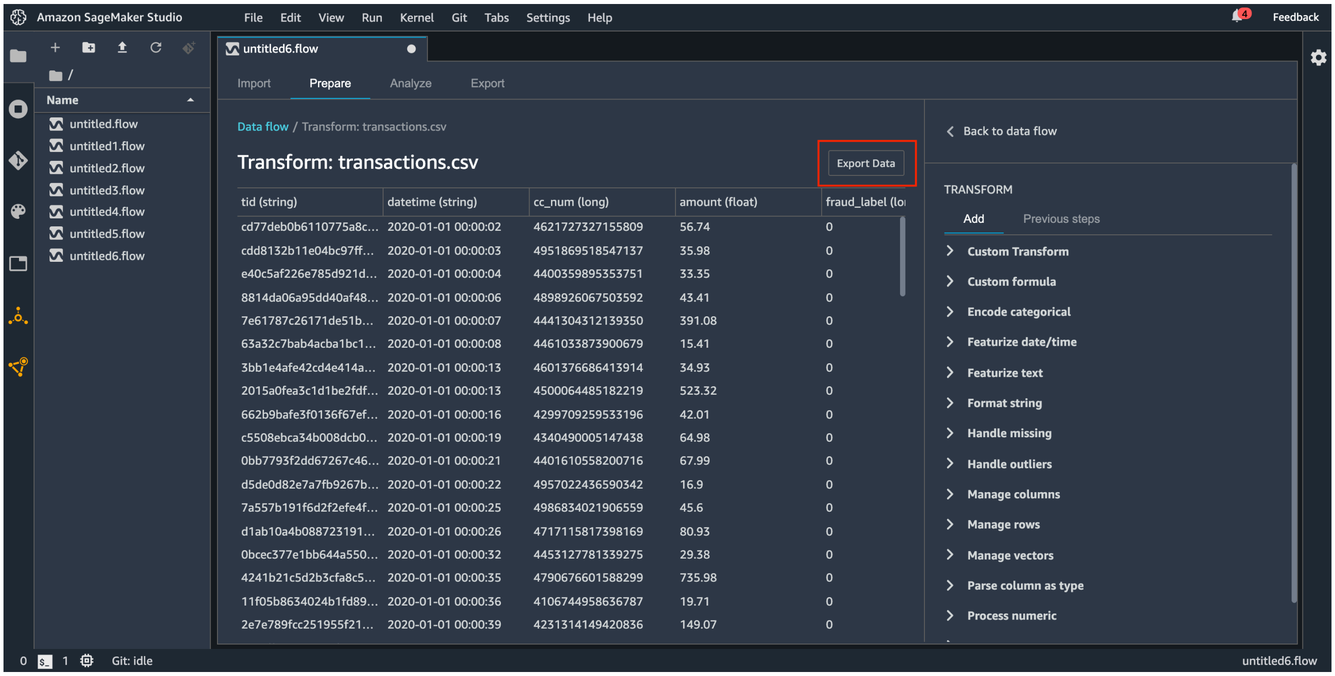
Export data

If you have a transformation on a small dataset that you want to export quickly, you can use the **Export data** method. When you start choose **Export data**, Data Wrangler works synchronously to export the data that you've transformed to Amazon S3. You can't use Data Wrangler until either it finishes exporting your data or you cancel the operation.

For information on using the **Export data** method in your Data Wrangler flow, see the following procedure.

To use the **Export data** method:

1. Choose a node in your Data Wrangler flow by opening (double-clicking on) it.



2. Configure how you want to export the data.
3. Choose **Export data**.

When you export your data flow to an Amazon S3 bucket, Data Wrangler stores a copy of the flow file in the S3 bucket. It stores the flow file under the *data_wrangler_flows* prefix. If you use the default Amazon S3 bucket to store your flow files, it uses the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio Classic in us-east-1, your imported datasets are stored in `sagemaker-us-east-1-111122223333`. In this example, your .flow files created in us-east-1 are stored in `s3://sagemaker-region-account number/data_wrangler_flows/`.

Export to Pipelines

When you want to build and deploy large-scale machine learning (ML) workflows, you can use Pipelines to create workflows that manage and deploy SageMaker AI jobs. With Pipelines, you can build workflows that manage your SageMaker AI data preparation, model training, and model deployment jobs. You can use the first-party algorithms that SageMaker AI offers by using Pipelines. For more information on Pipelines, see SageMaker Pipelines.

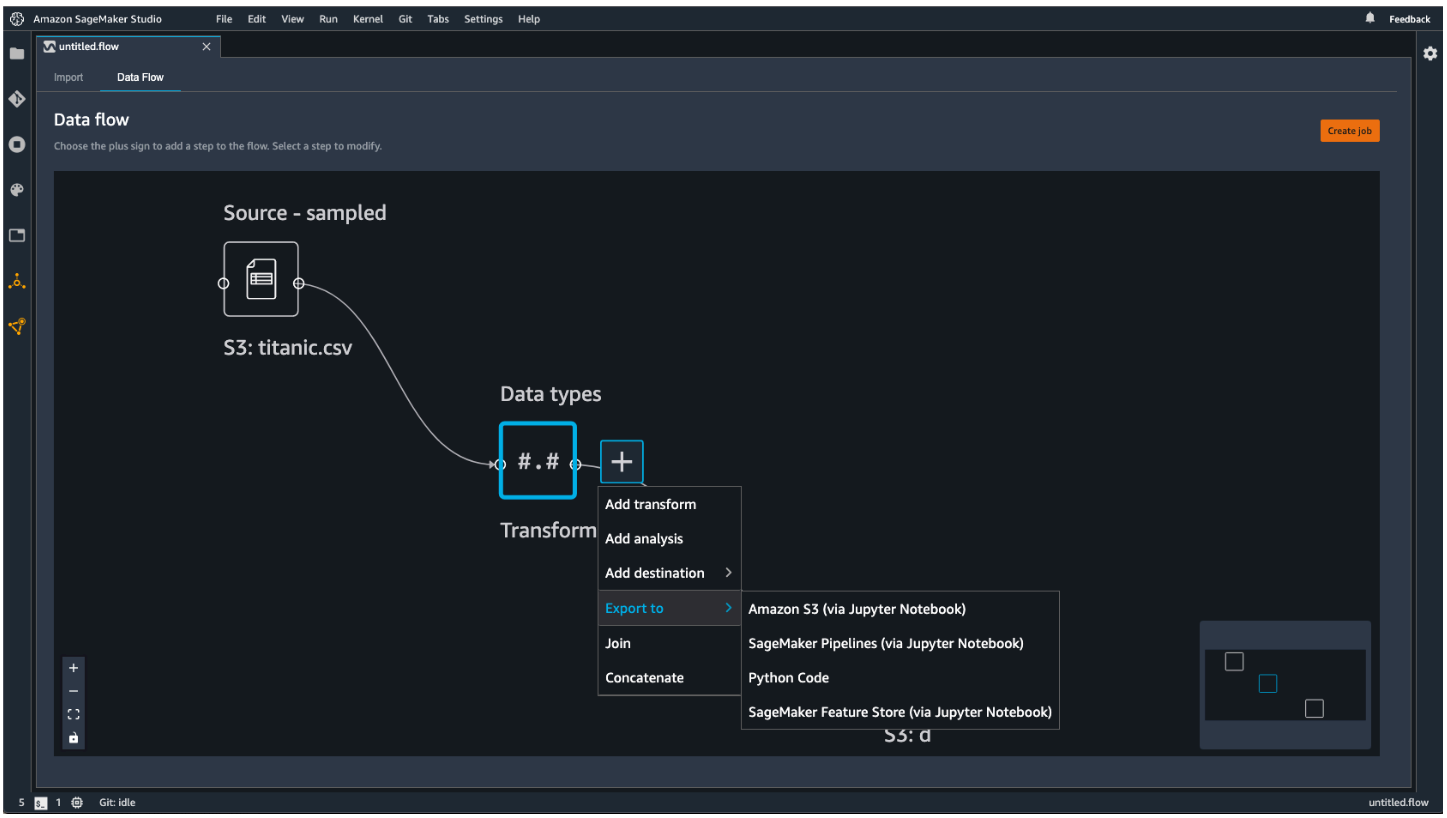
When you export one or more steps from your data flow to Pipelines, Data Wrangler creates a Jupyter notebook that you can use to define, instantiate, run, and manage a pipeline.

Use a Jupyter Notebook to Create a Pipeline

Use the following procedure to create a Jupyter notebook to export your Data Wrangler flow to Pipelines.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Pipelines.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Pipelines (via Jupyter Notebook)**.
4. Run the Jupyter notebook.



You can use the Jupyter notebook that Data Wrangler produces to define a pipeline. The pipeline includes the data processing steps that are defined by your Data Wrangler flow.

You can add additional steps to your pipeline by adding steps to the `steps` list in the following code in the notebook:

```
pipeline = Pipeline(
```

```
    name=pipeline_name,
    parameters=[instance_type, instance_count],
    steps=[step_process], #Add more steps to this list to run in your Pipeline
)
```

For more information on defining pipelines, see Define SageMaker AI Pipeline.

Export to an Inference Endpoint

Use your Data Wrangler flow to process data at the time of inference by creating a SageMaker AI serial inference pipeline from your Data Wrangler flow. An inference pipeline is a series of steps that results in a trained model making predictions on new data. A serial inference pipeline within Data Wrangler transforms the raw data and provides it to the machine learning model for a prediction. You create, run, and manage the inference pipeline from a Jupyter notebook within Studio Classic. For more information about accessing the notebook, see Use a Jupyter Notebook to create an inference endpoint.

Within the notebook, you can either train a machine learning model or specify one that you've already trained. You can either use Amazon SageMaker Autopilot or XGBoost to train the model using the data that you've transformed in your Data Wrangler flow.

The pipeline provides the ability to perform either batch or real-time inference. You can also add the Data Wrangler flow to SageMaker Model Registry. For more information about hosting models, see Multi-model endpoints.

Important

You can't export your Data Wrangler flow to an inference endpoint if it has the following transformations:

- Join
- Concatenate
- Group by

If you must use the preceding transforms to prepare your data, use the following procedure.

To prepare your data for inference with unsupported transforms

1. Create a Data Wrangler flow.

2. Apply the preceding transforms that aren't supported.
3. Export the data to an Amazon S3 bucket.
4. Create a separate Data Wrangler flow.
5. Import the data that you've exported from the preceding flow.
6. Apply the remaining transforms.
7. Create a serial inference pipeline using the Jupyter notebook that we provide.

For information about exporting your data to an Amazon S3 bucket see Export to Amazon S3. For information about opening the Jupyter notebook used to create the serial inference pipeline, see Use a Jupyter Notebook to create an inference endpoint.

Data Wrangler ignores transforms that remove data at the time of inference. For example, Data Wrangler ignores the Handle Missing Values transform if you use the **Drop missing** configuration.

If you've refit transforms to your entire dataset, the transforms carry over to your inference pipeline. For example, if you used the median value to impute missing values, the median value from refitting the transform is applied to your inference requests. You can either refit the transforms from your Data Wrangler flow when you're using the Jupyter notebook or when you're exporting your data to an inference pipeline. For information about refitting transforms, see Refit Transforms to The Entire Dataset and Export Them.

The serial inference pipeline supports the following data types for the input and output strings. Each data type has a set of requirements.

Supported datatypes

- `text/csv` – the datatype for CSV strings
  - The string can't have a header.
  - Features used for the inference pipeline must be in the same order as features in the training dataset.
  - There must be a comma delimiter between features.
  - Records must be delimited by a newline character.

  The following is an example of a validly formatted CSV string that you can provide in an inference request.

```
abc,0.0,"Doe, John",12345\ndef,1.1,"Doe, Jane",67890
```

- `application/json` – the datatype for JSON strings
  - The features used in the dataset for the inference pipeline must be in the same order as the features in the training dataset.
  - The data must have a specific schema. You define schema as a single `instances` object that has a set of `features`. Each `features` object represents an observation.

  The following is an example of a validly formatted JSON string that you can provide in an inference request.

```
{
    "instances": [
        {
            "features": ["abc", 0.0, "Doe, John", 12345]
        },
        {
            "features": ["def", 1.1, "Doe, Jane", 67890]
        }
    ]
}
```

Use a Jupyter Notebook to create an inference endpoint

Use the following procedure to export your Data Wrangler flow to create an inference pipeline.

To create an inference pipeline using a Jupyter notebook, do the following.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose **SageMaker AI Inference Pipeline (via Jupyter Notebook)**.
4. Run the Jupyter notebook.

When you run the Jupyter notebook, it creates an inference flow artifact. An inference flow artifact is a Data Wrangler flow file with additional metadata used to create the serial inference pipeline. The node that you're exporting encompasses all of the transforms from the preceding nodes.

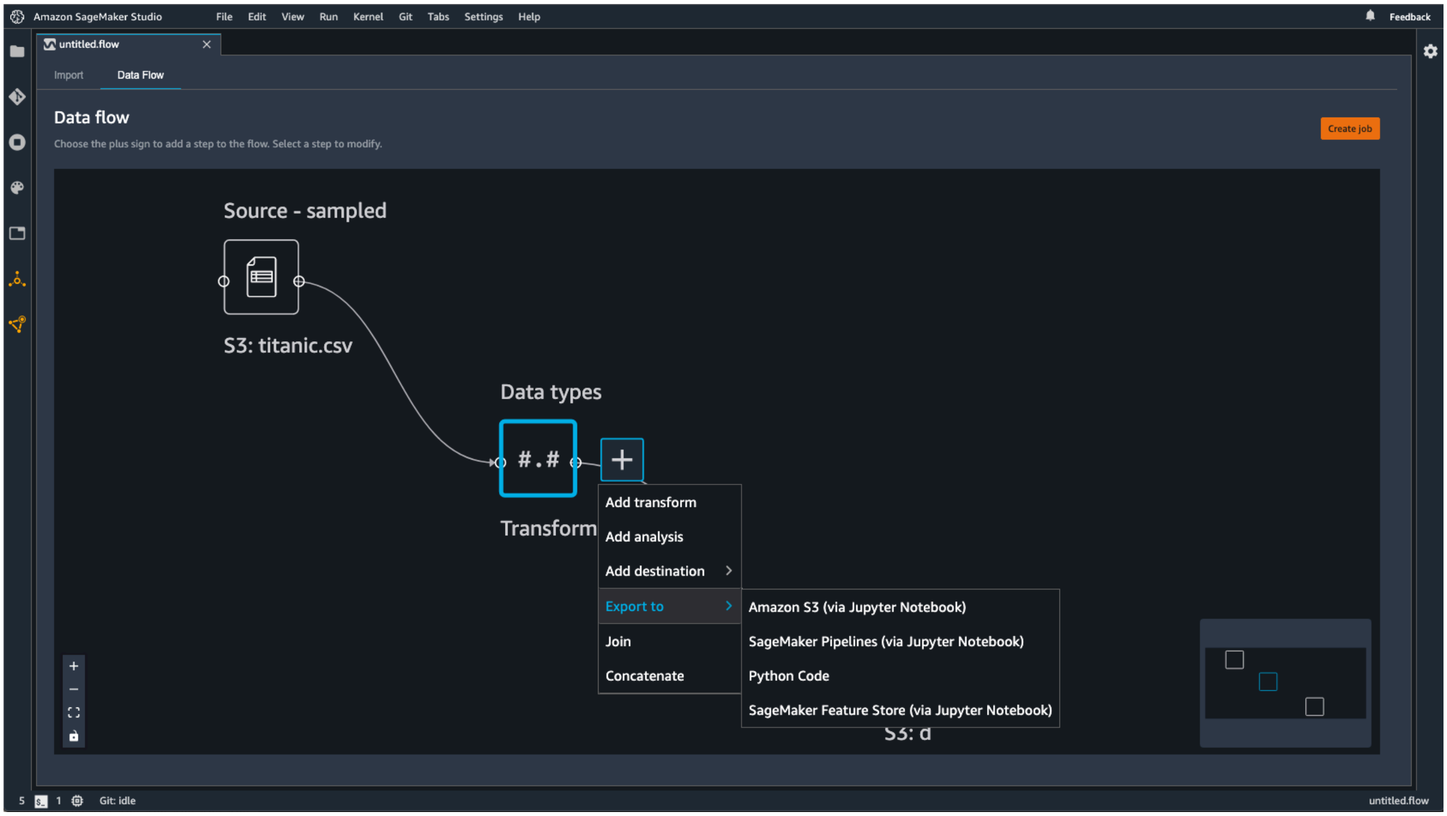
> **Important**
>
> Data Wrangler needs the inference flow artifact to run the inference pipeline. You can't use your own flow file as the artifact. You must create it by using the preceding procedure.

Export to Python Code

To export all steps in your data flow to a Python file that you can manually integrate into any data processing workflow, use the following procedure.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Python Code.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Python Code**.
4. Run the Jupyter notebook.



You might need to configure the Python script to make it run in your pipeline. For example, if you're running a Spark environment, make sure that you are running the script from an environment that has permission to access AWS resources.

Export to Amazon SageMaker Feature Store

You can use Data Wrangler to export features you've created to Amazon SageMaker Feature Store. A feature is a column in your dataset. Feature Store is a centralized store for features and their associated metadata. You can use Feature Store to create, share, and manage curated data for machine learning (ML) development. Centralized stores make your data more discoverable and reusable. For more information about Feature Store, see Amazon SageMaker Feature Store.

A core concept in Feature Store is a feature group. A feature group is a collection of features, their records (observations), and associated metadata. It's similar to a table in a database.

You can use Data Wrangler to do one of the following:

- Update an existing feature group with new records. A record is an observation in the dataset.
- Create a new feature group from a node in your Data Wrangler flow. Data Wrangler adds the observations from your datasets as records in your feature group.

If you're updating an existing feature group, your dataset's schema must match the schema of the feature group. All the records in the feature group are replaced with the observations in your dataset.

You can use either a Jupyter notebook or a destination node to update your feature group with the observations in the dataset.

If your feature groups with the Iceberg table format have a custom offline store encryption key, make sure you grant the IAM that you're using for the Amazon SageMaker Processing job permissions to use it. At a minimum, you must grant it permissions to encrypt the data that you're writing to Amazon S3. To grant the permissions, give the IAM role the ability to use the GenerateDataKey. For more information about granting IAM roles permissions to use AWS KMS keys see https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html

Destination Node

If you want to output a series of data processing steps that you've performed to a feature group, you can create a destination node. When you create and run a destination node, Data Wrangler updates a feature group with your data. You can also create a new feature group from the destination node UI. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to the feature group.

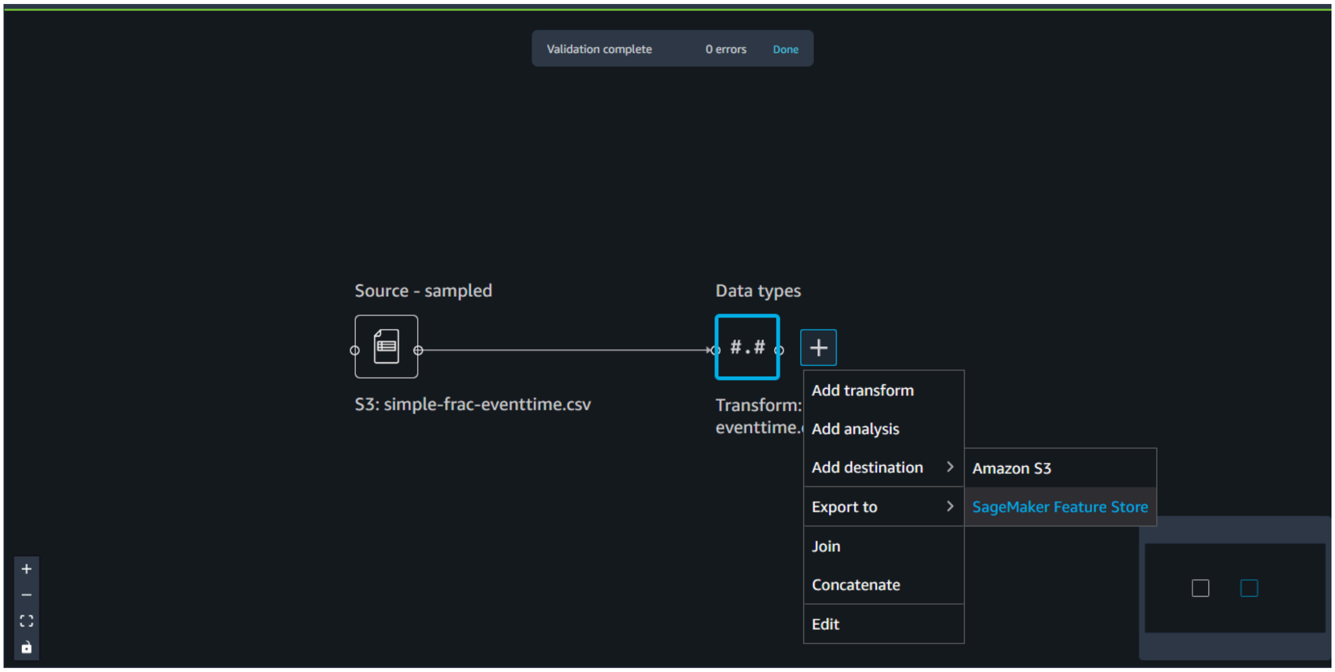
You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

Use the following procedure to create a destination node to update a feature group with the observations from your dataset.

To update a feature group using a destination node, do the following.

> **Note**
>
> You can choose **Create job** in the Data Wrangler flow to view the instructions for using a processing job to update the feature group.

1. Choose the **+** symbol next to the node containing the dataset that you'd like to export.
2. Under **Add destination**, choose **SageMaker AI Feature Store**.



3. Choose (double-click) the feature group. Data Wrangler checks whether the schema of the feature group matches the schema of the data that you're using to update the feature group.
4. (Optional) Select **Export to offline store only** for feature groups that have both an online store and an offline store. This option only updates the offline store with observations from your dataset.
5. After Data Wrangler validates the schema of your dataset, choose **Add**.

Use the following procedure to create a new feature group with data from your dataset.

You can store your feature group in one of the following ways:

- Online – Low-latency, high-availability cache for a feature group that provides real-time lookup of records. The online store allows quick access to the latest value for a record in a feature group.
- Offline – Stores data for your feature group in an Amazon S3 bucket. You can store your data offline when you don't need low-latency (sub-second) reads. You can use an offline store for features used in data exploration, model training, and batch inference.
- Both online and offline – Stores your data in both an online store and an offline store.

To create a feature group using a destination node, do the following.

1. Choose the **+** symbol next to the node containing the dataset that you'd like to export.
2. Under **Add destination**, choose **SageMaker AI Feature Store**.
3. Choose **Create Feature Group**.
4. In the following dialog box, if your dataset doesn't have an event time column, select **Create "EventTime" column**.
5. Choose **Next**.
6. Choose **Copy JSON Schema**. When you create a feature group, you paste the schema into the feature definitions.
7. Choose **Create**.
8. For **Feature group name**, specify a name for your feature group.
9. For **Description (optional)**, specify a description to make your feature group more discoverable.
10. To create a feature group for an online store, do the following.

    a. Select **Enable storage online**.

    b. For **Online store encryption key**, specify an AWS managed encryption key or an encryption key of your own.
11. To create a feature group for an offline store, do the following.

    a. Select **Enable storage offline**. Specify values for the following fields:

    - **S3 bucket name –** The name of the Amazon S3 bucket that stores the feature group.
    - (Optional) **Dataset directory name –** The Amazon S3 prefix that you're using to store the feature group.
    - **IAM Role ARN –** The IAM role that has access to Feature Store.
    - **Table Format –** Table format of your offline store. You can specify **Glue** or **Iceberg**. **Glue** is the default format.
    - **Offline store encryption key –** By default, Feature Store uses an AWS Key Management Service managed key, but you can use the field to specify a key of your own.

    b. Specify values for the following fields:

    - **S3 bucket name –** The name of the bucket storing the feature group.

- **(Optional) Dataset directory name –** The Amazon S3 prefix that you're using to store the feature group.
- **IAM Role ARN –** The IAM role that has access to feature store.
- **Offline store encryption key –** By default, Feature Store uses an AWS managed key, but you can use the field to specify a key of your own.

12. Choose **Continue**.
13. Choose **JSON**.
14. Remove the placeholder brackets in the window.
15. Paste the JSON text from Step 6.
16. Choose **Continue**.
17. For **RECORD IDENTIFIER FEATURE NAME**, choose the column in your dataset that has unique identifiers for each record in your dataset.
18. For **EVENT TIME FEATURE NAME**, choose the column with the timestamp values.
19. Choose **Continue**.
20. (Optional) Add tags to make your feature group more discoverable.
21. Choose **Continue**.
22. Choose **Create feature group**.
23. Navigate back to your Data Wrangler flow and choose the refresh icon next to the **Feature Group** search bar.

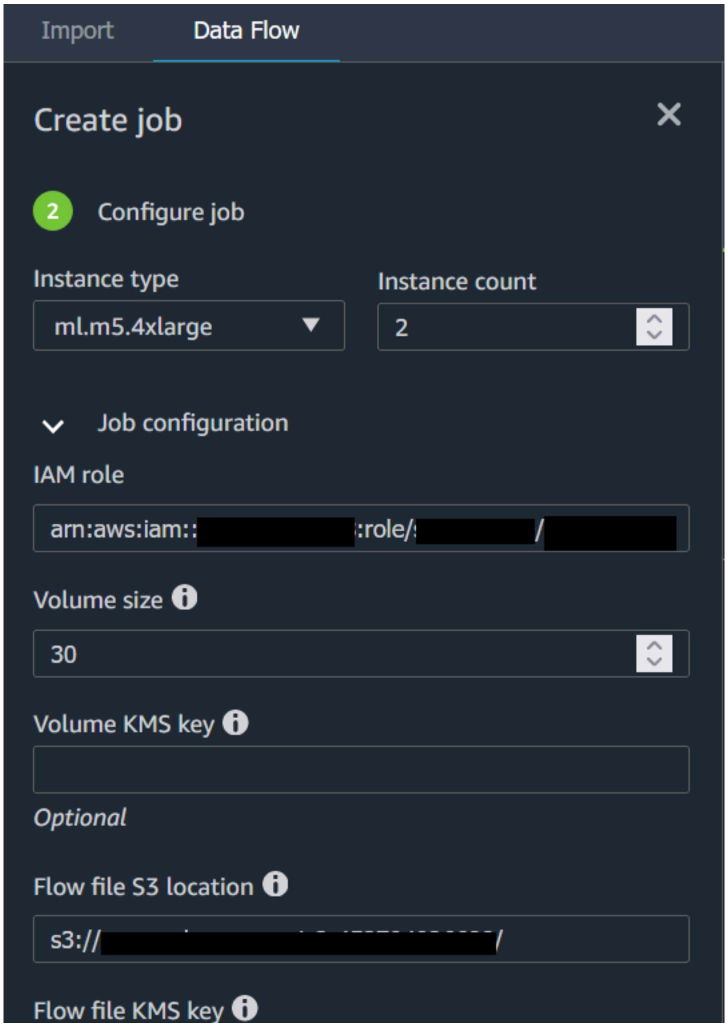
> **Note**
>
> If you've already created a destination node for a feature group within a flow, you can't create another destination node for the same feature group. If you want to create another destination node for the same feature group, you must create another flow file.

Use the following procedure to create a Data Wrangler job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

1. Choose **Create job**. The following image shows the pane that appears after you select **Create job**.

2. For **Job name**, specify the name of the export job.
3. Choose the destination nodes that you want to export.
4. (Optional) For **Output KMS Key**, specify an ARN, ID, or alias of an AWS KMS key. A KMS key is a cryptographic key. You can use the key to encrypt the output data from the job. For more information about AWS KMS keys, see [AWS Key Management Service](#).
5. The following image shows the **Configure job** page with the **Job configuration** tab open.



(Optional) Under **Trained parameters**. choose **Refit** if you've done the following:

- Sampled your dataset
- Applied a transform that uses your data to create a new column in the dataset

For more information about refitting the transformations you've made to an entire dataset, see [Refit Transforms to The Entire Dataset and Export Them](#).

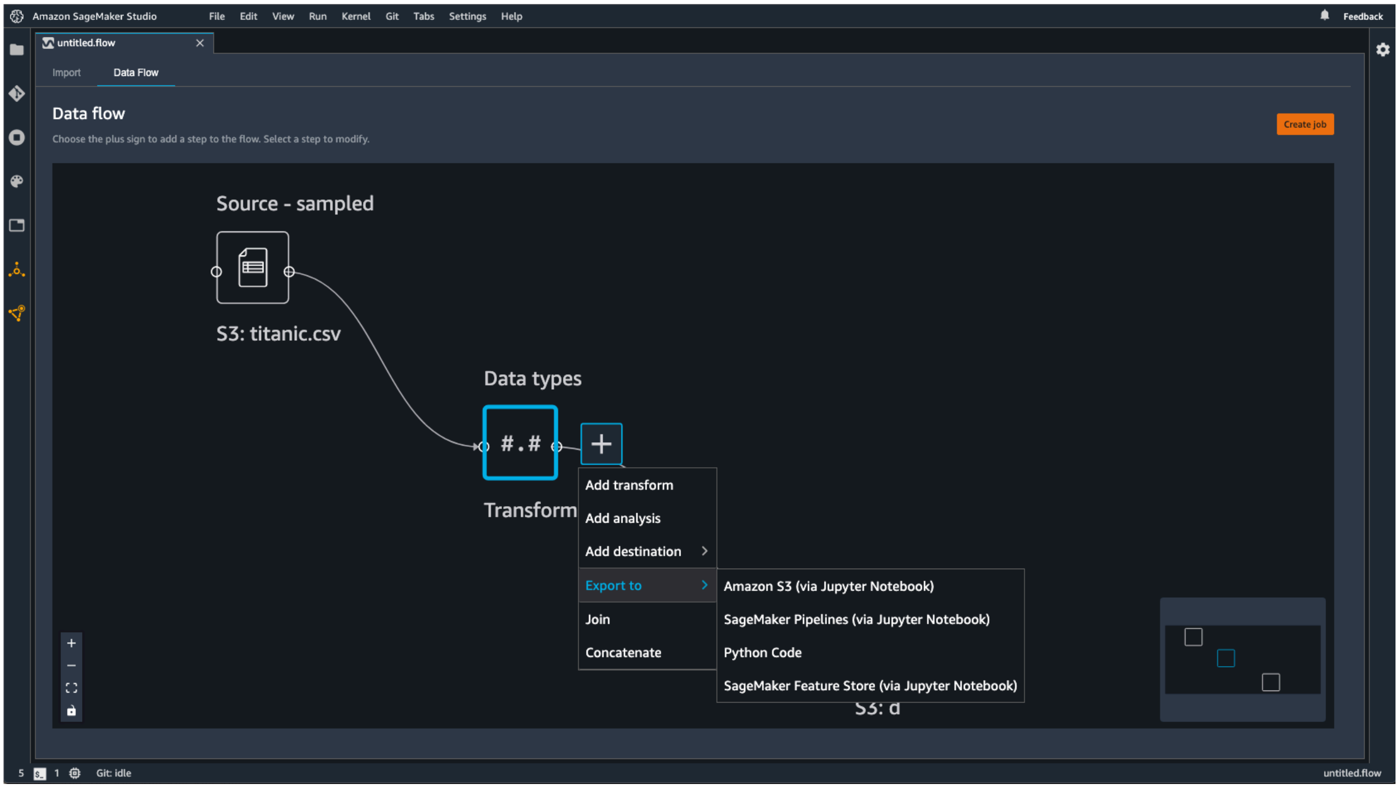
6. Choose **Configure job**.
7. (Optional) Configure the Data Wrangler job. You can make the following configurations:
   - **Job configuration**
   - **Spark memory configuration**
   - **Network configuration**
   - **Tags**
   - **Parameters**
   - **Associate Schedules**
8. Choose **Run**.

Jupyter notebook

Use the following procedure to a Jupyter notebook to export to Amazon SageMaker Feature Store.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Feature Store.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Amazon SageMaker Feature Store (via Jupyter Notebook)**.
4. Run the Jupyter notebook.



Running a Jupyter notebook runs a Data Wrangler job. Running a Data Wrangler job starts a SageMaker AI processing job. The processing job ingests the flow into an online and offline feature store.

Important

The IAM role you use to run this notebook must have the following AWS managed policies attached: `AmazonSageMakerFullAccess` and `AmazonSageMakerFeatureStoreAccess`.

You only need to enable one online or offline feature store when you create a feature group. You can also enable both. To disable online store creation, set `EnableOnlineStore` to `False`:

```
# Online Store Configuration
online_store_config = {
    "EnableOnlineStore": False
}
```

The notebook uses the column names and types of the dataframe you export to create a feature group schema, which is used to create a feature group. A feature group is a group of features defined in the feature store to describe a record. The feature group defines the schema and features contained in the feature group. A feature group definition is composed of a list of features, a record identifier feature name, an event time feature name, and configurations for its online store and offline store.

Each feature in a feature group can have one of the following types: *String*, *Fractional*, or *Integral*. If a column in your exported dataframe is not one of these types, it defaults to `String`.

The following is an example of a feature group schema.

```
column_schema = [
    {
        "name": "Height",
        "type": "long"
    },
    {
        "name": "Input",
        "type": "string"
    },
    {
        "name": "Output",
        "type": "string"
    },
    {
        "name": "Sum",
        "type": "string"
    },
    {
        "name": "Time",
        "type": "string"
    }
]
```

Additionally, you must specify a record identifier name and event time feature name:

- The *record identifier name* is the name of the feature whose value uniquely identifies a record defined in the feature store. Only the latest record per identifier value is stored in the online store. The record identifier feature name must be one of feature definitions' names.

- The *event time feature name* is the name of the feature that stores the `EventTime` of a record in a feature group. An `EventTime` is a point in time when a new event occurs that corresponds to the creation or update of a record in a feature. All records in the feature group must have a corresponding `EventTime`.

  The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see [Data Sources and Ingestion](#).

The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see [Data Sources and Ingestion](#).

Refit Transforms to The Entire Dataset and Export Them

When you import data, Data Wrangler uses a sample of the data to apply the encodings. By default, Data Wrangler uses the first 50,000 rows as a sample, but you can import the entire dataset or use a different sampling method. For more information, see [Import](#).

The following transformations use your data to create a column in the dataset:

- [Encode Categorical](#)
- [Featurize Text](#)
- [Handle Outliers](#)
- [Handle Missing Values](#)

If you used sampling to import your data, the preceding transforms only use the data from the sample to create the column. The transform might not have used all of the relevant data. For example, if you use the **Encode Categorical** transform, there might have been a category in the entire dataset that wasn't present in the sample.

You can either use a destination node or a Jupyter notebook to refit the transformations to the entire dataset. When Data Wrangler exports the transformations in the flow, it creates a SageMaker Processing job. When the processing job finishes, Data Wrangler saves the following files in either the default Amazon S3 location or an S3 location that you specify:

- The Data Wrangler flow file that specifies the transformations that are refit to the dataset

- The dataset with the refit transformations applied to it

You can open a Data Wrangler flow file within Data Wrangler and apply the transformations to a different dataset. For example, if you've applied the transformations to a training dataset, you can open and use the Data Wrangler flow file to apply the transformations to a dataset used for inference.

For a information about using destination nodes to refit transforms and export see the following pages:

- Export to Amazon S3
- Export to Amazon SageMaker Feature Store

Use the following procedure to run a Jupyter notebook to refit the transformations and export the data.

To run a Jupyter notebook and to refit the transformations and export your Data Wrangler flow, do the following.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export to**.
3. Choose the location to which you're exporting the data.
4. For the `refit_trained_params` object, set `refit` to `True`.
5. For the `output_flow` field, specify the name of the output flow file with the refit transformations.
6. Run the Jupyter notebook.

Create a Schedule to Automatically Process New Data

If you're processing data periodically, you can create a schedule to run the processing job automatically. For example, you can create a schedule that runs a processing job automatically when you get new data. For more information about processing jobs, see Export to Amazon S3 and Export to Amazon SageMaker Feature Store.

When you create a job you must specify an IAM role that has permissions to create the job. By default, the IAM role that you use to access Data Wrangler is the `SageMakerExecutionRole`.

The following permissions allow Data Wrangler to access EventBridge and allow EventBridge to run processing jobs:

- Add the following AWS Managed policy to the Amazon SageMaker Studio Classic execution role that provides Data Wrangler with permissions to use EventBridge:

  ```
  arn:aws:iam::aws:policy/AmazonEventBridgeFullAccess
  ```

  For more information about the policy, see AWS managed policies for EventBridge.
- Add the following policy to the IAM role that you specify when you create a job in Data Wrangler:

  JSON

  ```
  {
      "Version": "2012-10-17",
      "Statement": [
          {
              "Effect": "Allow",
              "Action": "sagemaker:StartPipelineExecution",
              "Resource": "arn:aws:sagemaker:us-east-1:111122223333:pipeline/
  data-wrangler-*"
          }
      ]
  }
  ```

  If you're using the default IAM role, you add the preceding policy to the Amazon SageMaker Studio Classic execution role.

  Add the following trust policy to the role to allow EventBridge to assume it.

  ```
  {
      "Effect": "Allow",
      "Principal": {
          "Service": "events.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
  }
  ```

Important

When you create a schedule, Data Wrangler creates an `eventRule` in EventBridge. You incur charges for both the event rules that you create and the instances used to run the processing job.

For information about EventBridge pricing, see Amazon EventBridge pricing. For information about processing job pricing, see Amazon SageMaker Pricing.

You can set a schedule using one of the following methods:

- CRON expressions

> **Note**
>
> Data Wrangler doesn't support the following expressions:
>
> - LW#
> - Abbreviations for days
> - Abbreviations for months

- RATE expressions
- Recurring – Set an hourly or daily interval to run the job.
- Specific time – Set specific days and times to run the job.

The following sections provide procedures on creating jobs.

CRON

Use the following procedure to create a schedule with a CRON expression.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.

5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.
8. For **Run Frequency**, choose **CRON**.
9. Specify a valid CRON expression.
10. Choose **Create**.
11. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

   > **Note**
   >
   > You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

12. Choose one of the following:
    - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.
13. Choose **Run**

RATE

Use the following procedure to create a schedule with a RATE expression.

To specify a schedule with a RATE expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.
5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.
8. For **Run Frequency**, choose **Rate**.

9. For **Value**, specify an integer.
10. For **Unit**, select one of the following:
    - **Minutes**
    - **Hours**
    - **Days**
11. Choose **Create**.
12. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

> **Note**
>
> You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:
    - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.
14. Choose **Run**

Recurring

Use the following procedure to create a schedule that runs a job on a recurring basis.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.
5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.

8. For **Run Frequency**, make sure **Recurring** is selected by default.
9. For **Every x hours**, specify the hourly frequency that the job runs during the day. Valid values are integers in the inclusive range of **1** and **23**.
10. For **On days**, select one of the following options:

    - **Every Day**
    - **Weekends**
    - **Weekdays**
    - **Select Days**

    - (Optional) If you've selected **Select Days**, choose the days of the week to run the job.

    > **Note**
    >
    > The schedule resets every day. If you schedule a job to run every five hours, it runs at the following times during the day:
    >
    > - 00:00
    > - 05:00
    > - 10:00
    > - 15:00
    > - 20:00

11. Choose **Create**.
12. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

    > **Note**
    >
    > You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:

    - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.

- **Schedule only –** Data Wrangler the job only runs on the schedules that you specify.

14. Choose **Run**

Specific time

Use the following procedure to create a schedule that runs a job at specific times.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.
5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.
8. Choose **Create**.
9. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

> **Note**
>
> You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

10. Choose one of the following:
    - **Schedule and run now –** Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - **Schedule only –** Data Wrangler the job only runs on the schedules that you specify.
11. Choose **Run**

You can use Amazon SageMaker Studio Classic view the jobs that are scheduled to run. Your processing jobs run within Pipelines. Each processing job has its own pipeline. It runs as a processing step within the pipeline. You can view the schedules that you've created within a pipeline. For information about viewing a pipeline, see [View the details of a pipeline](#).

Use the following procedure to view the jobs that you've scheduled.

To view the jobs you've scheduled, do the following.

1. Open Amazon SageMaker Studio Classic.
2. Open Pipelines
3. View the pipelines for the jobs that you've created.

   The pipeline running the job uses the job name as a prefix. For example, if you've created a job named `housing-data-feature-enginnering`, the name of the pipeline is `data-wrangler-housing-data-feature-engineering`.
4. Choose the pipeline containing your job.
5. View the status of the pipelines. Pipelines with a **Status** of **Succeeded** have run the processing job successfully.

To stop the processing job from running, do the following:

To stop a processing job from running, delete the event rule that specifies the schedule. Deleting an event rule stops all the jobs associated with the schedule from running. For information about deleting a rule, see [Disabling or deleting an Amazon EventBridge rule](#).

You can stop and delete the pipelines associated with the schedules as well. For information about stopping a pipeline, see [StopPipelineExecution](#). For information about deleting a pipeline, see [DeletePipeline](#).

Use an Interactive Data Preparation Widget in an Amazon SageMaker Studio Classic Notebook to Get Data Insights

Use the Data Wrangler data preparation widget to interact with your data, get visualizations, explore actionable insights, and fix data quality issues.

You can access the data preparation widget from an Amazon SageMaker Studio Classic notebook. For each column, the widget creates a visualization that helps you better understand its distribution. If a column has data quality issues, a warning appears in its header.

To see the data quality issues, select the column header showing the warning. You can use the information that you get from the insights and the visualizations to apply the widget's built-in transformations to help you fix the issues.

For example, the widget might detect that you have a column that only has one unique value and show you a warning. The warning provides the option to drop the column from the dataset.

Getting started with running the widget

Use the following information to help you get started with running a notebook.

Open a notebook in Amazon SageMaker Studio Classic. For information about opening a notebook, see Create or Open an Amazon SageMaker Studio Classic Notebook.

> **Important**
>
> To run the widget, the notebook must use one of the following images:
>
> - Python 3 (Data Science) with Python 3.7
> - Python 3 (Data Science 2.0) with Python 3.8
> - Python 3 (Data Science 3.0) with Python 3.10
> - SparkAnalytics 1.0
> - SparkAnalytics 2.0
>
> For more information about images, see Amazon SageMaker images available for use with Studio Classic.

Use the following code to import the data preparation widget and pandas. The widget uses pandas dataframes to analyze your data.

```
import pandas as pd
import sagemaker_datawrangler
```

The following example code loads a file into the dataframe called `df`.

```
df = pd.read_csv("example-dataset.csv")
```

You can use a dataset in any format that you can load as a pandas dataframe object. For more information about pandas formats, see IO tools (text, CSV, HDF5, …).

The following cell runs the `df` variable to start the widget.

```
df
```

The top of the dataframe has the following options:

- **View the Pandas table** – Switches between the interactive visualization and a pandas table.
- **Use all of the rows in your dataset to compute the insights. Using the entire dataset might increase the time it takes to generate the insights.** – If you don't select the option, Data Wrangler computes the insights for the first 10,000 rows of the dataset.

The dataframe shows the first 1000 rows of the dataset. Each column header has a stacked bar chart that shows the column's characteristics. It shows the proportion of valid values, invalid values, and missing values. You can hover over the different portions of the stacked bar chart to get the calculated percentages.

Each column has a visualization in the header. The following shows the types of visualizations the columns can have:

- Categorical – Bar chart
- Numeric – Histogram
- Datetime – Bar chart
- Text – Bar chart

For each visualization, the data preparation widget highlights outliers in orange.

When you choose a column, it opens a side panel. The side panel shows you the **Insights** tab. The pane provides a count for the following types of values:

- Invalid values – Values whose type doesn’t match the column type.
- Missing values – Values that are missing, such as `NaN` or `None`.
- Valid values – Values that are neither missing nor invalid.

For numeric columns, the **Insights** tab shows the following summary statistics:

- Minimum – The smallest value.
- Maximum – The largest value.
- Mean – The mean of the values.
- Mode – The value that appears most frequently.
- Standard deviation – The standard deviation of the values.

For categorical columns, the **Insights** tab shows the following summary statistics:

- Unique values – The number of unique values in the column.
- Top – The value that appears most frequently.

The columns that have warning icons in their headers have data quality issues. Choosing a column opens a **Data quality** tab that you can use to find transforms to help you fix the issue. A warning has one of the following severity levels:

- Low – Issues that might not affect your analysis, but can be useful to fix.
- Medium – Issues that are likely to affect your analysis, but are likely not critical to fix.
- High – Severe issues that we strongly recommend fixing.

Note

The widget sorts the column to show the values that have data quality issues at the top of the dataframe. It also highlights the values that are causing the issues. The color of the highlighting corresponds to the severity level.

Under **SUGGESTED TRANSFORMS**, you can choose a transform to fix the data quality issue. The widget can offer multiple transforms that can fix the issue. It can offer recommendations for the transforms that are best suited to the problem. You can move your cursor over the transform to get more information about it.

To apply a transform to the dataset, choose **Apply and export code**. The transform modifies the dataset and updates the visualization with modified values. The code for the transform appears in the following cell of the notebook. If you apply additional transforms to the dataset, the widget appends the transforms to the cell. You can use the code that the widget generates to do the following:

- Customize it to better fit your needs.
- Use it in your own workflows.

You can reproduce all the transforms you've made by rerunning all of the cells in the notebook.

The widget can provide insights and warnings for the target column. The target column is the column that you're trying to predict. Use the following procedure to get target column insights.

To get target column insights, do the following.

1. Choose the column that you're using as the target column.
2. Choose **Select as target column**.
3. Choose the problem type. The widget's insights and warnings are tailored to the problem types. The following are the problem types:
   - **Classification –** The target column has categorical data.
   - **Regression –** The target column has numeric data.
4. Choose **Run**.
5. (Optional) Under **Target Column Insights**, choose one of the suggested transforms.

Reference for the insights and transforms in the widget

For feature columns (columns that aren't the target column), you can get the following insights to warn you about issues with your dataset.

- **Missing values –** The column has missing values such as `None`, `NaN` (not a number), or `NaT` (not a timestamp). Many machine learning algorithms don’t support missing values in the input data. Filling them in or dropping the rows with missing data is therefore a crucial data preparation step. If you see the missing values warning, you can use one of the following transforms to correct the issue.
  - **Drop missing –** Drops rows with missing values. We recommend dropping rows when the percentage of rows with missing data is small and imputing the missing values isn't appropriate.

    - **Replace with new value** – Replaces textual missing values with `Other`. You can change `Other` to a different value in the output code. Replaces numeric missing values with 0.
    - **Replace with mean** – Replaces missing values with the mean of the column.
    - **Replace with median** – Replaces missing values with the median of the column.
    - **Drop column** – Drops the column with missing values from the dataset. We recommend dropping the entire column when there's a high percentage of rows with missing data.
- **Disguised missing values** – The column has disguised missing values. A disguised missing value is a value that isn't explicitly encoded as a missing value. For example, instead of using a `NaN` to indicate a missing value, the value could be `Placeholder`. You can use one of the following transforms to handle the missing values:
    - **Drop missing** – Drops rows with missing values
    - **Replace with new value** – Replaces textual missing values with `Other`. You can change `Other` to a different value in the output code. Replaces numeric missing values with 0.
- **Constant column** – The column only has one value. It therefore has no predictive power. We strongly recommend using the **Drop column** transform to drop the column from the dataset.
- **ID column** – The column has no repeating values. All of the values in the column are unique. They might be either IDs or database keys. Without additional information, the column has no predictive power. We strongly recommend using the **Drop column** transform to drop the column from the dataset.
- **High cardinality** – The column has a high percentage of unique values. High cardinality limits the predictive power of categorical columns. Examine the importance of the column in your analysis and consider using the **Drop column** transform to drop it.

For the target column, you can get the following insights to warn you about issues with your dataset. You can use the suggested transformation provided with the warning to correct the issue.

- **Mixed data types in target (Regression)** – There are some non-numeric values in the target column. There might be data entry errors. We recommend removing the rows that have the values that can't be converted.
- **Frequent label** – Certain values in the target column appear more frequently than what would be normal in the context of regression. There might be an error in data collection or processing. A frequently appearing category might indicate that either the value is used as a default value or that it’s a placeholder for missing values. We recommend using the **Replace with new value** transform to replace the missing values with `Other`.

- **Too few instances per class –** The target column has categories that appear rarely. Some of the categories don't have enough rows for the target column to be useful. You can use one of the following transforms:
  - **Drop rare target –** Drops unique values with fewer than ten observations. For example, drops the value `cat` if it appears nine times in the column.
  - **Replace rare target –** Replaces categories that appear rarely in the dataset with the value `Other`.
- **Classes too imbalanced (multi-class classification) –** There are categories in the dataset that appear much more frequently than the other categories. The class imbalance might affect prediction accuracy. For the most accurate predictions possible, we recommend updating the dataset with rows that have the categories that currently appear less frequently.
- **Large amount of classes/too many classes –** There's a large number of classes in the target column. Having many classes might result in longer training times or poor predictive quality. We recommend doing one of the following:
  - Grouping some of the categories into their own category. For example, if six categories are closely related, we recommend using a single category for them.
  - Using an ML algorithm that's resilient to multiple categories.

Security and Permissions

When you query data from Athena or Amazon Redshift, the queried dataset is automatically stored in the default SageMaker AI S3 bucket for the AWS Region in which you are using Studio Classic. Additionally, when you export a Jupyter Notebook from Amazon SageMaker Data Wrangler and run it, your data flows, or .flow files, are saved to the same default bucket, under the prefix *data_wrangler_flows*.

For high-level security needs, you can configure a bucket policy that restricts the AWS roles that have access to this default SageMaker AI S3 bucket. Use the following section to add this type of policy to an S3 bucket. To follow the instructions on this page, use the AWS Command Line Interface (AWS CLI). To learn how, see [Configuring the AWS CLI](#) in the IAM User Guide.

Additionally, you need to grant each IAM role that uses Data Wrangler permissions to access required resources. If you do not require granular permissions for the IAM role you use to access Data Wrangler, you can add the IAM managed policy, [`AmazonSageMakerFullAccess`](#), to an IAM role that you use to create your Studio Classic user. This policy grants you full permission to use

Data Wrangler. If you require more granular permissions, refer to the section, Grant an IAM Role Permission to Use Data Wrangler.

Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler

You can add a policy to the S3 bucket that contains your Data Wrangler resources using an Amazon S3 bucket policy. Resources that Data Wrangler uploads to your default SageMaker AI S3 bucket in the AWS Region you are using Studio Classic in include the following:

- Queried Amazon Redshift results. These are stored under the *redshift/* prefix.
- Queried Athena results. These are stored under the *athena/* prefix.
- The .flow files uploaded to Amazon S3 when you run an exported Jupyter Notebook Data Wrangler produces. These are stored under the *data_wrangler_flows/* prefix.

Use the following procedure to create an S3 bucket policy that you can add to restrict IAM role access to that bucket. To learn how to add a policy to an S3 bucket, see How do I add an S3 Bucket policy?.

To set up a bucket policy on the S3 bucket that stores your Data Wrangler resources:

1. Configure one or more IAM roles that you want to be able to access Data Wrangler.
2. Open a command prompt or shell. For each role that you create, replace *role-name* with the name of the role and run the following:

   ```
   $ aws iam get-role --role-name role-name
   ```

   In the response, you see a `RoleId` string which begins with `AROA`. Copy this string.
3. Add the following policy to the SageMaker AI default bucket in the AWS Region in which you are using Data Wrangler. Replace *region* with the AWS Region in which the bucket is located, and *account-id* with your AWS account ID. Replace `userIds` starting with *AROAEXAMPLEID* with the IDs of an AWS roles to which you want to grant permission to use Data Wrangler.

   JSON

   ```

            "AROAEXAMPLEID_2:*"
          ]
        }
      }
    }
  ]
}
```

Create an Allowlist for Data Wrangler

Whenever a user starts running Data Wrangler from the Amazon SageMaker Studio Classic user interface, they make call to the SageMaker AI application programming interface (API) to create a Data Wrangler application.

Your organization might not provide your users with permissions to make those API calls by default. To provide permissions, you must create and attach a policy to the user's IAM roles using the following policy template: Data Wrangler Allow List Example.

> **Note**
>
> The preceding policy example only gives your users access to the Data Wrangler application.

For information about creating a policy, see Creating policies on the JSON tab. When you're creating a policy, copy and paste the JSON policy from Data Wrangler Allow List Example in the **JSON** tab.

> **Important**
>
> Delete any IAM policies that prevent users from running the following operations:
>
> - CreateApp
> - DescribeApp
>
> If you don't delete the policies, your users could still be affected by them.

After you've creating the policy using the template, attach it to the IAM roles of your users. For information about attaching a policy, see Adding IAM identity permissions (console).

Grant an IAM Role Permission to Use Data Wrangler

You can grant an IAM role permission to use Data Wrangler with the general IAM managed policy, `AmazonSageMakerFullAccess`. This is a general policy that includes permissions required to use all SageMaker AI services. This policy grants an IAM role full access to Data Wrangler. You should be aware of the following when using `AmazonSageMakerFullAccess` to grant access to Data Wrangler:

- If you import data from Amazon Redshift, the **Database User** name must have the prefix `sagemaker_access`.
- This managed policy only grants permission to access buckets with one of the following in the name: `SageMaker AI`, `SageMaker AI`, `sagemaker`, or `aws-glue`. If want to use Data Wrangler to import from an S3 bucket without these phrases in the name, refer to the last section on this page to learn how to grant permission to an IAM entity to access your S3 buckets.

If you have high-security needs, you can attach the policies in this section to an IAM entity to grant permissions required to use Data Wrangler.

If you have datasets in Amazon Redshift or Athena that an IAM role needs to import from Data Wrangler, you must add a policy to that entity to access these resources. The following policies are the most restrictive policies you can use to give an IAM role permission to import data from Amazon Redshift and Athena.

To learn how to attach a custom policy to an IAM role, refer to [Managing IAM policies]() in the IAM User Guide.

Policy example to grant access to an Athena dataset import

The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy.

JSON

```

                "arn:aws:glue:*:*:table/sagemaker_featurestore/*",
                "arn:aws:glue:*:*:catalog",
                "arn:aws:glue:*:*:database/*"
            ]
        },
```

```
        {
            "Effect": "Allow",
            "Action": [
                "glue:DeleteTable"
            ],
            "Resource": [
                "arn:aws:glue:*:*:table/*/sagemaker_tmp_*",
                "arn:aws:glue:*:*:catalog",
                "arn:aws:glue:*:*:database/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "glue:GetDatabases",
                "glue:GetTable",
                "glue:GetTables"
            ],
            "Resource": [
                "arn:aws:glue:*:*:table/*",
                "arn:aws:glue:*:*:catalog",
                "arn:aws:glue:*:*:database/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "glue:CreateDatabase",
                "glue:GetDatabase"
            ],
            "Resource": [
                "arn:aws:glue:*:*:catalog",
                "arn:aws:glue:*:*:database/sagemaker_featurestore",
                "arn:aws:glue:*:*:database/sagemaker_processing",
                "arn:aws:glue:*:*:database/default",
                "arn:aws:glue:*:*:database/sagemaker_data_wrangler"
            ]
        }
    ]
}
```

Policy example to grant access to an Amazon Redshift dataset import

The following policy grants permission to set up an Amazon Redshift connection to Data Wrangler using database users that have the prefix `sagemaker_access` in the name. To grant permission to connect using additional database users, add additional entries under `"Resources"` in the following policy. The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy, if applicable.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "redshift-data:ExecuteStatement",
                "redshift-data:DescribeStatement",
                "redshift-data:CancelStatement",
                "redshift-data:GetStatementResult",
                "redshift-data:ListSchemas",
                "redshift-data:ListTables"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "redshift:GetClusterCredentials"
            ],
            "Resource": [
                "arn:aws:redshift:*:*:dbuser:*/sagemaker_access*",
                "arn:aws:redshift:*:*:dbname:*"
            ]
        }
    ]
}
```

Policy to grant access to an S3 bucket

If your dataset is stored in Amazon S3, you can grant an IAM role permission to access this bucket with a policy similar to the following. This example grants programmatic read-write access to the bucket named *test*.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::test"]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:DeleteObject"
      ],
      "Resource": ["arn:aws:s3:::test/*"]
    }
  ]
}
```

To import data from Athena and Amazon Redshift, you must grant an IAM role permission to access the following prefixes under the default Amazon S3 bucket in the AWS Region Data Wrangler in which is being used: `athena/`, `redshift/`. If a default Amazon S3 bucket does not already exist in the AWS Region, you must also give the IAM role permission to create a bucket in this region.

Additionally, if you want the IAM role to be able to use the Amazon SageMaker Feature Store, Pipelines, and Data Wrangler job export options, you must grant access to the prefix `data_wrangler_flows/` in this bucket.

Data Wrangler uses the `athena/` and `redshift/` prefixes to store preview files and imported datasets. To learn more, see [Imported Data Storage](#).

Data Wrangler uses the `data_wrangler_flows/` prefix to store .flow files when you run a Jupyter Notebook exported from Data Wrangler. To learn more, see Export.

Use a policy similar to the following to grant the permissions described in the preceding paragraphs.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/
data_wrangler_flows/",
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/
data_wrangler_flows/*",
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/athena",
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/athena/*",
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/redshift",
                "arn:aws:s3:::sagemaker-us-east-1-111122223333/redshift/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::sagemaker-us-east-1-111122223333"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets",
                "s3:GetBucketLocation"
            ],
            "Resource": "*"
```

```
        }
    ]
}
```

You can also access data in your Amazon S3 bucket from another AWS account by specifying the Amazon S3 bucket URI. To do this, the IAM policy that grants access to the Amazon S3 bucket in the other account should use a policy similar to the following example, where `BucketFolder` is the specific directory in the user's bucket `UserBucket`. This policy should be added to the user granting access to their bucket for another user.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
       {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::UserBucket/BucketFolder/*"
            },
                {
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket"
                ],
                "Resource": "arn:aws:s3:::UserBucket",
                "Condition": {
                "StringLike": {
                    "s3:prefix": [
                    "BucketFolder/*"
                    ]
                }
            }
        }
    ]
}
```

The user that is accessing the bucket (not the bucket owner) must add a policy similar to the following example to their user. Note that `AccountX` and `TestUser` below refers to the bucket owner and their user respectively.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/TestUser"
            },
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::UserBucket/BucketFolder/*"
            ]
        },
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/TestUser"
            },
            "Action": [
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::UserBucket"
            ]
        }
    ]
}
```

Policy example to grant access to use SageMaker AI Studio

Use a policy like to the following to create an IAM execution role that can be used to set up a Studio Classic instance.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeDomain",
                "sagemaker:ListDomains",
                "sagemaker:DescribeUserProfile",
                "sagemaker:ListUserProfiles",
                "sagemaker:*App",
                "sagemaker:ListApps"
            ],
            "Resource": "*"
        }
    ]
}
```

Snowflake and Data Wrangler

All permissions for AWS resources are managed via your IAM role attached to your Studio Classic instance. The Snowflake administrator manages Snowflake-specific permissions, as they can grant granular permissions and privileges to each Snowflake user. This includes databases, schemas, tables, warehouses, and storage integration objects. You must ensure that the correct permissions are set up outside of Data Wrangler.

Note that the Snowflake `COPY INTO Amazon S3` command moves data from Snowflake to Amazon S3 over the public internet by default, but data in transit is secured using SSL. Data at rest in Amazon S3 is encrypted with SSE-KMS using the default AWS KMS key.

With respect to Snowflake credentials storage, Data Wrangler does not store customer credentials. Data Wrangler uses Secrets Manager to store the credentials in a secret and rotates secrets as part of a best practice security plan. The Snowflake or Studio Classic administrator needs to ensure that the data scientist’s Studio Classic execution role is granted permission to perform

`GetSecretValue` on the secret storing the credentials. If already attached to the Studio Classic execution role, the `AmazonSageMakerFullAccess` policy has the necessary permissions to read secrets created by Data Wrangler and secrets created by following the naming and tagging convention in the instructions above. Secrets that do not follow the conventions must be separately granted access. We recommend using Secrets Manager to prevent sharing credentials over unsecured channels; however, note that a logged-in user can retrieve the plain-text password by launching a terminal or Python notebook in Studio Classic and then invoking API calls from the Secrets Manager API.

Data Encryption with AWS KMS

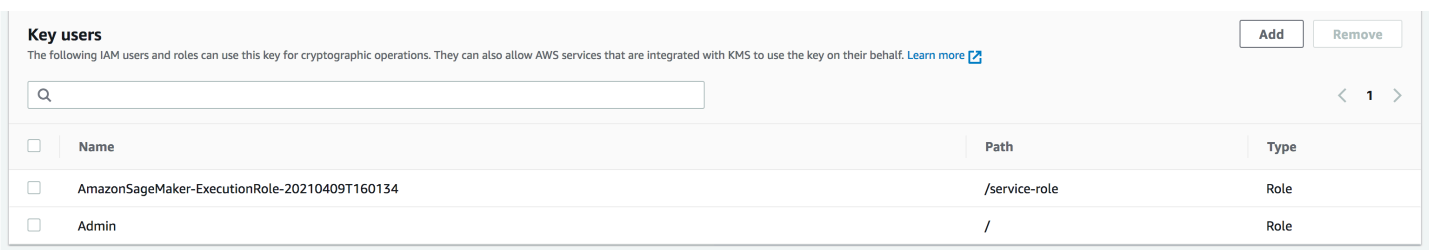
Within Data Wrangler, you can decrypt encrypted files and add them to your Data Wrangler flow. You can also encrypt the output of the transforms using either a default AWS KMS key or one that you provide.

You can import files if they have the following:

- server-side encryption
- SSE-KMS as the encryption type

To decrypt the file and import to a Data Wrangler flow, you must add the SageMaker Studio Classic user that you're using as a key user.

The following screenshot shows a Studio Classic user role added as a key user. See IAM Roles to access users under the left panel to make this change.



Amazon S3 customer managed key setup for Data Wrangler imported data storage

By default, Data Wrangler uses Amazon S3 buckets that have the following naming convention: `sagemaker-region-account number`. For example, if your account number is `111122223333` and you are using Studio Classic in us-east-1, your imported datasets are stored with the following naming convention: `sagemaker-us-east-1-111122223333`.

The following instructions explain how to set up a customer managed key for your default Amazon S3 bucket.

1. To enable server-side encryption and setup a customer managed key for your default S3 bucket, see Using KMS Encryption.
2. After following step 1, navigate to AWS KMS in your AWS Management Console. Find the customer managed key you selected in step 1 of the previous step and add the Studio Classic role as the key user. To do this, follow the instructions in Allows key users to use a customer managed key.

Encrypting the Data That You Export

You can encrypt the data that you export using one of the following methods:

- Specifying that your Amazon S3 bucket has object use SSE-KMS encryption.
- Specifying an AWS KMS key to encrypt the data that you export from Data Wrangler.

On the **Export data** page, specify a value for the **AWS KMS key ID or ARN**.

For more information on using AWS KMS keys, see Protecting Data Using Server-Side Encryption with AWS KMS keys Stored in AWSAWS Key Management Service (SSE-KMS) .

Amazon AppFlow Permissions

When you're performing a transfer, you must specify an IAM role that has permissions to perform the transfer. You can use the same IAM role that has permissions to use Data Wrangler. By default, the IAM role that you use to access Data Wrangler is the `SageMakerExecutionRole`.

The IAM role must have the following permissions:

- Permissions to Amazon AppFlow
- Permissions to the AWS Glue Data Catalog
- Permissions for AWS Glue to discover the data sources that are available

When you run a transfer, Amazon AppFlow stores metadata from the transfer in the AWS Glue Data Catalog. Data Wrangler uses the metadata from the catalog to determine whether it's available for you to query and import.

To add permissions to Amazon AppFlow, add the `AmazonAppFlowFullAccess` AWS managed policy to the IAM role. For more information about adding policies, see [Adding or removing IAM identity permissions](#).

If you're transferring data to Amazon S3, you must also attach the following policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketTagging",
        "s3:ListBucketVersions",
        "s3:CreateBucket",
        "s3:ListBucket",
        "s3:GetBucketPolicy",
        "s3:PutEncryptionConfiguration",
        "s3:GetEncryptionConfiguration",
        "s3:PutBucketTagging",
        "s3:GetObjectTagging",
        "s3:GetBucketOwnershipControls",
        "s3:PutObjectTagging",
        "s3:DeleteObject",
        "s3:DeleteBucket",
        "s3:DeleteObjectTagging",
        "s3:GetBucketPublicAccessBlock",
        "s3:GetBucketPolicyStatus",
        "s3:PutBucketPublicAccessBlock",
        "s3:PutAccountPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:PutBucketOwnershipControls",
        "s3:PutObjectVersionTagging",
        "s3:DeleteObjectVersionTagging",
        "s3:GetBucketVersioning",
        "s3:GetBucketAcl",
        "s3:PutObject",
        "s3:GetObject",
        "s3:GetAccountPublicAccessBlock",
```

```
            "s3:ListAllMyBuckets",
            "s3:GetAnalyticsConfiguration",
            "s3:GetBucketLocation"
          ],
          "Resource": "*"
        }
      ]
    }
```

To add AWS Glue permissions, add the `AWSGlueConsoleFullAccess` managed policy to the IAM role. For more information about AWS Glue permissions with Amazon AppFlow, see [link-to-appflow-page].

Amazon AppFlow needs to access AWS Glue and Data Wrangler for you to import the data that you've transferred. To grant Amazon AppFlow access, add the following trust policy to the IAM role.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:root",
                "Service": [
                    "appflow.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

To display the Amazon AppFlow data in Data Wrangler, add the following policy to the IAM role:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "glue:SearchTables",
            "Resource": [
                "arn:aws:glue:*:*:table/*/*",
                "arn:aws:glue:*:*:database/*",
                "arn:aws:glue:*:*:catalog"
            ]
        }
    ]
}
```

Using Lifecycle Configurations in Data Wrangler

You might have an Amazon EC2 instance that is configured to run Kernel Gateway applications, but not the Data Wrangler application. Kernel Gateway applications provide access to the environment and the kernels that you use to run Studio Classic notebooks and terminals. The Data Wrangler application is the UI application that runs Data Wrangler. Amazon EC2 instances that aren't Data Wrangler instances require a modification to their lifecycle configurations to run Data Wrangler. Lifecycle configurations are shell scripts that automate the customization of your Amazon SageMaker Studio Classic environment.

For more information about lifecycle configurations, see Use lifecycle configurations to customize Studio Classic.

The default lifecycle configuration for your instance doesn't support using Data Wrangler. You can make the following modifications to the default configuration to use Data Wrangler with your instance.

```
#!/bin/bash
set -eux
```

```
STATUS=$(
python3 -c "import sagemaker_dataprep"
echo $?
)
if [ "$STATUS" -eq 0 ]; then
echo 'Instance is of Type Data Wrangler'
else
echo 'Instance is not of Type Data Wrangler'

# Replace this with the URL of your git repository
export REPOSITORY_URL="https://github.com/aws-samples/sagemaker-studio-lifecycle-
config-examples.git"

git -C /root clone $REPOSTIORY_URL

fi
```

You can save the script as `lifecycle_configuration.sh`.

You attach the lifecycle configuration to your Studio Classic domain or user profile. For more information about creating and attaching a lifecycle configuration, see [Create and associate a lifecycle configuration](#).

The following instructions show you how to attach a lifecycle configuration to a Studio Classic domain or user profile.

You might run into errors when you're creating or attaching a lifecycle configuration. For information about debugging lifecycle configuration errors, [KernelGateway app failure](#).

Release Notes

Data Wrangler is regularly updated with new features and bug fixes. To upgrade the version of Data Wrangler you are using in Studio Classic, follow the instructions in [Shut down and Update Studio Classic Apps](#).

Release Notes
8/31/2023 New functionality:

Release Notes

You can now create a Data Quality and Insights report on your entire dataset. For more information, see Get Insights On Data and Data Quality.

5/20/2023

New functionality:

You can now import your data from Salesforce Data Cloud. For more information, see Import data from Salesforce Data Cloud.

4/18/2023

New functionality:

You can now get your data in a format that Amazon Personalize can interpret. For more information, see Map Columns for Amazon Personalize.

3/1/2023

New functionality:

You can now use Hive to import your data from Amazon EMR. For more information, see Import data from Amazon EMR.

12/10/2022

New functionality:

You can now export your Data Wrangler flow to an inference endpoint. For more information, see Export to an Inference Endpoint.

New functionality:

You can now use an interactive notebook widget for data preparation. For more information, see Use an Interactive Data Preparation Widget in an Amazon SageMaker Studio Classic Notebook to Get Data Insights.

New functionality:

Release Notes

You can now import data from SaaS platforms. For more information, see Import Data From Software as a Service (SaaS) Platforms.

10/12/2022

New functionality:

You can now reuse data flows for different data sets. For more information, see Reusing Data Flows for Different Datasets.

10/05/2022

New functionality:

You can now use Principal Component Analysis (PCA) as a transform. For more information, see Reduce Dimensionality within a Dataset.

10/05/2022

New functionality:

You can now refit parameters in your Data Wrangler flow. For more information, see Export.

10/03/2022

New functionality:

You can now deploy models from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow.

9/20/2022

New functionality:

You can now set data retention periods in Athena. For more information, see Import data from Athena.

6/9/2022

New functionality:

Release Notes

You can now use Amazon SageMaker Autopilot to train a model directly from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow.

5/6/2022

New functionality:

You can now use additional m5 and r5 instances. For more information, see Instances.

4/27/2022

New functionalities:

- You can now get a data quality report. For more information, see Get Insights On Data and Data Quality
- You can now perform random sampling and stratified sampling. For more information, see Sampling.

4/1/2022

New functionality:

You can now use Databricks as a data source. For more information, see Import data from Databricks (JDBC).

2/2/2022

New functionalities:

- You can now export using destination nodes. For more information, see Export
- You can import ORC and JSON files. For more information about file types, see Import.
- Data Wrangler now supports using the SMOTE transform. For more information, see Balance Data.
- Data Wrangler now supports similarity encoding for categorical data. For more information, see Similarity encode.
- Data Wrangler now supports unnesting JSON data. For more information, see Unnest JSON Data.

Release Notes

- Data Wrangler now supports expanding the values of an array into separate columns. For more information, see Explode Array.
- Data Wrangler now supports reaching out to the service team when you're having issues. For more information, see Troubleshoot.
- Data Wrangler supports editing and deleting steps in your data flow. For more information, see Delete a Step from Your Data Flow and Edit a Step in Your Data Wrangler Flow.
- You can now perform transformations on multiple columns. For more information, see Transform Data.
- Data Wrangler now supports cost allocation tags. For more information, see Using Cost Allocation Tags.

10/16/2021

New functionality:

Data Wrangler now supports Athena workgroups. For more information, see Import data from Athena.

10/6/2021

New functionality:

Data Wrangler now supports transforming time series data. For more information, see Transform Time Series.

7/15/2021

New functionalities:

- Snowflake and Data Wrangler is now supported. You can use Snowflake as a data source in Data Wrangler.
- Added support for custom field delimiter in CSV. Now comma, colon, semicolon, pipe (|) and Tab are supported.
- Now you can export results directly to Amazon S3.
- Added a few new multicollinearity analyzers: Variance Inflation Factors, Principal Component Analysis and Lasso feature selection.

Release Notes

Enhancements:

- The analyze charts can no longer be could be packed with overlapping labels.

Bug Fixes:

- One-hot encoder handles empty string gracefully.
- Fixed crashes that occured when a dataframe column name contained dots.

4/26/2021

Enhancements:

- Added support for distributed processing Jobs. You can use multiple instances when running a processing job.
- Data Wrangler Processing job now automatically coalesces small outputs when estimated result size is less than 1 gigabytes.
- Feature Store Notebook: Improved feature store ingestion performance
- Data Wrangler Processing jobs now use 1.x as the authoritative container tag for future releases.

Bug Fixes:

- Fixed rendering issues for faceted histogram.
- Fixed **Export to Processing Job** to support vector type columns.
- Fixed `Extract using regex` operator to return the first captured group if one or more exists in the regular expression or regex.

2/8/2021

New Functionalities:

- Data Wrangler Flows supports multiple instances.
- Updated Export to Data Wrangler Job Notebook to use SageMaker SDK 2.20.0.

Release Notes

- Updated Export to Pipeline Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to add XGBoost training example as an optional step.

Enhancements:

- To improve performance, importing CSV files that contain multiple lines in a single field is no longer supported.

Bug Fixes:

- Fixed type inference issue in Quick model.
- Fixed the bias metric bug in bias reports.
- Fixed the Featurize text transform to work with columns with missing values.
- Fixed Histogram and Scatter plot built-in visualizations to work with datasets that contain array-like columns.
- Athena query now re-runs if the query execution ID has expired.

Troubleshoot

If an issue arises when using Amazon SageMaker Data Wrangler, we recommend you do the following:

- If an error message is provided, read the message and resolve the issue it reports if possible.
- Make sure the IAM role of your Studio Classic user has the required permissions to perform the action. For more information, see Security and Permissions.
- If the issue occurs when you are trying to import from another AWS service, such as Amazon Redshift or Athena, make sure that you have configured the necessary permissions and resources to perform the data import. For more information, see Import.
- If you're still having issues, choose **Get help** at the top right of your screen to reach out to the Data Wrangler team. For more information, see the following images.

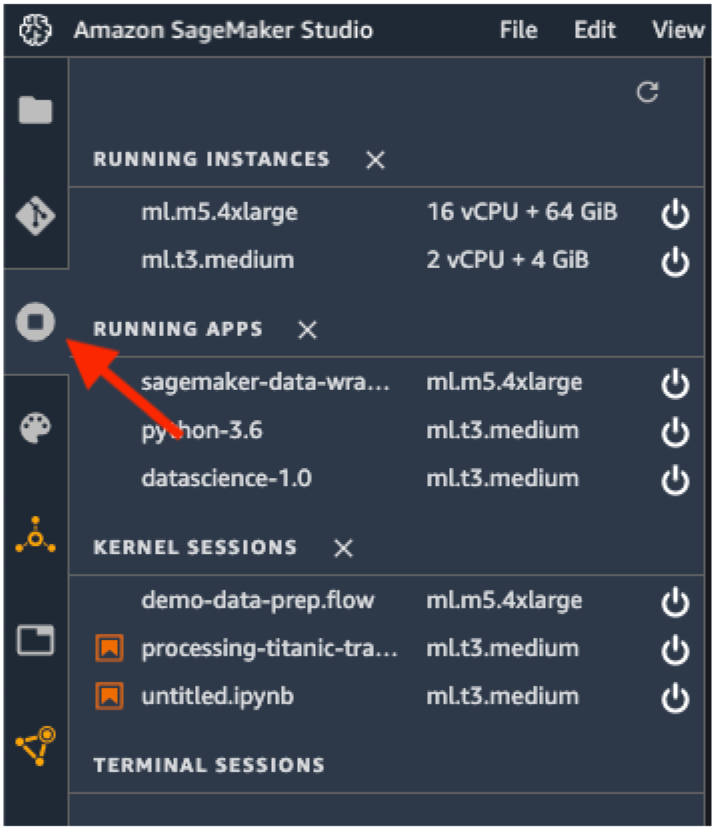
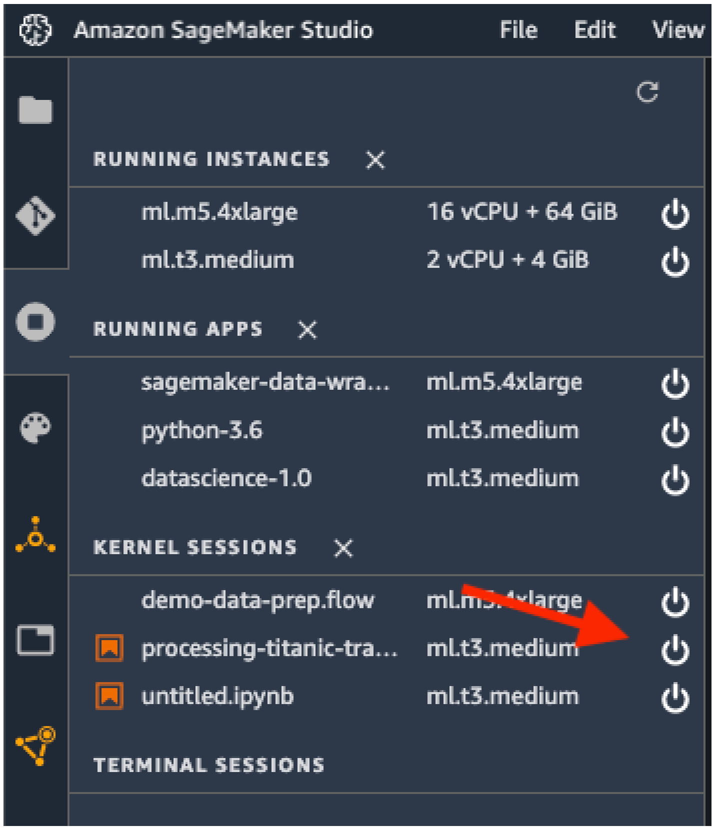
As a last resort, you can try restarting the kernel on which Data Wrangler is running.

1. Save and exit the .flow file for which you want to restart the kernel.
2. Select the **Running Terminals and Kernels** icon, as shown in the following image.



3. Select the **Stop** icon to the right of the .flow file for which you want to terminate the kernel, as shown in the following image.



4. Refresh the browser.
5. Reopen the .flow file on which you were working.

Troubleshooting issues with Amazon EMR

Use the following information to help you troubleshoot errors that might come up when you're using Amazon EMR.

- Connection failure – If the connection fails with the following message `The IP address of the EMR cluster isn't private error message`, your Amazon EMR cluster might not have been launched in a private subnet. As a security best practice, Data Wrangler only supports connecting to private Amazon EMR clusters. Choose a private EC2 subnet you launch an EMR cluster.
- Connection hanging and timing out – The issue is most likely due to a network connectivity issue. After you start connecting to the cluster, the screen doesn't refresh. After about 2 minutes, you might see the following error `JdbcAddConnectionError: An error occurred when trying to connect to presto: xxx: Connect to xxx failed: Connection timed out (Connection timed out) will display on top of the screen..`

The errors might have two root causes:

- The Amazon EMR and Amazon SageMaker Studio Classic are in different VPCs. We recommend launching both Amazon EMR and Studio Classic in the same VPC. You can also use VPC peering. For more information, see What is VPC peering?.
- The Amazon EMR master security group lacks the inbound traffic rule for the security group of Amazon SageMaker Studio Classic on the port used for Presto. To resolve the issue, allow inbound traffic on port 8889.

- Connection fails due to the connection type being misconfigured – You might see the following error message: `Data Wrangler couldn't create a connection to {connection_source} successfully. Try connecting to {connection_source} again. For more information, see Troubleshoot. If you’re still experiencing issues, contact support.`

  Check the authentication method. The authentication method that you've specified in Data Wrangler should match the authentication method that you're using on the cluster.

- You don't have HDFS permissions for LDAP authentication – Use the following guidance to resolve the issue Set up HDFS Permissions using Linux Credentials. You can log into the cluster using the following commands:

```
hdfs dfs -mkdir /user/USERNAME
hdfs dfs -chown USERNAME:USERNAME /user/USERNAME
```

- LDAP authentication missing connection key error – You might see the following error message: `Data Wrangler couldn't connect to EMR hive successfully. JDBC connection is missing required connection key(s): PWD.`

  For LDAP authentication, you must specify both a username and a password. The JDBC URL stored in Secrets Manager is missing property `PWD`.

- When you're troubleshooting the LDAP configuration: We recommend making sure that the LDAP authenticator (LDAP server) is correctly configured to connect to the Amazon EMR cluster. Use the `ldapwhoami` command to help you resolve the configuration issue. The following are example commands that you can run:
  - For LDAPS – `ldapwhoami -x -H ldaps://ldap-server`
  - For LDAP – `ldapwhoami -x -H ldap://ldap-server`

Either command should return `Anonymous` if you've configured the authenticator successfully.

Troubleshooting with Salesforce

Lifecycle configuration error

When your user opens Studio Classic for the first time, they might get an error saying that there's something wrong with their lifecycle configuration. Use Amazon CloudWatch to access the logs written by your lifecycle configuration script. For more information about debugging lifecycle configurations, see Debug lifecycle configurations.

If you aren't able to debug the error, you can create the configuration file manually. You must create the file every time you delete or restart the Jupyter server. Use the following procedure to create the file manually.

To create a configuration file

1. Navigate to Studio Classic.
2. Choose **File**, then **New**, then **Terminal**.
3. Create `.sfgenie_identity_provider_oauth_config`.
4. Open the file in a text editor.
5. Add a JSON object containing the Amazon Resource Name (ARN) of the Secrets Manager secret to the file. You can use the following template to create the object.

```
{
  "secret_arn": "example-secret-ARN"
}
```

6. Save your changes to the file.

Unable to access Salesforce Data Cloud from the Data Wrangler flow

After your user chooses **Salesforce Data Cloud** from your Data Wrangler flow, they might get an error indicating the prerequisites to set up the connection haven't been met. It might be caused by following errors:

- The Salesforce secret in Secrets Manager hasn't been created.

- The Salesforce secret in Secrets Manager has been created, but it's missing the Salesforce tag.
- The Salesforce secret in Secrets Manager has been created in the wrong AWS Region. For example, your user won't be able to access the Salesforce Data Cloud in `ca-central-1` because you've created the secret in `us-east-1`. You can either replicate the secret to `ca-central-1` or create a new secret with the same credentials in `ca-central-1`. For information about replicating secrets, see [Replicate an AWS Secrets Manager secret to other AWS Regions](#).
- The policy that your users are using to access Amazon SageMaker Studio Classic are missing permissions for AWS Secrets Manager
- There's a typo in the Secrets Manager ARN of the JSON object that you've specified through your lifecycle configuration.
- There's a typo in the Secrets Manager secret containing your Salesforce OAuth configuration

Blank page showing `redirect_uri_mismatch`

After your users choose **Save and Connect**, they might get redirected to a page that shows `redirect_uri_mismatch`. The callback URI that you've registered in your Salesforce Connected App settings is either missing or incorrect.

Use the following URL to check that your Studio Classic URL is correctly registered in your Salesforce org's Connected App settings: `https://EXAMPLE_SALESFORCE_ORG/lightning/setup/NavigationMenus/home/`. For more information about using the connected app settings, navigate to the following URL: `https://EXAMPLE_SALESFORCE_ORG/lightning/setup/NavigationMenus/home/`.

> **Note**
>
> It takes roughly ten minutes to propagate the URI within Salesforce's systems.

Shared spaces

Shared spaces doesn't currently work with the Salesforce Data Cloud integration. You can either delete the shared spaces in the Amazon SageMaker AI domain that you intend to use, or you can use another domain that doesn't have shared spaces set up.

OAuth Redirect Error

Your users should be able to import their data from the Salesforce Data Cloud after they choose **Connect**. If they're running into an error, we recommend asking them to do the following:

- Tell them to be patient – When they get redirected back to Amazon SageMaker Studio Classic, it can take up to a minute to complete the authentication process. While they're getting redirected, we recommend telling them to avoid interacting with the browser. For example, they shouldn't close the browser tab, switch to another tab, or interact with the Data Wrangler flow. Interacting with the browser might remove the authorization code required to connect to the data cloud.
- Have your users reconnect to the data cloud – There are transient issues that can cause a connection to the Salesforce Data Cloud to fail. Have your users create a new Data Wrangler flow and try connecting to the Salesforce Data Cloud again.
- Make sure your users close all other tabs with Amazon SageMaker Studio Classic – Having Studio Classic open in multiple tabs can cause the Salesforce Data Cloud connection to fail. Make sure your users only have one Studio Classic tab open.
- Multiple users accessing Studio Classic at the same time – Only one user should access an Amazon SageMaker AI domain at a time. If multiple users access the same domain, the connection that a user is trying to create to the Salesforce Data Cloud might fail.

Updating both Data Wrangler and Studio Classic might also fix their error. For information about updating Data Wrangler, see Update Data Wrangler. For information about updating Studio Classic, see Shut down and Update SageMaker Studio Classic.

If none of the preceding troubleshooting steps work, you might find an error message from Salesforce with a corresponding description embedded in the Studio Classic URL. The following is an example of a message you could find: `error=invalid_client_id&error_description=client%20identifier%20invalid`.

You can look at the error message in the URL and try to address the issues it presents. If the error message or description is unclear, we recommend searching the Salesforce Knowledge Base. If searching the knowledge base doesn't work, you can reach out to the Salesforce help desk for more assistance.

Data Wrangler takes a long time to load

When your users are getting redirected back to Data Wrangler from the Salesforce Data Cloud, they might experience long load times.

If this is the user's first time using Data Wrangler or they've deleted the kernel, it might take about 5 minutes to provision the new Amazon EC2 instance to use Data Wrangler.

If this isn't the user's first time using Data Wrangler and they haven't deleted the kernel, you can ask them to refresh the page or close as many browser tabs as possible.

If none of the preceding interventions work, have them set up a new connection to the Salesforce Data Cloud.

User fails to export their data with an `Invalid batch Id` error

When your user exports the transformations that they've made to their Salesforce data, the SageMaker Processing job that Data Wrangler uses on the backend might fail. The Salesforce Data Cloud might be temporarily unavailable or there could be a caching issue.

To address the issue, we recommend having your users go back to the step where they're importing the data and changing the order of the columns that they're querying . For example, they can change the following query:

```
SELECT col_A, col_B FROM table
```

To the following query:

```
SELECT col_B, col_A FROM table
```

After they've changed the order of the columns and made sure that the subsequent transformations they've made are still valid, they can start exporting their data again.

Users can't export a very large dataset

If your users imported a very large dataset from the Salesforce Data Cloud, they might not be able to export the transformations that they've made. A large dataset might have too many rows, or it can result from a complex query.

We recommend having your users take the following actions:

- Simplifying their SQL query

- Sampling their data

The following are some strategies that they can use to simplify their queries:

- Specify column names instead of using the * operator
- Finding a subset of the data that they'd like to import instead of using a larger subset
- Minimizing joins between very large datasets

They can use sampling to reduce the number of rows in their dataset. For information about sampling methods, your users can refer to Sampling.

Users can't export data due to invalid refresh token

Data Wrangler uses a JDBC driver to integrate with the Salesforce Data Cloud. The method for authentication is OAuth. For OAuth, the refresh token and the access token are two different pieces of data that are used to authorize access to resources within your Salesforce Data Cloud.

The access token, or core token, is what allows you to access your Salesforce data and run queries directly through Data Wrangler. It's short lived and designed to expire quickly. To maintain access to your Salesforce data, Data Wrangler uses the refresh token to get a new access token from Salesforce.

You might have set the refresh to expire too quickly to get a new access token for your users. You might have to revisit your refresh token policy to make sure that it can accommodate queries that take a long time to run for your users. For information about configuring your refresh token policy, see `https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ConnectedApplication/home/`.

Queries failing or tables not loading

Salesforce experiences service outages. Even if you’ve configured everything correctly, your users might not be able to import their data for periods of time.

Service outages can happen for maintenance reasons. We recommend checking in the following day to see if the issue has been resolved.

If you’re experiencing issues for more than a day, we recommend contacting Salesforce’s help desk for further assistance. For information about contacting Salesforce, see How would you like to contact Salesforce?

`OAUTH_APP_BLOCKED` during Studio Classic redirect

When your user gets redirected back to Amazon SageMaker Studio Classic, they might notice the query parameter `error=OAUTH_APP_BLOCKED` within the URL. They're might be experiencing a transient issue that should resolve itself within a day.

It's possible that you've blocked their access to the Connected App as well. For information about resolving the issue, see `https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ConnectedApplication/home/`.

`OAUTH_APP_DENIED` during Studio Classic redirect

When your user gets redirected back to Amazon SageMaker Studio Classic, they might notice the query parameter `error=OAUTH_APP_ACCESS_DENIED` within the URL. You haven't given their profile type permissions to access the `Connected App` associated with Data Wrangler.

To resolve their access issue, navigate to `https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ManageUsers/home/` and check whether the user is assigned to the correct profile.

Increase Amazon EC2 Instance Limit

You might see the following error message when you're using Data Wrangler: `The following instance type is not available: ml.m5.4xlarge. Try selecting a different instance below.`

The message can indicate that you need to select a different instance type, but it can also indicate that you don't have enough Amazon EC2 instances to successfully run Data Wrangler on your workflow. You can increase the number of instances by using the following procedure.

To increase the number of instances, do the following.

1. Open the AWS Management Console.
2. In the search bar, specify **`Services Quotas`**.
3. Choose **Service Quotas**.
4. Choose **AWS services**.
5. In the search bar, specify **`Amazon SageMaker AI`**.
6. Choose **Amazon SageMaker AI**.

7. Under **Service quotas**, specify **`Studio KernelGateway Apps running on` *`ml.m5.4xlarge`* `instance`**.

> **Note**
>
> ml.m5.4xlarge is the default instance type for Data Wrangler. You can use other instance types and request quota increases for them. For more information, see [Instances](#).

8. Select **Studio KernelGateway Apps running on *`ml.m5.4xlarge`* instance**.
9. Choose **Request quota increase**.
10. For **Change quota value**, specify a value greater than **Applied quota value**.
11. Choose **Request**.

If your request is approved, AWS sends a notification to the email address associated with your account. You can also check the status of your request by choosing **Quota request history** on the **Service Quotas** page. Processed requests have a **Status** of **Closed**.

Update Data Wrangler

To update Data Wrangler to the latest release, first shut down the corresponding KernelGateway app from the Amazon SageMaker Studio Classic control panel. After the KernelGateway app is shut down, restart it by opening a new or existing Data Wrangler flow in Studio Classic. When you open a new or existing Data Wrangler flow, the kernel that starts contains the latest version of Data Wrangler.

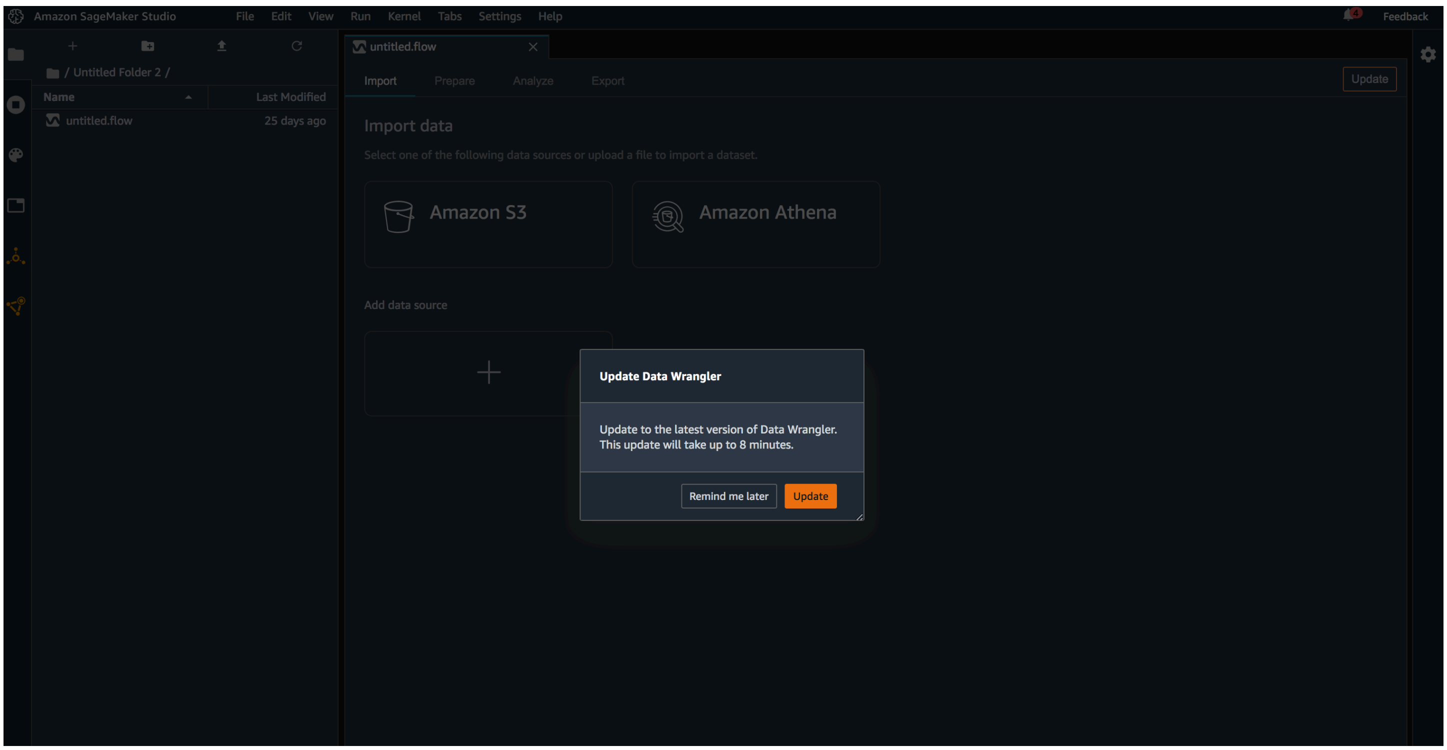
Update your Studio Classic and Data Wrangler instance

1. Navigate to your [SageMaker AI Console](#).
2. Choose SageMaker AI and then Studio Classic.
3. Choose your user name.
4. Under **Apps**, in the row displaying the **App name**, choose **Delete app** for the app that starts with `sagemaker-data-wrang`, and for the JupyterServer app.
5. Choose **Yes, delete app**.
6. Type `delete` in the confirmation box.
7. Choose **Delete**.

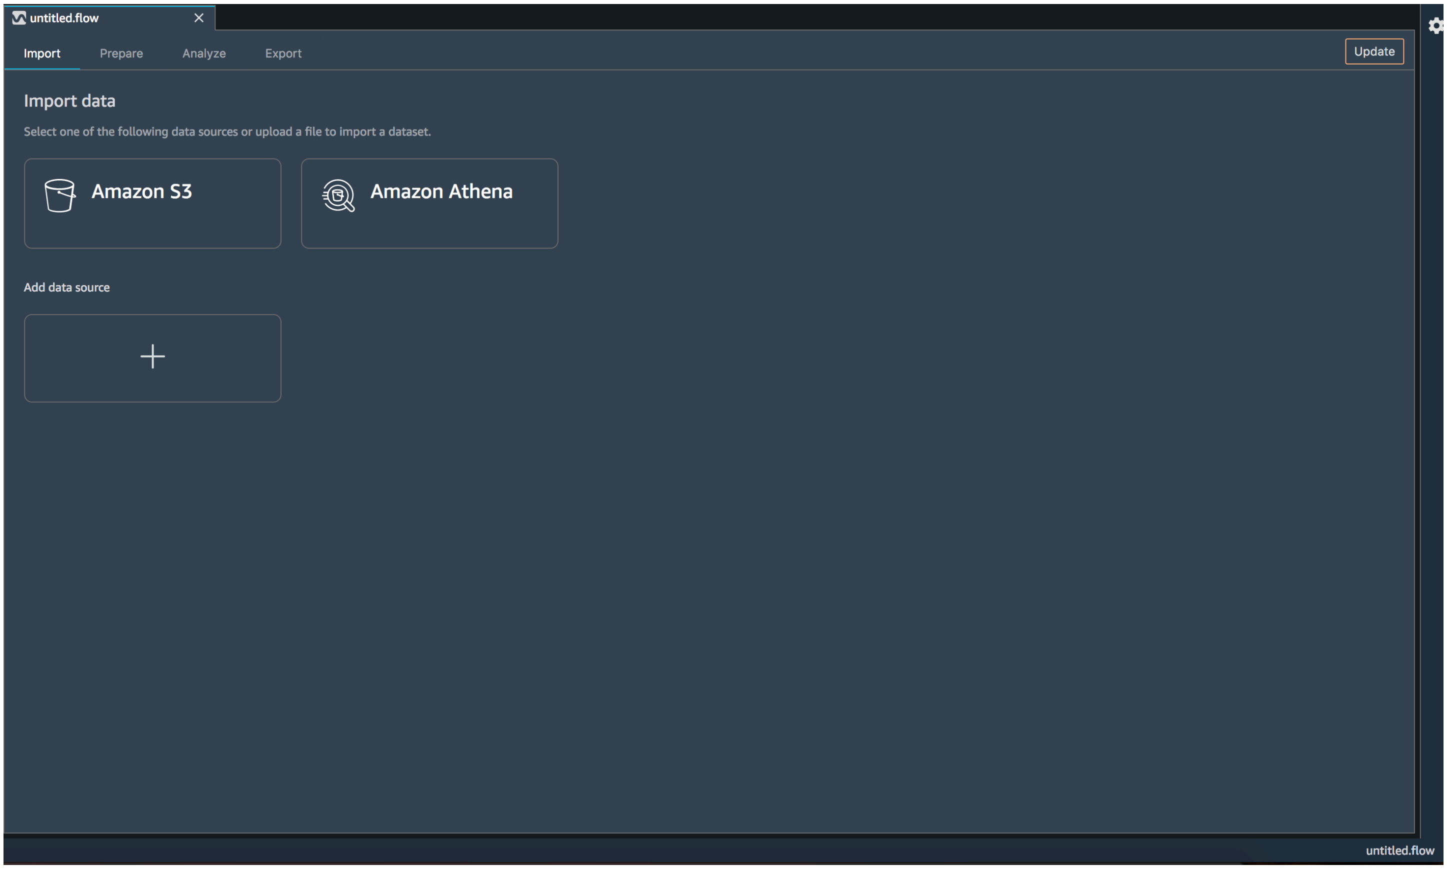
8. Reopen your Studio Classic instance. When you begin to create a Data Wrangler flow, your instance now uses the latest version of Data Wrangler.

Alternatively, if you are using a Data Wrangler application version that is not the latest version, and you have an existing Data Wrangler flow open, you are prompted to update your Data Wrangler application version in the Studio Classic UI. The following screenshot shows this prompt.

> **Important**
>
> This updates the Data Wrangler kernel gateway app only. You still need to shut down the JupyterServer app in your user account. To do this, follow the preceding steps.



You can also choose **Remind me later**, in which case an **Update** button appears in the top-right corner of the screen.



Shut Down Data Wrangler

When you are not using Data Wrangler, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To avoid losing work, save your data flow before shutting Data Wrangler down. To save your data flow in Studio Classic, choose **File** and then choose **Save Data Wrangler Flow**. Data Wrangler automatically saves your data flow every 60 seconds.

To shut down the Data Wrangler instance in Studio Classic

1. In Studio Classic, select the **Running Instances and Kernels** icon ().
2. Under **RUNNING APPS** is the **sagemaker-data-wrangler-1.0** app. Select the shutdown icon () next to this app .

Data Wrangler runs on an ml.m5.4xlarge instance. This instance disappears from **RUNNING INSTANCES** when you shut down the Data Wrangler app.

Important

If you open Data Wrangler again, an Amazon EC2 instance starts running the application and you will be charged for the compute. In addition to compute, you are also charged for the storage that you use. For example, you're charged for any Amazon S3 buckets that you're using with Data Wrangler.

If you find that you're still getting charged for Data Wrangler after shutting down your applications, there's a Jupyter extension that you can use to automatically shut down idle sessions. For information about the extension, see SageMaker-Studio-Autoshutdown-Extension.

After you shut down the Data Wrangler app, it has to restart the next time you open a Data Wrangler flow file. This can take a few minutes.

Data transformation workloads with SageMaker Processing

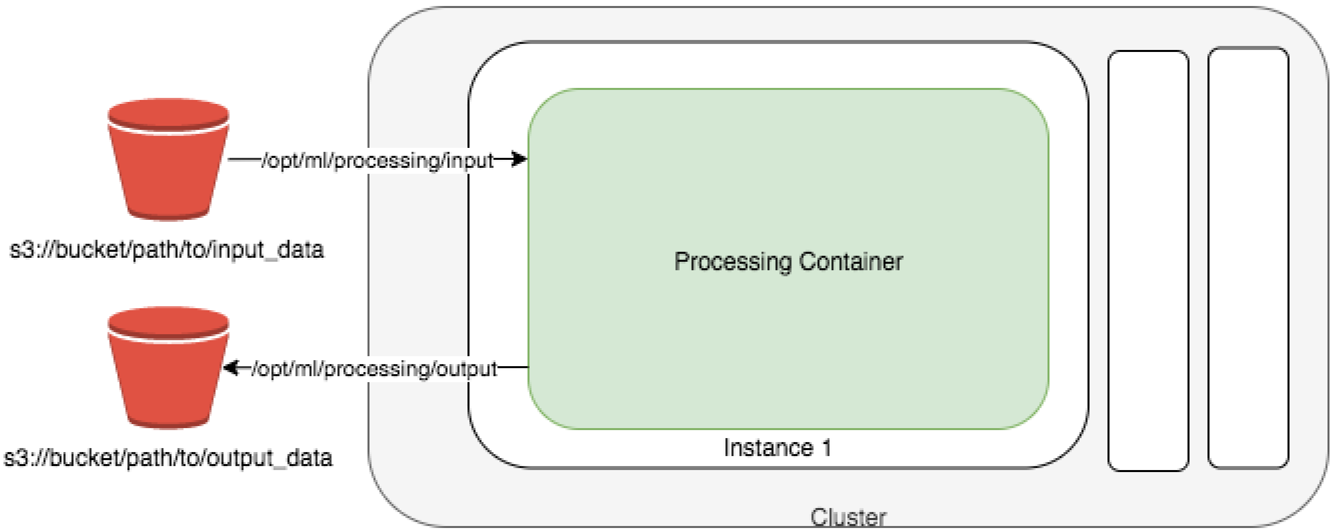
SageMaker Processing refers to SageMaker AI’s capabilities to run data pre and post processing, feature engineering, and model evaluation tasks on SageMaker AI's fully-managed infrastructure. These tasks are executed as processing jobs. The following provides information and resources to learn about SageMaker Processing.

Using SageMaker Processing API, data scientists can run scripts and notebooks to process, transform, and analyze datasets to prepare them for machine learning. When combined with the other critical machine learning tasks provided by SageMaker AI, such as training and hosting, Processing provides you with the benefits of a fully managed machine learning environment, including all the security and compliance support built into SageMaker AI. You have the flexibility to use the built-in data processing containers or to bring your own containers for custom processing logic and then submit jobs to run on SageMaker AI managed infrastructure.

> **Note**
>
> You can create a processing job programmatically by calling the CreateProcessingJob API action in any language supported by SageMaker AI or by using the AWS CLI. For information on how this API action translates into a function in the language of your choice, see the See Also section of CreateProcessingJob and choose an SDK. As an example, for Python users, refer to the Amazon SageMaker Processing section of SageMaker Python SDK. Alternatively, see the full request syntax of create_processing_job in the AWS SDK for Python (Boto3).

The following diagram shows how Amazon SageMaker AI spins up a Processing job. Amazon SageMaker AI takes your script, copies your data from Amazon Simple Storage Service (Amazon S3), and then pulls a processing container. The underlying infrastructure for a Processing job is fully managed by Amazon SageMaker AI. After you submit a processing job, SageMaker AI launches the compute instances, processes and analyzes the input data, and releases the resources upon completion. The output of the Processing job is stored in the Amazon S3 bucket you specified.

> **Note**
>
> Your input data must be stored in an Amazon S3 bucket. Alternatively, you can use Amazon Athena or Amazon Redshift as input sources.



> **Tip**
>
> To learn best practices for distributed computing of machine learning (ML) training and processing jobs in general, see [Distributed computing with SageMaker AI best practices](#).

Use Amazon SageMaker Processing Sample Notebooks

We provide two sample Jupyter notebooks that show how to perform data preprocessing, model evaluation, or both.

For a sample notebook that shows how to run scikit-learn scripts to perform data preprocessing and model training and evaluation with the SageMaker Python SDK for Processing, see scikit-learn Processing. This notebook also shows how to use your own custom container to run processing workloads with your Python libraries and other specific dependencies.

For a sample notebook that shows how to use Amazon SageMaker Processing to perform distributed data preprocessing with Spark, see Distributed Processing (Spark). This notebook also shows how to train a regression model using XGBoost on the preprocessed dataset.

For instructions on how to create and access Jupyter notebook instances that you can use to run these samples in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

Amazon SageMaker Processing provides Amazon CloudWatch logs and metrics to monitor processing jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information, see Amazon SageMaker AI metrics in Amazon CloudWatch and CloudWatch Logs for Amazon SageMaker AI.

Run a Processing Job with Apache Spark

Apache Spark is a unified analytics engine for large-scale data processing. Amazon SageMaker AI provides prebuilt Docker images that include Apache Spark and other dependencies needed to run distributed data processing jobs. The following provides an example on how to run a Amazon SageMaker Processing job using Apache Spark.

With the Amazon SageMaker Python SDK, you can easily apply data transformations and extract features (feature engineering) using the Spark framework. For information about using the SageMaker Python SDK to run Spark processing jobs, see Data Processing with Spark in the Amazon SageMaker Python SDK.

A code repository that contains the source code and Dockerfiles for the Spark images is available on GitHub.

You can use the `sagemaker.spark.PySparkProcessor` or `sagemaker.spark.SparkJarProcessor` class to run your Spark application inside of a processing job. Note you can set MaxRuntimeInSeconds to a maximum runtime limit of 5 days. With respect to execution time, and number of instances used, simple spark workloads see a near linear relationship between the number of instances vs. time to completion.

The following code example shows how to run a processing job that invokes your PySpark script `preprocess.py`.

```
from sagemaker.spark.processing import PySparkProcessor
```

```
spark_processor = PySparkProcessor(
    base_job_name="spark-preprocessor",
    framework_version="2.4",
    role=role,
    instance_count=2,
    instance_type="ml.m5.xlarge",
    max_runtime_in_seconds=1200,
)

spark_processor.run(
    submit_app="preprocess.py",
    arguments=['s3_input_bucket', bucket,
               's3_input_key_prefix', input_prefix,
               's3_output_bucket', bucket,
               's3_output_key_prefix', output_prefix]
)
```

For an in-depth look, see the Distributed Data Processing with Apache Spark and SageMaker Processing example notebook.

If you are not using the Amazon SageMaker AI Python SDK and one of its Processor classes to retrieve the pre-built images, you can retrieve these images yourself. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). For a complete list of the available pre-built Docker images, see the available images document.

To learn more about using the SageMaker Python SDK with Processing containers, see Amazon SageMaker AI Python SDK.

Run a Processing Job with scikit-learn

You can use Amazon SageMaker Processing to process data and evaluate models with scikit-learn scripts in a Docker image provided by Amazon SageMaker AI. The following provides an example on how to run a Amazon SageMaker Processing job using scikit-learn.

For a sample notebook that shows how to run scikit-learn scripts using a Docker image provided and maintained by SageMaker AI to preprocess data and evaluate models, see scikit-learn Processing. To use this notebook, you need to install the SageMaker AI Python SDK for Processing.

This notebook runs a processing job using `SKLearnProcessor` class from the the SageMaker Python SDK to run a scikit-learn script that you provide. The script preprocesses data, trains a model using a SageMaker training job, and then runs a processing job to evaluate the trained model. The processing job estimates how the model is expected to perform in production.

To learn more about using the SageMaker Python SDK with Processing containers, see the SageMaker Python SDK. For a complete list of pre-built Docker images available for processing jobs, see Docker Registry Paths and Example Code.

The following code example shows how the notebook uses `SKLearnProcessor` to run your own scikit-learn script using a Docker image provided and maintained by SageMaker AI, instead of your own Docker image.

```
from sagemaker.sklearn.processing import SKLearnProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput

sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                     role=role,
                                     instance_type='ml.m5.xlarge',
                                     instance_count=1)

sklearn_processor.run(code='preprocessing.py',
                      inputs=[ProcessingInput(
                        source='s3://path/to/my/input-data.csv',
                        destination='/opt/ml/processing/input')],
                      outputs=[ProcessingOutput(source='/opt/ml/processing/output/
train'),
                               ProcessingOutput(source='/opt/ml/processing/output/
validation'),
                               ProcessingOutput(source='/opt/ml/processing/output/
test')]
                     )
```

To process data in parallel using Scikit-Learn on Amazon SageMaker Processing, you can shard input objects by S3 key by setting `s3_data_distribution_type='ShardedByS3Key'` inside a `ProcessingInput` so that each instance receives about the same number of input objects.

Data Processing with Framework Processors

A `FrameworkProcessor` can run Processing jobs with a specified machine learning framework, providing you with an Amazon SageMaker AI–managed container for whichever machine learning framework you choose. `FrameworkProcessor` provides premade containers for the following machine learning frameworks: Hugging Face, MXNet, PyTorch, TensorFlow, and XGBoost.

The FrameworkProcessor class also provides you with customization over the container configuration. The FrameworkProcessor class supports specifying a source directory source_dir for your processing scripts and dependencies. With this capability, you can give the processor access to multiple scripts in a directory instead of only specifying one script. FrameworkProcessor also supports including a requirements.txt file in the source_dir for customizing the Python libraries to install in the container.

For more information on the FrameworkProcessor class and its methods and parameters, see FrameworkProcessor in the *Amazon SageMaker AI Python SDK*.

To see examples of using a FrameworkProcessor for each of the supported machine learning frameworks, see the following topics.

Topics

Code example using HuggingFaceProcessor in the Amazon SageMaker Python SDK

Hugging Face is an open-source provider of natural language processing (NLP) models. The HuggingFaceProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with Hugging Face scripts. When you use the HuggingFaceProcessor, you can leverage an Amazon-built Docker container with a managed Hugging Face environment so that you don't need to bring your own container.

The following code example shows how you can use the HuggingFaceProcessor to run your Processing job using a Docker image provided and maintained by SageMaker AI. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```
from sagemaker.huggingface import HuggingFaceProcessor
```

```
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the HuggingFaceProcessor
hfp = HuggingFaceProcessor(
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.g4dn.xlarge',
    transformers_version='4.4.2',
    pytorch_version='1.6.0',
    base_job_name='frameworkprocessor-hf'
)

#Run the processing job
hfp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data/'
        )
    ],
    outputs=[
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/
train/', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test/',
 destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='val', source='/opt/ml/processing/output/val/',
 destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}')
    ]
)
```

If you have a `requirements.txt` file, it should be a list of libraries you want to install in the container. The path for `source_dir` can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for `source_dir`. To learn more about the `HuggingFaceProcessor` class, see [Hugging Face Estimator](#) in the *Amazon SageMaker AI Python SDK*.

MXNet Framework Processor

Apache MXNet is an open-source deep learning framework commonly used for training and deploying neural networks. The MXNetProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with MXNet scripts. When you use the MXNetProcessor, you can leverage an Amazon-built Docker container with a managed MXNet environment so that you don't need to bring your own container.

The following code example shows how you can use the MXNetProcessor to run your Processing job using a Docker image provided and maintained by SageMaker AI. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```
from sagemaker.mxnet import MXNetProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the MXNetProcessor
mxp = MXNetProcessor(
    framework_version='1.8.0',
    py_version='py37',
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.c5.xlarge',
    base_job_name='frameworkprocessor-mxnet'
)

#Run the processing job
mxp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data/'
        )
    ],
    outputs=[
        ProcessingOutput(
```

```
            output_name='processed_data',
            source='/opt/ml/processing/output/',
            destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'
        )
    ]
)
```

If you have a `requirements.txt` file, it should be a list of libraries you want to install in the container. The path for `source_dir` can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for `source_dir`. To learn more about the `MXNetProcessor` class, see [MXNet Estimator](#) in the *Amazon SageMaker Python SDK*.

PyTorch Framework Processor

PyTorch is an open-source machine learning framework. The `PyTorchProcessor` in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with PyTorch scripts. When you use the `PyTorchProcessor`, you can leverage an Amazon-built Docker container with a managed PyTorch environment so that you don't need to bring your own container.

The following code example shows how you can use the `PyTorchProcessor` to run your Processing job using a Docker image provided and maintained by SageMaker AI. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the `source_dir` argument, and you can have a `requirements.txt` file located inside your `source_dir` directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in `requirements.txt` in the container for you.

For the PyTorch versions supported by SageMaker AI, see the available [Deep Learning Container images](#).

```
from sagemaker.pytorch.processing import PyTorchProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the PyTorchProcessor
pytorch_processor = PyTorchProcessor(
    framework_version='1.8',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
```

```
    base_job_name='frameworkprocessor-PT'
)

#Run the processing job
pytorch_processor.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input'
        )
    ],
    outputs=[
        ProcessingOutput(output_name='data_structured', source='/opt/ml/processing/tmp/
data_structured', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train',
 destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='validation', source='/opt/ml/processing/output/
val', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test',
 destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='logs', source='/opt/ml/processing/logs',
 destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}')
    ]
)
```

If you have a `requirements.txt` file, it should be a list of libraries you want to install in the container. The path for `source_dir` can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for `source_dir`. To learn more about the `PyTorchProcessor` class, see PyTorch Estimator in the *Amazon SageMaker Python SDK*.

TensorFlow Framework Processor

TensorFlow is an open-source machine learning and artificial intelligence library. The `TensorFlowProcessor` in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with TensorFlow scripts. When you use the `TensorFlowProcessor`, you can leverage an Amazon-built Docker container with a managed TensorFlow environment so that you don’t need to bring your own container.

The following code example shows how you can use the `TensorFlowProcessor` to run your Processing job using a Docker image provided and maintained by SageMaker AI. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the `source_dir` argument, and you can have a `requirements.txt` file located inside your `source_dir` directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in `requirements.txt` in the container for you.

```
from sagemaker.tensorflow import TensorFlowProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the TensorFlowProcessor
tp = TensorFlowProcessor(
    framework_version='2.3',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-TF',
    py_version='py37'
)

#Run the processing job
tp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        ),
        ProcessingInput(
            input_name='model',
            source=f's3://{BUCKET}/{S3_PATH_TO_MODEL}',
            destination='/opt/ml/processing/input/model'
        )
    ],
    outputs=[
        ProcessingOutput(
            output_name='predictions',
            source='/opt/ml/processing/output',
            destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'
        )
```

```
    ]
)
```

If you have a `requirements.txt` file, it should be a list of libraries you want to install in the container. The path for `source_dir` can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for `source_dir`. To learn more about the `TensorFlowProcessor` class, see [TensorFlow Estimator](#) in the *Amazon SageMaker Python SDK*.

XGBoost Framework Processor

XGBoost is an open-source machine learning framework. The `XGBoostProcessor` in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with XGBoost scripts. When you use the XGBoostProcessor, you can leverage an Amazon-built Docker container with a managed XGBoost environment so that you don’t need to bring your own container.

The following code example shows how you can use the `XGBoostProcessor` to run your Processing job using a Docker image provided and maintained by SageMaker AI. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the `source_dir` argument, and you can have a `requirements.txt` file located inside your `source_dir` directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in `requirements.txt` in the container for you.

```
from sagemaker.xgboost import XGBoostProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the XGBoostProcessor
xgb = XGBoostProcessor(
    framework_version='1.2-2',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-XGB',
)

#Run the processing job
xgb.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
```

```
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        )
    ],
    outputs=[
        ProcessingOutput(
            output_name='processed_data',
            source='/opt/ml/processing/output/',
            destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'
        )
    ]
)
```

If you have a `requirements.txt` file, it should be a list of libraries you want to install in the container. The path for `source_dir` can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for `source_dir`. To learn more about the `XGBoostProcessor` class, see [XGBoost Estimator](#) in the *Amazon SageMaker Python SDK*.

Use Your Own Processing Code

You can install libraries to run your scripts in your own processing container or, in a more advanced scenario, you can build your own processing container that satisfies the contract to run in Amazon SageMaker AI. For more information about containers in SageMaker AI, see Docker containers for training and deploying models. For a formal specification that defines the contract for an Amazon SageMaker Processing container, see How to Build Your Own Processing Container (Advanced Scenario).

Topics

- Run Scripts with Your Own Processing Container
- How to Build Your Own Processing Container (Advanced Scenario)

Run Scripts with Your Own Processing Container

You can use scikit-learn scripts to preprocess data and evaluate your models. To see how to run scikit-learn scripts to perform these tasks, see the scikit-learn Processing sample notebook.

This notebook uses the `ScriptProcessor` class from the Amazon SageMaker Python SDK for Processing.

The following example shows a general workflow for using a `ScriptProcessor` class with your own processing container. The workflow shows how to create your own image, build your container, and use a `ScriptProcessor` class to run a Python preprocessing script with the container. The processing job processes your input data and saves the processed data in Amazon Simple Storage Service (Amazon S3).

Before using the following examples, you need to have your own input data and a Python script prepared to process your data. For an end-to-end, guided example of this process, refer back to the scikit-learn Processing sample notebook.

1. Create a Docker directory and add the Dockerfile used to create the processing container. Install pandas and scikit-learn into it. (You could also install your own dependencies with a similar RUN command.)

```
mkdir docker

%%writefile docker/Dockerfile

FROM python:3.7-slim-buster

RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3
ENV PYTHONUNBUFFERED=TRUE

ENTRYPOINT ["python3"]
```

2. Build the container using the docker command, create an Amazon Elastic Container Registry (Amazon ECR) repository, and push the image to Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
region = boto3.Session().region_name
ecr_repository = 'sagemaker-processing-container'
tag = ':latest'
processing_repository_uri = '{}.dkr.ecr.{}.amazonaws.com/{}'.format(account_id,
 region, ecr_repository + tag)

# Create ECR repository and push docker image
```

```
!docker build -t $ecr_repository docker
!aws ecr get-login-password --region {region} | docker login --username AWS --
password-stdin {account_id}.dkr.ecr.{region}.amazonaws.com
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $processing_repository_uri
!docker push $processing_repository_uri
```

3. Set up the `ScriptProcessor` from the SageMaker Python SDK to run the script. Replace *`image_uri`* with the URI for the image you created, and replace *`role_arn`* with the ARN for an AWS Identity and Access Management role that has access to your target Amazon S3 bucket.

```
from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput

script_processor = ScriptProcessor(command=['python3'],
                image_uri='image_uri',
                role='role_arn',
                instance_count=1,
                instance_type='ml.m5.xlarge')
```

4. Run the script. Replace *`preprocessing.py`* with the name of your own Python processing script, and replace *`s3://path/to/my/input-data.csv`* with the Amazon S3 path to your input data.

```
script_processor.run(code='preprocessing.py',
                     inputs=[ProcessingInput(
                        source='s3://path/to/my/input-data.csv',
                        destination='/opt/ml/processing/input')],
                     outputs=[ProcessingOutput(source='/opt/ml/processing/output/
train'),
                               ProcessingOutput(source='/opt/ml/processing/output/
validation'),
                               ProcessingOutput(source='/opt/ml/processing/output/
test')])
```

You can use the same procedure with any other library or system dependencies. You can also use existing Docker images. This includes images that you run on other platforms such as [Kubernetes](https://kubernetes.io/).

How to Build Your Own Processing Container (Advanced Scenario)

You can provide Amazon SageMaker Processing with a Docker image that has your own code and dependencies to run your data processing, feature engineering, and model evaluation workloads. The following provides information on how to build your own processing container.

The following example of a Dockerfile builds a container with the Python libraries scikit-learn and pandas, which you can run as a processing job.

```
FROM python:3.7-slim-buster

# Install scikit-learn and pandas
RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3

# Add a Python script and configure Docker to run it
ADD processing_script.py /
ENTRYPOINT ["python3", "/processing_script.py"]
```

For an example of a processing script, see Get started with SageMaker Processing.

Build and push this Docker image to an Amazon Elastic Container Registry (Amazon ECR) repository and ensure that your SageMaker AI IAM role can pull the image from Amazon ECR. Then you can run this image on Amazon SageMaker Processing.

How Amazon SageMaker Processing Runs Your Processing Container Image

Amazon SageMaker Processing runs your processing container image in a similar way as the following command, where `AppSpecification.ImageUri` is the Amazon ECR image URI that you specify in a `CreateProcessingJob` operation.

```
docker run [AppSpecification.ImageUri]
```

This command runs the `ENTRYPOINT` command configured in your Docker image.

You can also override the entrypoint command in the image or give command-line arguments to your entrypoint command using the `AppSpecification.ContainerEntrypoint` and `AppSpecification.ContainerArgument` parameters in your `CreateProcessingJob` request. Specifying these parameters configures Amazon SageMaker Processing to run the container similar to the way that the following command does.

```
docker run --entry-point [AppSpecification.ContainerEntrypoint]
[AppSpecification.ImageUri] [AppSpecification.ContainerArguments]
```

For example, if you specify the `ContainerEntrypoint` to be `[python3, -v, /processing_script.py]` in your `CreateProcessingJob` request, and `ContainerArguments` to be `[data-format, csv]`, Amazon SageMaker Processing runs your container with the following command.

```
python3 -v /processing_script.py data-format csv
```

When building your processing container, consider the following details:

- Amazon SageMaker Processing decides whether the job completes or fails depending on the exit code of the command run. A processing job completes if all of the processing containers exit successfully with an exit code of 0, and fails if any of the containers exits with a non-zero exit code.
- Amazon SageMaker Processing lets you override the processing container's entrypoint and set command-line arguments just like you can with the Docker API. Docker images can also configure the entrypoint and command-line arguments using the `ENTRYPOINT` and CMD instructions. The way `CreateProcessingJob`'s `ContainerEntrypoint` and `ContainerArgument` parameters configure a Docker image's entrypoint and arguments mirrors how Docker overrides the entrypoint and arguments through the Docker API:
  - If neither `ContainerEntrypoint` nor `ContainerArguments` are provided, Processing uses the default `ENTRYPOINT` or CMD in the image.
  - If `ContainerEntrypoint` is provided, but not `ContainerArguments`, Processing runs the image with the given entrypoint, and ignores the `ENTRYPOINT` and CMD in the image.
  - If `ContainerArguments` is provided, but not `ContainerEntrypoint`, Processing runs the image with the default `ENTRYPOINT` in the image and with the provided arguments.
  - If both `ContainerEntrypoint` and `ContainerArguments` are provided, Processing runs the image with the given entrypoint and arguments, and ignores the `ENTRYPOINT` and CMD in the image.
- You must use the exec form of the `ENTRYPOINT` instruction in your Dockerfile (`ENTRYPOINT ["executable", "param1", "param2"]`) instead of the shell form (`ENTRYPOINT command param1 param2`). This lets your processing container receive `SIGINT` and `SIGKILL` signals, which Processing uses to stop processing jobs with the `StopProcessingJob` API.

- /opt/ml and all its subdirectories are reserved by SageMaker AI. When building your Processing Docker image, don't place any data required by your processing container in these directories.
- If you plan to use GPU devices, make sure that your containers are nvidia-docker compatible. Include only the CUDA toolkit in containers. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

How Amazon SageMaker Processing Configures Input and Output For Your Processing Container

When you create a processing job using the CreateProcessingJob operation, you can specify multiple ProcessingInput and ProcessingOutput. values.

You use the ProcessingInput parameter to specify an Amazon Simple Storage Service (Amazon S3) URI to download data from, and a path in your processing container to download the data to. The ProcessingOutput parameter configures a path in your processing container from which to upload data, and where in Amazon S3 to upload that data to. For both ProcessingInput and ProcessingOutput, the path in the processing container must begin with /opt/ml/processing/ .

For example, you might create a processing job with one ProcessingInput parameter that downloads data from s3://your-data-bucket/path/to/input/csv/data into /opt/ml/processing/csv in your processing container, and a ProcessingOutput parameter that uploads data from /opt/ml/processing/processed_csv to s3://your-data-bucket/path/to/output/csv/data. Your processing job would read the input data, and write output data to /opt/ml/processing/processed_csv. Then it uploads the data written to this path to the specified Amazon S3 output location.

Important

Symbolic links (symlinks) can not be used to upload output data to Amazon S3. Symlinks are not followed when uploading output data.

How Amazon SageMaker Processing Provides Logs and Metrics for Your Processing Container

When your processing container writes to `stdout` or `stderr`, Amazon SageMaker Processing saves the output from each processing container and puts it in Amazon CloudWatch logs. For information about logging, see CloudWatch Logs for Amazon SageMaker AI.

Amazon SageMaker Processing also provides CloudWatch metrics for each instance running your processing container. For information about metrics, see Amazon SageMaker AI metrics in Amazon CloudWatch.

How Amazon SageMaker Processing Configures Your Processing Container

Amazon SageMaker Processing provides configuration information to your processing container through environment variables and two JSON files—`/opt/ml/config/processingjobconfig.json` and `/opt/ml/config/resourceconfig.json`— at predefined locations in the container.

When a processing job starts, it uses the environment variables that you specified with the `Environment` map in the `CreateProcessingJob` request. The `/opt/ml/config/processingjobconfig.json` file contains information about the hostnames of your processing containers, and is also specified in the `CreateProcessingJob` request.

The following example shows the format of the `/opt/ml/config/processingjobconfig.json` file.

```
{
    "ProcessingJobArn": "<processing_job_arn>",
    "ProcessingJobName": "<processing_job_name>",
    "AppSpecification": {
        "ImageUri": "<image_uri>",
        "ContainerEntrypoint": null,
        "ContainerArguments": null
    },
    "Environment": {
        "KEY": "VALUE"
    },
    "ProcessingInputs": [
        {
            "InputName": "input-1",
            "S3Input": {
```

```
                "LocalPath": "/opt/ml/processing/input/dataset",
                "S3Uri": "<s3_uri>",
                "S3DataDistributionType": "FullyReplicated",
                "S3DataType": "S3Prefix",
                "S3InputMode": "File",
                "S3CompressionType": "None",
                "S3DownloadMode": "StartOfJob"
            }
        }
    ],
    "ProcessingOutputConfig": {
        "Outputs": [
            {
                "OutputName": "output-1",
                "S3Output": {
                    "LocalPath": "/opt/ml/processing/output/dataset",
                    "S3Uri": "<s3_uri>",
                    "S3UploadMode": "EndOfJob"
                }
            }
        ],
        "KmsKeyId": null
    },
    "ProcessingResources": {
        "ClusterConfig": {
            "InstanceCount": 1,
            "InstanceType": "ml.m5.xlarge",
            "VolumeSizeInGB": 30,
            "VolumeKmsKeyId": null
        }
    },
    "RoleArn": "<IAM role>",
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 86400
    }
}
```

The `/opt/ml/config/resourceconfig.json` file contains information about the hostnames of your processing containers. Use the following hostnames when creating or running distributed processing code.

```
{
  "current_host": "algo-1",
```

```
  "hosts": ["algo-1","algo-2","algo-3"]
}
```

Don't use the information about hostnames contained in /etc/hostname or /etc/hosts because it might be inaccurate.

Hostname information might not be immediately available to the processing container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.

Save and Access Metadata Information About Your Processing Job

To save metadata from the processing container after exiting it, containers can write UTF-8 encoded text to the /opt/ml/output/message file. After the processing job enters any terminal status ("Completed", "Stopped", or "Failed"), the "ExitMessage" field in DescribeProcessingJob contains the first 1 KB of this file. Access that initial part of file with a call to DescribeProcessingJob, which returns it through the ExitMessage parameter. For failed processing jobs, you can use this field to communicate information about why the processing container failed.

> **Important**
>
> Don't write sensitive data to the /opt/ml/output/message file.

If the data in this file isn't UTF-8 encoded, the job fails and returns a ClientError. If multiple containers exit with an ExitMessage, the content of the ExitMessage from each processing container is concatenated, then truncated to 1 KB.

Run Your Processing Container Using the SageMaker AI Python SDK

You can use the SageMaker Python SDK to run your own processing image by using the Processor class. The following example shows how to run your own processing container with one input from Amazon Simple Storage Service (Amazon S3) and one output to Amazon S3.

```
from sagemaker.processing import Processor, ProcessingInput, ProcessingOutput

processor = Processor(image_uri='<your_ecr_image_uri>',
                     role=role,
```

```
                      instance_count=1,
                      instance_type="ml.m5.xlarge")

processor.run(inputs=[ProcessingInput(
                        source='<s3_uri or local path>',
                        destination='/opt/ml/processing/input_data')],
                    outputs=[ProcessingOutput(
                        source='/opt/ml/processing/processed_data',
                        destination='<s3_uri>')],
                    )
```

Instead of building your processing code into your processing image, you can provide a `ScriptProcessor` with your image and the command that you want to run, along with the code that you want to run inside that container. For an example, see Run Scripts with Your Own Processing Container.

You can also use the scikit-learn image that Amazon SageMaker Processing provides through `SKLearnProcessor` to run scikit-learn scripts. For an example, see Run a Processing Job with scikit-learn.

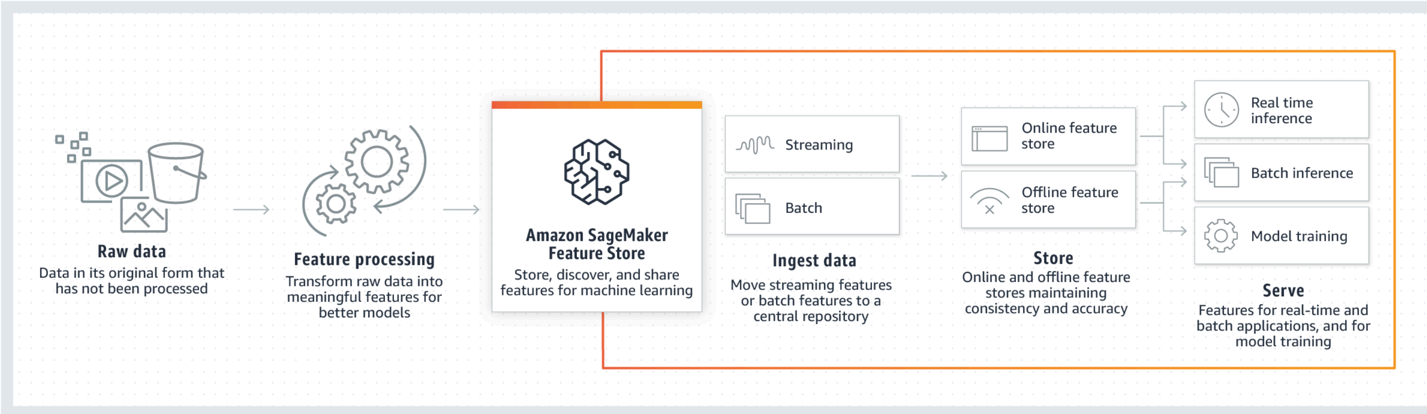
Create, store, and share features with Feature Store

The machine learning (ML) development process includes extracting raw data, transforming it into *features* (meaningful inputs for your ML model). Those features are then stored in a serviceable way for data exploration, ML training, and ML inference. Amazon SageMaker Feature Store simplifies how you create, store, share, and manage features. This is done by providing feature store options and reducing repetitive data processing and curation work.

Among other things, with Feature Store you can:

- Simplify feature processing, storing, retrieving, and sharing features for ML development across accounts or in an organization.
- Track your feature processing code development, apply your feature processor to the raw data, and ingest your features into Feature Store in a consistent way. This reduces training-serving skew, a common issue in ML where the difference between performance during training and serving can impact the accuracy of your ML model.
- Store your features and associated metadata in feature groups, so features can be easily discovered and reused. Feature groups are mutable and can evolve their schema after creation.
- Create feature groups that can be configured to include an online or offline store, or both, to manage your features and automate how features are stored for your ML tasks.
  - The online store retains only the latest records for your features. This is primarily designed for supporting real-time predictions that need low millisecond latency reads and high throughput writes.
  - The offline store keeps all records for your features as a historical database. This is primarily intended for data exploration, model training, and batch predictions.

The following diagram shows how you can use Feature Store as part of your ML pipeline. Once you read in your raw data, you can use Feature Store to transform the raw data into features and ingest them into your feature group. The features can be ingested via streaming or batches to the feature group's online and offline stores. The features can then be served for data exploration, model training, and real-time or batch inference.



How Feature Store works

In Feature Store, features are stored in a collection called a *feature group*. You can visualize a feature group as a table in which each column is a feature, with a unique identifier for each row. In principle, a feature group is composed of features and values specific to each feature. A `Record` is a collection of values for features that correspond to a unique `RecordIdentifier`. Altogether, a `FeatureGroup` is a group of features defined in your `FeatureStore` to describe a `Record`.

You can use Feature Store in the following modes:

- **Online** – In online mode, features are read with low latency (milliseconds) reads and used for high throughput predictions. This mode requires a feature group to be stored in an online store.
- **Offline** – In offline mode, large streams of data are fed to an offline store, which can be used for training and batch inference. This mode requires a feature group to be stored in an offline store. The offline store uses your S3 bucket for storage and can also fetch data using Athena queries.
- **Online and Offline** – This includes both online and offline modes.

You can ingest data into feature groups in Feature Store in two ways: streaming or in batches. When you ingest data through streaming, a collection of records are pushed to Feature Store by calling a synchronous `PutRecord` API call. This API enables you to maintain the latest feature values in Feature Store and to push new feature values as soon an update is detected.

Alternatively, Feature Store can process and ingest data in batches. For example, you can author features using Amazon SageMaker Data Wrangler and export a notebook from Data Wrangler. The notebook can be a SageMaker Processing job that ingests the features in batches to a Feature Store feature group. This mode allows for batch ingestion into the offline store. It also supports ingestion into the online store if the feature group is configured for both online and offline use.

Create feature groups

To ingest features into Feature Store, you must first define the feature group and the feature definitions (feature name and data type) for all features that belong to the feature group. After they are created, feature groups are mutable and can evolve their schema. Feature group names are unique within an AWS Region and AWS account. When creating a feature group, you can also create the metadata for the feature group. The metadata can contain a short description, storage configuration, features for identifying each record, and the event time. Furthermore, the metadata can include tags to store information such as the author, data source, version, and more.

> **Important**
>
> `FeatureGroup` names or associated metadata such as description or tags should not contain any personal identifiable information (PII) or confidential information.

Find, discover, and share features

After you create a feature group in Feature Store, other authorized users of the feature store can share and discover it. Users can browse through a list of all feature groups in Feature Store or discover existing feature groups by searching by feature group name, description, record identifier name, creation date, and tags.

Real-time inference for features stored in the online store

With Feature Store, you can enrich your features stored in the online store in real time with data from a streaming source (clean stream data from another application) and serve the features with low millisecond latency for real-time inference.

You can also perform joins across different `FeatureGroups` for real-time inference by querying two different `FeatureGroups` in the client application.

Offline store for model training and batch inference

Feature Store provides offline storage for feature values in your S3 bucket. Your data is stored in your S3 bucket using a prefixing scheme based on event time. The offline store is an append-only store, enabling Feature Store to maintain a historical record of all feature values. Data is stored in the offline store in Parquet format for optimized storage and query access.

You can query, explore, and visualize features using Data Wrangler from the console. Feature Store supports combining data to produce, train, validate, and test data sets, and allows you to extract data at different points in time.

Feature data ingestion

Feature generation pipelines can be created to process large batches (1 million rows of data or more) or small batches, and to write feature data to the offline or online store. Streaming sources such as Amazon Managed Streaming for Apache Kafka or Amazon Kinesis can also be used as data sources from which features are extracted and directly fed to the online store for training, inference, or feature creation.

You can push records to Feature Store by calling the synchronous `PutRecord` API call. Since this is a synchronous API call, it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon as an update is detected. These are also called *streaming features*.

When feature data is ingested and updated, Feature Store stores historical data for all features in the offline store. For batch ingest, you can pull feature values from your S3 bucket or use Athena to query. You can also use Data Wrangler to process and engineer new features that can then be exported to a chosen S3 bucket to be accessed by Feature Store. For batch ingestion, you can configure a processing job to batch ingest your data into Feature Store, or you can pull feature values from your S3 bucket using Athena.

To remove a `Record` from your online store, use the [`DeleteRecord`] API call. This will also add the deleted record to the offline store.

Resilience in Feature Store

Feature Store is distributed across multiple Availability Zones (AZs). An AZ is an isolated location within an AWS Region. If some AZs fail, Feature Store can use other AZs. For more information about AZs, see [Resilience in Amazon SageMaker AI].

Get started with Amazon SageMaker Feature Store

The following topics give information about using Amazon SageMaker Feature Store. First learn the Feature Store concepts, then how to manage permissions to use Feature Store, how to create and use feature groups using Studio Classic, Jupyter or JupyterLab notebook, how to use Feature Store using the User Interface through the console, and how to delete feature groups using the console and AWS SDK for Python (Boto3).

The instructions on using Feature Store through the console depends on if you have enabled Studio or Studio Classic as your default experience. For information on accessing Studio Classic, see Launch Studio Classic Using the Amazon SageMaker AI Console.

Topics

Feature Store concepts

We list common terms used in Amazon SageMaker Feature Store, followed by example diagrams to visualize a few concepts:

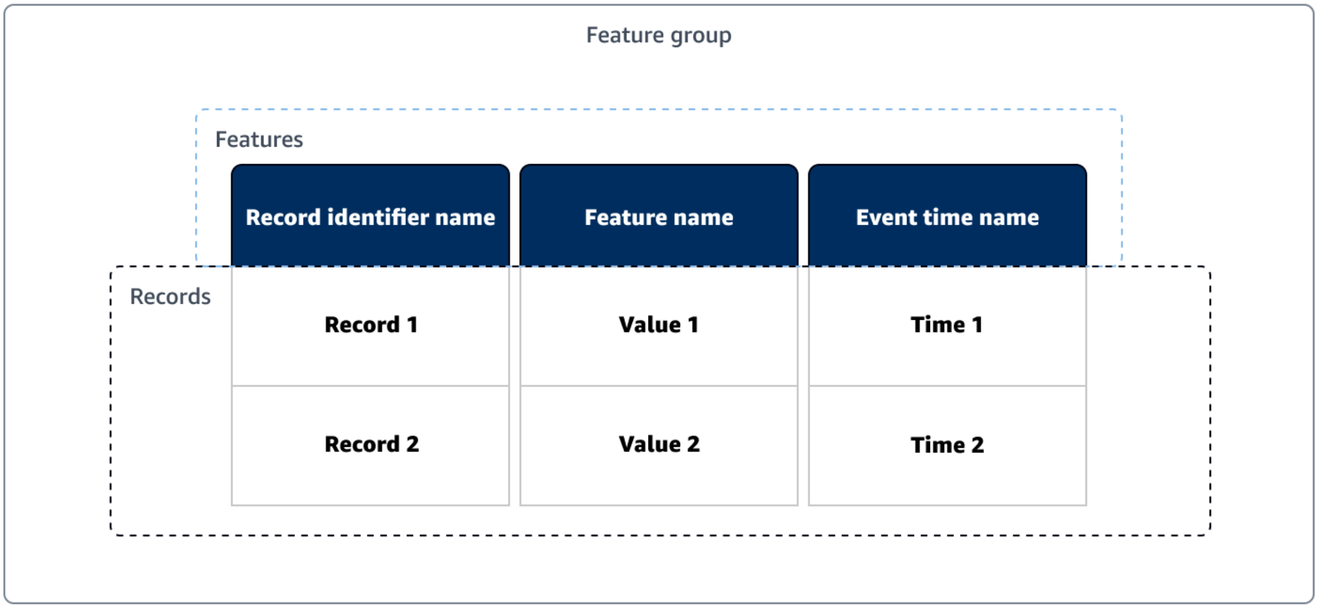
- **Feature Store**: Storage and data management layer for machine learning (ML) features. Serves as the single source of truth to store, retrieve, remove, track, share, discover, and control access to features. In the following example diagram, the Feature Store is a store for your feature groups, which contains your ML data, and provides additional services.
- **Online store**: Low latency, high availability store for a feature group that enables real-time lookup of records. The online store allows quick access to the latest record via the `GetRecord` API.
- **Offline store**: Stores historical data in your Amazon S3 bucket. The offline store is used when low (sub-second) latency reads are not needed. For example, the offline store can be used when you want to store and serve features for exploration, model training, and batch inference.
- **Feature group**: The main resource of Feature Store that contains the data and metadata used for training or predicting with a ML model. A feature group is a logical grouping of features used to describe records. In the following example diagram, a feature group contains your ML data.
- **Feature**: A property that is used as one of the inputs to train or predict using your ML model. In the Feature Store API a feature is an attribute of a record. In the following example diagram, a feature describes a column in your ML data table.

- **Feature definition**: Consists of a name and one of the data types: integral, string or fractional. A feature group contains a list of feature definitions. For more information on Feature Store data types, see Data types.
- **Record**: Collection of values for features for a single record identifier. A combination of record identifier and event time values uniquely identify a record within a feature group. In the following example diagram, a record is a row in your ML data table.
- **Record identifier name**: The record identifier name is the name of the feature that identifies the records. It must refer to one of the names of a feature defined in the feature group's feature definitions. Each feature group is defined with a record identifier name.
- **Event time**: Timestamp that you provide corresponding to when the record event occurred. All records in a feature group must have a corresponding event time. The online store only contains the record corresponding to the latest event time, whereas the offline store contains all historic records. For more information on event time formats, see Data types.
- **Ingestion**: Adding new records to a feature group. Ingestion is typically achieved via the `PutRecord` API.

Topics

Concepts overview diagram

The following example diagram conceptualizes a few Feature Store concepts:



The Feature Store contains your feature groups and a feature group contains your ML data. In the example diagram, the original feature group contains a data table that has three features (each describing a column) and two records (rows).

- A feature's definition describes the feature name and data type of the feature values that are associated with records.
- A record contains the feature values and is uniquely identified by its record identifier and must include the event time.

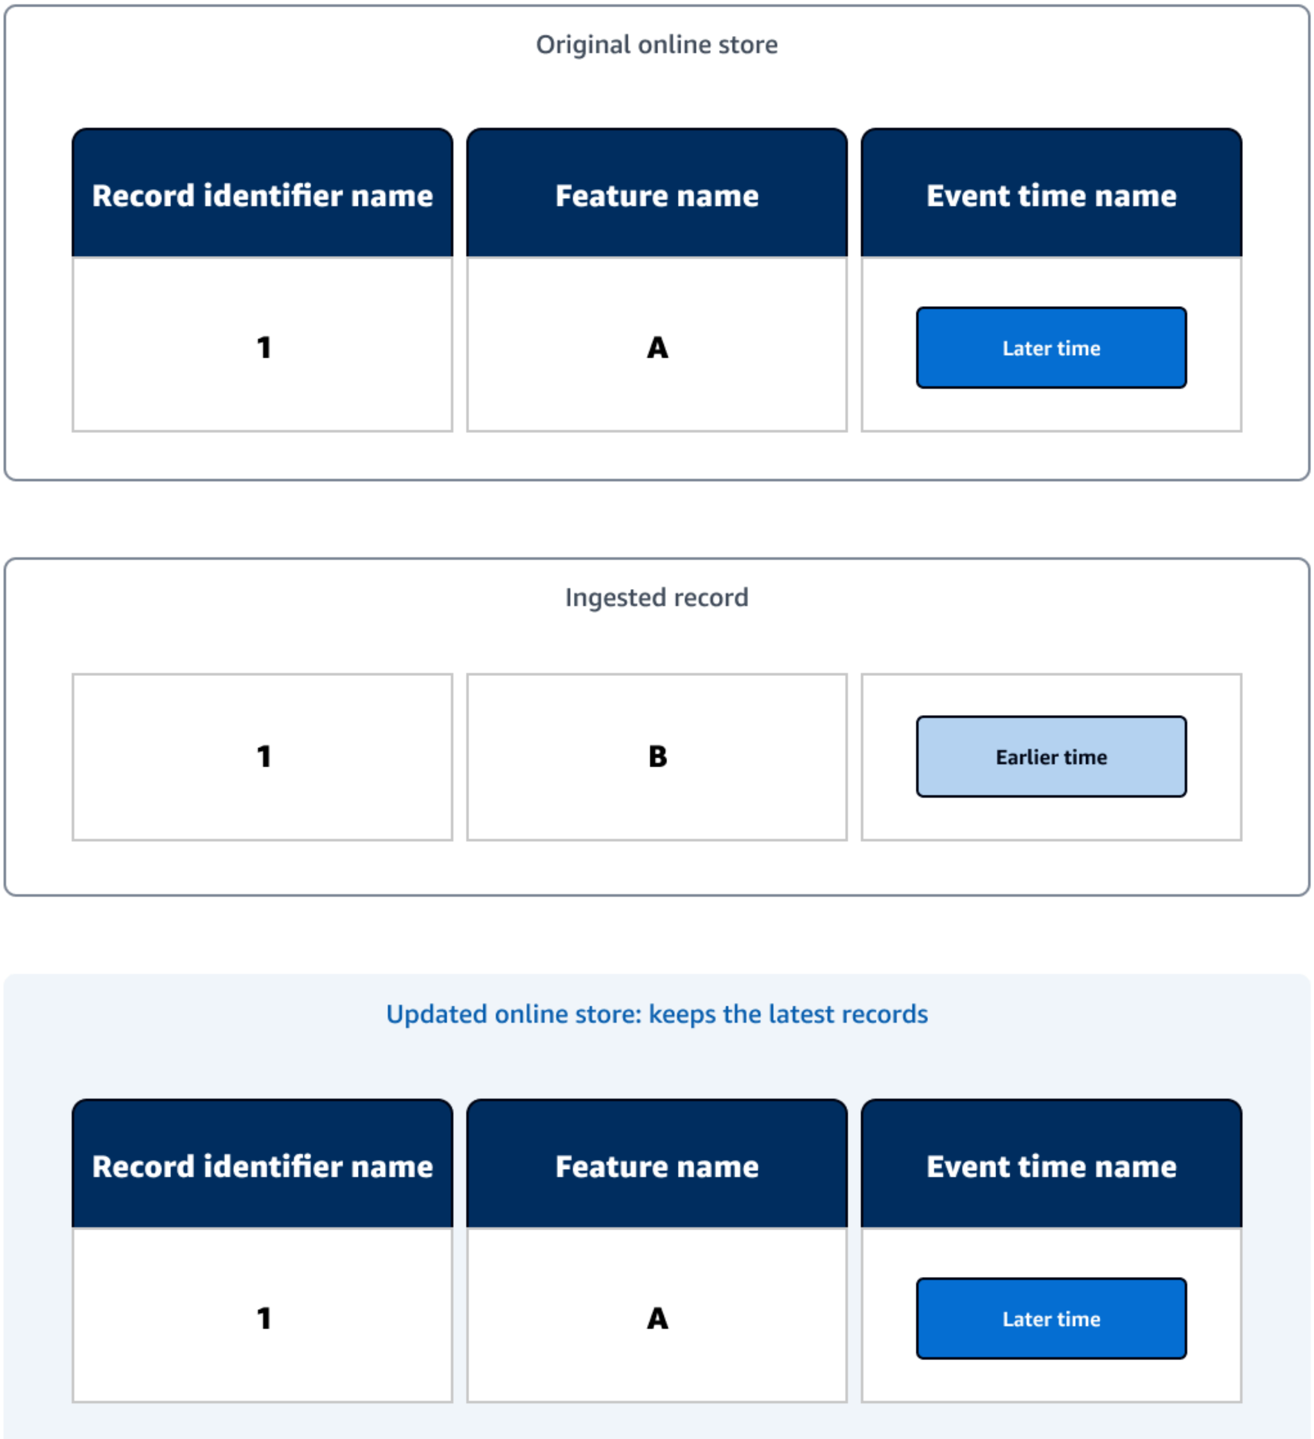
Ingestion diagrams

Ingestion is the action of adding a record or records to an existing feature group. The online and offline stores are updated differently for different storage use cases.

Ingestion to the online store example

The online store acts as a real-time look-up of records and only keeps the most up-to-date records. Once a record is ingested into an existing online store, the updated online store will only keep the record with the latest event time.

In the following example diagram, the original online store contains a ML data table with one record. A record is ingested with the same record identifier name as the original record, and the ingested record has an earlier event time than the original record. As the updated online store only keeps the record with the latest event time, the updated online store contains the original record.



Ingestion to the offline store example

The offline store acts as a historical look-up of records and keeps all records. After a new record is ingested into an existing offline store, the updated offline store will keep the new record.

In the following example diagram, the original offline store contains a ML data table with one record. A record is ingested with the same record identifier name as the original record, and the ingested record has an event time earlier than the original record. As the updated offline store keeps all of the records, the updated offline store contains both records.

Original offline store

Record identifier name	Feature name	Event time name
1	A	Later time

Ingested record

1	B	Earlier time

Updated offline store: keeps all records

Record identifier name	Feature name	Event time name
1	A	Later time
1	B	Earlier time

Adding policies to your IAM role

To get started with Amazon SageMaker Feature Store you must have a role and add the required policy to your role, `AmazonSageMakerFeatureStoreAccess`. The following is a walkthrough on how to view the policies attached to a role and how to add a policy to your role. For information on how to create a role, see How to use SageMaker AI execution roles. For information on how to get your execution role, see Get your execution role.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left of the IAM console, choose **Roles**.
3. In the search bar enter the role you are using for Amazon SageMaker Feature Store.

   For examples on how to find your execution role ARN for a notebook within SageMaker AI, see Get your execution role. The role is at the end of the execution role ARN.
4. After you enter the role in the search bar, choose the role.

   Under **Permissions policies** you can view the policies attached to the role.
5. After you choose the role, choose **Add permissions**, then choose **Attach policies**.
6. In the search bar under **Other permissions policies** enter `AmazonSageMakerFeatureStoreAccess` and press enter. If the policy does not show, you may already have the policy attached, listed under your **Current permissions policies**.
7. After you press enter, select the **check box** next to the policy and then choose **Add permissions**.
8. After you have attached the policy to your role, the policy will appear under **Permissions policies** for your IAM role.

Use Feature Store with SDK for Python (Boto3)

The feature group is the main Feature Store resource that contains your machine learning (ML) data and metadata stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features and records. A feature group's definition is composed of a configurations for its online and offline store and a list of feature definitions that are used to describe the values of your records. The feature definitions must include a record identifier name and an event time name. For more information on feature store concepts, see Feature Store concepts.

Prior to using a feature store you typically load your dataset, run transformations, and set up your features for ingestion. This process has a lot of variation and is highly dependent on your data. The example code in the following topics refer to the [Introduction to Feature Store] and [Fraud Detection with Amazon SageMaker Feature Store] example notebooks, respectively. Both use the AWS SDK for Python (Boto3). For more Feature Store examples and resources, see [Amazon SageMaker Feature Store resources].

Feature Store supports the following feature types: `String`, `Fractional` (IEEE 64-bit floating point value), and `Integral` (Int64 - 64 bit signed integral value). The default type is set to `String`. This means that, if a column in your dataset is not of a `float` or `long` feature type, it defaults to `String` in your feature store.

You may use a schema to describe your data's columns and data types. You pass this schema into `FeatureDefinitions`, a required parameter for a `FeatureGroup`. You can use the SDK for Python (Boto3), which has automatic data type detection when you use the `load_feature_definitions` function.

The default behavior when a new feature record is added with an already existing record ID is as follows. In the offline store, the new record will be appended. In the online store, if the event time of the new record is less than the existing event time then nothing will happen, but if the event time of the new record is greater than or equal to the existing event time, the record will be overwritten.

When you create a new feature group you can choose one of the following table formats:

- AWS Glue (Default)
- Apache Iceberg

Ingesting data, especially when streaming, can result in a large number of small files deposited into the offline store. This can negatively impact query performance due the higher number of file operations required. To avoid potential performance issues, use the Apache Iceberg table format when creating new feature groups. With Iceberg you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. If you choose the Iceberg option when creating new feature groups, Amazon SageMaker Feature Store will create the Iceberg tables using Parquet file format, and register the tables with the AWS Glue Data Catalog.

> **Important**
>
> Note that for feature groups in Iceberg table format, you must specify `String` as the value for the event time. If you specify any other type, you can't create the feature group successfully.

In the following we list some available Feature Store managed resources.

Topics

Introduction to Feature Store example notebook

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
>
> AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

The example code on this page refers to the Introduction to Feature Store example notebook. We recommend that you run this notebook in Studio Classic, notebook instances, or JupyterLab because the code in this guide is conceptual and not fully functional if copied.

Use the following to clone the aws/amazon-sagemaker-examples GitHub repository, containing the example notebook:

- **For Studio Classic**

Launch Studio Classic. You can open Studio Classic if Studio or Studio Classic is enabled as your default experience. For instructions on how to open Studio Classic, see Launch Studio Classic Using the Amazon SageMaker AI Console.

Clone the aws/amazon-sagemaker-examples GitHub repository to Studio Classic by following the steps in Clone a Git Repository in SageMaker Studio Classic.

- **For Amazon SageMaker notebook instances**

  Launch SageMaker notebook instance by following the instructions in Access Notebook Instances.

Now that you have the SageMaker AI example notebooks, navigate to the `amazon-sagemaker-examples/sagemaker-featurestore` directory and open the Introduction to Feature Store example notebook.

Step 1: Set up your SageMaker AI session

To start using Feature Store, create a SageMaker AI session. Then, set up the Amazon Simple Storage Service (Amazon S3) bucket that you want to use for your features. The Amazon S3 bucket is your offline store. The following code uses the SageMaker AI default bucket and adds a custom prefix to it.

> **Note**
>
> The role that you use to run the notebook must have the following managed policies attached to it: `AmazonS3FullAccess` and `AmazonSageMakerFeatureStoreAccess`. For information about adding policies to your IAM role, see Adding policies to your IAM role.

```
# SageMaker Python SDK version 2.x is required
import sagemaker
import sys
```

```
import boto3
import pandas as pd
import numpy as np
import io
```

```
from sagemaker.session import Session
from sagemaker import get_execution_role

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```

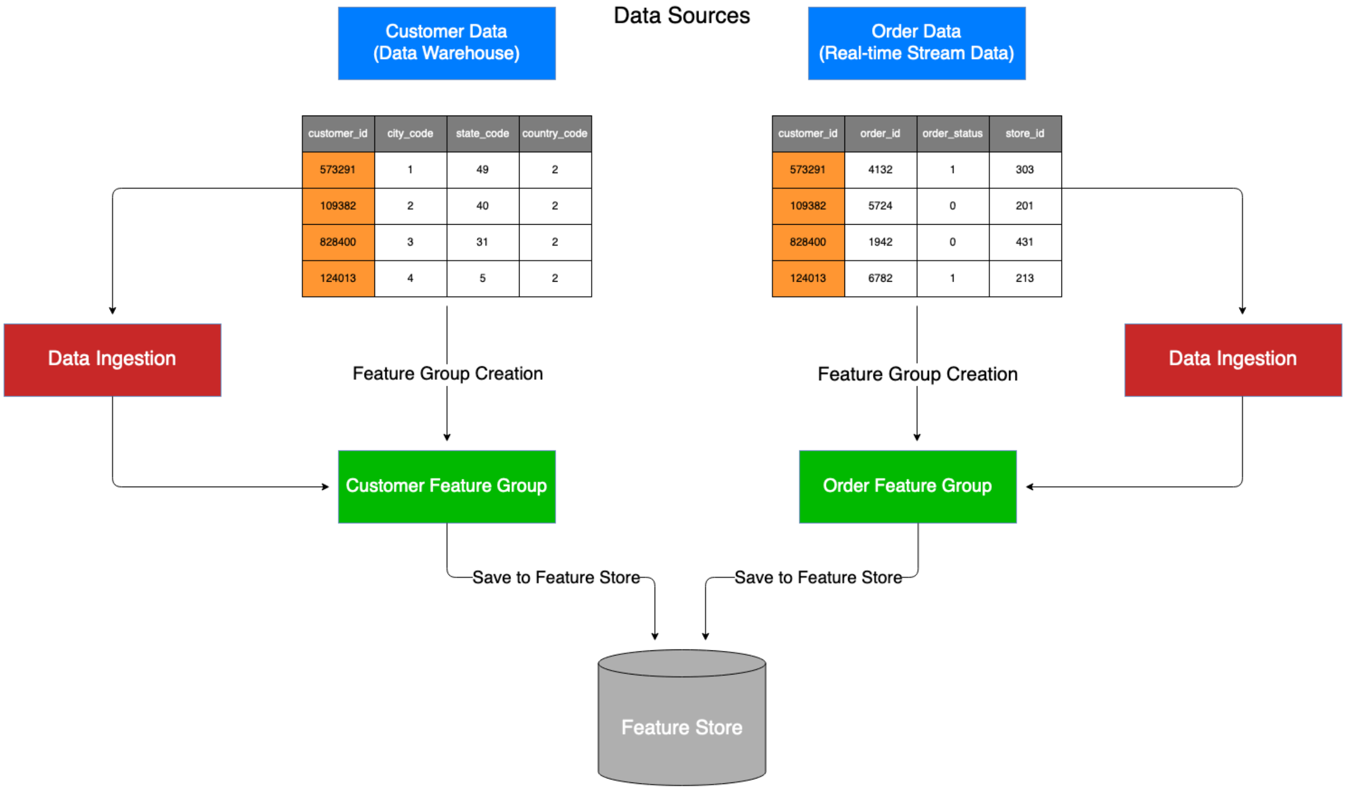
Step 2: Inspect your data

In this notebook example, we ingest synthetic data from the GitHub repository that hosts the full notebook.

```
customer_data = pd.read_csv("data/feature_store_introduction_customer.csv")
orders_data = pd.read_csv("data/feature_store_introduction_orders.csv")

print(customer_data.head())
print(orders_data.head())
```

The following diagram illustrates the steps that data goes through before Feature Store ingests it. In this notebook, we illustrate the use case where you have data from multiple sources and want to store them independently in a Feature Store. Our example considers data from a data warehouse (customer data), and data from a real-time streaming service (order data).



Step 3: Create feature groups

We first start by creating feature group names for customer_data and orders_data. Following this, we create two feature groups, one for `customer_data` and another for `orders_data`:

```
import time
from time import strftime, gmtime
customers_feature_group_name = 'customers-feature-group-' + strftime('%d-%H-%M-%S',
 gmtime())
orders_feature_group_name = 'orders-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
```

Instantiate a `FeatureGroup` object for `customers_data` and `orders_data`:

```
from sagemaker.feature_store.feature_group import FeatureGroup

customers_feature_group = FeatureGroup(
    name=customers_feature_group_name, sagemaker_session=sagemaker_session
)
orders_feature_group = FeatureGroup(
    name=orders_feature_group_name, sagemaker_session=sagemaker_session
```

```
)
```

```
import time
current_time_sec = int(round(time.time()))
record_identifier_feature_name = "customer_id"
```

Append `EventTime` feature to your data frame. This parameter is required, and timestamps each data point:

```
customer_data["EventTime"] = pd.Series([current_time_sec]*len(customer_data),
 dtype="float64")
orders_data["EventTime"] = pd.Series([current_time_sec]*len(orders_data),
 dtype="float64")
```

Load feature definitions to your feature group:

```
customers_feature_group.load_feature_definitions(data_frame=customer_data)
orders_feature_group.load_feature_definitions(data_frame=orders_data)
```

The following calls `create` to create two feature groups, `customers_feature_group` and `orders_feature_group`, respectively:

```
customers_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)

orders_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)
```

To confirm that your feature group was created, we display it by using `DescribeFeatureGroup` and `ListFeatureGroups` APIs:

```
customers_feature_group.describe()
```

```
orders_feature_group.describe()
```

```
sagemaker_session.boto_session.client('sagemaker',
 region_name=region).list_feature_groups() # We use the boto client to list
 FeatureGroups
```

Step 4: Ingest data into a feature group

After feature groups are created, we can put data into them. If you're using the SageMaker AI AWS SDK for Python (Boto3), use the `ingest` API call. If you're using SDK for Python (Boto3), then use the `PutRecord` API. It will take less than 1 minute to ingest data both of these options. This example uses the SageMaker AI SDK for Python (Boto3), so it uses the `ingest` API call:

```
def check_feature_group_status(feature_group):
    status = feature_group.describe().get("FeatureGroupStatus")
    while status == "Creating":
        print("Waiting for Feature Group to be Created")
        time.sleep(5)
        status = feature_group.describe().get("FeatureGroupStatus")
    print(f"FeatureGroup {feature_group.name} successfully created.")

check_feature_group_status(customers_feature_group)
check_feature_group_status(orders_feature_group)
```

```
customers_feature_group.ingest(
    data_frame=customer_data, max_workers=3, wait=True
)
```

```
orders_feature_group.ingest(
    data_frame=orders_data, max_workers=3, wait=True
)
```

Using an arbitrary customer record id, 573291 we use `get_record` to check that the data has been ingested into the feature group.

```
customer_id = 573291
```

```
sample_record = sagemaker_session.boto_session.client('sagemaker-featurestore-runtime',
 region_name=region).get_record(FeatureGroupName=customers_feature_group_name,
 RecordIdentifierValueAsString=str(customer_id))
```

```
print(sample_record)
```

The following demonstrates how to use the `batch_get_record` to get a batch of records.

```
all_records = sagemaker_session.boto_session.client(
    "sagemaker-featurestore-runtime", region_name=region
).batch_get_record(
    Identifiers=[
        {
            "FeatureGroupName": customers_feature_group_name,
            "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
        },
        {
            "FeatureGroupName": orders_feature_group_name,
            "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
        },
    ]
)
```

```
print(all_records)
```

Step 5: Clean up

Here we remove the Feature Groups that we created.

```
customers_feature_group.delete()
orders_feature_group.delete()
```

Step 6: Next steps

In this example notebook, you learned how to get started with Feature Store, create feature groups, and ingest data into them.

For an advanced example on how to use Feature Store for a fraud detection use case, see [Fraud Detection with Feature Store](https://sagemaker-examples.readthedocs.io/).

Step 7: Code examples for programmers

In this notebook we used a variety of different API calls. Most of them are accessible through the SageMaker Python SDK, however some only exist within Boto3. You can invoke the SageMaker Python SDK API calls directly on your Feature Store objects, whereas to invoke API calls that exist within Boto3, you must first access a Boto3 client through your Boto3 and SageMaker AI sessions: for example, `sagemaker_session.boto_session.client()`.

The following is a list of API calls for this notebook. These calls exist within the SDK for Python and exist in Boto3, for your reference:

SDK for Python (Boto3) API Calls

```
describe()
ingest()
delete()
create()
load_feature_definitions()
```

Boto3 API Calls

```
list_feature_groups()
get_record()
```

Fraud detection with Feature Store example notebook

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
> AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

The example code on this page refers to the example notebook: Fraud Detection with Amazon SageMaker Feature Store. We recommend that you run this notebook in Studio Classic, notebook instances, or JupyterLab because the code in this guide is conceptual and not fully functional if copied.

Use the following to clone the aws/amazon-sagemaker-examples GitHub repository, containing the example notebook.

- **For Studio Classic**

  First launch Studio Classic. You can open Studio Classic if Studio or Studio Classic is enabled as your default experience. To open Studio Classic, see Launch Studio Classic Using the Amazon SageMaker AI Console.

  Clone the aws/amazon-sagemaker-examples GitHub repository to Studio Classic by following the steps in Clone a Git Repository in SageMaker Studio Classic.
- **For Amazon SageMaker notebook instances**

  First launch SageMaker notebook instance by following the instructions in Access Notebook Instances.

  Then, follow the instructions in Add a Git repository to your Amazon SageMaker AI account.

Now that you have the SageMaker AI example notebooks, navigate to the `amazon-sagemaker-examples/sagemaker-featurestore` directory and open the Fraud Detection with Amazon SageMaker Feature Store example notebook.

Step 1: Set up your Feature Store session

To start using Feature Store, create a SageMaker AI session, Boto3 session, and a Feature Store session. Also, set up the Amazon S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker AI default bucket and adds a custom prefix to it.

> **Note**
>
> The role that you use to run the notebook must have the following managed policies attached to it: `AmazonSageMakerFullAccess` and `AmazonSageMakerFeatureStoreAccess`. For information about adding policies to your IAM role, see Adding policies to your IAM role.

```
import boto3
import sagemaker
from sagemaker.session import Session

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
boto_session = boto3.Session(region_name=region)
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
prefix = 'sagemaker-featurestore'
offline_feature_store_bucket = 's3://{}/{}'.format(default_bucket, prefix)

sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
featurestore_runtime = boto_session.client(service_name='sagemaker-featurestore-
runtime', region_name=region)

feature_store_session = Session(
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
    sagemaker_featurestore_runtime_client=featurestore_runtime
)
```

Step 2: Load datasets and partition data into feature groups

Load your data into data frames for each of your features. You use these data frames after you set up the feature group. In the fraud detection example, you can see these steps in the following code.

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import io

s3_client = boto3.client(service_name='s3', region_name=region)

fraud_detection_bucket_name = 'sagemaker-featurestore-fraud-detection'
identity_file_key = 'sampled_identity.csv'
transaction_file_key = 'sampled_transactions.csv'

identity_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
 Key=identity_file_key)
transaction_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
 Key=transaction_file_key)
```

```
identity_data = pd.read_csv(io.BytesIO(identity_data_object['Body'].read()))
transaction_data = pd.read_csv(io.BytesIO(transaction_data_object['Body'].read()))

identity_data = identity_data.round(5)
transaction_data = transaction_data.round(5)

identity_data = identity_data.fillna(0)
transaction_data = transaction_data.fillna(0)

# Feature transformations for this dataset are applied before ingestion into
 FeatureStore.
# One hot encode card4, card6
encoded_card_bank = pd.get_dummies(transaction_data['card4'], prefix = 'card_bank')
encoded_card_type = pd.get_dummies(transaction_data['card6'], prefix = 'card_type')

transformed_transaction_data = pd.concat([transaction_data, encoded_card_type,
 encoded_card_bank], axis=1)
transformed_transaction_data =
 transformed_transaction_data.rename(columns={"card_bank_american express":
 "card_bank_american_express"})
```

Step 3: Set up feature groups

When you set up your feature groups, you need to customize the feature names with a unique name and set up each feature group with the `FeatureGroup` class.

```
from sagemaker.feature_store.feature_group import FeatureGroup
feature_group_name = "some string for a name"
feature_group = FeatureGroup(name=feature_group_name,
 sagemaker_session=feature_store_session)
```

For example, in the fraud detection example, the two feature groups are `identity` and `transaction`. In the following code you can see how the names are customized with a timestamp, and then each group is set up by passing in the name and the session.

```
import time
from time import gmtime, strftime, sleep
from sagemaker.feature_store.feature_group import FeatureGroup

identity_feature_group_name = 'identity-feature-group-' + strftime('%d-%H-%M-%S',
 gmtime())
```

```
transaction_feature_group_name = 'transaction-feature-group-' + strftime('%d-%H-%M-%S',
 gmtime())

identity_feature_group = FeatureGroup(name=identity_feature_group_name,
 sagemaker_session=feature_store_session)
transaction_feature_group = FeatureGroup(name=transaction_feature_group_name,
 sagemaker_session=feature_store_session)
```

Step 4: Set up record identifier and event time features

In this step, you specify a record identifier name and an event time feature name. This name maps to the column of the corresponding features in your data. For example, in the fraud detection example, the column of interest is `TransactionID`. `EventTime` can be appended to your data when no timestamp is available. In the following code, you can see how these variables are set, and then `EventTime` is appended to both feature's data.

```
record_identifier_name = "TransactionID"
event_time_feature_name = "EventTime"
current_time_sec = int(round(time.time()))
identity_data[event_time_feature_name] =
 pd.Series([current_time_sec]*len(identity_data), dtype="float64")
transformed_transaction_data[event_time_feature_name] =
 pd.Series([current_time_sec]*len(transaction_data), dtype="float64")
```

Step 5: Load feature definitions

You can now load the feature definitions by passing a data frame containing the feature data. In the following code for the fraud detection example, the identity feature and transaction feature are each loaded by using `load_feature_definitions`, and this function automatically detects the data type of each column of data. For developers using a schema rather than automatic detection, see the Export Feature Groups from Data Wrangler example for code that shows how to load the schema, map it, and add it as a `FeatureDefinition` that you can use to create the `FeatureGroup`. This example also covers a AWS SDK for Python (Boto3) implementation, which you can use instead of the SageMaker Python SDK.

```
identity_feature_group.load_feature_definitions(data_frame=identity_data); # output is
 suppressed
transaction_feature_group.load_feature_definitions(data_frame=transformed_transaction_data);
 # output is suppressed
```

Step 6: Create a feature group

In this step, you use the `create` function to create the feature group. The following code shows all of the available parameters. The online store is not created by default, so you must set this as `True` if you want to enable it. The `s3_uri` is the S3 bucket location of your offline store.

```
# create a FeatureGroup
feature_group.create(
    description = "Some info about the feature group",
    feature_group_name = feature_group_name,
    record_identifier_name = record_identifier_name,
    event_time_feature_name = event_time_feature_name,
    feature_definitions = feature_definitions,
    role_arn = role,
    s3_uri = offline_feature_store_bucket,
    enable_online_store = True,
    online_store_kms_key_id = None,
    offline_store_kms_key_id = None,
    disable_glue_table_creation = False,
    data_catalog_config = None,
    tags = ["tag1","tag2"])
```

The following code from the fraud detection example shows a minimal `create` call for each of the two features groups being created.

```
identity_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)

transaction_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)
```

When you create a feature group, it takes time to load the data, and you need to wait until the feature group is created before you can use it. You can check status using the following method.

```
status = feature_group.describe().get("FeatureGroupStatus")
```

While the feature group is being created, you receive `Creating` as a response. When this step has finished successfully, the response is `Created`. Other possible statuses are `CreateFailed`, `Deleting`, or `DeleteFailed`.

Step 7: Work with feature groups

Now that you've set up your feature group, you can perform any of the following tasks:

Topics

Describe a feature group

You can retrieve information about your feature group with the `describe` function.

```
feature_group.describe()
```

List feature groups

You can list all of your feature groups with the `list_feature_groups` function.

```
sagemaker_client.list_feature_groups()
```

Put records in a feature group

You can use the `ingest` function to load your feature data. You pass in a data frame of feature data, set the number of workers, and choose to wait for it to return or not. The following example demonstrates using the `ingest` function.

```
feature_group.ingest(
    data_frame=feature_data, max_workers=3, wait=True
)
```

For each feature group you have, run the `ingest` function on the feature data you want to load.

Get records from a feature group

You can use the `get_record` function to retrieve the data for a specific feature by its record identifier. The following example uses an example identifier to retrieve the record.

```
record_identifier_value = str(2990130)
featurestore_runtime.get_record(FeatureGroupName=transaction_feature_group_name,
 RecordIdentifierValueAsString=record_identifier_value)
```

An example response from the fraud detection example:

```
...
'Record': [{'FeatureName': 'TransactionID', 'ValueAsString': '2990130'},
  {'FeatureName': 'isFraud', 'ValueAsString': '0'},
  {'FeatureName': 'TransactionDT', 'ValueAsString': '152647'},
  {'FeatureName': 'TransactionAmt', 'ValueAsString': '75.0'},
  {'FeatureName': 'ProductCD', 'ValueAsString': 'H'},
  {'FeatureName': 'card1', 'ValueAsString': '4577'},
...
```

Generate hive DDL commands

The SageMaker Python SDK’s `FeatureStore` class also provides the functionality to generate Hive DDL commands. The schema of the table is generated based on the feature definitions. Columns are named after feature name and data-type are inferred based on feature type.

```
print(feature_group.as_hive_ddl())
```

Example output:

```
CREATE EXTERNAL TABLE IF NOT EXISTS sagemaker_featurestore.identity-feature-
group-27-19-33-00 (
  TransactionID INT
  id_01 FLOAT
  id_02 FLOAT
  id_03 FLOAT
  id_04 FLOAT
 ...
```

Build a training dataset

Feature Store automatically builds an AWS Glue data catalog when you create feature groups and you can turn this off if you want. The following describes how to create a single training dataset with feature values from both identity and transaction feature groups created earlier in this topic. Also, the following describes how to run an Amazon Athena query to join data stored in the offline store from both identity and transaction feature groups.

To start, create an Athena query using `athena_query()` for both identity and transaction feature groups. The `table_name` is the AWS Glue table that is autogenerated by Feature Store.

```
identity_query = identity_feature_group.athena_query()
transaction_query = transaction_feature_group.athena_query()

identity_table = identity_query.table_name
transaction_table = transaction_query.table_name
```

Write and execute an Athena query

You write your query using SQL on these feature groups, and then execute the query with the `.run()` command and specify your Amazon S3 bucket location for the data set to be saved there.

```
# Athena query
query_string = 'SELECT * FROM "'+transaction_table+'" LEFT JOIN "'+identity_table+'" ON
 "'+transaction_table+'".transactionid = "'+identity_table+'".transactionid'

# run Athena query. The output is loaded to a Pandas dataframe.
dataset = pd.DataFrame()
identity_query.run(query_string=query_string,
 output_location='s3://'+default_s3_bucket_name+'/query_results/')
identity_query.wait()
dataset = identity_query.as_dataframe()
```

From here you can train a model using this data set and then perform inference.

Delete a feature group

You can delete a feature group with the `delete` function.

```
feature_group.delete()
```

The following code example is from the fraud detection example.

```
identity_feature_group.delete()
transaction_feature_group.delete()
```

For more information, see the Delete a feature group API.

Using Amazon SageMaker Feature Store in the console

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.

AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can use Amazon SageMaker Feature Store on the console to create, view, update, and monitor your feature groups. Monitoring in this guide includes viewing pipeline executions and lineage of your feature groups. This guide provides instructions on how to achieve these tasks from the console.

For Feature Store examples and resources using the Amazon SageMaker APIs and AWS SDK for Python (Boto3), see Amazon SageMaker Feature Store resources.

Topics

Create a feature group from the console

The create feature group process has four steps:

1. Enter feature group information.
2. Enter feature definitions.
3. Enter required features.
4. Enter feature group tags.

Consider which of the following options fits your use case:

- Create an online store, an offline store, or both. For more information about the differences between online and offline stores, see Feature Store concepts.
- Use a default AWS Key Management Service key or your own KMS key. The default key is AWS KMS key (SSE-KMS). You can reduce AWS KMS request costs by configuring use of Amazon S3 Bucket Keys on the offline store Amazon S3 bucket. The Amazon S3 Bucket Key must be enabled before using the bucket for your feature groups. For more information about reducing the cost by using Amazon S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

  You can use the same key for both online and offline stores, or have a unique key for each. For more information about AWS KMS, see AWS Key Management Service.
- If you create an offline store:
  - Decide if you want to create an Amazon S3 bucket or use an existing one. When using an existing one, you must know the Amazon S3 bucket URL or Amazon S3 bucket name and dataset directory name, if applicable.

- Choose which Amazon Resource Name (ARN) to use to specify the IAM role. For more information about how to find your role and attached policies, see Adding policies to your IAM role.
- Decide whether to use the AWS Glue (default) or Apache Iceberg table format. In most use cases, you use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).

You can use the console to view the lineage of a feature group. The instructions for using Feature Store on the console vary depending on whether you enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Create feature groups if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** from the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. Choose **Create feature group**.
5. Under **Feature group details**, enter a feature group name.
6. (Optional) Enter a description of the feature group.
7. Under **Feature group storage configuration**, choose a storage configuration from the dropdown list. For information about storage configurations, see Feature Store storage configurations.
8. If you have chosen to enable the online storage:

   a. If you *only* enable the online storage, you can choose a **Storage type** from the dropdown list. For information about online store storage types, see Online store.

   b. (Optional) Apply **Time to Live (TTL)** by toggling the switch to **On** and specifying the **Time to Live duration** value and unit. This will update the default TTL duration for all records added to the feature group *after the feature group is created*. For more information about TTL, see Time to live (TTL) duration for records.
9. If you have chosen to enable the offline storage:

   a. Under the **Amazon S3 bucket name**, enter a new bucket name, or enter an existing bucket URL, manually.

   b. From the **Table format** dropdown list, choose the table format. In most use cases, you should use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).

   c. Under **IAM role ARN**, choose the IAM role ARN you want to attach to this feature group. For more information about how to find your role and attached policies, see Adding policies to your IAM role.

   d. If you have chosen to enable the offline storage **Table format** and AWS Glue (default) **Table format**, under **Data catalog**, you can choose one of the following two options:

      - **Use default values for your AWS Glue Data Catalog**.
      - Provide your existing Data Catalog name, table name, and database name to extend your existing AWS Glue Data Catalog.

10. Under the **Online store encryption key** or **Offline store encryption key** dropdown list, choose one of the following options:

    - **Use AWS managed AWS KMS key (default)**
    - **Enter an AWS KMS key ARN** and enter your AWS KMS key ARN under **Offline store encryption key ARN**. For more information about AWS KMS, see AWS Key Management Service.

11. If applicable, you will have the option to choose your throughput mode, which impacts how you are charged. Under **Throughput mode**, choose a mode from the dropdown list and input the read and write capacities when available. For information about throughput modes, like when the mode can be applied and capacity units, see Throughput modes.

12. After you specify all of the required information, the **Continue** button appears available. Choose **Continue**.

13. Under **Specify feature definitions**, you have two options for providing a schema for your features: a JSON editor, or a table editor.

    - JSON editor: In the **JSON** tab, enter or copy and paste your feature definitions in the JSON format.
    - Table editor: In the **Table** tab, enter the feature feature name and choose the corresponding data type for each feature in your feature group. Choose **+ Add feature definitions** to include more features. Be aware that you cannot remove feature definitions from your feature groups. However, you can add and update feature definitions after the feature group is created.

There must be at least two features in a feature group that represent the record identifier and event time:

- The record **Feature type** can be a string, fractional, or an integral.
- The event time **Feature type** must be a string or a fractional. However, if you chose the Iceberg table format, the event time must be a string.

14. After all of the features are included, choose **Continue**.
15. Under **Select required features**, you must specify the record identifier and event time features. Do this by choosing the feature name under **Record identifier feature name** and **Event time feature name** dropdown lists, respectively.
16. After you choose the record identifier and event time features, choose **Continue**.
17. (Optional) To add tags for the feature group, choose **Add new tag**. Then enter a tag key and the corresponding value under **Key** and **Value**, respectively.
18. Choose **Continue**.
19. Under **Review feature group**, review the feature group information. To edit any step, choose the **Edit** button that corresponds to that step. This brings you to the corresponding step for editing. To return to step 5, choose **Continue** until you return to step 5.
20. After you finalize the setup for your feature group, choose **Create feature group**.

    If an issue occurs during setup, a pop-up alert message appears at the bottom of the page with tips for solving the issue. You can return to previous steps to fix the issues by choosing **Edit** for the step with conflicts.

    After the feature group has been successfully created, a green pop-up message appears at the bottom of the page. The new feature group also appears in your feature groups catalog.

Create feature groups if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon

   ()

   on the left navigation pane.
3. Choose **Data**.

4. From the dropdown list, choose **Feature Store**.

5. Choose **Create feature group**.

6. Under **Feature group details**, enter a feature group name.

7. (Optional) Enter a description of the feature group.

8. Under **Feature group storage configuration**, choose a storage configuration from the dropdown list. For information about storage configurations, see Feature Store storage configurations.

9. If you have chosen to enable the online storage:

   a. If you *only* enable the online storage, you may choose a **Storage type** from the dropdown list. For information about online store storage types, see Online store.

   b. (Optional) Apply **Time to Live (TTL)** by toggling the switch to **On** and specifying the **Time to Live duration** value and unit. This will update the default TTL duration for all records added to the feature group *after the feature group is created*. For more information about TTL, see Time to live (TTL) duration for records.

10. If you have chosen to enable the offline storage:

    a. Under the **Amazon S3 bucket name**, enter a new bucket name or enter an existing bucket URL manually.

    b. From the **Table format** dropdown list, choose the table format. In most use cases, you should use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).

    c. Under **IAM role ARN**, choose the IAM role ARN you want to attach to this feature group. For more information about how to find your role and attached policies, see Adding policies to your IAM role.

    d. If you have chosen to enable the offline storage **Table format** and AWS Glue (default) **Table format**, under **Data catalog**, you can choose one of the following two options:

       - **Use default values for your AWS Glue Data Catalog**.
       - Provide your existing Data Catalog name, table name, and database name to extend your existing AWS Glue Data Catalog.

11. Under the **Online store encryption key** or **Offline store encryption key** dropdown list, choose one of the following options:

    - **Use AWS managed AWS KMS key (default)**

- **Enter an AWS KMS key ARN** and enter your AWS KMS key ARN under **Offline store encryption key ARN**. For more information about AWS KMS, see AWS Key Management Service.

12. After you specify all of the required information, the **Continue** button appears available. Choose **Continue**.
13. Under **Specify feature definitions**, you have two options for providing a schema for your features: a JSON editor, or a table editor.

    - JSON editor: In the **JSON** tab, enter or copy and paste your feature definitions in the JSON format.
    - Table editor: In the **Table** tab, enter the feature feature name and choose the corresponding data type for each feature in your feature group. Choose **+ Add feature definitions** to include more features. Be aware that you cannot remove feature definitions from your feature groups. However, you can add and update feature definitions after the feature group is created.

    There must be at least two features in a feature group that represent the record identifier and event time:

    - The record **Feature type** can be a string, fractional, or an integral.
    - The event time **Feature type** must be a string or a fractional. However, if you chose the Iceberg table format, the event time must be a string.
14. After all of the features are included, choose **Continue**.
15. Under **Select required features**, you must specify the record identifier and event time features. Do this by choosing the feature name under **Record identifier feature name** and **Event time feature name** dropdown lists, respectively.
16. After you choose the record identifier and event time features, choose **Continue**.
17. (Optional) To add tags for the feature group, choose **Add new tag**. Then enter a tag key and the corresponding value under **Key** and **Value**, respectively.
18. Choose **Continue**.
19. Under **Review feature group**, review the feature group information. To edit any step, choose the **Edit** button that corresponds to that step. This brings you to the corresponding step for editing. To return to step 5, choose **Continue** until you return to step 5.
20. After you finalize the setup for your feature group, choose **Create feature group**.

If an issue occurs during setup, a pop-up alert message appears at the bottom of the page with tips for solving the issue. You can return to previous steps to fix the issues by choosing **Edit** for the step with conflicts.

After the feature group has been successfully created, a green pop-up message appears at the bottom of the page. The new feature group also appears in your feature groups catalog.

View feature group details from the console

You can view details of your feature groups after a feature group has successfully been created in the Feature Store.

You can use the console or the Amazon SageMaker Feature Store API to view your feature group details. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View feature group details if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature group catalog** tab, choose your feature group name from the list. This opens the feature group page.
6. On the **Features** tab, you can find a list of all of the features. Use the filter to refine your list. Choose a feature to view its details.
7. Under the **Details** tab and the **Information** subtab, you can review your feature group information. This includes **Latest execution**, **Offline storage settings**, **Online storage settings**, and more.
8. Under the **Details** tab and the **Tags** subtab, you can review your feature group tags. Choose **Add new tag** to add a new tag or **Remove** to remove a tag.
9. Under the **Pipeline Executions** tab, you can view the associated pipelines or pipeline executions for your feature group.

10. Under the **Lineage** tab, you can view the lineage of your feature group.

View feature group details if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in [Launch Amazon SageMaker Studio Classic](#).
2. Choose the **Home** icon () in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature group catalog** tab, choose your feature group name from the list. This opens the feature group page.
7. On the **Features** tab, you can find a list of all of the features. Use the filter to refine your list. Choose a feature to view its details.
8. Under the **Details** tab and the **Information** subtab, you can review your feature group information, including **Latest execution**, **Offline storage settings**, **Online storage settings**, and more.
9. Under the **Details** tab and the **Tags** subtab, you can review your feature group tags. Choose **Add new tag** to add a new tag or **Remove** to remove a tag.
10. Under the **Pipeline Executions** tab, you can view the associated pipelines or pipeline executions for your feature group.
11. Under the **Lineage** tab, you can view the lineage of your feature group.

Update a feature group from the console

You can update your feature groups after a feature group has successfully been created in the Feature Store.

You can use the console or the Amazon SageMaker Feature Store API to update a feature group. The instructions for using Feature Store through the console depends on if you have enabled [Amazon SageMaker Studio](#) or [Amazon SageMaker Studio Classic](#) as your default experience.

Update a feature group if Studio is your default experience (console)

1. Open the Studio console by following the instructions in [Launch Amazon SageMaker Studio](#).
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature group catalog** tab, search for and choose your feature group name from the list. This opens the feature group page.
6. Choose **Update feature group**.
7. (Optional) If applicable, you can change your throughput mode, which impacts how you are charged. Under **Throughput mode**, choose a mode from the dropdown list and input the read and write capacities when available. For information about throughput modes, like when the mode can be applied and capacity units, see [Throughput modes](#).
8. (Optional) If your feature group uses the online store, you can update the default **Time to Live (TTL)**. If TTL hasn't been enabled for the feature group, toggle the switch button under **Time to Live (TTL)** to **On**. You can specify the TTL value and unit under **Time to Live duration**. This will update the default TTL duration for all records added to the feature group *after the feature group is updated*.
9. (Optional) You can add feature definitions to your feature group but be aware that you cannot remove feature definitions from your feature groups. To add a feature definition, choose **+ Add feature definition** and then specify the new feature definition name under the **Name** column and select the feature type under the **Feature type** column.
10. Choose **Save changes**.
11. To confirm your changes, choose **Confirm**.

Update a feature group if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in [Launch Amazon SageMaker Studio Classic](#).
2. Choose the **Home** icon () in the left navigation pane.
3. Choose **Data**.

4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature group catalog** tab, search for and choose your feature group name from the list. This opens the feature group page.
7. Choose **Update feature group**.
8. (Optional) If your feature group uses the online store, you can update the default **Time to Live (TTL)**. If TTL hasn't been enabled for the feature group, toggle the switch button under **Time to Live (TTL)** to **On**. You can specify the TTL value and unit under **Time to Live duration**. This will update the default TTL duration for all records added to the feature group *after the feature group is updated*.
9. (Optional) You can add feature definitions to your feature group but be aware that you cannot remove feature definitions from your feature groups. To add a feature definition, choose **+ Add feature definition** and then specify the new feature definition name under the **Name** column and select the feature type under the **Feature type** column.
10. Choose **Save changes**.
11. To confirm your changes, choose **Confirm**.

View pipeline executions from the console

You can view the latest pipeline execution information for a feature or feature group under **Pipeline executions**. You can also get links to pipelines, executions, code, and other useful execution information.

You can use the console to view your pipeline executions. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View pipeline executions if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Choose a feature group or feature to view their pipeline executions.

6. Choose the **Pipeline executions** tab.
7. Search for a pipeline from the **Select a pipeline** dropdown list.
8. You can view the links for the pipeline, execution, and code details. You can also view the execution owner, status, date, and duration.

View pipeline executions if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon () in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Choose a feature group or feature to view their pipeline executions.
7. Choose the **Pipeline executions** tab.
8. Search for a pipeline from the **Select a pipeline** dropdown list.
9. You can view the links for the pipeline, execution, and code details. You can also view the execution owner, status, date, and duration.

View lineage from the console

You can view the lineage of a feature group. The lineage includes the information about the execution code of your feature processing workflow, what data sources were used, and how they are ingested to the feature group or feature.

You can use the console to view the lineage of a feature group. The instructions on using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View lineage if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.

2. Choose **Data** from the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Choose a feature group or feature to view its lineage details.
6. Choose the **Lineage** tab.
7. Choose a feature group or pipeline node to expand the node. This contains more information about a feature group or pipeline.
8. You can zoom in, zoom out, or recenter the lineage graph by using the buttons on the bottom left of the screen.
9. You can move through the lineage map when you choose and drag the screen. To move your lineage maps using nodes as the focal point, you can press **Tab** or **Shift+Tab** to switch between nodes.
10. If applicable, you can navigate the lineage upstream (left, earlier) or downstream (right, most recent). Do this by choosing a node and then choosing **Query upstream lineage** or **Query downstream lineage**.

View lineage if Studio Classic is your default experience (console)

1. Open Studio Classic by following the instructions in [Launch Amazon SageMaker Studio Classic](#).
2. Choose the **Home** icon ( ) in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Choose a feature group or feature to view its lineage details.
7. Choose the **Lineage** tab.
8. Choose a feature group or pipeline node to expand the node. This contains more information about a feature group or pipeline.
9. You can zoom in, zoom out, or recenter the lineage graph by using the buttons on the bottom left of the screen.

10. You can move through the lineage map when you choose and drag the screen. To move your lineage maps using nodes as the focal point, you can press **Tab** or **Shift+Tab** to switch between nodes.
11. If applicable, you can navigate the lineage upstream (left, earlier) or downstream (right, most recent). Do this by choosing a node and then choosing **Query upstream lineage** or **Query downstream lineage**.

Delete a feature group

You can use the console or the Amazon SageMaker Feature Store API to delete your feature group. The instructions on using Feature Store through the console depends on if you have enabled Studio or Studio Classic as your default experience. For more information about the differences between the two, or how to change your default, see Amazon SageMaker Studio.

The following sections provide an overview on how to delete a feature group.

Topics

Delete a feature group using the console

This section shows two ways to delete a feature group in the console, depending on your default experience: Studio or Studio Classic.

Delete feature group if Studio is your default experience (console)

1. Open the Studio console by following instructions in Launch Amazon SageMaker Studio Classic.
2. Choose **Data** in the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. In the **Feature Group Catalog** tab, choose the feature group to delete under **Feature group name**.
6. Choose **Delete feature group**.

7. In the pop-up window, confirm deletion by entering **delete** in the field, then choose **Delete**.

Delete feature group if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in [Launch Amazon SageMaker Studio Classic](#).
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. In the **Feature Group Catalog** tab, choose the feature group to delete under **Feature group name**.
7. Choose **Delete feature group**.
8. In the pop-up window, confirm deletion by typing **delete** in the field, then choose **Delete**.

Delete feature group example Python code

The following code uses the [DeleteFeatureGroup](#) API operation to delete your feature group using the AWS SDK for Python (Boto3). It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see [Introduction to Feature Store example notebook](#).

```
import sagemaker
from sagemaker.feature_store.feature_group import FeatureGroup

sagemaker_session = sagemaker.Session()
fg_name = 'your-feature-group-name'

my_fg = FeatureGroup(name=fg_name, sagemaker_session=sagemaker_session)
my_fg.delete()
```

Add features and records to a feature group

You can use the Amazon SageMaker Feature Store API or the console to update and describe your feature group as well as add features and records to your feature group. A feature group is an object that contains your data and a feature describes a column in the table. When you add a feature to the feature group you are effectively adding a column to the table. When you add a new record to the feature group you are filling in values for features associated with a specific record identifier. For more information on Feature Store concepts, see Feature Store concepts.

After you successfully add features to a feature group, you cannot remove those features. The features that you have added do not add any data to your records. You can add new records to the feature group or overwrite them using the PutRecord API. For examples on updating, describing, and putting records into a feature group, see Example code.

You can use the console to add features to a feature group. For more information on how to update your feature groups using the console, see Update a feature group from the console.

The following sections provide an overview of using Feature Store APIs to add features to a feature group followed by examples. With the API, you can also add or overwrite records after you've updated the feature group.

Topics

API

Use the `UpdateFeatureGroup` operation to add features to a feature group.

You can use the `DescribeFeatureGroup` operation to see if you've added the features successfully.

To add or overwrite records, use the `PutRecord` operation.

To see the updates that you've made to a record, use the `GetRecord` operation. To see the updates that you've made to multiple records, use the `BatchGetRecord` operation. It can take up to five minutes for the updates that you've made to appear.

You can use the example code in the following section to walk through adding features and records using the AWS SDK for Python (Boto3).

Example code

The example code walks you through the following process:

1. Adding features to the feature group
2. Verifying that you've added them successfully
3. Adding a record to the feature group
4. Verifying that you've added it successfully

Step 1: Add features to a feature group

The following code uses the UpdateFeatureGroup operation to add new features to the feature group. It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see Introduction to Feature Store example notebook.

```
import boto3

sagemaker_client = boto3.client("sagemaker")

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    FeatureAdditions=[
        {"FeatureName": "new-feature-1", "FeatureType": "Integral"},
        {"FeatureName": "new-feature-2", "FeatureType": "Fractional"},
        {"FeatureName": "new-feature-3", "FeatureType": "String"}
    ]
)
```

The following code uses the DescribeFeatureGroup operation to check the status of the update. If the LastUpdateStatus field is `Successful`, you've added the features successfully.

```
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

Step 2: Add a new record to the feature group

The following code uses the PutRecord operation to add records to the feature group that you've created.

```
record_identifier_value = 'new_record'

sagemaker_featurestore_runtime_client = boto3.client("sagemaker-featurestore-runtime")

sagemaker_runtime_client.put_record(
    FeatureGroupName=feature_group_name,
    Record=[
        {
            'FeatureName': "record-identifier-feature-name",
            'ValueAsString': record_identifier_value
        },
        {
            'FeatureName': "event-time-feature",
            'ValueAsString': "timestamp-that-feature-store-returns"
        },
        {
            'FeatureName': "new-feature-1",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-2",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-3",
            'ValueAsString': "value-as-string"
        },
    ]
)
```

Use the GetRecord operation to see which records in your feature group don't have data for the features that you've added. You can use the PutRecord operation to overwrite the records that don't have data for the features that you've added.

Delete records from your feature groups

You can use the Amazon SageMaker Feature Store API to delete records from your feature groups. A feature group is an object that contains your machine learning (ML) data, where the columns of your data are described by features and your data are contained in records. A record contains values for features that are associated with a specific record identifier.

There are two storage configurations for your feature groups: online store and offline store. The online store only keeps the record with the latest event time and is typically used for real-time lookup for ML inference. The offline store keeps all records and acts as a historical database and is typically used for feature exploration, ML training, and batch inference.

For more information on Feature Store concepts, see Ingestion diagrams.

There are two ways to delete records from your feature groups, and the behavior is different depending on the storage configuration. In the following topics we will describe how to soft and hard delete records from the online and offline stores and provide examples.

Topics

Delete records from the online store

You can soft or hard delete a record from the online store using the `DeleteRecord` API by using the `DeletionMode` request parameter to specify `SoftDelete` (default) or `HardDelete`. For more information on the `DeleteRecord` API, see `DeleteRecord` in the Amazon SageMaker API Reference.

With the online store:

- When you soft delete (default), the record is no longer retrievable by GetRecord or BatchGetRecord and the feature column values are set to `null`, except for the `RecordIdentifer` and `EventTime` feature values.
- When you hard delete, the record is completely removed from the online store.

In both cases Feature Store appends the deleted record marker to the `OfflineStore`. The deleted record marker is a record with the same `RecordIdentifer` as the original, but with `is_deleted` value set to `True`, `EventTime` set to the delete input `EventTime`, and other feature values set to `null`.

Note that the `EventTime` specified in `DeleteRecord` should be set later than the `EventTime` of the existing record in the `OnlineStore` for that same `RecordIdentifer`. If it is not, the deletion does not occur:

- For `SoftDelete`, the existing (not deleted) record remains in the `OnlineStore`, though the delete record marker is still written to the `OfflineStore`.
- `HardDelete` returns `EventTime`: `400 ValidationException` to indicate that the delete operation failed. No delete record marker is written to the `OfflineStore`.

The following examples use the SDK for Python (Boto3) [`delete_record`] operation to delete a record from a feature group. To delete a record from a feature group, you will need:

- Feature group name (*`feature-group-name`*)
- Record identifier value as a string (*`record-identifier-value`*)
- Deletion event time (*`deletion-event-time`*)

  The deletion event time should be later than the event time of the record you wish to delete.

Online store soft delete example

For soft delete you will need use the `DeleteRecord` API and can use the default `DeletionMode` or set the `DeletionMode` to `SoftDelete`.

```
import boto3
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-time',
    TargetStores=[
        'OnlineStore',
    ],
    DeletionMode='SoftDelete'
)
```

Online store hard delete example

For hard delete you will need use the `DeleteRecord` API and set the `DeletionMode` to `HardDelete`.

```
import boto3
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-timestamp',
    TargetStores=[
        'OnlineStore',
    ],
    DeletionMode='HardDelete'
)
```

Delete records from the offline store

With Amazon SageMaker Feature Store you can soft and hard delete a record from the `OfflineStore` Iceberg table format. With the `OfflineStore` Iceberg table format:

- When you soft delete a record the latest version of the Iceberg table file will not contain the record, but previous versions will still contain the record and can be accessed using time travel. For information on time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.
- When you hard delete a record you are removing previous versions of the Iceberg table that contain the record. In this case you should specify which versions of the Iceberg table you wish to delete.

Obtain your Iceberg table name

To soft and hard delete from your `OfflineStore` Iceberg table, you will need to obtain your Iceberg table name, *`iceberg-table-name`*. The following instructions assumes you have already used Feature Store to create a feature group using the offline store storage configuration using the Iceberg table format, with `DisableGlueTableCreation = False` (default). For more information on creating feature groups, see Get started with Amazon SageMaker Feature Store.

To obtain your *iceberg-table-name*, use the [DescribeFeatureGroup] API to obtain [DataCatalogConfig]. This contains the metadata of the Glue table which serves as data catalog for the OfflineStore. The TableName within the DataCatalogConfig is your *iceberg-table-name*.

Amazon Athena offline store soft and hard delete example

The following instructions use Amazon Athena to soft delete then hard delete a record from the OfflineStore Iceberg table. This assumes that the record you intend to delete in your OfflineStore is a deleted record marker. For information on the deleted record marker in your OfflineStore, see Delete records from the online store.

1. Obtain your Iceberg table name, *iceberg-table-name*. For information on how to obtain your Iceberg table name, see Obtain your Iceberg table name.
2. Run the DELETE command to soft delete the records on the OfflineStore, such that the latest version (or snapshot) of the Iceberg table will not contain the records. The following example deletes the records where is_deleted is 'True' and the previous event-time versions of the those records .You may add additional conditions based on other features to restrict the deletion. For more information on using DELETE with Athena, see DELETE in the Athena user guide.

```
DELETE FROM iceberg-table-name WHERE record-id-feature-name IS IN ( SELECT record-id-feature-name FROM iceberg-table-name WHERE is_deleted = 'True')
```

   The soft deleted records are still viewable on previous file versions by performing time travel. For information on performing time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.
3. Remove the record from previous versions of your Iceberg tables to hard delete the record from OfflineStore:

   a. Run the OPTIMIZE command to rewrite the data files into a more optimized layout, based on their size and number of associated delete files. For more information on optimizing Iceberg tables and the syntax, see Optimizing Iceberg tables in the Athena user guide.

   ```
   OPTIMIZE iceberg-table-name REWRITE DATA USING BIN_PACK
   ```

   b. (Optional, only need to run once) Run the ALTER TABLE command to alter the Iceberg table set values, and set when previous file versions are to be hard deleted according to your specifications. This can be done by assigning values to `vacuum_min_snapshots_to_keep` and `vacuum_max_snapshot_age_seconds` properties. For more information on altering your Iceberg table set properties, see ALTER TABLE SET PROPERTIES in the Athena user guide. For more information on Iceberg table property key-value pairs, see Table properties in the Athena user guide.

```
ALTER TABLE iceberg-table-name SET TBLPROPERTIES (
  'vacuum_min_snapshots_to_keep'='your-specified-value',
  'vacuum_max_snapshot_age_seconds'='your-specified-value'
)
```

c. Run the `VACUUM` command to remove no longer needed data files for your Iceberg tables, not referenced by the current version. The `VACUUM` command should run after the deleted record is no longer referenced in the current snapshot. For example, `vacuum_max_snapshot_age_seconds` after the deletion. For more information on `VACUUM` with Athena and the syntax, see `VACUUM`.

```
VACUUM iceberg-table-name
```

Apache Spark offline store soft and hard delete example

To soft and then hard delete a record from the `OfflineStore` Iceberg table using Apache Spark, you can follow the same instructions as in the Amazon Athena offline store soft and hard delete example above, but using Spark procedures. For a full list of procedures, see Spark Procedures in the Apache Iceberg documentation.

- When soft deleting from the `OfflineStore`: instead of using the `DELETE` command in Athena, use the `DELETE FROM` command in Apache Spark.
- To remove the record from previous versions of your Iceberg tables to hard delete the record from `OfflineStore`:
  - When changing your Iceberg table configuration: instead of using the `ALTER TABLE` command from Athena, use `expire_snapshots` procedure.
  - To remove no longer needed data files from your Iceberg tables: instead of using the `VACUUM` command in Athena, use the `remove_orphan_files` procedure.

Collection types

Collection types provide a way to organize and structure data for efficient retrieval and analysis. They are used in ML databases to define the schema of a dataset and its elements. In Amazon SageMaker Feature Store, the supported collection types include list, set, and vector.

Collections are a grouping of elements in which each element within the collection must have the same feature type (`String`, `Integral`, or `Fractional`). For example, a collection can contain elements with all of the element feature types as `Fractional`, but a collection cannot contain elements with some feature types as `Fractional` and some feature types as `String`.

Only `InMemory` online store feature groups currently support collection types. The following list describes the collection type options.

List: An ordered collection of elements.

- The length of the list is determined by how many elements are in the collection.
- Example: You can have a list such as [‘a’, ‘b’, ‘a’], because the list preserves the order and can have repeat elements.

Set: An unordered collection of unique elements.

- The length of the set is determined by how many unique elements are in the collection.
- Example: You cannot have a set such as [‘a’, 'b', 'a'], because it contains a repeat element. The set will instead have the elements [‘a’, ‘b’], because the set only contains unique elements.

Vector: A specialized list that represents a fixed-size array of elements. The order of the elements hold significance, such that the positions of the elements represent certain properties of the data.

- The elements in the vector collection type *must* have the `Fractional` feature type.
- You may only have one vector collection type per online store `InMemory` tier feature group.
- The dimension (number of elements in the vector) of the vector is predetermined by you and is specified using `VectorDimension`. The max dimension limit is 8192.
- Example: You can have a vector such as [4.2, -6.3, 4.2], where the first, second, and third elements can represent the x, y, and z positions in physical space.

There are no limits on the length of the collections, as long as they don't exceed the maximum size of a record. For the maximum size of a record, see Quotas, naming rules and data types.

Time to live (TTL) duration for records

Amazon SageMaker Feature Store provides the option for records to be hard deleted from the online store after a time duration is reached, with time to live (TTL) duration (`TtlDuration`). The record will expire after the record's `EventTime` plus the `TtlDuration` is reached, or `ExpiresAt = EventTime + TtlDuration`. The `TtlDuration` can be applied at a feature group level, where all records within the feature group will have the `TtlDuration` by default, or at an individual record level. If `TtlDuration` is unspecified, the default value is `null` and the record will remain in the online store until it is overwritten.

A record deleted using `TtlDuration` is hard deleted, or completely removed from the online store, and the deleted record is added to the offline store. For more information on hard delete and deletion modes, see `DeleteRecord` in the Amazon SageMaker API Reference guide. When a record is hard deleted it immediately becomes inaccessible using Feature Store APIs.

> **Important**
>
> TTL typically deletes expired items within a few days. Depending on the size and activity level of a table, the actual delete operation of an expired item can vary. Because TTL is meant to be a background process, the nature of the capacity used to expire and delete items via TTL is variable (but free of charge). For more information on how items are deleted from a DynamoDB table, see How it works: DynamoDB Time to Live (TTL).

`TtlDuration` must be a dictionary containing a `Unit` and a `Value`, where the `Unit` must be a string with values "Seconds", "Minutes", "Hours", "Days", or "Weeks" and `Value` must be an integer greater than or equal to 1. `TtlDuration` can be applied while using the `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs. See the request and response syntax in the SDK for Python (Boto3) documentation for `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs.

- When `TtlDuration` is applied at a feature group level (using the `CreateFeatureGroup` or `UpdateFeatureGroup` APIs), the applied `TtlDuration` becomes the default `TtlDuration` for all records that are added to the feature group *from the point in time that the API is called*. When applying `TtlDuration` with the `UpdateFeatureGroup` API, this will *not* become the default `TtlDuration` for records that were created *before* the API is called.

To remove the default `TtlDuration` from an existing feature group, use the `UpdateFeatureGroup` API and set the `TtlDuration` `Unit` and `Value` to `null`.

- When `TtlDuration` is applied at a record level (for example, using `PutRecord` API), the `TtlDuration` duration applies to that record and is used instead of the feature group level default `TtlDuration`.
- When `TtlDuration` is applied on a feature group level it may take a few minutes for `TtlDuration` to come into effect.
- If `TtlDuration` is used when there is no online store, you will receive a `Validation Exception (400)` error.

The following example code shows how to apply `TtlDuration` while updating a feature group, such that the records added to the feature group *after running the API* will by default expire four weeks after their event times.

```
import boto3

sagemaker_client = boto3.client("sagemaker")
feature_group_name = '<YOUR_FEATURE_GROUP_NAME>'

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    OnlineStoreConfig={
        TtlDuration:{
            Unit: "Weeks",
            Value: 4
        }
    }
)
```

You can use the `DescribeFeatureGroup` API to view the default `TtlDuration`.

To view the expiration times, `ExpiresAt` (in UTC time ISO-8601 format), while using the `GetRecord` or `BatchGetRecord` APIs you must set `ExpirationTimeResponse` to `ENABLED`. See the request and response syntax in the SDK for Python (Boto3) documentation for [DescribeFeatureGroup](), [GetRecord](), and [BatchGetRecord]() APIs.

Feature Store storage configurations

Amazon SageMaker Feature Store consists of an online store and an offline store. The online store enables real-time lookup of features for inference, while the offline store contains historical data for model training and batch inference. When creating a feature group, you have the option of enabling either the online store, offline store, or both. When you enable both, they sync to avoid discrepancies between training and serving data. For more information about the online and offline stores and other Feature Store concepts, see Feature Store concepts.

The following topics discuss online store storage types and offline store table formats.

Topics

- Online store
- Offline store
- Throughput modes

Online store

The online store is a low-latency, high-availability data store that provides real-time lookup of features. It is typically used for machine learning (ML) model serving. You can chose between the standard online store (`Standard`) or an in-memory tier online store (`InMemory`), at the point when you create a feature group. In this way, you can select the storage type that best matches the read and write patterns for a particular application, while considering performance and cost. For more details about pricing, see Amazon SageMaker Pricing.

The online store contains the following `StorageType` options. For more information about the online store contents, see `OnlineStoreConfig`.

Standard tier storage type

The `Standard` tier is a managed low-latency data store for online store feature groups. It provides fast data retrieval for ML model service for your applications. `Standard` is the default storage type.

In-memory tier storage type

The `InMemory` tier is a managed data store for online store feature groups that supports very low-latency retrieval. It provides large-scale real-time data retrieval for ML model serving used for high throughput applications. The `InMemory` tier is powered by Amazon ElastiCache (Redis OSS). For more information, see [What is Amazon ElastiCache (Redis OSS)?](#).

The online store `InMemory` tier supports collection types, namely list, set, and vector. For more information about the `InMemory` collection types, see [Collection types](#).

Feature Store provides low latency read and writes to the online store. The application latency is primarily made up of two primary components: infrastructure or network latency and Feature Store API latency. Reduction of network latency helps with getting the lowest latency reads and writes to Feature Store. You can reduce the network latency to Feature Store by deploying AWS PrivateLink to Feature Store Runtime endpoint. With AWS PrivateLink, you can privately access all Feature Store Runtime API operations from your Amazon Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An AWS PrivateLink deployment with the `privateDNSEnabled` option set as true:

- It keeps all Feature Store read/write traffic within your VPC.
- It keeps traffic in the same AZ as the client that originated it when using Feature Store. This avoids the “hops” between AZs reducing the network latency.

Follow the steps in [Access an AWS service using an interface VPC endpoint](#) to setup AWS PrivateLink to Feature Store. The service name for Feature Store Runtime in AWS PrivateLink is `com.amazonaws.region.sagemaker.featurestore-runtime`.

The `InMemory` tier online store scales automatically based about storage usage and requests. The automated scaling can take a few minutes to adapt to a new usage pattern if it changes rapidly. During automated scaling:

- Write operations to the feature group may receive throttling errors. You should retry your requests a few minutes later.
- Read operations to the feature group may receive throttling errors. Standard retry strategies are suitable in this case.
- Read operations may see elevated latency.

The default `InMemory` tier feature group maximum size is 50 GiB.

Note that the `InMemory` tier currently supports online feature groups only, not online+offline feature groups, so there is not replication between online and offline stores for the `InMemory` tier. Also, the `InMemory` tier does not currently support customer managed KMS keys.

Offline store

The offline store is used for historical data when sub-second retrieval is not needed. It is typically used for data exploration, model training, and batch inference.

When you enable both the online and offline stores for your feature group, both stores sync to avoid discrepancies between training and serving data. Please note that an online store feature group with the `InMemory` storage type enabled does not currently support a corresponding feature group in the offline store (no online to offline replication). For more information about ML model serving in Amazon SageMaker Feature Store, see Online store.

The offline store contains the following `TableFormat` options. For information about the offline store contents, see `OfflineStoreConfig` in the Amazon SageMaker API Reference.

Glue table format

The `Glue` format (default) is a standard Hive type table format for AWS Glue. With AWS Glue, you can discover, prepare, move, and integrate data from multiple sources. It also includes additional productivity and data ops tooling for authoring, running jobs, and implementing business workflows. For more information about AWS Glue, see What is AWS Glue?.

Iceberg table format

The `Iceberg` format (recommended) is an open table format for very large analytic tables. With `Iceberg`, you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. For more information about optimizing Iceberg tables, see the Amazon Athena and AWS Lake Formation user guides.

`Iceberg` manages large collections of files as tables and supports modern analytical data lake operations. If you choose the `Iceberg` option when creating new feature groups, Amazon SageMaker Feature Store creates the `Iceberg` tables using Parquet file format, and registers the tables with the AWS Glue Data Catalog. For more information about `Iceberg` table formats, see Using Apache Iceberg tables.

> **Important**
>
> Note that for feature groups in `Iceberg` table format, you must specify `String` as the feature type for the event time. If you specify any other type, you can't create the feature group successfully.

Throughput modes

Amazon SageMaker Feature Store provides two pricing models to choose from: on-demand (`On-demand`) and provisioned (`Provisioned`) throughput modes. `On-demand` works best for less predictable traffic, while `Provisioned` works best for consistent and predictable traffic.

You have the option to switch between `On-demand` and `Provisioned` throughput modes for a given feature group, to accommodate periods in which application traffic patterns are changing or less predictable. You can only update your feature group throughput mode to `On-demand` once in a 24 hour period. The throughput mode can be updated programmatically using the UpdateFeatureGroup API or through the console UI. For more information about using the console, see Using Amazon SageMaker Feature Store in the console.

You can use the `Provisioned` throughput mode with offline-only feature groups or feature groups with the `Standard` storage type. For other storage configurations, the `On-demand` throughput mode is used. For information about the online and offline storage configurations, see Online store and Offline store, respectively.

For more details about pricing, see Amazon SageMaker Pricing.

Topics

- On-demand throughput mode
- Provisioned throughput mode
- Throughput mode metrics
- Throughput mode limits

On-demand throughput mode

The `On-demand` (default) throughput mode works best when you are using feature groups with unknown workload, unpredictable application traffic, and you cannot forecast the capacity requirements.

The `On-demand` mode charges you for the reads and writes that your application performs on your feature groups. You do not need to specify how much read and write throughput you expect your application to perform because Feature Store instantly accommodates your workloads as they ramp up or down. You pay only for what you use, which is measured in `ReadRequestsUnits` and `WriteRequestsUnits`.

You can enable the `On-demand` throughput mode using the CreateFeatureGroup or UpdateFeatureGroup APIs or through the console UI. For more information about using the console UI, see Using Amazon SageMaker Feature Store in the console.

> **Important**
>
> You can only update your feature group throughput mode to `On-demand` once in a 24 hour period.

Provisioned throughput mode

The `Provisioned` throughput mode works best when you are using feature groups with predictable workloads and you can forecast the capacity requirements to control costs. This can make it more cost effective for certain workloads where you can anticipate throughput requirements in advance.

When you set a feature group to `Provisioned` mode, you specify capacity units which are the maximum amount of capacity that an application can consume from a feature group. If your application exceeds this `Provisioned` throughput capacity, it is subject to request throttling.

The following includes information about the read and write capacity units.

- Retrieving a single record of up to 4 KB using the `GetRecord` API will consume *at least* 1 RCU (read capacity unit). Retrieving larger payloads may take more. The total number of read capacity units required depends on the item size, including a small per record metadata added by the Feature Store service.
- A single write request with a payload of 1 KB using the `PutRecord` API will consume *at least* 1 WCU (write capacity unit), with fractional payloads rounded up to nearest KB. It may consume more depending on the event time, deletion status of the record, and time to live (TTL) status. For more information about TTL, see Time to live (TTL) duration for records.

Important

When setting your capacity units please consider the following:

- You will be charged for the read and write capacities you provision for your feature group, even if you do not fully utilize the `Provisioned` capacity.
- If you set a read or write capacity too low, your requests may experience throttling.
- In some cases, records may consume an extra capacity unit due to record level metadata that is added by the Feature Store service to enable various features.
- Retrieving only a subset of features using `GetRecord` or `BatchGetRecord` APIs will still consume RCU corresponding to the entire record.
- For write capacity, you should provision 2x the recent peak capacity to avoid throttling when performing backfills or bulk ingestion that may result in a large number of historical record writes. This is because writing historical records consumes additional write capacity.
- Feature Store does not currently support auto scaling for `Provisioned` mode.

You can enable the `On-demand` throughput mode using the CreateFeatureGroup or UpdateFeatureGroup APIs or through the console UI. For more information about using the console UI, see Using Amazon SageMaker Feature Store in the console.

The following describes how you can increase or decrease the RCU and WCU throughput for your feature groups when `Provisioned` mode is enabled.

Increasing provisioned throughput

You can increase RCU or WCU as often as needed using the UpdateFeatureGroup API or the console UI.

Decreasing provisioned throughput

You can decrease RCU and WCU (or both) for feature groups using UpdateFeatureGroup API or the console UI.

There is a default quota on the number of `Provisioned` capacity decreases you can perform on your feature group per day. A day is defined according to Universal Time Coordinated (UTC). On a given day, you can start by performing up to four decreases within one hour as long as you have not performed any other decreases yet during that day. Subsequently, you can perform one additional decrease per hour as long as there were no decreases in the preceding hour. This effectively brings the maximum number of decreases in a day to 27 times (4 decreases in the first hour, and 1 decrease for each of the subsequent 1-hour windows in a day).

Throughput mode metrics

A feature group in `On-demand` mode will emit `ConsumedReadRequestsUnits` and `ConsumedWriteRequestsUnits` metrics. A feature group in `Provisioned` mode will emit `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` metrics. For more information about Feature Store metrics, see Amazon SageMaker Feature Store metrics.

Throughput mode limits

Each AWS account has default service quotas or limits that are applied to help ensure availability and manage billing risks. For information about the default quotas and limits, see Quotas, naming rules and data types.

In some cases, these limits may be lower than what is stated in the documentation. If you need higher limits, you can submit a request for an increase. It's a good idea to do so before reaching current limits to avoid interruptions to your work. For information about service quotas and how to request a quota increase, see AWS service quotas.

Data sources and ingestion

Records are added to your feature groups through ingestion. Depending on your desired use case, the ingested records may be kept within the feature group or not. This depends on the storage configuration, if your feature group uses the offline or online store. The offline store is used as a historical database, that is typically used for data exploration, machine learning (ML) model training, and batch inference. The online store is used as a real-time lookup of records, that is typically used for ML model serving. For more information on Feature Store concepts and ingestion, see Feature Store concepts.

There are multiple ways to bring your data into Amazon SageMaker Feature Store. Feature Store offers a single API call for data ingestion called `PutRecord` that enables you to ingest data in batches or from streaming sources. You can use Amazon SageMaker Data Wrangler to engineer features and then ingest your features into your Feature Store. You can also use Amazon EMR for batch data ingestion through a Spark connector.

In the following topics we will discuss the difference between

Topics

Stream ingestion

You can use streaming sources such as Kafka or Kinesis as a data source, where records are extracted from, and directly feed records to the online store for training, inference or feature creation. Records can be ingested into your feature group by using the synchronous `PutRecord` API call. Since this is a synchronous API call it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon an update is detected. These are also called *streaming* features.

Data Wrangler with Feature Store

Data Wrangler is a feature of Studio Classic that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. Data Wrangler enables you to engineer your features and ingest them into your online or offline store feature groups.

The following instructions exports a Jupyter notebook that contains all of the source code needed to create a Feature Store feature group that adds your features from Data Wrangler to an online or offline store.

The instructions on exporting your Data Wrangler data flow to Feature Store on the console vary depending on whether you enabled enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Export your Data Wrangler data flow to Feature Store if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** from the left panel, to expand the dropdown list.
3. From the dropdown list, choose **Data Wrangler**.
4. If you have an instance of Amazon SageMaker Canvas already running, choose **Open Canvas**.

   If you don't have an instance of SageMaker Canvas running, choose **Run in Canvas**.

5. On the SageMaker Canvas console, choose **Data Wrangler** in the left navigation pane.
6. Choose **Data flows** to view your data flows.
7. Choose **+** to expand the dropdown list.
8. Choose **Export data flow** to expand the dropdown list.
9. Choose **Save to SageMaker Feature Store (via JupyterLab Notebook)**.
10. **Under Export data flow as notebook**, choose one of the following options:
    - **Download a local copy** to download the dataflow to your local machine.
    - **Export to S3 location** to download the dataflow to an Amazon Simple Storage Service location and enter the Amazon S3 location or choose **Browse** to find your Amazon S3 location.
11. Choose **Export**.

Export your Data Wrangler data flow to Feature Store if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in [Launch Amazon SageMaker Studio Classic](#).
2. Choose the **Home** icon ( ) in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Data Wrangler**.
5. Choose your workflow.
6. Choose the **Export** tab.
7. Choose **Export Step**.
8. Choose **Feature Store**.

After the feature group has been created, you can also select and join data across multiple feature groups to create new engineered features in Data Wrangler and then export your data set to an Amazon S3 bucket.

For more information on how to export to Feature Store, see [Export to SageMaker AI Feature Store](#).

Batch ingestion with Amazon SageMaker Feature Store Spark

Amazon SageMaker Feature Store Spark is a Spark connector that connects the Spark library to Feature Store. Feature Store Spark simplifies data ingestion from Spark `DataFrames` to feature groups. Feature Store supports batch data ingestion with Spark, using your existing ETL pipeline, on Amazon EMR, GIS, an AWS Glue job, an Amazon SageMaker Processing job, or a SageMaker notebook.

Methods for installing and implementing batch data ingestion are provided for Python and Scala developers. Python developers can use the open-source `sagemaker-feature-store-pyspark` Python library for local development, installation on Amazon EMR, and for Jupyter Notebooks by following the instructions in the Amazon SageMaker Feature Store Spark GitHub repository. Scala developers can use the Feature Store Spark connector available in the Amazon SageMaker Feature Store Spark SDK Maven central repository.

You can use the Spark connector to ingest data in the following ways, depending on if the online store, offline store, or both are enabled.

1. Ingest by default – If the online store is enabled, Spark connector first ingests your dataframe into the online store using the PutRecord API. Only the record with the largest event time remains in the online store. If the offline store is enabled, within 15 minutes Feature Store ingests your dataframe into the offline store. For more information about how the online and offline stores work, see Feature Store concepts.

   You can accomplish this by not specifying `target_stores` in the `.ingest_data(...)` method.

2. Offline store direct ingestion – If offline store is enabled, Spark connector batch ingests your dataframe directly into the offline store. Ingesting the dataframe directly into the offline store doesn't update the online store.

   You can accomplish this by setting `target_stores=["OfflineStore"]` in the `.ingest_data(...)` method.

3. Online store only – If online store is enabled, Spark connector ingests your dataframe into the online store using the PutRecord API. Ingesting the dataframe directly into the online store doesn't update the offline store.

   You can accomplish this by setting `target_stores=["OnlineStore"]` in the `.ingest_data(...)` method.

For information about using the different ingestion methods, see Example implementations.

Topics

Feature Store Spark installation

Scala users

The Feature Store Spark SDK is available in the Amazon SageMaker Feature Store Spark SDK Maven central repository for Scala users.

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- `iceberg-spark-runtime` >= 0.14.0
- Scala >= 2.12.x
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)

Declare the dependency in POM.xml

The Feature Store Spark connector has a dependency on the `iceberg-spark-runtime` library. You must therefore add corresponding version of the `iceberg-spark-runtime` library to the dependency if you're ingesting data into a feature group that you've auto-created with the Iceberg table format. For example, if you're using Spark 3.1, you must declare the following in your project's `POM.xml`:

```
<dependency>
<groupId>software.amazon.sagemaker.featurestore</groupId>
<artifactId>sagemaker-feature-store-spark-sdk_2.12</artifactId>
<version>1.0.0</version>
</dependency>

<dependency>
  <groupId>org.apache.iceberg</groupId>
  <artifactId>iceberg-spark-runtime-3.1_2.12</artifactId>
```

```
    <version>0.14.0</version>
</dependency>
```

Python users

The Feature Store Spark SDK is available in the open-source Amazon SageMaker Feature Store Spark GitHub repository.

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)
- Kernel = `conda_python3`

We recommend setting the `$SPARK_HOME` to the directory where you have Spark installed. During installation, Feature Store uploads the required JAR to `SPARK_HOME`, so that the dependencies load automatically. Spark starting a JVM is required to make this PySpark library work.

Local installation

To find more info about the installation, enable verbose mode by appending `--verbose` to the following installation command.

```
pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

Installation on Amazon EMR

Create an Amazon EMR cluster with the release version 6.1.0 or later. Enable SSH to help you troubleshoot any issues.

You can do one of the following to install the library:

- Create a custom step within Amazon EMR.
- Connect to your cluster using SSH and install the library from there.

Note

The following information uses Spark version 3.1, but you can specify any version that meets the requirements.

```
export SPARK_HOME=/usr/lib/spark
sudo -E pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all: --verbose
```

Note

If you want to install the dependent JARs automatically to SPARK_HOME, do not use the bootstrap step.

Installation on a SageMaker notebook instance

Install a version of PySpark that's compatible with the Spark connector using the following commands:

```
!pip3 install pyspark==3.1.1
!pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

If you're performing batch ingestion to the offline store, the dependencies aren't within the notebook instance environment.

```
from pyspark.sql import SparkSession
import feature_store_pyspark

extra_jars = ",".join(feature_store_pyspark.classpath_jars())

spark = SparkSession.builder \
    .config("spark.jars", extra_jars) \
    .config("spark.jars.packages", "org.apache.hadoop:hadoop-
aws:3.2.1,org.apache.hadoop:hadoop-common:3.2.1") \
    .getOrCreate()
```

Installation on notebooks with GIS

Important

You must use AWS Glue Version 2.0 or later.

Use the following information to help you install the PySpark connector in an AWS Glue Interactive Session (GIS).

Amazon SageMaker Feature Store Spark requires a specific Spark connector JAR during the initialization of the session to be uploaded to your Amazon S3 bucket. For more information on uploading the required JAR to your S3 bucket, see Retrieving the JAR for Feature Store Spark.

After you've uploaded the JAR, you must provide the GIS sessions with the JAR using the following command.

```
%extra_jars s3:/<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-store-spark-sdk.jar
```

To install Feature Store Spark in the AWS Glue runtime, use the `%additional_python_modules` magic command within the GIS notebook. AWS Glue runs `pip` to the modules that you've specified under `%additional_python_modules`.

```
%additional_python_modules sagemaker-feature-store-pyspark-3.1
```

Before you start the AWS Glue session, you must use both of the preceding magic commands.

Installation on an AWS Glue job

Important

You must use AWS Glue Version 2.0 or later.

To install the Spark connector on a AWS Glue job, use the `--extra-jars` argument to provide the necessary JARs and `--additional-python-modules` to install the Spark Connector as job parameters when you create the AWS Glue job as shown in the following example. For more information on uploading the required JAR to your S3 bucket, see Retrieving the JAR for Feature Store Spark.

```
glue_client = boto3.client('glue', region_name=region)
response = glue_client.create_job(
    Name=pipeline_id,
    Description='Feature Store Compute Job',
    Role=glue_role_arn,
    ExecutionProperty={'MaxConcurrentRuns': max_concurrent_run},
    Command={
        'Name': 'glueetl',
        'ScriptLocation': script_location_uri,
        'PythonVersion': '3'
    },
    DefaultArguments={
        '--TempDir': temp_dir_location_uri,
        '--additional-python-modules': 'sagemaker-feature-store-pyspark-3.1',
        '--extra-jars': "s3:/<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-
store-spark-sdk.jar",
        ...
    },
    MaxRetries=3,
    NumberOfWorkers=149,
    Timeout=2880,
    GlueVersion='3.0',
    WorkerType='G.2X'
)
```

Installation on an Amazon SageMaker Processing job

To use Feature Store Spark with Amazon SageMaker Processing jobs, bring your own image. For more information about bringing your image, see Custom images. Add the installation step to a Dockerfile. After you've pushed the Docker image to an Amazon ECR repository, you can use the PySparkProcessor to create the processing job. For more information about creating a processing job with the PySpark processor, see Run a Processing Job with Apache Spark.

The following is an example of adding an installation step to the Dockerfile.

```
FROM <ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/sagemaker-spark-processing:3.1-
cpu-py38-v1.0
```

```
RUN /usr/bin/python3 -m pip install sagemaker-feature-store-pyspark-3.1 --no-
binary :all: --verbose
```

Retrieving the JAR for Feature Store Spark

To retrieve the Feature Store Spark dependency JAR, you must install the Spark connector from the Python Package Index (PyPI) repository using `pip` in any Python environment with network access. A SageMaker Jupyter Notebook is an example of a Python environment with network access.

The following command installs the Spark connector.

```
!pip install sagemaker-feature-store-pyspark-3.1
```

After you've installed Feature Store Spark, you can retrieve the JAR location and upload the JAR to Amazon S3.

The `feature-store-pyspark-dependency-jars` command provides the location of the necessary dependency JAR that Feature Store Spark added. You can use the command to retrieve the JAR and upload it to Amazon S3.

```
jar_location = !feature-store-pyspark-dependency-jars
jar_location = jar_location[0]

s3_client = boto3.client("s3")
s3_client.upload_file(jar_location, "<YOUR_BUCKET>","spark-connector-jars/sagemaker-
feature-store-spark-sdk.jar")
```

Example implementations

Example Python script

FeatureStoreBatchIngestion.py

```
from pyspark.sql import SparkSession
from feature_store_pyspark.FeatureStoreManager import FeatureStoreManager
import feature_store_pyspark
```

```
spark = SparkSession.builder \
                    .getOrCreate()

# Construct test DataFrame
columns = ["RecordIdentifier", "EventTime"]
data = [("1","2021-03-02T12:20:12Z"), ("2", "2021-03-02T12:20:13Z"), ("3",
 "2021-03-02T12:20:14Z")]

df = spark.createDataFrame(data).toDF(*columns)

# Initialize FeatureStoreManager with a role arn if your feature group is created by
 another account
feature_store_manager= FeatureStoreManager("arn:aws:iam::111122223333:role/role-
arn")

# Load the feature definitions from input schema. The feature definitions can be
 used to create a feature group
feature_definitions = feature_store_manager.load_feature_definitions_from_schema(df)

feature_group_arn = "arn:aws:sagemaker:<AWS_REGION>:<ACCOUNT_ID>:feature-
group/<YOUR_FEATURE_GROUP_NAME>"

# Ingest by default. The connector will leverage PutRecord API to ingest your data
 in stream
# https://docs.aws.amazon.com/sagemaker/latest/APIReference/
API_feature_store_PutRecord.html
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn)

# To select the target stores for ingestion, you can specify the target store as the
 paramter
# If OnlineStore is selected, the connector will leverage PutRecord API to ingest
 your data in stream
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn, target_stores=["OfflineStore", "OnlineStore"])

# If only OfflineStore is selected, the connector will batch write the data to
 offline store directly
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn, target_stores=["OfflineStore"])

# To retrieve the records failed to be ingested by spark connector
failed_records_df = feature_store_manager.get_failed_stream_ingestion_data_frame()
```

Submit a Spark job with example Python script

The PySpark version requires an extra dependent JAR to be imported, so extra steps are needed to run the Spark application.

If you did not specify `SPARK_HOME` during installation, then you have to load required JARs in JVM when running `spark-submit`. `feature-store-pyspark-dependency-jars` is a Python script installed by the Spark library to automatically fetch the path to all JARs for you.

```
spark-submit --jars `feature-store-pyspark-dependency-
jars` FeatureStoreBatchIngestion.py
```

If you are running this application on Amazon EMR, we recommended that you run the application in client mode, so that you do not need to distribute the dependent JARs to other task nodes. Add one more step in Amazon EMR cluster with Spark argument similar to the following:

```
spark-submit --deploy-mode client --master yarn s3:/<PATH_TO_SCRIPT>/
FeatureStoreBatchIngestion.py
```

Example Scala script

FeatureStoreBatchIngestion.scala

```
import software.amazon.sagemaker.featurestore.sparksdk.FeatureStoreManager
import org.apache.spark.sql.types.{StringType, StructField, StructType}
import org.apache.spark.sql.{Row, SparkSession}

object TestSparkApp {
  def main(args: Array[String]): Unit = {

    val spark = SparkSession.builder().getOrCreate()

    // Construct test DataFrame
    val data = List(
      Row("1", "2021-07-01T12:20:12Z"),
```

```
      Row("2", "2021-07-02T12:20:13Z"),
      Row("3", "2021-07-03T12:20:14Z")
    )

    val schema = StructType(
      List(StructField("RecordIdentifier", StringType), StructField("EventTime",
 StringType))
    )

    val df = spark.createDataFrame(spark.sparkContext.parallelize(data), schema)

    // Initialize FeatureStoreManager with a role arn if your feature group is
 created by another account
    val featureStoreManager = new
 FeatureStoreManager("arn:aws:iam::111122223333:role/role-arn")

    // Load the feature definitions from input schema. The feature definitions can
 be used to create a feature group
    val featureDefinitions =
 featureStoreManager.loadFeatureDefinitionsFromSchema(df)

    val featureGroupArn = "arn:aws:sagemaker:<AWS_REGION>:<ACCOUNT_ID>:feature-
group/<YOUR_FEATURE_GROUP_NAME>"

    // Ingest by default. The connector will leverage PutRecord API to ingest your
 data in stream
    // https://docs.aws.amazon.com/sagemaker/latest/APIReference/
API_feature_store_PutRecord.html
    featureStoreManager.ingestData(df, featureGroupArn)

    // To select the target stores for ingestion, you can specify the target store
 as the paramter
    // If OnlineStore is selected, the connector will leverage PutRecord API to
 ingest your data in stream
    featureStoreManager.ingestData(df, featureGroupArn, List("OfflineStore",
 "OnlineStore"))

    // If only OfflineStore is selected, the connector will batch write the data to
 offline store directly
    featureStoreManager.ingestData(df, featureGroupArn, ["OfflineStore"])

    // To retrieve the records failed to be ingested by spark connector
    val failedRecordsDf = featureStoreManager.getFailedStreamIngestionDataFrame()
  }
```

```
}
```

Submit a Spark job

Scala

You should be able to use Feature Store Spark as a normal dependency. No extra instruction is needed to run the application on all platforms.

Feature Processing

Amazon SageMaker Feature Store Feature Processing is a capability with which you can transform raw data into machine learning (ML) features. It provides you with a Feature Processor SDK with which you can transform and ingest data from batch data sources into your feature groups. With this capability, Feature Store takes care of the underlying infrastructure including provisioning the compute environments and creating and maintaining Pipelines to load and ingest data. This way you can focus on your feature processor definitions that includes a transformation function (for example, count of product views, mean of transaction value), sources (where to apply this transformation on), and sinks (where to write the computed feature values to).

Feature Processor pipeline is a Pipelines pipeline. As a Pipelines, you can also track scheduled Feature Processor pipelines with SageMaker AI lineage in the console. For more information on SageMaker AI Lineage, see Amazon SageMaker ML Lineage Tracking This includes tracking scheduled executions, visualizing lineage to trace features back to their data sources, and viewing shared feature processors in a single environment. For information on using Feature Store with the console, see View pipeline executions from the console.

Topics

- Example Feature Processing code for common use cases

Feature Store Feature Processor SDK

Declare a Feature Store Feature Processor definition by decorating your transformation functions with the `@feature_processor` decorator. The SageMaker AI SDK for Python (Boto3) automatically loads data from the configured input data sources, applies the decorated transformation function, and then ingests the transformed data to a target feature group. Decorated transformation functions must conform to the expected signature of the `@feature_processor` decorator. For more information about the `@feature_processor` decorator, see @feature_processor Decorator in the Amazon SageMaker Feature Store Read the Docs.

With the `@feature_processor` decorator, your transformation function runs in a Spark runtime environment where the input arguments provided to your function and its return value are Spark DataFrames. The number of input parameters in your transformation function must match the number of inputs configured in the `@feature_processor` decorator.

For more information on the `@feature_processor` decorator, see the Feature Processor Feature Store SDK for Python (Boto3).

The following code are basic examples on how to use the `@feature_processor` decorator. For more specific example usage cases, see Example Feature Processing code for common use cases.

The Feature Processor SDK can be installed from the SageMaker Python SDK and its extras using the following command.

```
pip install sagemaker[feature-processor]
```

In the following examples, *`us-east-1`* is the region of the resource, *`111122223333`* is the resource owner account ID, and *`your-feature-group-name`* is the feature group name.

The following is a basic feature processor definition, where the `@feature_processor` decorator configures a CSV input from Amazon S3 to be loaded and provided to your transformation function (for example, `transform`), and prepares it for ingestion to a feature group. The last line runs it.

```
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/')
```

```
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-
name'

@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df):
   return csv_input_df

transform()
```

The `@feature_processor` parameters include:

- `inputs` (List[str]): A list of data sources that are used in your Feature Store Feature Processor. If your data sources are feature groups or stored in Amazon S3 you may be able to use Feature Store provided data source definitions for feature processor. For a full list of Feature Store provided data source definitions, see the [Feature Processor Data Source](#) in the Amazon SageMaker Feature Store Read the Docs.
- `output` (str): The ARN of the feature group to ingest the output of the decorated function.
- `target_stores` (Optional[List[str]]): A list of stores (for example, `OnlineStore` or `OfflineStore`) to ingest to the output. If unspecified, data is ingested to all of the output feature group's enabled stores.
- `parameters` (Dict[str, Any]): A dictionary to be provided to your transformation function.
- `enable_ingestion` (bool): A flag to indicate whether the transformation function's outputs are ingested to the output feature group. This flag is useful during the development phase. If unspecified, ingestion is enabled.

Optional wrapped function parameters (provided as an argument if provided in the function signature) include:

- `params` (Dict[str, Any]): The dictionary defined in the `@feature_processor` parameters. It also contains system configured parameters that can be referenced with the key `system`, such as the `scheduled_time` parameter.
- `spark` (SparkSession): A reference to the SparkSession instance initialized for the Spark Application.

The following code is an example of using the `params` and `spark` parameters.

```
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor
```

```
CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/')
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-
name'

@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df, params, spark):

   scheduled_time = params['system']['scheduled_time']
   csv_input_df.createOrReplaceTempView('csv_input_df')
   return spark.sql(f'''
        SELECT *
        FROM csv_input_df
        WHERE date_add(event_time, 1) >= {scheduled_time}
   ''')

transform()
```

The `scheduled_time` system parameter (provided in the `params` argument to your function) is an important value to support retrying each execution. The value can help to uniquely identify the Feature Processor's execution and can be used as a reference point for daterange–based inputs (for example, only loading the last 24 hours worth of data) to guarantee the input range independent of the code's actual execution time. If the Feature Processor runs on a schedule (see Scheduled and event based executions for Feature Processor pipelines) then its value is fixed to the time it is scheduled to run. The argument can be overridden during synchronous execution using the SDK's execute API to support use cases such as data backfills or re-running a missed past execution. Its value is the current time if the Feature Processor runs any other way.

For information about authoring Spark code, see the Spark SQL Programming Guide.

For more code samples for common use-cases, see the Example Feature Processing code for common use cases.

Note that transformation functions decorated with `@feature_processor` do not return a value. To programmatically test your function, you can remove or monkey patch the `@feature_processor` decorator such that it acts as a pass-through to the wrapped function. For more details on the `@feature_processor` decorator, see Amazon SageMaker Feature Store Python SDK.

Running Feature Store Feature Processor remotely

To run your Feature Processors on large data sets that require hardware more powerful than what is locally available, you can decorate your code with the `@remote` decorator to run your local Python code as a single or multi-node distributed SageMaker training job. For more information on running your code as a SageMaker training job, see [Run your local code as a SageMaker training job](#).

The following is a usage example of the `@remote` decorator along with the `@feature_processor` decorator.

```
from sagemaker.remote_function.spark_config import SparkConfig
from sagemaker.remote_function import remote
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://bucket/prefix-to-csv/')
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:123456789012:feature-group/feature-group'

@remote(
    spark_config=SparkConfig(),
    instance_type="ml.m5.2xlarge",
    dependencies="/local/requirements.txt"
)
@feature_processor(
    inputs=[CSV_DATA_SOURCE],
    output=OUTPUT_FG,
)
def transform(csv_input_df):
   return csv_input_df

transform()
```

The `spark_config` parameter indicates that the remote job runs as a Spark application. The `SparkConfig` instance can be used to configure the Spark Configuration and provide additional dependencies to the Spark application such as Python files, JARs, and files.

For faster iterations when developing your feature processing code, you can specify the `keep_alive_period_in_seconds` argument in the `@remote` decorator to retain configured resources in a warm pool for subsequent training jobs. For more information on warm pools, see [`KeepAlivePeriodInSeconds`](#) in the API Reference guide.

The following code is an example of local `requirements.txt`:

```
sagemaker>=2.167.0
```

This will install the corresponding SageMaker SDK version in remote job which is required for executing the method annotated by `@feature-processor`.

Creating and running Feature Store Feature Processor pipelines

The Feature Processor SDK provides APIs to promote your Feature Processor Definitions into a fully managed SageMaker AI Pipeline. For more information on Pipelines, see Pipelines overview. To convert your Feature Processor Definitions in to a SageMaker AI Pipeline, use the `to_pipeline` API with your Feature Processor definition. You can schedule executions of your Feature Processor Definition can be scheduled, operationally monitor them with CloudWatch metrics, and integrate them with EventBridge to act as event sources or subscribers. For more information about monitoring pipelines created with Pipelines, see Monitor Amazon SageMaker Feature Store Feature Processor pipelines.

To view your Feature Processor pipelines, see View pipeline executions from the console.

If your function is also decorated with the `@remote` decorator, then its configurations is carried over to the Feature Processor pipeline. You can specify advanced configurations such as compute instance type and count, runtime dependencies, network and security configurations using the `@remote` decorator.

The following example uses the `to_pipeline` and `execute` APIs.

```
from sagemaker.feature_store.feature_processor import (
    execute, to_pipeline, describe, TransformationCode
)

pipeline_name="feature-processor-pipeline"
pipeline_arn = to_pipeline(
    pipeline_name=pipeline_name,
    step=transform,
    transformation_code=TransformationCode(s3_uri="s3://bucket/prefix"),
)

pipeline_execution_arn = execute(
    pipeline_name=pipeline_name
)
```

The `to_pipeline` API is semantically an upsert operation. It updates the pipeline if it already exists; otherwise, it creates a pipeline.

The `to_pipeline` API optionally accepts an Amazon S3 URI that references a file containing the Feature Processor definition to associate it with the Feature Processor pipeline to track the transformation function and its versions in its SageMaker AI machine learning lineage.

To retrieve a list of every Feature Processor pipeline in your account, you can use the `list_pipelines` API. A subsequent request to the `describe` API returns details related to the Feature Processor pipeline including, but not limited to, Pipelines and schedule details.

The following example uses the `list_pipelines` and `describe` APIs.

```
from sagemaker.feature_store.feature_processor import list_pipelines, describe

feature_processor_pipelines = list_pipelines()

pipeline_description = describe(
    pipeline_name = feature_processor_pipelines[0]
)
```

Scheduled and event based executions for Feature Processor pipelines

Amazon SageMaker Feature Store Feature Processing pipeline executions can be configured to start automatically and asynchronously based on a preconfigured schedule or as a result of another AWS service event. For example, you can schedule Feature Processing pipelines to execute on the first of every month or chain two pipelines together so that a target pipeline is executed automatically after a source pipeline execution completes.

Topics

- Schedule based executions
- Event based executions

Schedule based executions

The Feature Processor SDK provides a `schedule` API to run Feature Processor pipelines on a recurring basis with Amazon EventBridge Scheduler integration. The schedule can be specified with an `at`, `rate`, or `cron` expression using the `ScheduleExpression` parameter with the same expressions supported by Amazon EventBridge. The schedule API is semantically an upsert operation in that it updates the schedule if it already exists; otherwise, it creates it. For more information on the EventBridge expressions and examples, see Schedule types on EventBridge Scheduler in the EventBridge Scheduler User Guide.

The following examples use the Feature Processor `schedule` API, using the `at`, `rate`, and `cron` expressions.

```
from sagemaker.feature_store.feature_processor import schedule
pipeline_name='feature-processor-pipeline'

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="at(2020-11-30T00:00:00)"
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="rate(24 hours)"
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="cron(0 0-23/1 ? * * 2023-2024)"
)
```

The default timezone for date and time inputs in the `schedule` API are in UTC. For more information about EventBridge Scheduler schedule expressions, see `ScheduleExpression` in the EventBridge Scheduler API Reference documentation.

Scheduled Feature Processor pipeline executions provide your transformation function with the scheduled execution time, to be used as an idempotency token or a fixed reference point for date range–based inputs. To disable (i.e., pause) or re-enable a schedule, use the `state` parameter of the `schedule` API with `'DISABLED'` or `'ENABLED'`, respectively.

For information about Feature Processor, see Feature Processor SDK data sources.

Event based executions

A Feature Processing pipeline can be configured to automatically execute when an AWS event occurs. The Feature Processing SDK provides a `put_trigger` function that accepts a list of source events and a target pipeline. The source events must be instances of `FeatureProcessorPipelineEvent`, that specifies a pipeline and execution status events.

The `put_trigger` function configures an Amazon EventBridge rule and target to route events and allows you to specify an EventBridge event pattern to respond to any AWS event. For information on these concepts, see Amazon EventBridge rules, targets, and event patterns.

Triggers can be enabled or disabled. EventBridge will start a target pipeline execution using the role provided in the `role_arn` parameter of the `put_trigger` API. The execution role is used by default if the SDK is used in a Amazon SageMaker Studio Classic or Notebook environment. For information on how to get your execution role, see Get your execution role.

The following example sets up:

- A SageMaker AI Pipeline using the `to_pipeline` API, that takes in your target pipeline name (`target-pipeline`) and your transformation function (`transform`). For information on your Feature Processor and transform function, see Feature Processor SDK data sources.
- A trigger using the `put_trigger` API, that takes in `FeatureProcessorPipelineEvent` for the event and your target pipeline name (`target-pipeline`).

  The `FeatureProcessorPipelineEvent` defines the trigger for when the status of your source pipeline (`source-pipeline`) becomes `Succeeded`. For information on the Feature Processor Pipeline event function, see `FeatureProcessorPipelineEvent` in the Feature Store Read the Docs.

```
from sagemaker.feature_store.feature_processor import put_trigger, to_pipeline,
 FeatureProcessorPipelineEvent

to_pipeline(pipeline_name="target-pipeline", step=transform)

put_trigger(
    source_pipeline_events=[
        FeatureProcessorPipelineEvent(
            pipeline_name="source-pipeline",
            status=["Succeeded"]
        )
    ],
    target_pipeline="target-pipeline"
)
```

For an example of using event based triggers to create continuous executions and automatic retries for your Feature Processor pipeline, see Continuous executions and automatic retries using event based triggers.

For an example of using event based triggers to create continuous *streaming* and automatic retries using event based triggers, see Streaming custom data source examples.

Monitor Amazon SageMaker Feature Store Feature Processor pipelines

AWS provides monitoring tools to watch your Amazon SageMaker AI resources and applications in real time, report when something goes wrong, and take automatic actions when appropriate. Feature Store Feature Processor pipelines are Pipelines, so the standard monitoring mechanisms and integrations are available. Operational metrics such as execution failures can be monitored via Amazon CloudWatch metrics and Amazon EventBridge events.

For more information on how to monitor and operationalize Feature Store Feature Processor, see the following resources:

- Monitoring AWS resources in Amazon SageMaker AI - General guidance on monitoring and auditing activity for SageMaker AI resources.
- SageMaker pipelines metrics - CloudWatch Metrics emitted by Pipelines.
- SageMaker pipeline execution state change - EventBridge events emitted for Pipelines and executions.
- Troubleshooting Amazon SageMaker Pipelines - General debugging and troubleshooting tips for Pipelines.

Feature Store Feature Processor execution logs can be found in Amazon CloudWatch Logs under the `/aws/sagemaker/TrainingJobs` log group, where you can find the execution log streams using lookup conventions. For executions created by directly invoking the `@feature_processor` decorated function, you can find logs in your local execution environment's console. For `@remote` decorated executions, the CloudWatch Logs stream name contains the name of the function and the execution timestamp. For Feature Processor pipeline executions, the CloudWatch Logs stream for the step contains the `feature-processor` string and the pipeline execution ID.

Feature Store Feature Processor pipelines and recent execution statuses can be found in Amazon SageMaker Studio Classic for a given feature group in the Feature Store UI. Feature groups related to the Feature Processor pipelines as either inputs or outputs are displayed in the UI. In addition, the lineage view can provide context into upstream executions, such as data producing Feature

Processor pipelines and data sources, for further debugging. For more information on using the lineage view using Studio Classic, see View lineage from the console.

IAM permissions and execution roles

To use the The Amazon SageMaker Python SDK requires permissions to interact with AWS services. The following policies are required for full Feature Processor functionality. You can attach the AmazonSageMakerFullAccess and AmazonEventBridgeSchedulerFullAccess AWS Managed Policies attached to your IAM role. For information on attaching policies to your IAM role, see Adding policies to your IAM role. See the following examples for details.

The trust policy of the role to which this policy is applied must allow the "scheduler.amazonaws.com", "sagemaker.amazonaws.com", and "glue.amazonaws.com" principles.

JSON

Feature Processor restrictions, limits, and quotas

Amazon SageMaker Feature Store Feature Processing relies on SageMaker AI machine learning (ML) lineage tracking. The Feature Store Feature Processor uses lineage contexts to represent and track Feature Processing Pipelines and Pipeline versions. Each Feature Store Feature Processor consumes at least two lineage contexts (one for the Feature Processing Pipeline and another for the version). If the input or output data source of a Feature Processing Pipeline changes, an additional lineage context is created. You can update SageMaker AI ML lineage limits by reaching out to AWS support for a limit increase. Default limits for resources used by Feature Store Feature Processor are as follows. For information on SageMaker AI ML lineage tracking, see Amazon SageMaker ML Lineage Tracking.

For more information on SageMaker AI quotas, see Amazon SageMaker AI endpoints and quotas.

Lineage limits per Region

- Contexts – 500 (soft limit)
- Artifacts – 6,000 (soft limit)
- Associations – 6,000 (soft limit)

Training Limits per Region

- Longest run time for a training job – 432,000 seconds
- Maximum number of instances per training job – 20
- The maximum number of `CreateTrainingJob` requests that you can make, per second, in this account in the current Region – 1 TPS
- Keep alive period for cluster reuse – 3,600 seconds

Maximum number of Pipelines and concurrent pipeline executions per Region

- Maximum number of pipelines allowed per account – 500
- Maximum number of concurrent pipeline executions allowed per account – 20
- Time at which pipeline executions time out – 672 hours

Data sources

Amazon SageMaker Feature Store Feature Processing supports multiple data sources. The Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. In addition, you can author custom data sources to load data from other data sources. For information about Feature Store provided data sources, see Feature Processor data source Feature Store Python SDK.

Topics

Feature Processor SDK data sources

The Amazon SageMaker Feature Store Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

For examples on how to use the Feature Store Python SDK data source definitions, see Example Feature Processing code for common use cases.

FeatureGroupDataSource

The `FeatureGroupDataSource` is used to specify a feature group as an input data source for a Feature Processor. Data can be loaded from an offline store feature group. Attempting to load your data from an online store feature group will result in a validation error. You can specify start and end offsets to limit the data that is loaded to a specific time range. For example, you can specify a start offset of ‘14 days' to load only the last two weeks of data, and you can additionally specify an end offset of '7 days' to limit the input to the previous week of data.

Feature Store provided data source definitions

The Feature Store Python SDK contain data source definitions that can be used to specify various input data sources for a Feature Processor. These include CSV, Parquet, and Iceberg table sources. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

Custom data sources

On this page we will describe how to create a custom data source class and show some usage examples. With custom data sources, you can use the SageMaker AI SDK for Python (Boto3) provided APIs in the same way as if you are using Amazon SageMaker Feature Store provided data sources.

To use a custom data source to transform and ingest data into a feature group using Feature Processing, you will need to extend the `PySparkDataSource` class with the following class members and function.

- `data_source_name` (str): an arbitrary name for the data source. For example, Amazon Redshift, Snowflake, or a Glue Catalog ARN.
- `data_source_unique_id` (str): a unique identifier that refers to the specific resource being accessed. For example, table name, DDB Table ARN, Amazon S3 prefix. All usage of the same `data_source_unique_id` in custom data sources will be associated to the same data source in the lineage view. Lineage includes information about the execution code of a feature processing workflow, what data sources were used, and how they are ingested into the feature group or feature. For information about viewing lineage of a feature group in **Studio**, see View lineage from the console.
- `read_data` (func): a method used to connect with the feature processor. Returns a Spark data frame. For examples, see Custom data source examples.

Both `data_source_name` and `data_source_unique_id` are used to uniquely identify your lineage entity. The following is an example for a custom data source class named `CustomDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
from pyspark.sql import DataFrame

class CustomDataSource(PySparkDataSource):

    data_source_name = "custom-data-source-name"
    data_source_unique_id = "custom-data-source-id"

    def read_data(self, parameter, spark) -> DataFrame:
        your own code here to read data into a Spark dataframe
        return dataframe
```

Custom data source examples

This section provides examples of custom data sources implementations for Feature Processors. For more information on custom data sources, see Custom data sources.

Security is a shared responsibility between AWS and our customers. AWS is responsible for protecting the infrastructure that runs the services in the AWS Cloud. Customers are responsible for all of their necessary security configuration and management tasks. For example, secrets such as access credentials to data stores should not be hard coded in your custom data sources. You can use AWS Secrets Manager to manage these credentials. For information about Secrets Manager, see What is AWS Secrets Manager? in the AWS Secrets Manager user guide. The following examples will use Secrets Manager for your credentials.

Topics

Amazon Redshift Clusters (JDBC) custom data source examples

Amazon Redshift offers a JDBC driver that can be used to read data with Spark. For information about how to download the Amazon Redshift JDBC driver, see Download the Amazon Redshift JDBC driver, version 2.1.

To create the custom Amazon Redshift data source class, you will need to overwrite the `read_data` method from the Custom data sources.

To connect with an Amazon Redshift cluster you need your:

- Amazon Redshift JDBC URL (*`jdbc-url`*)

  For information about obtaining your Amazon Redshift JDBC URL, see Getting the JDBC URL in the Amazon Redshift Database Developer Guide.
- Amazon Redshift user name (*`redshift-user`*) and password (*`redshift-password`*)

  For information about how to create and manage database users using the Amazon Redshift SQL commands, see Users in the Amazon Redshift Database Developer Guide.
- Amazon Redshift table name (*`redshift-table-name`*)

  For information about how to create a table with some examples, see CREATE TABLE in the Amazon Redshift Database Developer Guide.
- (Optional) If using Secrets Manager, you'll need the secret name (*`secret-redshift-account-info`*) where you store your Amazon Redshift access username and password on Secrets Manager.

For information about Secrets Manager, see [Find secrets in AWS Secrets Manager](#) in the AWS Secrets Manager User Guide.

- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see [region_name](#) in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and override the `read_data` for your custom data source class, `DatabricksDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
import json
import boto3

class RedshiftDataSource(PySparkDataSource):

    data_source_name = "Redshift"
    data_source_unique_id = "redshift-resource-arn"

    def read_data(self, spark, params):
        url = "jdbc-url?user=redshift-user&password=redshift-password"
        aws_iam_role_arn = "redshift-command-access-role"
        secret_name = "secret-redshift-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        jdbc_url = url.replace("jdbc-url", secrets["jdbcurl"]).replace("redshift-user",
 secrets['username']).replace("redshift-password", secrets['password'])

        return spark.read \
             .format("jdbc") \
             .option("url", url) \
```

```
            .option("driver", "com.amazon.redshift.Driver") \
            .option("dbtable", "redshift-table-name") \
            .option("tempdir", "s3a://your-bucket-name/your-bucket-prefix") \
            .option("aws_iam_role", aws_iam_role_arn) \
            .load()
```

The following example shows how to connect `RedshiftDataSource` to your `feature_processor` decorator.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
    spark_config={"spark.jars.packages": "com.amazon.redshift:redshift-
jdbc42:2.1.0.16"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jdbc driver by defining `SparkConfig` and pass it to the `@remote` decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars.packages": "com.amazon.redshift:redshift-jdbc42:2.1.0.16"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
```

```
)
def transform(input_df):
    return input_df
```

Snowflake custom data source examples

Snowflake provides a Spark connector that can be used for your `feature_processor` decorator. For information about Snowflake connector for Spark, see Snowflake Connector for Spark in the Snowflake documentation.

To create the custom Snowflake data source class, you will need to override the `read_data` method from the Custom data sources and add the Spark connector packages to the Spark classpath.

To connect with a Snowflake data source you need:

- Snowflake URL (*`sf-url`*)

  For information about URLs for accessing Snowflake web interfaces, see Account Identifiers in the Snowflake documentation.
- Snowflake database (*`sf-database`*)

  For information about obtaining the name of your database using Snowflake, see CURRENT_DATABASE in the Snowflake documentation.
- Snowflake database schema (*`sf-schema`*)

  For information about obtaining the name of your schema using Snowflake, see CURRENT_SCHEMA in the Snowflake documentation.
- Snowflake warehouse (*`sf-warehouse`*)

  For information about obtaining the name of your warehouse using Snowflake, see CURRENT_WAREHOUSE in the Snowflake documentation.
- Snowflake table name (*`sf-table-name`*)
- (Optional) If using Secrets Manager, you'll need the secret name (*`secret-snowflake-account-info`*) where you store your Snowflake access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.

- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the Snowflake user name and password from Secrets Manager and override the `read_data` function for your custom data source class `SnowflakeDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
from sagemaker.feature_store.feature_processor import feature_processor
import json
import boto3

class SnowflakeDataSource(PySparkDataSource):

    sf_options = {
        "sfUrl" : "sf-url",
        "sfDatabase" : "sf-database",
        "sfSchema" : "sf-schema",
        "sfWarehouse" : "sf-warehouse",
    }

    data_source_name = "Snowflake"
    data_source_unique_id = "sf-url"

    def read_data(self, spark, params):
        secret_name = "secret-snowflake-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        self.sf_options["sfUser"] = secrets.get("username")
        self.sf_options["sfPassword"] = secrets.get("password")
```

```
        return spark.read.format("net.snowflake.spark.snowflake") \
                        .options(**self.sf_options) \
                        .option("dbtable", "sf-table-name") \
                        .load()
```

The following example shows how to connect `SnowflakeDataSource` to your `feature_processor` decorator.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[SnowflakeDataSource()],
    output=feature-group-arn,
    target_stores=["OfflineStore"],
    spark_config={"spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-
spark_3.3"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the packages via defining `SparkConfig` and pass it to `@remote` decorator. The Spark packages in the following example are such that `spark-snowflake_2.12` is the Feature Processor Scala version, `2.12.0` is the Snowflake version you wish to use, and `spark_3.3` is the Feature Processor Spark version.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-spark_3.3"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[SnowflakeDataSource()],
    output="feature-group-arn>",
```

```
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

Databricks (JDBC) custom data source examples

Spark can read data from Databricks by using the Databricks JDBC driver. For information about the Databricks JDBC driver, see Configure the Databricks ODBC and JDBC drivers in the Databricks documentation.

> **Note**
>
> You can read data from any other database by including the corresponding JDBC driver in Spark classpath. For more information, see JDBC To Other Databases in the Spark SQL Guide.

To create the custom Databricks data source class, you will need to override the `read_data` method from the Custom data sources and add the JDBC jar to the Spark classpath.

To connect with a Databricks data source you need:

- Databricks URL (*`databricks-url`*)

  For information about your Databricks URL, see Building the connection URL for the Databricks driver in the Databricks documentation.
- Databricks personal access token (*`personal-access-token`*)

  For information about your Databricks access token, see Databricks personal access token authentication in the Databricks documentation.
- Data catalog name (*`db-catalog`*)

  For information about your Databricks catalog name, see Catalog name in the Databricks documentation.
- Schema name (*`db-schema`*)

  For information about your Databricks schema name, see Schema name in the Databricks documentation.

- Table name (*db-table-name*)

  For information about your Databricks table name, see [Table name](#) in the Databricks documentation.

- (Optional) If using Secrets Manager, you'll need the secret name (*secret-databricks-account-info*) where you store your Databricks access username and password on Secrets Manager.

  For information about Secrets Manager, see [Find secrets in AWS Secrets Manager](#) in the AWS Secrets Manager User Guide.

- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see [region_name](#) in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and overwrite the `read_data` for your custom data source class, `DatabricksDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
import json
import boto3

class DatabricksDataSource(PySparkDataSource):

    data_source_name = "Databricks"
    data_source_unique_id = "databricks-url"

    def read_data(self, spark, params):
        secret_name = "secret-databricks-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )
```

```
        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        jdbc_url = secrets["jdbcurl"].replace("personal-access-token", secrets['pwd'])

        return spark.read.format("jdbc") \
                        .option("url", jdbc_url) \
                        .option("dbtable","`db-catalog`.`db-schema`.`db-table-name`") \
                        .option("driver", "com.simba.spark.jdbc.Driver") \
                        .load()
```

The following example shows how to upload the JDBC driver jar, *jdbc-jar-file-name*.jar, to Amazon S3 in order to add it to the Spark classpath. For information about downloading the Spark JDBC driver (*jdbc-jar-file-name*.jar) from Databricks, see Download JDBC Driverin the Databricks website.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[DatabricksDataSource()],
    output=feature-group-arn,
    target_stores=["OfflineStore"],
    spark_config={"spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-
file-name.jar"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jars by defining `SparkConfig` and pass it to the `@remote` decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-file-name.jar"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
```

```
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[DatabricksDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

Streaming custom data source examples

You can connect to streaming data sources like Amazon Kinesis, and author transforms with Spark Structured Streaming to read from streaming data sources. For information about the Kinesis connector, see Kinesis Connector for Spark Structured Streaming in GitHub. For information about Amazon Kinesis, see What Is Amazon Kinesis Data Streams? in the Amazon Kinesis Developer Guide.

To create the custom Amazon Kinesis data source class, you will need to extend the `BaseDataSource` class and override the `read_data` method from Custom data sources.

To connect to an Amazon Kinesis data stream you need:

- Kinesis ARN (*kinesis-resource-arn*)

  For information on Kinesis data stream ARNs, see Amazon Resource Names (ARNs) for Kinesis Data Streams in the Amazon Kinesis Developer Guide.
- Kinesis data stream name (*kinesis-stream-name*)
- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

```
from sagemaker.feature_store.feature_processor import BaseDataSource
from sagemaker.feature_store.feature_processor import feature_processor

class KinesisDataSource(BaseDataSource):

    data_source_name = "Kinesis"
    data_source_unique_id = "kinesis-resource-arn"
```

```
    def read_data(self, spark, params):
        return spark.readStream.format("kinesis") \
            .option("streamName", "kinesis-stream-name") \
            .option("awsUseInstanceProfile", "false") \
            .option("endpointUrl", "https://kinesis.your-region.amazonaws.com")
            .load()
```

The following example demonstrates how to connect `KinesisDataSource` to your `feature_processor` decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig
import feature_store_pyspark.FeatureStoreManager as fsm

def ingest_micro_batch_into_fg(input_df, epoch_id):
    feature_group_arn = "feature-group-arn"
    fsm.FeatureStoreManager().ingest_data(
        input_data_frame = input_df,
        feature_group_arn = feature_group_arn
    )

@remote(
    spark_config=SparkConfig(
        configuration={
            "Classification": "spark-defaults",
            "Properties":{
                "spark.sql.streaming.schemaInference": "true",
                "spark.jars.packages": "com.roncemer.spark/spark-sql-
kinesis_2.13/1.2.2_spark-3.2"
            }
        }
    ),
    instance_type="ml.m5.2xlarge",
    max_runtime_in_seconds=2419200 # 28 days
)
@feature_processor(
    inputs=[KinesisDataSource()],
    output="feature-group-arn"
)
def transform(input_df):
    output_stream = (
```

```
        input_df.selectExpr("CAST(rand() AS STRING) as partitionKey", "CAST(data AS 
STRING)")
        .writeStream.foreachBatch(ingest_micro_batch_into_fg)
        .trigger(processingTime="1 minute")
        .option("checkpointLocation", "s3a://checkpoint-path")
        .start()
    )
    output_stream.awaitTermination()
```

In the example code above we use a few Spark Structured Streaming options while streaming micro-batches into your feature group. For a full list of options, see the Structured Streaming Programming Guide in the Apache Spark documentation.

- The `foreachBatch` sink mode is a feature that allows you to apply operations and write logic on the output data of each micro-batch of a streaming query.

  For information on `foreachBatch`, see Using Foreach and ForeachBatch in the Apache Spark Structured Streaming Programming Guide.
- The `checkpointLocation` option periodically saves the state of the streaming application. The streaming log is saved in checkpoint location *`s3a://checkpoint-path`*.

  For information on the `checkpointLocation` option, see Recovering from Failures with Checkpointing in the Apache Spark Structured Streaming Programming Guide.
- The `trigger` setting defines how often the micro-batch processing is triggered in a streaming application. In the example, the processing time trigger type is used with one-minute micro-batch intervals, specified by `trigger(processingTime="1 minute")`. To backfill from a stream source, you can use the available-now trigger type, specified by `trigger(availableNow=True)`.

  For a full list of `trigger` types, see Triggers in the Apache Spark Structured Streaming Programming Guide.

Continuous streaming and automatic retries using event based triggers

The Feature Processor uses SageMaker Training as compute infrastructure and it has a maximum runtime limit of 28 days. You can use event based triggers to extend your continuous streaming for a longer period of time and recover from transient failures. For more information on schedule and event based executions, see Scheduled and event based executions for Feature Processor pipelines.

The following is an example of setting up an event based trigger to keep the streaming Feature Processor pipeline running continuously. This uses the streaming transform function defined in the previous example. A target pipeline can be configured to be triggered when a `STOPPED` or `FAILED` event occurs for a source pipeline execution. Note that the same pipeline is used as the source and target so that it run continuously.

```
import sagemaker.feature_store.feature_processor as fp
from sagemaker.feature_store.feature_processor import FeatureProcessorPipelineEvent
from sagemaker.feature_store.feature_processor import
 FeatureProcessorPipelineExecutionStatus

streaming_pipeline_name = "streaming-pipeline"
streaming_pipeline_arn = fp.to_pipeline(
    pipeline_name = streaming_pipeline_name,
    step = transform # defined in previous section
)

fp.put_trigger(
    source_pipeline_events=FeatureProcessorPipelineEvents(
        pipeline_name=source_pipeline_name,
        pipeline_execution_status=[
            FeatureProcessorPipelineExecutionStatus.STOPPED,
            FeatureProcessorPipelineExecutionStatus.FAILED]
    ),
    target_pipeline=target_pipeline_name
)
```

Example Feature Processing code for common use cases

The following examples provide sample Feature Processing code for common use cases. For a more detailed example notebook showcasing specific use cases, see [Amazon SageMaker Feature Store Feature Processing notebook](#).

In the following examples, *`us-east-1`* is the region of the resource, *`111122223333`* is the resource owner account ID, and *`your-feature-group-name`* is the feature group name.

The `transactions` data set used in the following examples has the following schema:

```
'FeatureDefinitions': [
  {'FeatureName': 'txn_id', 'FeatureType': 'String'},
  {'FeatureName': 'txn_time', 'FeatureType': 'String'},
  {'FeatureName': 'credit_card_num', 'FeatureType': 'String'},
```

```
  {'FeatureName': 'txn_amount', 'FeatureType': 'Fractional'}
]
```

Topics

Joining data from multiple data sources

```
@feature_processor(
    inputs=[
        CSVDataSource('s3://bucket/customer'),
        FeatureGroupDataSource('transactions')
    ],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-
name'
)
def join(transactions_df, customer_df):
  '''Combine two data sources with an inner join on a common column'''

  return transactions_df.join(
    customer_df, transactions_df.customer_id == customer_df.customer_id, "inner"
  )
```

Sliding window aggregates

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-
name'
)
def sliding_window_aggregates(transactions_df):
    '''Aggregates over 1-week windows, across 1-day sliding windows.'''
    from pyspark.sql.functions import window, avg, count
```

```
    return (
        transactions_df
            .groupBy("credit_card_num", window("txn_time", "1 week", "1 day"))
            .agg(avg("txn_amount").alias("avg_week"), count("*").alias("count_week"))
            .orderBy("window.start")
            .select("credit_card_num", "window.start", "avg_week", "count_week")
    )
```

Tumbling window aggregates

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'
)
def tumbling_window_aggregates(transactions_df, spark):
    '''Aggregates over 1-week windows, across 1-day tumbling windows, as a SQL
 query.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
        SELECT credit_card_num, window.start, AVG(amount) AS avg, COUNT(*) AS count
        FROM transactions
        GROUP BY credit_card_num, window(txn_time, "1 week")
        ORDER BY window.start
    ''')
```

Promotion from the offline store to online store

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    target_stores=['OnlineStore'],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)
def offline_to_online():
    '''Move data from the offline store to the online store of the same feature
 group.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
        SELECT txn_id, txn_time, credit_card_num, amount
        FROM
            (SELECT *,
```

```
            row_number()
            OVER
                (PARTITION BY txn_id
                ORDER BY "txn_time" DESC, Api_Invocation_Time DESC, write_time DESC)
            AS row_number
            FROM transactions)
        WHERE row_number = 1
    ''')
```

Transformations with the Pandas library

Transformations with the Pandas library

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    target_stores=['OnlineStore'],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)
def pandas(transactions_df):
    '''Author transformations using the Pandas interface.

    Requires PyArrow to be installed via pip.
    For more details: https://spark.apache.org/docs/latest/api/python/user_guide/
pandas_on_spark
    '''
    import pyspark.pandas as ps

    # PySpark DF to Pandas-On-Spark DF (Distributed DF with Pandas interface).
    pandas_on_spark_df = transactions_df.pandas_api()
    # Pandas-On-Spark DF to Pandas DF (Single Machine Only).
    pandas_df = pandas_on_spark_df.to_pandas()

    # Reverse: Pandas DF to Pandas-On-Spark DF
    pandas_on_spark_df = ps.from_pandas(pandas_df)
    # Reverse: Pandas-On-Spark DF to PySpark DF
    spark_df = pandas_on_spark_df.to_spark()

    return spark_df
```

Continuous executions and automatic retries using event based triggers

```
from sagemaker.feature_store.feature_processor import put_trigger, to_pipeline,
 FeatureProcessorPipelineEvent
```

```
from sagemaker.feature_store.feature_processor import
 FeatureProcessorPipelineExecutionStatus

streaming_pipeline_name = "target-pipeline"

to_pipeline(
    pipeline_name=streaming_pipeline_name,
    step=transform
)

put_trigger(
    source_pipeline_events=[
        FeatureProcessorPipelineEvent(
            pipeline_name=streaming_pipeline_name,
            pipeline_execution_status=[
            FeatureProcessorPipelineExecutionStatus.STOPPED,
            FeatureProcessorPipelineExecutionStatus.FAILED]
        )
    ],
    target_pipeline=streaming_pipeline_name
)
```

Find features in your feature groups

With Amazon SageMaker Feature Store, you can search for the features that you created in your feature groups. You can search through all of your features without needing to select a feature group first. The search functionality helps find the features that are relevant to your use case.

> **Note**
>
> The feature groups where you're searching for features must be within your AWS Region and AWS account. For shared feature groups, the feature groups must be made discoverable to your AWS account. For more instructions on how to share the feature group catalog and grant discoverability, see Share your feature group catalog.

If you're on a team, and teammates are looking for features to use in their models, they can search through the features in all of the feature groups.

You can add searchable parameters and descriptions to make your features more discoverable. For more information, see Adding searchable metadata to your features.

You can search for features using either the console or by using the [Search](#) API operation in SageMaker AI. The following table lists all of the searchable metadata and whether you can search for it in the console or with the API.

Searchable metadata	API field name	Searchable in the console?
All Parameters	AllParameters	Yes
Creation time	CreationTime	Yes
Description	Description	Yes
Feature group name	FeatureGroupName	No
Feature name	FeatureName	Yes
Feature type	FeatureType	No
Last modified time	LastModifiedTime	No
Parameters	Parameters.*key*	Yes

How to search for your features

The instructions for using Feature Store through the console depends on whether you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience. Choose one of the following instructions based on your use case.

Search for features if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
5. Under the **Feature Catalog** tab, choose **My account** to view your feature groups.
6. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.

7. You can search for your feature in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features, specify time ranges, or clear (deselect) columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.

Search for features if Studio Classic is your default experience (console)

Use the latest version of Amazon SageMaker Studio Classic so that you have the most recent version of the search functionality. For information about updating Studio Classic, see Shut down and Update SageMaker Studio Classic.

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon () in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
6. Under the **Feature Catalog** tab, choose **My account** to view your feature groups.
7. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
8. You can search for your feature in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features, specify time ranges, or clear (deselect) columns that you don't want to query.

- For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.

Search for your features using SDK for Python (Boto3)

The code in this section uses the `Search` operation in the AWS SDK for Python (Boto3) to run the search query to find features in your feature groups. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

The following code shows different example search queries using the API:

```
# Return all features in your feature groups
sagemaker_client.search(
    Resource="FeatureMetadata",
)

# Search for all features that belong to a feature group that contain the "ver"
 substring
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
        ]
    }
)

# Search for all features that belong to a feature group that have the EXACT name
 "airport"
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
```

```
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            },
        ]
    }
)

# Search for all features that belong to a feature group that contains the name "ver"
AND have a name that contains "wha"
AND have a parameter (key or value) that contains "hea"

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllParameters',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ]
    }
)

# Search for all features that belong to a feature group with substring "ver" in its
 name
OR features that have a name that contain "wha"
OR features that have a parameter (key or value) that contains "hea"

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
```

```
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllParameters',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all features that belong to a feature group with substring "ver" in its
 name
OR features that have a name that contain "wha"
OR parameters with the value 'Sage' for the 'org' key

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Parameters.org',
```

```
                'Operator': 'Contains',
                'Value': 'Sage'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)
```

Find feature groups in your Feature Store

With Amazon SageMaker Feature Store, you can search for the feature groups using either the console or the Search operation. You can use the search functionality to find features and feature groups that are relevant to the models that you're creating. You can use the search functionality to quickly find the feature groups that are relevant to your use case.

Note

The feature groups that you're searching for must be within your AWS Region and AWS account, or shared with and made discoverable to your AWS account. For more information about how to share the feature group catalog and grant discoverability, see Share your feature group catalog.

The following table shows the searchable fields and whether you can use the console to search for a specific field.

You can search for features using either Amazon SageMaker Studio Classic or the `Search` operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in the console. Tags are searchable for your own feature groups but are not searchable for feature groups made discoverable to you.

Searchable metadata	API field name	Searchable in the console?	Searchable with cross account?
All Tags	AllTags	Yes	No

Searchable metadata	API field name	Searchable in the console?	Searchable with cross account?
Creation Failure Reason	FailureReason	No	No
Creation Status	FeatureGroupStatus	Yes	Yes
Creation time	CreationTime	Yes	Yes
Description	Description	Yes	Yes
Event Time Feature Name	EventTimeFeatureNa me	No	No
Feature Definitions	FeatureDefinitions	No	No
Feature Group ARN	FeatureGroupARN	No	No
Feature Group Name	FeatureGroupName	Yes	Yes
Offline Store Configuration	OfflineStoreConfig	No	No
Offline Store Status	OfflineStoreStatus	Yes	Yes
Last Update Status	LastUpdateStatus	No	No
Record Identfier Feature Name	RecordIdentifierFe atureName	Yes	Yes
Tags	Tags.key	Yes	No

How to find feature groups

You can use the console or the Amazon SageMaker Feature Store API to find your feature groups. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Find feature groups if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature Group Catalog** tab, choose **My account** to view your feature groups.
6. Under the **Feature Group Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
7. You can search for your feature groups in the **Search** dropdown list:
   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your feature groups, you can specify time ranges, clear (deselect) columns that you don't want to query, choose stores to search, or search by status.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, see Enabling cross account access.

Find feature groups if Studio Classic is your default experience (console)

Use the latest version of Amazon SageMaker Studio Classic to get the most recent version of the search functionality if you are accessing Feature Store through the Studio Classic application. For information about updating Studio Classic, see Shut down and Update SageMaker Studio Classic.

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon ( ) in the left navigation pane.
3. Choose **Data**.

4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature Group Catalog** tab, choose **My account** to view your feature groups.
7. Under the **Feature Group Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
8. You can search for your feature groups in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your feature groups more easily, you can specify time ranges, clear (deselect) columns that you don't want to query, choose stores to search, or search by status.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, see Enabling cross account access.

Find feature groups using SDK for Python (Boto3)

The code in this section uses the `Search` operation in the AWS SDK for Python (Boto3) to run the search query to find feature groups. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

The following code shows different example search queries using the API:

```
# Return all feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
)

# Search for feature groups that are shared with your account
sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
```

```
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="SameAccount"
)

# Search for all feature groups with a name that contains the "ver" substring
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
        ]
    }
)

# Search for all feature groups that have the EXACT name "airport"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            },
        ]
    }
)

# Search for all feature groups that contains the name "ver"
```

```
# AND have a record identifier feature name that contains "wha"
# AND have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllTags',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ]
    }
)

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR feature groups that have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllTags',
```

```
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR tags with the value 'Sage' for the 'org' key
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Tags.org',
                'Operator': 'Contains',
                'Value': 'Sage'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all offline only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
```

```
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'NotEquals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'Exists'
            }
        ]
    }
)

# Search for all online only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'Equals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'NotExists'
            }
        ]
    }
)

# Search for all feature groups that are BOTH online and offline
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'Equals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'Exists'
            }
```

```
        ]
    }
)
```

You can also use python SDK of AWS RAM APIs to create resource share. The API signature is given below. To use python SDK of AWS RAM API, you need attach AWS RAM full access managed policy with execution Role.

```
response = client.create_resource_share(
    name='string',
    resourceArns=[
        'string',
    ],
    principals=[
        'string',
    ],
    tags=[
        {
            'key': 'string',
            'value': 'string'
        },
    ],
    allowExternalPrincipals=True|False,
    clientToken='string',
    permissionArns=[
        'string',
    ]
)
```

Adding searchable metadata to your features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:

- Description – A searchable description of the feature.
- Parameters – Searchable key-value pairs.

The description can have up to 255 characters. For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either the console or the `UpdateFeatureMetadata` operation.

How to add searchable metadata to your features

You can use the console or the Amazon SageMaker Feature Store API to add searchable metadata to your features. Instructions for using Feature Store through the console depend on whether you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Add searchable metadata to features if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
5. To view your feature groups, under the **Feature Catalog** tab, choose **My account**.
6. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others make discoverable to you. Under **Created by**, you can view the resource owner account ID of the feature group.
7. You can search for your feature in the **Search** dropdown list.
   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone doesn't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.
8. Choose your feature.
9. Choose **Edit metadata**.

10. In the **Description** field, add or update the description.
11. In the **Parameters** field under **Parameters**, specify a key-value pair for the parameter.
12. (Optional) Choose **Add new parameter** to add another parameter.
13. Choose **Save changes**.
14. Choose **Confirm**.

Add searchable metadata to your features if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in [Launch Studio Classic Using the Amazon SageMaker AI Console](#).
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
6. To view your feature groups, under the **Feature Catalog** tab, choose **My account**.
7. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that other accounts made discoverable to you. Under **Created by**, you can view the resource owner account ID of the feature group.
8. You can search for your feature in the **Search** dropdown list.

    - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you don't want to query.
    - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone doesn't allow you to edit metadata or feature definitions. For more information about granting access permissions, see[Enabling cross account access](#).
9. Choose your feature.
10. Choose **Edit metadata**.
11. In the **Description** field, add or update the description.

12. In the **Parameters** field under **Parameters**, specify a key-value pair for the parameter.
13. (Optional) Choose **Add new parameter** to add another parameter.
14. Choose **Save changes**.
15. Choose **Confirm**.

Add searchable metadata to your features using SDK for Python (Boto3)

The code in this section uses the `UpdateFeatureMetadata` operation in the AWS SDK for Python (Boto3) to add searchable metadata to your features for different scenarios. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

- `FeatureGroupName`
- `Feature`
- `Parameters`

The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterAdditions=[
        {"Key": "example-key-0", "Value": "example-value-0"},
        {"Key": "example-key-1", "Value": "example-value-1"},
    ]
)
```

Add a description to a feature

To add a description to a feature, specify values for the following fields:

- `FeatureGroupName`

- `Feature`
- `Description`

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- `FeatureGroupName`
- `Feature`

Specify the keys for the parameters that you're removing under `ParameterRemovals`.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
        ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- `FeatureGroupName`
- `Feature`

Specify an empty string for `Description`.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description=""
)
```

Example code

After you've updated the metadata for a feature, you can use the DescribeFeatureMetadata operation to see the updates that you've made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3). The example code does the following:

1. Sets up your SageMaker AI environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

Step 1: Setup

To start using Feature Store, create SageMaker AI, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker AI default bucket and adds a custom prefix to it.

> **Note**
>
> The role that you use must have the following managed policies attached to it: `AmazonS3FullAccess` and `AmazonSageMakerFeatureStoreAccess`.

```
# SageMaker Python SDK version 2.x is required
%pip install 'sagemaker>=2.0.0'
import sagemaker
```

```
import sys
```

```

import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
```

Step 2: Create a feature group and add features

The following code is an example of creating a feature group with feature definitions.

```

feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {"FeatureName": "feature-1", "FeatureType": "String"},
    {"FeatureName": "feature-2", "FeatureType": "String"},
    {"FeatureName": "feature-3", "FeatureType": "String"},
    {"FeatureName": "feature-4", "FeatureType": "String"},
    {"FeatureName": "feature-5", "FeatureType": "String"}
]
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
        FeatureDefinitions=feature_definitions,
        OnlineStoreConfig={"EnableOnlineStore": True}
    )
except ClientError as e:
```

```
    if e.response["Error"]["Code"] == "ResourceInUse":
        pass
    else:
        raise e
```

Step 3: Add metadata

Before you add metadata, use the [DescribeFeatureGroup](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_DescribeFeatureGroup.html) operation to make sure that the status of the feature group is `Created`.

```
sagemaker_client.describe_feature_group(
        FeatureGroupName=feature_group_name
    )
```

Add a description to the feature.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    Description="new description"
)
```

You can use the [DescribeFeatureMetadata](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_DescribeFeatureMetadata.html) operation to see if you successfully updated the description for the feature group.

```
    sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

You can also use it to add parameters to the feature group.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
```

```
    ParameterAdditions=[
        {"Key": "team", "Value": "featurestore"},
        {"Key": "org", "Value": "sagemaker"},
    ]
)
```

You can use the DescribeFeatureMetadata operation again to see if you have successfully added the parameters.

```
    sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

Create a dataset from your feature groups

After a Feature Store feature group has been created in an offline store, you can choose to use the following methods to get your data:

- Using the Amazon SageMaker Python SDK
- Running SQL queries in the Amazon Athena

Important

Feature Store requires data to be registered in a AWS Glue data catalog. By default, Feature Store automatically builds an AWS Glue data catalog when you create a feature group.

After you've created feature groups for your offline store and populated them with data, you can create a dataset by running queries or using the SDK to join data stored in the offline store from different feature groups. You can also join the feature groups to a single pandas dataframe. You can use Amazon Athena to write and execute SQL queries.

Note

To make sure that your data is up to date, you can set up a AWS Glue crawler to run on a schedule.

To set up a AWS Glue crawler, specify an IAM role that the crawler is using to access the offline store’s Amazon S3 buckets. For more information, see Create an IAM role.

For more information on how to use AWS Glue and Athena to build a training dataset for model training and inference, see Use Feature Store with SDK for Python (Boto3).

Using the Amazon SageMaker Python SDK to get your data from your feature groups

You can use the Feature Store APIs to create a dataset from your feature groups. Data scientists create ML datasets for training by retrieving ML feature data from one or more feature groups in the offline store. Use the `create_dataset()` function to create the dataset. You can use the SDK to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from the feature groups and a pandas data frame.

By default, Feature Store doesn't include records that you've deleted from the dataset. It also doesn't include duplicated records. A duplicate record has the record ID and timestamp value in the event time column.

Before you use the SDK to create a dataset, you must start a SageMaker AI session. Use the following code to start the session.

```
import boto3
from sagemaker.session import Session
from sagemaker.feature_store.feature_store import FeatureStore

region = boto3.Session().region_name
boto_session = boto3.Session(region_name=region)

sagemaker_client = boto_session.client(
    service_name="sagemaker", region_name=region
 )
featurestore_runtime = boto_session.client(
    service_name="sagemaker-featurestore-runtime",region_name=region
)

feature_store_session = Session(
```

```
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
    sagemaker_featurestore_runtime_client=featurestore_runtime,
)

feature_store = FeatureStore(feature_store_session)
```

The following code shows an example of creating a dataset from multiple feature groups. The following code snippet uses the example feature groups "*base_fg_name*", "*first_fg_name*", and "*second_fg_name*", which may not exist or have the same schema within your Feature Store. It is recommended to replace these feature groups with feature groups that exist within your Feature Store. For information on how to create a feature group, see Step 3: Create feature groups.

```
from sagemaker.feature_store.feature_group import FeatureGroup

s3_bucket_name = "offline-store-sdk-test"

base_fg_name = "base_fg_name"
base_fg = FeatureGroup(name=base_fg_name, sagemaker_session=feature_store_session)

first_fg_name = "first_fg_name"
first_fg = FeatureGroup(name=first_fg_name, sagemaker_session=feature_store_session)

second_fg_name = "second_fg_name"
second_fg = FeatureGroup(name=second_fg_name, sagemaker_session=feature_store_session)

feature_store = FeatureStore(feature_store_session)
builder = feature_store.create_dataset(
    base=base_fg,
    output_path=f"s3://{amzn-s3-demo-bucket1}",
).with_feature_group(first_fg
).with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The following code shows an example of creating a dataset from multiple feature groups and a pandas dataframe.

```
base_data = [[1, 187512346.0, 123, 128],
             [2, 187512347.0, 168, 258],
             [3, 187512348.0, 125, 184],
             [1, 187512349.0, 195, 206]]
base_data_df = pd.DataFrame(
```

```
    base_data,
    columns=["base_id", "base_time", "base_feature_1", "base_feature_2"]
)

builder = feature_store.create_dataset(
    base=base_data_df,
    event_time_identifier_feature_name='base_time',
    record_identifier_feature_name='base_id',
    output_path=f"s3://{s3_bucket_name}"
).with_feature_group(first_fg
).with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The Feature Store APIs provides you with helper methods for the `create_dataset` function. You can use them to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from multiple feature groups and a pandas dataframe.
- Create a dataset from a single feature group and a pandas dataframe.
- Create a dataset using a point in time accurate join where records in the joined feature group follow sequentially.
- Create a dataset with the duplicated records, instead of following the default behavior of the function.
- Create a dataset with the deleted records, instead of following the default behavior of the function.
- Create a dataset for time periods that you specify.
- Save the dataset as a CSV file.
- Save the dataset as a pandas dataframe.

The *base* feature group is an important concept for joins. The base feature group is the feature group that has other feature groups or the pandas dataframe joined to it. For each dataset

You can add the following optional methods to the `create_dataset` function to configure how you're creating dataset:

- `with_feature_group` – Performs an inner join between the base feature group and another feature group using the record identifier and the target feature name in the base feature group. The following provides information about the parameters that you specify:

  - `feature_group` – The feature group that you're joining.
  - `target_feature_name_in_base` – The name of the feature in the base feature group that you're using as a key in the join. The record identifier in the other feature groups are the other keys that Feature Store uses in the join.
  - `included_feature_names` – A list of strings representing the feature names of the base feature group. You can use the field to specify the features that you want to include in the dataset.
  - `feature_name_in_target` – Optional string representing the feature in the target feature group that will be compared to the target feature in the base feature group.
  - `join_comparator` – Optional `JoinComparatorEnum` representing the comparator used when joining the target feature in the base feature group and the feature in the target feature group. These `JoinComparatorEnum` values can be `GREATER_THAN`, `GREATER_THAN_OR_EQUAL_TO`, `LESS_THAN`, `LESS_THAN_OR_EQUAL_TO`, `NOT_EQUAL_TO` or `EQUALS` by default.
  - `join_type` – Optional `JoinTypeEnum` representing the type of join between the base and target feature groups. These `JoinTypeEnum` values can be `LEFT_JOIN`, `RIGHT_JOIN`, `FULL_JOIN`, `CROSS_JOIN` or `INNER_JOIN` by default.
- `with_event_time_range` – Creates a dataset using the event time range that you specify.
- `as_of` – Creates a dataset up to a timestamp that you specify. For example, if you specify `datetime(2021, 11, 28, 23, 55, 59, 342380)` as the value, creates a dataset up to November 28th, 2021.
- `point_time_accurate_join` – Creates a dataset where all of the event time values of the base feature group is less than all the event time values of the feature group or pandas dataframe that you're joining.
- `include_duplicated_records` – Keeps duplicated values in the feature groups.
- `include_deleted_records` – Keeps deleted values in the feature groups.
- `with_number_of_recent_records_by_record_identifier` – An integer that you specify to determine how many of the most recent records appear in the dataset.
- `with_number_of_records_by_record_identifier` – An integer that represents how many records appear in the dataset.

After you've configured the dataset, you can specify the output using one of the following methods:

- `to_csv_file` – Saves the dataset as a CSV file.
- `to_dataframe` – Saves the dataset as a pandas dataframe.

You can retrieve data that comes after a specific period in time. The following code retrieves data after a timestamp.

```
fg1 = FeatureGroup("example-feature-group-1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-S3-path"
).with_number_of_records_from_query_results(5).to_csv_file()
```

You can also retrieve data from a specific time period. You can use the following code to get data for a specific time range:

```
fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="example-S3-path"
).with_event_time_range(
    datetime(2021, 11, 28, 23, 55, 59, 342380),
    datetime(2020, 11, 28, 23, 55, 59, 342380)
).to_csv_file() #example time range specified in datetime functions
```

You might want to join multiple feature groups to a pandas dataframe where the event time values of the feature group happen no later than the event time of the data frame. Use the following code as a template to help you perform the join.

```
fg1 = FeatureGroup("fg1")
fg2 = FeatureGroup("fg2")
events = [['2020-02-01T08:30:00Z', 6, 1],
          ['2020-02-02T10:15:30Z', 5, 2],
          ['2020-02-03T13:20:59Z', 1, 3],
          ['2021-01-01T00:00:00Z', 1, 4]]
df = pd.DataFrame(events, columns=['event_time', 'customer-id', 'title-id'])
feature_store.create_dataset(
    base=df,
    event_time_identifier_feature_name='event_time',
    record_identifier_feature_name='customer_id',
    output_path="s3://example-S3-path"
```

```
).with_feature_group(fg1, "customer-id"
).with_feature_group(fg2, "title-id"
).point_in_time_accurate_join(
).to_csv_file()
```

You can also retrieve data that comes after a specific period in time. The following code retrieves data after the time specified by the timestamp in the `as_of` method.

```
fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-s3-file-path"
).as_of(datetime(2021, 11, 28, 23, 55, 59, 342380)
).to_csv_file() # example datetime values
```

Sample Amazon Athena queries

You can write queries in Amazon Athena to create a dataset from your feature groups. You can also write queries that create a dataset from feature groups and a single pandas dataframe.

Interactive Exploration

This query selects the first 1000 records.

```
SELECT *
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
LIMIT 1000
```

Latest snapshot without duplicates

This query selects the latest non-duplicate records.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1;
```

Latest snapshot without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from the offline store.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1 and
NOT is_deleted;
```

Time Travel without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from a particular point in time.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
    where <EventTimeFeatureName> <= timestamp '<timestamp>')
    -- replace timestamp '<timestamp>' with just <timestamp>  if EventTimeFeature is of
 type fractional
WHERE row_num = 1 and
NOT is_deleted
```

Cross account feature group discoverability and access

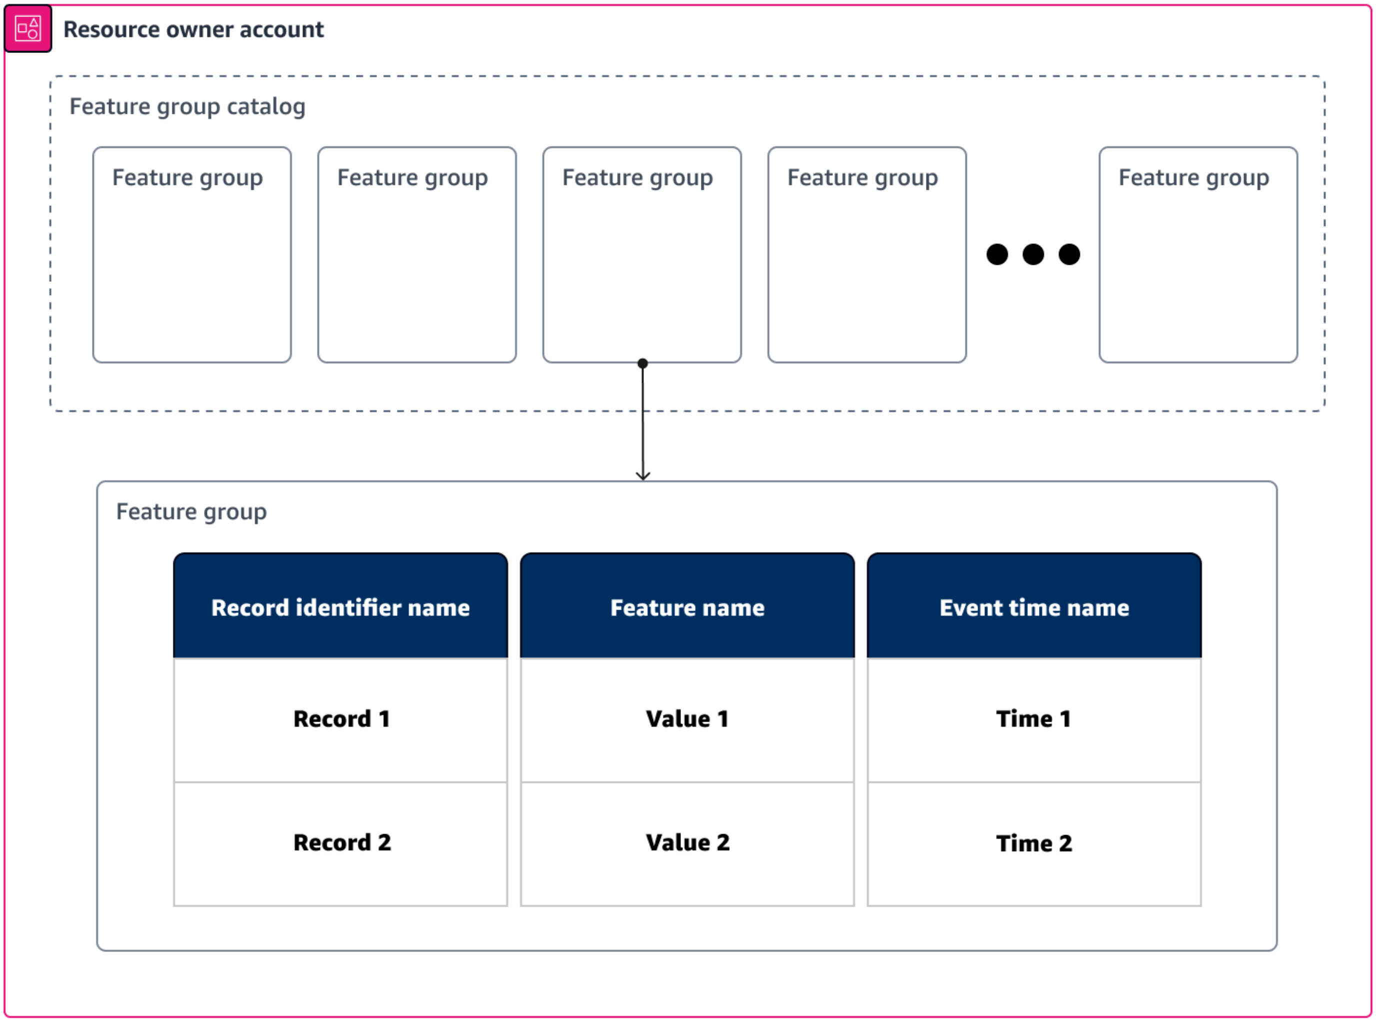
Data scientists and data engineers can benefit from exploring and accessing features that span multiple accounts, in order to promote data consistency, streamline collaboration, and reduce duplication of effort.

With Amazon SageMaker Feature Store, you can share feature group resources across accounts. The resources that can be shared in Feature Store are feature group entities or the feature group catalog, where the feature group catalog contains all of the feature group entities on your account. The resource owner account shares resources with the resource consumer accounts. There are two distinct categories of permissions associated with sharing resources:

- **Discoverability permission**: *Discoverability* means being able to see feature group names and metadata. When you share the feature group catalog and grant the discoverability permission, all feature group entities in the account that you share from (resource owner account) become discoverable by the accounts that you are sharing with (resource consumer account). For example, if you make the feature group catalog in the resource owner account discoverable to a resource consumer account, then principals of the resource consumer account can see all feature groups contained in the resource owner account. It means discoverability is “all or nothing” at the account level (regionalized). This permission is granted to resource consumer accounts by using the feature group catalog resource type.
- **Access permissions**: When you grant an access permission, you do so at a feature group resource level (not at account level). This gives you more granular control over granting access to data. The type of access permissions that can be granted are: read-only, read-write, and admin. For example, you can select only certain feature groups from the resource owner account to be accessible by principals of the resource consumer account, depending on your business needs. This permission is granted to resource consumer accounts by using the feature group resource type and specifying feature group entities.

The distinction between discoverability and access is important to keep in mind when you set up cross account sharing. Also, the methods of sharing resources differ depending on whether you are sharing online or offline feature groups. For information about online and offline feature groups, see Feature Store concepts. In the following topics, you can learn how to apply discoverability and access permissions to your shared resources.

The following example diagram visualizes the feature group catalog resource versus a feature group resource entity. The feature group catalog contains *all* of your feature group entities and can be shared using the discoverability permission. When granted a discoverability permission, the resource consumer account can search and discover *all* feature group entities within the resource owner account. A feature group entity contains your machine learning data and can be shared using the access permission. When granted an access permission, the resource consumer account can access the feature group data, with access determined by the relevant access permission.



Topics

- Enabling cross account discoverability
- Enabling cross account access

Enabling cross account discoverability

With AWS Resource Access Manager (AWS RAM) you can securely share the feature group catalog, which contains all of your feature group and feature resources, with other AWS accounts. This lets members of your team search and discover feature groups and features that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

This section covers how the resource owner account can choose the feature group catalog and grant discoverability privilege to resource consumer accounts, and then how the resource consumer accounts with the discoverability privilege can use search and discover the feature groups within the resource owner account. The discoverability permission does not grant access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access.

The following topics discuss how to share the feature group catalog and how to search for shared resources with discoverability permissions applied.

Topics

- Share your feature group catalog
- Search discoverable resources

Share your feature group catalog

The feature group catalog, `DefaultFeatureGroupCatalog`, contains *all* feature group entities owned by the resource owner account. The catalog can be shared by the resource owner account to grant discoverability to a single or multiple resource consumer accounts. This is done by creating a resource share in AWS Resource Access Manager (AWS RAM). A feature group is the main resource in Amazon SageMaker Feature Store and is composed of feature definitions and records that are managed by Feature Store. For more information about feature groups, see Feature Store concepts.

Discoverability means that the resource consumer accounts can search for the discoverable resources. The discoverable resources are viewed as if they were in their own account (excluding tags). When allowing the feature group catalog to be discoverable, the resource consumer accounts by default are not granted access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access.

In order to enable cross account discoverability you will need to specify the SageMaker AI Resource Catalog and the feature group catalog while using the AWS RAM Create a resources share instructions in the AWS RAM developer guide. In the following we give the specifications for using the AWS RAM console instructions.

1. **Specify resource share details**:
   - Resource type: Choose **SageMaker AI Resource Catalogs**.
   - ARN: Choose the feature group catalog ARN with the format: `arn:aws:sagemaker:us-east-1:111122223333:sagemaker-catalog/DefaultFeatureGroupCatalog`

     `us-east-1` is the region of the resource and *`111122223333`* is the resource owner account ID.
   - Resource ID: Choose `DefaultFeatureGroupCatalog`.
2. **Associate managed permissions**:
   - Managed permission: Choose `AWSRAMPermissionSageMakerCatalogResourceSearch`.
3. **Grant access to principals**:
   - Choose the principal types (AWS account, Organization, or Organizational unit) and enter the appropriate ID.

     If you are an organization, you may want to take advantage of AWS Organizations. With Organizations you can share resources with individual AWS accounts, all accounts in your organization, or with an Organization Unit (OU). This simplifies applying permissions, without having to apply permissions to each account. For more information about sharing your resources and granting permissions within AWS, see Enable resource sharing within AWS Organizations in the AWS Resource Access Manager Developer Guide.
4. **Review and create**:
   - Review then choose **Create resource share**.

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. For more information on accepting and viewing resources in AWS RAM, see Access AWS resources shared with you. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled. In this case principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share, see Search discoverable resources.

Share the feature group catalog using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID *111122223333* within the region *us-east-1*. The resource owner is creating a resource share named *test-cross-account-catalog*. They are sharing the feature group catalog with the resource consumer account ID *444455556666*. To use the Python SDK for AWS RAM APIs, attach the `AWSRAMPermissionSageMakerCatalogResourceSearch` policy with the execution role. See AWS RAM APIs for more details.

```
#Call list resource catalogs as a prerequisite for RAM share
sagemaker_client.list_resource_catalogs()

# Share DefaultFeatureGroupCatalog with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-catalog', # Change to your custom resource share name
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:sagemaker-catalog/' +
 'DefaultFeatureGroupCatalog', # Change 111122223333 to the resource owner account ID
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ["arn:aws:ram::aws:permission/
AWSRAMPermissionSageMakerCatalogResourceSearch"] #
```

```
 AWSRAMPermissionSageMakerCatalogResourceSearch is the only policy allowed for
 SageMaker Catalog
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Search discoverable resources

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability or access (read-only, read-write, or admin) privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to shared resources and examples showing how to search for discoverable feature groups.

Accept an invitation to shared resources

As the resource consumer account, you receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open the Shared with me: Resource shares page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Respond to the resource share invitation.

Search discoverable feature groups example

Once resources are shared with a resource consumer account with the discoverability permission applied, the resource consumer account can search for and discover the shared resources in Amazon SageMaker Feature Store using the console UI and the Feature Store SDK. Note that you cannot search on tags for cross account resources. The maximum number of feature group catalogs viewable is 1000. For more information about granting discoverability permissions, see Enabling cross account discoverability.

For details about viewing shared feature groups in the console, see Find feature groups in your Feature Store.

In the following example, the resource consumer account uses SageMaker AI search to search for resources made discoverable to them when `CrossAccountFilterOption` is set to `"CrossAccount"`:

```
from sagemaker.session import Session

sagemaker_session = Session(boto_session=boto_session)

sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="CrossAccount"
)
```

For more information about SageMaker AI search and the request parameters, see Search in the Amazon SageMaker API Reference.

Enabling cross account access

The access permissions are read-only, read-write, and admin permissions. The permission name, description, and list of specific APIs available for each permission are listed in the following:

- Read-only permission (`AWSRAMPermissionSageMakerFeatureGroupReadOnly`): The read privilege allows resource consumer accounts to read records in the shared feature groups and view details and metadata.

  - `DescribeFeatureGroup`: Retrieves details about a feature group and its configuration
  - `DescribeFeatureMetadata`: Shows the metadata for a feature within a feature group
  - `BatchGetRecord`: Retrieves a batch of records from a feature group
  - `GetRecord`: Retrieves a record from a feature group
- Read-write permission (`AWSRAMPermissionSagemakerFeatureGroupReadWrite`): The read-write privilege allows resource consumer accounts to write records to, and delete records from, the shared feature groups, in addition to read permissions.
  - `PutRecord`: Writes a record to a feature group
  - `DeleteRecord`: Removes a record from a feature group
  - APIs listed in `AWSRAMPermissionSageMakerFeatureGroupReadOnly`
- Admin permission (`AWSRAMPermissionSagemakerFeatureGroupAdmin`): The admin privilege allows the resource consumer accounts to update the description and parameters of features within the shared feature groups, update the configuration of the shared feature groups, in addition to read-write permissions.
  - `DescribeFeatureMetadata`: Shows the metadata for a feature within a feature group
  - `UpdateFeatureGroup`: Updates a feature group configuration
  - `UpdateFeatureMetadata`: Updates description and parameters of a feature in the feature group
  - APIs listed in `AWSRAMPermissionSagemakerFeatureGroupReadWrite`

In the following topics you can learn how to share online store and offline feature groups—there are differences between the two when it comes to sharing.

Topics

- Share online feature groups with AWS Resource Access Manager
- Cross account offline store access

Share online feature groups with AWS Resource Access Manager

With AWS Resource Access Manager (AWS RAM) you can securely share Amazon SageMaker Feature Store online feature groups with other AWS accounts. Members of your team can explore and access feature groups that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

Note that there is a soft maximum limit to the transactions per second (TPS) per API per AWS account. The maximum TPS limit applies to *all* transactions on the resources within the resource owner account, so transactions from the resource consumer accounts also count towards this maximum limit. For information about service quotas and how to request a quota increase, see AWS service quotas.

This section covers how the resource owner account can choose feature groups and grant access privileges (read-only, read-write, and admin) to resource consumer accounts, and then how the resource consumer accounts with access privileges can use those feature groups. The access permissions do not allow for the resource consumer accounts to search and discover feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

The following topics show how to share Feature Store online store resources using the AWS RAM console. For information about sharing your resources and granting permissions within AWS using the AWS RAM console or AWS Command Line Interface (AWS CLI), see Sharing your AWS resources.

Topics

- Share your feature group entities
- Use online store shared resources with access permissions

Share your feature group entities

As the resource owner account you can use the feature group resource type for Amazon SageMaker Feature Store to share feature group entities, by creating a resource share in AWS Resource Access Manager (AWS RAM).

Use the following instructions along with the [Sharing your AWS resources] instructions in the AWS RAM User Guide.

When sharing the feature group resource type using the AWS RAM console, you need to make the following choices.

1. **Specify resource share details**:

   - Resource type: Choose **SageMaker AI Feature Groups**.
   - ARN: Choose your feature group ARN with the format: `arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name`.

     `us-east-1` is the region of the resource, `111122223333` is the resource owner account ID, and *`your-feature-group-name`* is the feature group you are sharing.
   - Resource ID: Choose the feature group, *`your-feature-group-name`*, to which you want to grant access permissions.
2. **Associate managed permissions**:

   - Managed permission: Choose the access permission. For more information about access permissions, see Enabling cross account access.
3. **Grant access to principals**:

   - Choose the principal type (AWS account, Organization, Organizational unit, IAM role, or IAM user) and enter the appropriate ID or ARN.
4. **Review and create**:

   - Review then choose **Create resource share**.

Granting any access permission does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the discoverability permission to the resource consumer accounts, where *all* of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

If the resource consumer accounts are only granted access permissions, the feature group entities can still be viewed on AWS RAM. To view resources on AWS RAM, see Access AWS resources shared with you in the AWS RAM User Guide.

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Using shared AWS resources in the AWS RAM User Guide.

Share online store feature groups using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID `111122223333` creating a resource share named `'test-cross-account-fg'`, sharing the feature group named `'my-feature-group'` with the resource consumer account ID `444455556666` while granting the `AWSRAMPermissionSageMakerFeatureGroupReadOnly` permission. For more information about access permissions, see Enabling cross account access. To use the Python SDK for AWS RAM APIs, you need to attach AWS RAM full access managed policy with execution role. See create_resource_share AWS RAM API for more details.

```
import boto3

# Choose feature group name
feature_group_name = 'my-feature-group' # Change to your feature group name

# Share 'my-feature-group' with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-fg', # Change to your custom resource share name
```

```
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:feature-group/' + feature_group_name,
 # Change 111122223333 to the resource owner account ID
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ["arn:aws:ram::aws:permission/
AWSRAMPermissionSageMakerFeatureGroupReadOnly"]
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Use online store shared resources with access permissions

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability, read-only, write, or admin privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to access shared resources and provide examples showing how to view and interact with shared feature groups.

Accept an invitation to access shared resources using AWS RAM

As the resource consumer account, you will receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open the Shared with me: Resource shares page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Using shared AWS resources in the AWS RAM User Guide.

View shared resources on the AWS RAM console

Granting any access permissions does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

To view the shared resources on the AWS RAM console, open the Shared with me: Resource shares page in the AWS RAM console.

Read and write actions with a shared feature groups example

Once your resource consumer account is granted the appropriate permissions by the resource owner account, you can perform actions on the shared resources using the Feature Store SDK. You can do this by providing the resource ARN as the `FeatureGroupName`. To obtain the Feature Group ARN, you can use the AWS SDK for Python (Boto3) `DescribeFeatureGroup` function or use the console UI. For information about using the console UI to view feature group details, see View feature group details from the console.

The following examples use `PutRecord` and `GetRecord` with a shared feature group entity. See the request and response syntax in the AWS SDK for Python (Boto3) documentation for `PutRecord` and `GetRecordAPIs`.

```
import boto3

sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Put record into feature group named 'test-fg' within the resource owner account ID
 111122223333
featurestore_runtime.put_record(
    FeatureGroupName="arn:aws:sagemaker:us-east-1:111122223333:feature-group/test-fg",
    Record=[value.to_dict() for value in record] # You will need to define record prior
 to calling PutRecord
)
```

```
import boto3

sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Choose record identifier
```

```
record_identifier_value = str(2990130)

# Get record from feature group named 'test-fg' within the resource owner account ID
 111122223333
featurestore_runtime.get_record(
    FeatureGroupName="arn:aws:sagemaker:us-east-1:111122223333:feature-group/test-fg",
    RecordIdentifierValueAsString=record_identifier_value
)
```

For more information about granting permissions to feature group entities, see Share your feature group entities.

Cross account offline store access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). You can set this up using the steps in the following section.

Topics

Step 1: Set up the offline store access role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the `AmazonSageMakerFeatureStoreAccess` policy or to use an existing role that already has the `AmazonSageMakerFeatureStoreAccess` policy attached. This document refers to this policy as `Account-A-Offline-Feature-Store-Role-ARN`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        }
    ]
}
```

The preceding code snippet shows the `AmazonSageMakerFeatureStoreAccess` policy. The `Resource` section of the policy is scoped down by default to S3 buckets with names that contain `SageMaker`, `Sagemaker`, or `sagemaker`. This means the offline store Amazon S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your Amazon S3 bucket policy in the console, customize the `Resource` section to be `arn:aws:s3:::your-offline-store-bucket-name`, and then attach to the role.

Additionally, this role must have AWS KMS permissions attached. At a minimum, it requires the `kms:GenerateDataKey` permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross account scenario and how to set it up. The following example shows an inline policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:*:111122223333:key/*"
```

```
        }
    ]
}
```

The `Resource` section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

Step 2: Set up an offline store Amazon S3 bucket in Account B

Create an Amazon S3 bucket in Account B. If you are using the default `AmazonSageMakerFeatureStoreAccess` policy, the bucket name must include `SageMaker`, `Sagemaker`, or `sagemaker`. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as `Account-B-Offline-Feature-Store-Bucket`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3CrossAccountBucketAccess",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetBucketAcl"
            ],
            "Principal": {
                "AWS": [
                    "*Account-A-Offline-Feature-Store-Role-ARN*"
                ],
            },
            "Resource": [
                "arn:aws:s3:::offline-store-bucket-name/*",
                "arn:aws:s3:::offline-store-bucket-name"
            ]
        }
    ]
}
```

In the preceding policy, the principal is `Account-A-Offline-Feature-Store-Role-ARN`, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under `Principal`.

Step 3: Set up an offline store AWS KMS encryption key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for Amazon S3 objects in the offline store. For cross account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, `Account-A-Offline-Feature-Store-Role-ARN` from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as `Account-A-Offline-Feature-Store-KMS-Key-ARN`.

```
{
    "Version": "2012-10-17",
    "Id": "key-consolepolicy-3",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::Account-A-Account-Id:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::Account-A-Account-Id:role/Administrator",
                ]
            },
            "Action": [
                "kms:Create*",
                "kms:Describe*",
                "kms:Enable*",
                "kms:List*",
                "kms:Put*",
                "kms:Update*",
```

```
                "kms:Revoke*",
                "kms:Disable*",
                "kms:Get*",
                "kms:Delete*",
                "kms:TagResource",
                "kms:UntagResource",
                "kms:ScheduleKeyDeletion",
                "kms:CancelKeyDeletion"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow Feature Store to get information about the customer managed 
 key",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": [
                "kms:Describe*",
                "kms:Get*",
                "kms:List*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "*Account-A-Offline-Feature-Store-Role-ARN*",
                    "*arn:aws:iam::Account-B-Account-Id:root*"
                ]
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:DescribeKey",
                "kms:CreateGrant",
                "kms:RetireGrant",
                "kms:ReEncryptFrom",
                "kms:ReEncryptTo",
                "kms:GenerateDataKey",
                "kms:ListAliases",
```

```
                "kms:ListGrants"
            ],
            "Resource": "*",
        }
    ]
}
```

Step 4: Create a feature group in Account A

Next, create the feature group in Account A, with an offline store Amazon S3 bucket in Account B. To do this, provide the following parameters for `RoleArn`, `OfflineStoreConfig.S3StorageConfig.KmsKeyId`, and `OfflineStoreConfig.S3StorageConfig.S3Uri`, respectively:

- Provide `Account-A-Offline-Feature-Store-Role-ARN` as the `RoleArn`.
- Provide `Account-A-Offline-Feature-Store-KMS-Key-ARN` for `OfflineStoreConfig.S3StorageConfig.KmsKeyId`.
- Provide `Account-B-Offline-Feature-Store-Bucket` for `OfflineStoreConfig.S3StorageConfig.S3Uri`.

Security and access control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide a AWS Key Management Service customer managed key to encrypt all your data at rest. In case you do not provide a AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide a AWS KMS key for encrypting data, then you can call various APIs for data management such as `PutRecord`, `GetRecord`, `DeleteRecord`.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

Using AWS KMS permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore. Feature Store supports an option to encrypt your online or offline store under customer managed key. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only symmetric customer managed keys. You cannot use an asymmetric customer managed key to encrypt your data in your online or offline store. For help determining whether a customer managed key is symmetric or asymmetric, see Identifying symmetric and asymmetric customer managed keys.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the key policies, IAM policies and grants to control access to the customer managed key. You can enable and disable the customer managed key, enable and disable automatic key rotation, and delete the customer managed key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in AWS CloudTrail logs.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will incur a charge for each API call and AWS Key Management Service quotas apply to each customer managed key.

Authorizing use of a customer managed Key for your online store

If you use a customer managed key to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default AWS owned KMS key to protect your online or offline stores in your AWS account.

Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

- "kms:Encrypt", "kms:Decrypt", "kms:DescribeKey", "kms:CreateGrant", "kms:RetireGrant", "kms:ReEncryptFrom", "kms:ReEncryptTo", "kms:GenerateDataKey", "kms:ListAliases", "kms:ListGrants", "kms:RevokeGrant"

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for `kms:ViaService` should be `sagemaker.*.amazonaws.com`.

> **Note**
>
> The `kms:ViaService` condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to your customer managed key, and use the same AWS KMS key for both the online and offline store, then it will fail the `CreateFeatureGroup` API operation.

- Gives the customer managed key administrators read-only access to the customer managed key and permission to revoke grants, including the grants that Feature Store uses to protect your data.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```
{"Id": "key-policy-feature-store",
   "Version":"2012-10-17",

         "kms:DescribeKey",
         "kms:CreateGrant",
         "kms:RetireGrant",
         "kms:ReEncryptFrom",
         "kms:ReEncryptTo",
         "kms:GenerateDataKey",
         "kms:ListAliases",
         "kms:ListGrants"
       ],
       "Resource": "*",
       "Condition": {"StringLike": {"kms:ViaService" : "sagemaker.*.amazonaws.com"
          }
       }
     },
     {"Sid":  "Allow administrators to view the customer managed key and revoke
 grants",
       "Effect": "Allow",
       "Principal": {"AWS": "arn:aws:iam::111122223333:role/featurestore-admin"
        },
       "Action": [
         "kms:Describe*",
         "kms:Get*",
         "kms:List*",
         "kms:RevokeGrant"
       ],
       "Resource": "*"
     },
     {"Sid": "Enable IAM User Permissions",
       "Effect": "Allow",
```

```
        "Principal": {"AWS": "arn:aws:iam::123456789:root"
        },
        "Action": "kms:*",
        "Resource": "*"
      }
    ]
  }
```

Using grants to authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the `ListGrants` operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per `FeatureGroup` using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

Monitoring Feature Store interaction with AWS KMS

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.

Accessing data in your online store

The **caller (either user or role)** to **ALL DataPlane operations (Put, Get, DeleteRecord)** must have below permissions on the customer managed key:

```
"kms:Decrypt"
```

Authorizing use of a customer managed key for your offline store

The **roleArn** that is passed as a parameter to `createFeatureGroup` must have below permissions to the OfflineStore KmsKeyId:

```
"kms:GenerateDataKey"
```

> **Note**
>
> The key policy for the online store also works for the offline store, only when the `kms:ViaService` condition is not specified.

> **Important**
>
> You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

Logging Feature Store operations by using AWS CloudTrail

Amazon SageMaker Feature Store is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Feature Store. CloudTrail captures all of the API calls for Feature Store listed on this page. The logged events include API calls from Feature Store resource management and data operations. When you create a trail, you activate continuous delivery of CloudTrail events from Feature Store to an Amazon S3 bucket. Using the information collected by CloudTrail, you can determine the request that was made to Feature Store, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Management events

Management events capture operations performed on Feature Store resources in your AWS account. For example, the log generated from the management events provides visibility if a user creates or deletes a Feature Store. The following APIs log management events with Amazon SageMaker Feature Store.

- `CreateFeatureGroup`
- `DeleteFeatureGroup`
- `DescribeFeatureGroup`
- `UpdateFeatureGroup`

Amazon SageMaker API calls and management events are logged by default when you create the account, as described in Logging Amazon SageMaker AI API calls using AWS CloudTrail. For more information, see Logging management events for trails.

Data events

Data events capture data plane operations performed using the Feature Store resources in your AWS account. For example, the log generated from the data events provides visibility if a user adds or deletes a record within a feature group. The following APIs log data events with Amazon SageMaker Feature Store.

- `BatchGetRecord`
- `DeleteRecord`
- `GetRecord`
- `PutRecord`

Data events are *not* logged by CloudTrail trails by default. To activate logging of data events, turn on logging of data plane API activity in CloudTrail. For more information, see CloudTrail's Logging data events for trails.

The following is an example CloudTrail event for a `PutRecord` API call:

```
{
    "eventVersion": "1.08",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "USERPRINCIPALID",
        "arn": "arn:aws:iam::123456789012:user/user",
        "accountId": "123456789012",
```

```
        "accessKeyId": "USERACCESSKEYID",
        "userName": "your-user-name"
    },
    "eventTime": "2023-01-01T01:00:00Z",
    "eventSource": "sagemaker.amazonaws.com",
    "eventName": "PutRecord",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "your-user-agent",
    "requestParameters": {
        "featureGroupName": "your-feature-group-name"
    },
    "responseElements": null,
    "requestID": "request-id",
    "eventID": "event-id",
    "readOnly": false,
    "resources": [
        {
            "accountId": "123456789012",
            "type": "AWS::SageMaker::FeatureGroup",
            "ARN": "arn:aws:sagemaker:us-east-1:123456789012:feature-group/your-
feature-group-name"
        }
    ],
    "eventType": "AwsApiCall",
    "managementEvent": false,
    "recipientAccountId": "123456789012",
    "eventCategory": "Data",
    "tlsDetails": {
        ...
    }
}
```

Quotas, naming rules and data types

Quota terminologies

- Read Request Unit (RRU): Measure of read throughput, where the number of RRUs per read request is equal to the ceiling of read record's size divided into 4KB chunks. The minimum RRU per request is 0.

- Write Request Unit (WRU): Measure of write throughput, where the number of WRUs per write request is equal to the ceiling of the written record's size divided into 1KB chunks. The minimum WRU per request is 1 (including delete operations).

Limits and quotas

> **Note**
>
> Soft limits can be increased based on your needs.

- **Maximum number of feature groups per AWS account:** Soft limit of 100.
- **Maximum number of feature definitions per feature group:** 2500.
- **Maximum number of RRU per record identifier:** 2400 RRU per second.
- **Maximum number of WRU per record identifier:** 500 WRU per second.
- **Max Read Capacity Units (RCU) that can be provisioned on a single feature group:** 40000 RCU.
- **Max Write Capacity Units (WCU) that can be provisioned on a single feature group:** 40000 WCU.
- **Max Read Capacity Units that can be provisioned across all feature groups in a region:** 80000 RCU.
- **Max Write Capacity Units that can be provisioned across all feature groups in a region:** 80000 WCU.
- **Maximum Transactions per second (TPS) per API per AWS account:** Soft limit of 10000 TPS per API excluding the `BatchGetRecord` API call, which has a soft limit of 500 TPS.
- **Maximum size of a record:** 350KB.
- **Maximum size of a record identifier:** 2KB.
- **Maximum size of a feature value:** 350KB.
- **Maximum number of concurrent feature group creation workflows:** 4.
- **BatchGetRecord API:** Can contain as many as 100 records and can query up to 100 feature groups.

For information about service quotas and how to request a quota increase, see AWS service quotas.

Naming rules

- **Reserved Words:** The following are reserved words and cannot be used as feature names in feature definitions: `is_deleted`, `write_time`, and `api_invocation_time`.

Data types

- **String Feature Type:** Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.
- **Fractional Feature Type:** Fractional feature values must conform to a double precision floating point number as defined by the IEEE 754 standard.
- **Integral Feature Type:** Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of -2^{63} and a maximum value: $2^{63} - 1$.
- **Event Time Features:** All feature groups have an event time feature with nanosecond precision. Any event time with lower than nanosecond precision will lead to backwards incompatibility. The feature can have a feature type of either String or Fractional.
  - A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): [yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-dd'T'HH:mm:ss.SSSSSSSSSZ].
  - A fractional event time value is accepted as seconds from unix epoch. Event times must be in the range of [0000-01-01T00:00:00.000000000Z, 9999-12-31T23:59:59.999999999Z]. For feature groups in the `Iceberg` table format, you can only use String type for the event time.

Amazon SageMaker Feature Store offline store data format

Amazon SageMaker Feature Store supports the AWS Glue and Apache Iceberg table formats for the offline store. You can choose the table format when you're creating a new feature group. AWS Glue is the default format.

Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call `PutRecord`, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format when writing your data to your offline store. Specifically, when your data is written to your offline store, the data can be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple `Records`.

For the Iceberg format, Feature Store saves the table's metadata in the same Amazon S3 bucket that you're using to store the offline store data. You can find it under the `metadata` prefix.

Feature Store also exposes the [OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri](#) field, which can be found from in the [DescribeFeatureGroup](#) API call. This is the S3 path under which the files for the specific feature group are written.

The following additional fields are added by Feature Store to each record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the `PutRecord` or `DeleteRecord` call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
- **write_time** – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.
- **is_deleted** – `False` by default. If `DeleteRecord` is called, a new `Record` is inserted into `RecordIdentifierValue` and set to `True` in the offline store.

Amazon SageMaker Feature Store offline store URI structures

In the following examples `amzn-s3-demo-bucket` is the Amazon S3 bucket within your account, *`example-prefix`* is your example prefix, *`111122223333`* is your account ID, *`AWS Region`* is your region, *`feature-group-name`* is the name of your feature group.

AWS Glue table format

Records in the offline store stored using the AWS Glue table format are partitioned by event time into hourly partitions. You can't configure the partitioning scheme. The following URI structure shows the organization of a Parquet file using the AWS Glue format:

```
s3://amzn-s3-demo-bucket/example-prefix/111122223333/sagemaker/AWS Region/offline-store/feature-group-name-feature-group-creation-time/data/year=year/month=month/day=day/hour=hour/timestamp_of_latest_event_time_in_file_16-random-alphanumeric-digits.parquet
```

The following example is the output location of a Parquet file for a file with *`feature-group-name`* as `customer-purchase-history-patterns`:

```
s3://amzn-s3-demo-bucket/example-prefix/111122223333/sagemaker/AWS Region/offline-store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/hour=00/20200631T064401Z_108934320012Az11.parquet
```

Iceberg table format

Records in the offline store stored in the Iceberg table format are partitioned by event time into daily partitions. You can't configure the partitioning scheme. The following URI structure shows the organization of the data files saved in the Iceberg table format:

```
s3://amzn-s3-demo-bucket/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/feature-group-name-feature-group-creation-time/data/8-random-alphanumeric-
digits/event-time-feature-name_trunc=event-time-year-event-time-month-event-time-day/
timestamp-of-latest-event-time-in-file_16-random-alphanumeric-digits.parquet
```

The following example is the output location of a Parquet file for a file with *`feature-group-name`* as `customer-purchase-history-patterns`, and the *`event-time-feature-name`* is `EventTime`:

```
s3://amzn-s3-demo-bucket/example-prefix/111122223333/sagemaker/AWS Region/
offline-store/customer-purchase-history-patterns-1593511200/data/0aec19ca/
EventTime_trunc=2022-11-09/20221109T215231Z_yolTtpyuWbkaeGIl.parquet
```

The following example is the location of a metadata file for data files saved in the Iceberg table format.

```
s3://amzn-s3-demo-bucket/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/feature-group-name-feature-group-creation-time/metadata/
```

Amazon SageMaker Feature Store resources

The following lists the available resources for Amazon SageMaker Feature Store users. For the Feature Store main page, see [Amazon SageMaker Feature Store](#).

Feature Store example notebooks and workshops

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks from the following table. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: `AmazonSageMakerFeatureStoreAccess`.

See IAM Roles to access your role and attach this policy. For a walkthrough on how to view the policies attached to a role and how to add a policy to your role, see Adding policies to your IAM role.

The following table lists a variety of resources to help you get started with Feature Store. This table contains examples, instructions, and example notebooks to guide you in how to use Feature Store for the first time to specific use cases. The code in these resources use the SageMaker AI SDK for Python (Boto3).

Page	Description
Get started with Amazon SageMaker Feature Store in Read the Docs.	A list of example notebooks to introduce you to Feature Store and its features to help you get started.
Amazon SageMaker Feature Store guide in Read the Docs.	A Feature Store guide on how to set up, create a feature group, load data into a feature group, and how to use Feature Store in general.
Amazon SageMaker Feature Store end-to-end workshop in the `aws-samples` Github repository	An end-to-end Feature Store workshop.
Feature Store example notebooks in the SageMaker AI example notebooks repository.	Specific use case example notebooks for Feature Store.

Feature Store Python SDK and API

Python Software Development Kit (SDK) and Application Programming Interface (API) are tools used for creating software applications. The Feature Store SDK for Python (Boto3) and API are listed in the following table.

Page	Description
Feature Store APIs in the Amazon SageMaker Python SDK Read the Docs	The Feature Store APIs in Read the Docs.

Page	Description
Feature Store Python SDK in the Amazon SageMaker Python SDK Github repository	The Feature Store Python SDK Github repository.
Feature Store Runtime operations and data types in the SDK for Python (Boto3) documentation	Feature Store Runtime client that contains all data plane API operations and data types for Feature Store.
Amazon SageMaker Feature Store Runtime in the Amazon SageMaker API Reference	Some feature group level actions supported by Feature Store. If the API operation or data type you are looking for is not listed here, please use search in the guide.
Amazon SageMaker Feature Store Runtime in the Amazon SageMaker API Reference	Record level actions supported by Feature Store. If the API operation or data type you are looking for is not listed here, please use search in the guide.

Reserve training plans for your training jobs or HyperPod clusters

Amazon SageMaker training plans is a capability that allows you to reserve and help maximize the use of GPU capacity for large-scale AI model training workloads. This feature provides access to highly sought-after instance types that cover a range of GPU-accelerated computing options, including the latest NVIDIA GPU technologies and AWS trainium chips. With SageMaker training plans, you can secure predictable access to these high-demand, high-performance computational resources within your specified timelines and budgets, without the need to manage underlying infrastructure. This flexibility is particularly valuable for organizations dealing with the challenges of acquiring and scheduling these oversubscribed compute instances for their mission-critical AI workloads.

What are SageMaker training plans

SageMaker training plans allow you to reserve compute capacity tailored to your target resource needs, such as SageMaker training jobs or SageMaker HyperPod clusters. The service automatically handles the reservation, provisioning of accelerated compute resources, infrastructure setup, workload execution, and recovery from infrastructure failures.

SageMaker training plans consist of one or more Reserved Capacity blocks, each defined by the following parameters:

- Specific instance type
- Quantity of instances
- Availability Zone
- Duration
- Start and end times

> **Note**
>
> - Training plans are specific to their target resource (either SageMaker Training Job or SageMaker HyperPod) and cannot be interchanged.

- Multiple Reserved Capacity blocks in a single training plan may be discontinuous. This means there can be gaps between the Reserved Capacity blocks.

Benefits of SageMaker training plans

SageMaker training plans offer the following benefits:

- **Predictable Access**: Reserve GPU capacity for your machine learning workloads within specified time frames.
- **Cost Management**: Plan and budget for large-scale training requirements in advance.
- **Automated Resource Management**: SageMaker training plans handle the provisioning and management of infrastructure.
- **Flexibility**: Create training plans for various resources, including SageMaker training jobs and SageMaker HyperPod clusters.
- **Fault Tolerance**: Benefit from automatic recovery from infrastructure failures and workload migration across Availability Zones for SageMaker AI training jobs.

SageMaker training plans advance reservation and flexible start times

SageMaker training plans allow you to reserve compute capacity in advance, with flexible start times and durations.

- **Advance reservation**: You can reserve a training plan up to 8 weeks (56 days) in advance of the start date.
- **Minimum lead time**: SageMaker training plans offerings may be available to start within 30 minutes of reservation, subject to availability.

> **Note**
>
> You can search for and purchase a plan that will be accessible within 30 minutes. To ensure timely activation, the payment transaction must successfully complete at least 5 minutes before the desired start time. For example, if you want a plan to start at 2:00

PM, you can make a last-minute search as late as 1:30 PM and complete your purchase by 1:55 PM to guarantee the plan is ready by 2:00 PM.

- **Reservation duration and instance quantity**: SageMaker training plans allow you to reserve instances with specific duration and quantity options. For available instance types in a given AWS Region, duration, and quantity options, see the section called “Supported instance types, AWS Regions, and pricing”.
- **End time**: Training Plans always end at 11:30 AM UTC on the final day of the reservation.
- **Training plan termination**: If you're using training jobs as a target resource and 30 minutes remain in a Reserved Capacity, SageMaker training plans initiates the process of terminating any running instances within that block until the next Reserved Capacity becomes active. You retain full access to your training plan until 30 minutes before the final Reserved Capacity block's end time.

  If your target resource is a SageMaker HyperPod cluster, this time limit is one hour.

SageMaker training plans user workflow

SageMaker training plans work through the following steps:

Admin steps:

1. **Search and review**: Find available plan offerings that match your compute requirements, such as instance type, count, start time, and duration.
2. **Create a plan**: Reserve a training plan that meets your needs using the ID of your chosen plan offering.
3. **Payment and scheduling**: Upon successful upfront payment, the plan status becomes `Scheduled`.

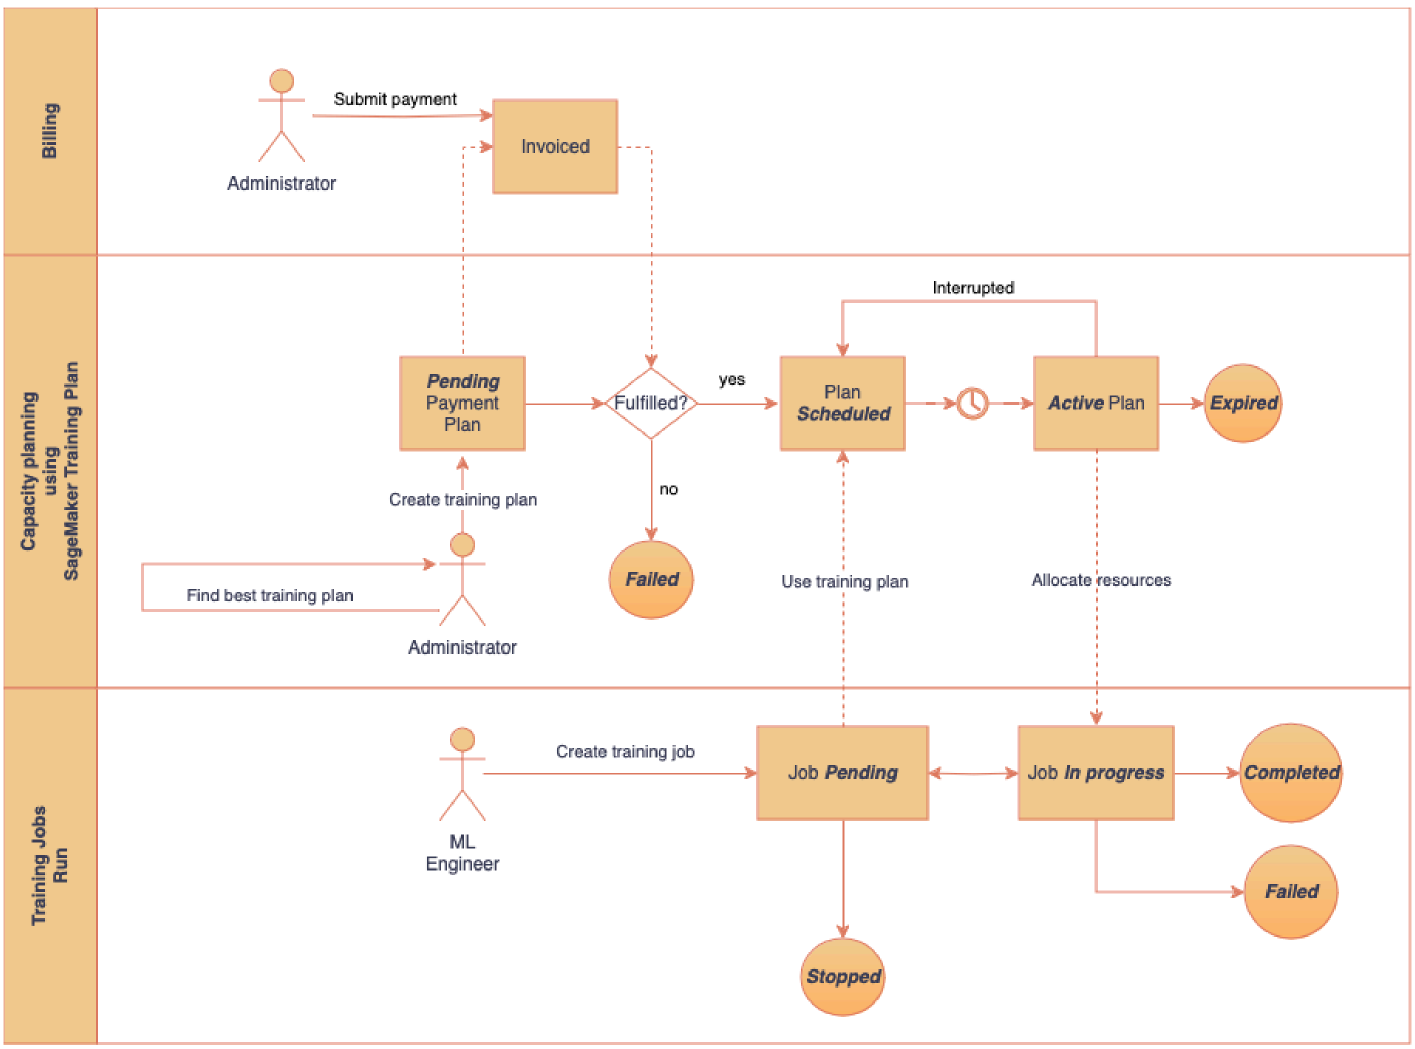
Steps for plan users / ML engineers:

1. **Resource allocation**: Use your plan to queue SageMaker AI training jobs or allocate to a SageMaker HyperPod cluster instance group.
2. **Activation**: When the plan start date arrives, it becomes `Active`. Based on available reserved capacity, SageMaker training plans automatically launch training jobs or provision instance groups.

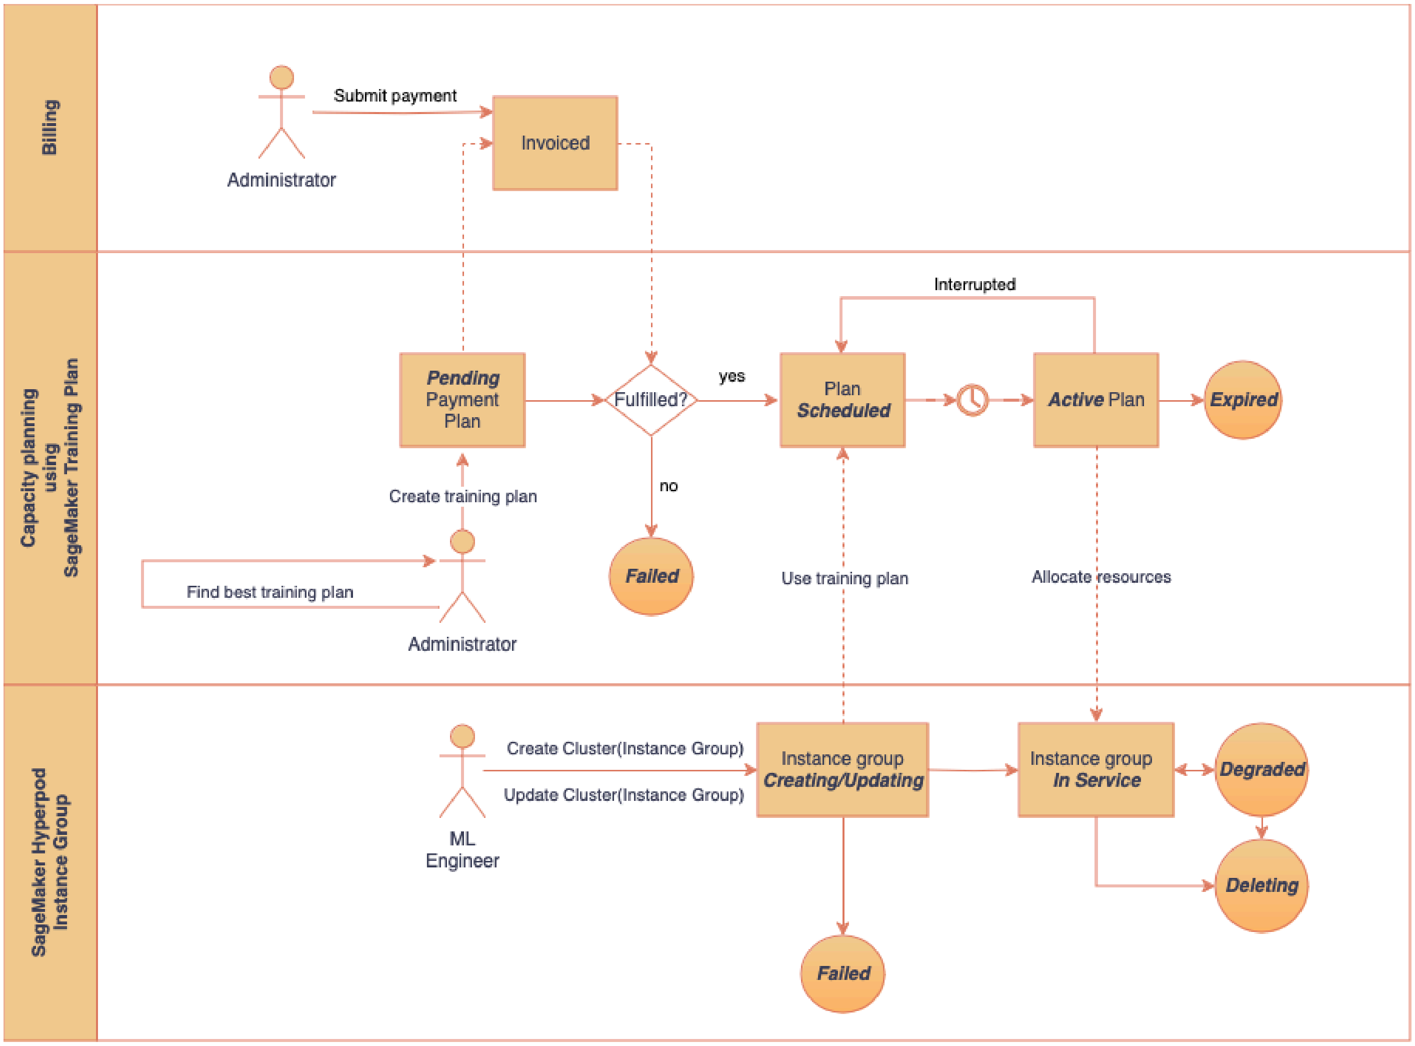
> **Note**
>
> The status of the training plan transitions from `Scheduled` to `Active` when a Reserved Capacity period begins, and then back to `Scheduled` when waiting for the next Reserved Capacity period to start.

The following diagrams provide a comprehensive overview of how SageMaker training plans interact with different target resources, illustrating a plan's lifecycle and its role in resource allocation for both SageMaker training jobs and SageMaker HyperPod clusters.

- **Training plans for SageMaker Training Job**: The first diagram illustrates the end-to-end workflow of the interaction between a training plan and SageMaker Training Job.



- **Training plans for SageMaker HyperPod clusters**: The second diagram illustrates the end-to-end workflow of the interaction between a training plan and a SageMaker HyperPod instance group.



Supported instance types, AWS Regions, and pricing

Training plans support reservations for the following specific high-performance instance types, each available in select AWS Regions:

- **ml.p4d.24xlarge**
- **ml.p5.48xlarge**
- **ml.p5e.48xlarge**
- **ml.p5en.48xlarge**
- **ml.trn1.32xlarge**

- **ml.trn2.48xlarge**
- **ml.p6-b200.48xlarge**
- **ml.c6i-32xlargesc**

UltraServers

- **ml.p6e-gb200.36xlarge**
- **ml.p6e-gb200.72xlarge**

> **Note**
>
> The availability of instance types may change over time. For the most up-to-date information on available instance types according to Region, as well as their respective prices, see SageMaker Pricing. Scroll down to the **Amazon SageMaker HyperPod flexible training plans** section under **On-Demand Pricing**. Select a Region to view the list of available instance types.

The availability across multiple regions allows to choose the most suitable location for workloads, considering factors such as data residency requirements and proximity to other AWS services.

> **Important**
>
> - You can use SageMaker training plans to reserve instances with the following reservation duration and instance quantity options.
>   - Reservation durations are available in 1-day increments from 1 to 182 days.
>   - The reservation instance quantity options are 1, 2, 4, 8, 16, 32 or 64 instances.
> - Make sure that your Training Jobs or HyperPod service quotas allow a maximum number of instances per instance type that exceeds the number of instances specified in your plan. To view your current quotas or request a quota increase, see the section called "Quotas and pricing".

UltraServers in SageMaker AI

UltraServers in SageMaker AI offer a set of instances interconnected via a high bandwidth network domain. For example, the P6e-GB200 UltraServer connects up to 18 `p6e-gb200.36xlarge` instances under one NVIDIA NVLink domain. With 4 NVIDIA Blackwell GPUs per instance, each P6e-GB200 UltraServer supports 72 GPUs, so you can run your largest AI workloads with high performance on SageMaker AI.

When you use UltraServers with SageMaker AI, you get performance combined with SageMaker AI's managed infrastructure, built-in fault resiliency features, integrated monitoring capabilities, and native integration with other SageMaker AI and AWS services. This integration allows you to focus on model development and deployment while SageMaker AI handles the undifferentiated heavy lifting of managing AI infrastructure.

> **Note**
>
> UltraServers are available only in the Dallas Local Zone (us-east-1-dfw-2a), which is an extension of the US East (N. Virginia) Region. For more information, see Getting started with AWS Local Zones

Considerations

Consider the following when using UltraServers with SageMaker AI:

- You can use UltraServers for both SageMaker HyperPod and SageMaker training jobs.
- You can only purchase UltraServers in full units. For more information about instance and pricing information, see Amazon SageMaker HyperPod flexible training plans in Amazon SageMaker AI pricing.
- If you're using UltraServers with HyperPod, HyperPod automatically adds topology labels to your resources to help you with resource allocation. For more information, see Using topology-aware scheduling in Amazon SageMaker HyperPod.
- SageMaker AI and UltraServers offer various capabilities that enhance the resiliency of your workloads, including preemptive checks and automatic fault detection and mitigation. Depending on what the issue is, SageMaker AI can run actions to recover your workloads, such as restarting instances, replacing failed instances with spares, and replacing failed UltraServers.

- For added resilience, you can configure instances within an UltraServer to be used as spares. Keeping a spare instance within the UltraServer ensures that SageMaker AI can quickly respond to an instance failure while minimizing any impact to your jobs. We recommend that you keep one spare instance per UltraServer. You don't have to reserve any spare instances, but this might hinder support options and slow down failure recovery. You purchase UltraServers by wholes, so the number of spares that you reserve doesn't affect pricing.
- To see the status and instances within an UltraServer, use the ListTrainingPlans API operation or the AWS console to see training plans. Using these tools, you can see the total number of available instances, instances currently in use, unhealthy instances, the number of configured spares, and other information. Possible health statuses are `ok`, `impaired`, and `insufficient-data`.

SageMaker training plans search behavior

When searching for a training plan offering, SageMaker training plans use the following approach to maximize resource availability and flexibility for users, even when demand is high and Reserved Capacity blocks are scarce:

- **Initial continuous search**: SageMaker training plans first attempt to find a single, continuous block of Reserved Capacity that matches the specified duration within the start and end dates, while meeting all other specified criteria, including target resource, requested instance type, and number of instances.
- **Two-block search**: SageMaker training plans don't return a "no capacity" result if a single continuous Reserved Capacity block meeting all criteria is unavailable. Instead, it automatically attempts to fulfill the request using two separate Reserved Capacity blocks, splitting the total duration across two time segments.

  This two-block approach provides more flexibility in resource allocation, potentially securing high-demand instances that would otherwise be unavailable.

> **Note**
>
> SageMaker training plans return up to three offerings of one or two segments. For example, for a 48-hour duration plan, SageMaker training plans might offer a plan with two 24-hour blocks, one continuous 48-hour block, and two blocks with uneven duration.

Considerations

> **Important**
>
> - Training plans cannot be modified once purchased.
> - Training plans cannot be shared across AWS accounts or within your AWS Organization.

- When searching for training plan offerings, SageMaker training plans adapts its search strategy based on the target resources:

  For SageMaker HyperPod clusters:

  - Offerings are limited to a single Availability Zone (AZ).
  - This ensures consistent network performance and data locality within the cluster.

  For SageMaker training jobs:

  - Offerings can span multiple Availability Zones.
  - This is particularly relevant when the plan offering contains multiple discontinuous reserved capacities.
  - For example, a plan might include capacity in AZ-A for one Reserved Capacity block and AZ-B for another. SageMaker training plans can automatically move workloads across Availability Zones (AZs) based on resource availability.

    This multi-AZ approach for training jobs provides greater flexibility in resource allocation, increasing the chances of finding suitable capacity for your workload. However, you should be aware that your jobs may run in different AZs during different parts of your reservation period.
- When presented with a two-block offering, users should carefully consider if this split allocation meets their workload requirements. This may require adjusting job scheduling or workload distribution to accommodate the non-continuous nature of the reservation.

IAM for SageMaker training plans

SageMaker training plans requires specific permissions for two distinct roles::

1. **Plan creator role**: Users assigned the *Plan Creator* role need permissions to search training plan offerings, create new training plans, list and describe training plans.

2. **Plan user role**: Users with the *Plan User* role require permissions to use training plans in SageMaker training jobs or when creating and updating SageMaker HyperPod clusters.

Before using SageMaker training plans, update permissions based on your access method:

- For AWS Management Console or SageMaker SDKs users: Update the permissions of the IAM role configured for the console user or API user.
- For AWS CLI users: Ensure your AWS CLI profile is correctly configured with the appropriate credentials and permissions.
- For Studio application users such as JupyterLab, set permissions on the execution role associated with the space used by the application.

You can set these permissions using either a managed policy or individual more granular permissions.

For information about how to update the permissions policy for a role, see Update permissions for a role. For information about how to find and update an execution role, see Get your execution role.

> **Note**
>
> Administrators should carefully consider which users need the ability to create training plans and assign permissions accordingly.

Managed policies

- For plan creators: `AmazonSageMakerTrainingPlanCreateAccess` provides access to create and manage training plans.
- For plan users: `AmazonSageMakerFullAccess` includes the permissions to use training plans.

> **Note**
>
> - The `AmazonSageMakerFullAccess` managed policy is designed as an ease-of-use policy primarily for experimentation purposes. While it provides broad access to SageMaker AI features, including the use of training plans, it's important to note:

- This policy is not recommended for production environments due to its broad permissions.
- It does not include permissions for creating training plans, as `CreateTrainingPlan` is considered an administrative action requiring upfront payment.
- For production use cases, we strongly recommend creating custom policies that adhere to the principle of least privilege, granting only the specific permissions required for each role.

Individual permissions

The following list details the granular permissions that should be set in the IAM policy statements of a role, based on the specific actions a user needs to perform with SageMaker training plans:

Training plans list of permissions

- `SearchTrainingPlanOfferings`: This permission allows users to search for available training plan offerings.

```
{
  "Sid": "SearchTrainingPlanOfferingsPermissions",
  "Effect": "Allow",
  "Action": [
    "sagemaker:SearchTrainingPlanOfferings"
  ],
  "Resource": "*"
}
```

- `CreateTrainingPlan`: This permission allows users to create new training plans.

> **Note**
>
> You must also include permissions for `CreateReservedCapacity` and `AddTags`, and specify both `training-plan` and `reserved-capacity` resource types.

```
{
  "Sid": "CreateTrainingPlanPermissions",
  "Effect": "Allow",
```

```
  "Action": [
    "sagemaker:CreateTrainingPlan",
    "sagemaker:CreateReservedCapacity",
    "sagemaker:AddTags"
  ],
  "Resource": [
    "arn:aws:sagemaker:*:*:training-plan/*",
    "arn:aws:sagemaker:*:*:reserved-capacity/*"
  ]
}
```

- `DescribeTrainingPlan` : This permission allows users to view details of existing training plans.

```
{
  "Sid": "DescribeTrainingPlanPermissions",
  "Effect": "Allow",
  "Action": [
    "sagemaker:DescribeTrainingPlan"
  ],
  "Resource": [
    "arn:aws:sagemaker:::training-plan/*"
  ]
}
```

- `ListTrainingPlans`: This permission allows users to list all training plans in their AWS account.

```
{
  "Sid": "ListTrainingPlansPermissions",
  "Effect": "Allow",
  "Action": [
    "sagemaker:ListTrainingPlans"
  ],
  "Resource": "*"
}
```

Individual permissions per type of user

This section provides a detailed breakdown of the individual permissions required for each role, as mentioned in the the section called “IAM for SageMaker training plans” section.

For plan creators, the following permissions are necessary:

- `sagemaker:SearchTrainingPlanOfferings`
- `sagemaker:CreateTrainingPlan`
- `sagemaker:CreateReservedCapacity`
- `sagemaker:AddTags`
- `sagemaker:DescribeTrainingPlan`
- `sagemaker:ListTrainingPlans`

Plan users require these permissions:

- `sagemaker:CreateTrainingJob` (for SageMaker Training Job)
- `sagemaker:CreateCluster` and `sagemaker:UpdateCluster` (for SageMaker HyperPod)
- Access to the `training-plan` and `reserved-capacity` resources; When configuring IAM policies for SageMaker training plans, include permissions for both `training-plan` and `reserved-capacity` resources. These resources are required for both SageMaker training jobs and SageMaker HyperPod clusters. This allows your IAM roles to interact with SageMaker training plans resources and manage Reserved Capacity.
  - For SageMaker training jobs, ensure your policy includes the `"arn:aws:sagemaker:::training-plan/"` and `"arn:aws:sagemaker:::reserved-capacity/"` resource ARNs.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob"
        ...// other existing known required actions
      ],
      "Resource": [
        "arn:aws:sagemaker:::training-job/",
        "arn:aws:sagemaker:::training-plan/",
        "arn:aws:sagemaker:::reserved-capacity/*"
      ]
    }
```

```
  ]
}
```

Similarly, for SageMaker HyperPod configurations, include these same ARNs in addition to the cluster-specific resources.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateCluster",
        "sagemaker:UpdateCluster",
        ...// other existing known required actions
      ],
      "Resource": [
        "arn:aws:sagemaker:::cluster/",
        "arn:aws:sagemaker:::training-plan/",
        "arn:aws:sagemaker:::reserved-capacity/*"
      ]
    }
  ]
}
```

Training plans creation

To reserve compute capacity using the SageMaker training plans capability, follow these steps:

1. **Identify your target resource:** Begin by determining whether you need capacity for SageMaker training jobs or SageMaker HyperPod clusters.
2. **Specify your capacity requirements :** Define your capacity needs in detail. This includes selecting the appropriate instance type for your workload, determining the number of instances required, and specifying the duration of use. For information about the supported instance types in a given AWS Region, duration, and quantity options, see the section called “Supported instance types, AWS Regions, and pricing”.
3. **Search for available training plan offerings:** Once you specify your requirements, use SageMaker training plans' search functionality to find available training plan offerings across one or more segments. Each offering includes details such as start time, specific availability

zone for Reserved Capacity, and plan price. Review these offerings, considering factors like cost-effectiveness, geographical preferences, and alignment with your specified needs.

If no suitable plan is available, adjust your search criteria and look for a new set of offerings.

4. **Create a training plan based on a suitable offering:** After identifying a suitable offering, proceed to create your training plan. This process involves selecting your chosen offering and initiating the reservation.

   - The training plan reservation creates an invoice.
   - The payment for the total amount is collected as part of the fulfillment process. Once the payment is completed, the plan is ready for scheduling your SageMaker training jobs or creating HyperPod clusters.

   To learn about how to use training plans for your SageMaker training jobs , see the section called “Training plans utilization for SageMaker training jobs”.

   To learn about how to use training plans for your HyperPod clusters, see the section called “Training plans utilization for SageMaker HyperPod clusters”.

You can create a training plan using either the SageMaker AI console or programmatic methods. The SageMaker AI console offers a visual, graphical interface with a comprehensive view of your options, while programmatic creation can be done using the AWS CLI or SageMaker SDKs to interact directly with the training plans API.

For step-by-step console instructions and detailed API references, refer to the respective sections in this documentation.

Topics

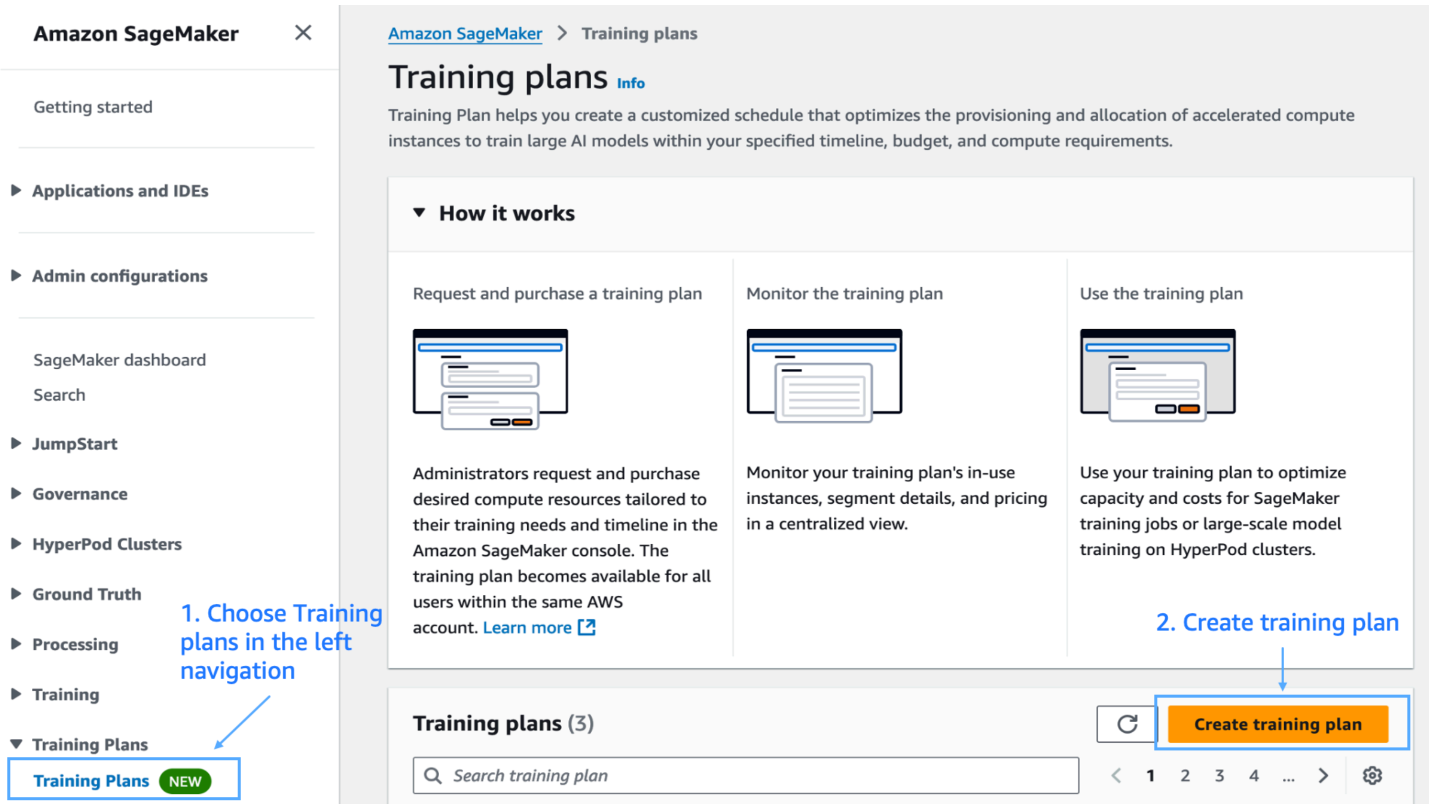
- SageMaker training plans creation using the SageMaker AI console
- SageMaker training plans creation using the SageMaker API, or AWS CLI

SageMaker training plans creation using the SageMaker AI console

SageMaker training plans offer a convenient way to create training plans through the SageMaker AI console UI, allowing users to easily schedule their machine learning training resources. This guide walks you through the process of creating a training plan for SageMaker training jobs and SageMaker HyperPod clusters using the SageMaker AI console. By following these steps, you will search for training plan offerings, review available options, and purchase the plan that best fits your needs.

To create a training plan visually using a UI:

1. Start by navigating to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Training Plans** in the left pane menu.
3. From there, choose the **Create training plan** button in the main content area to start the process of setting up your customized training schedule.



Next, search for plan offerings that match your compute requirements.

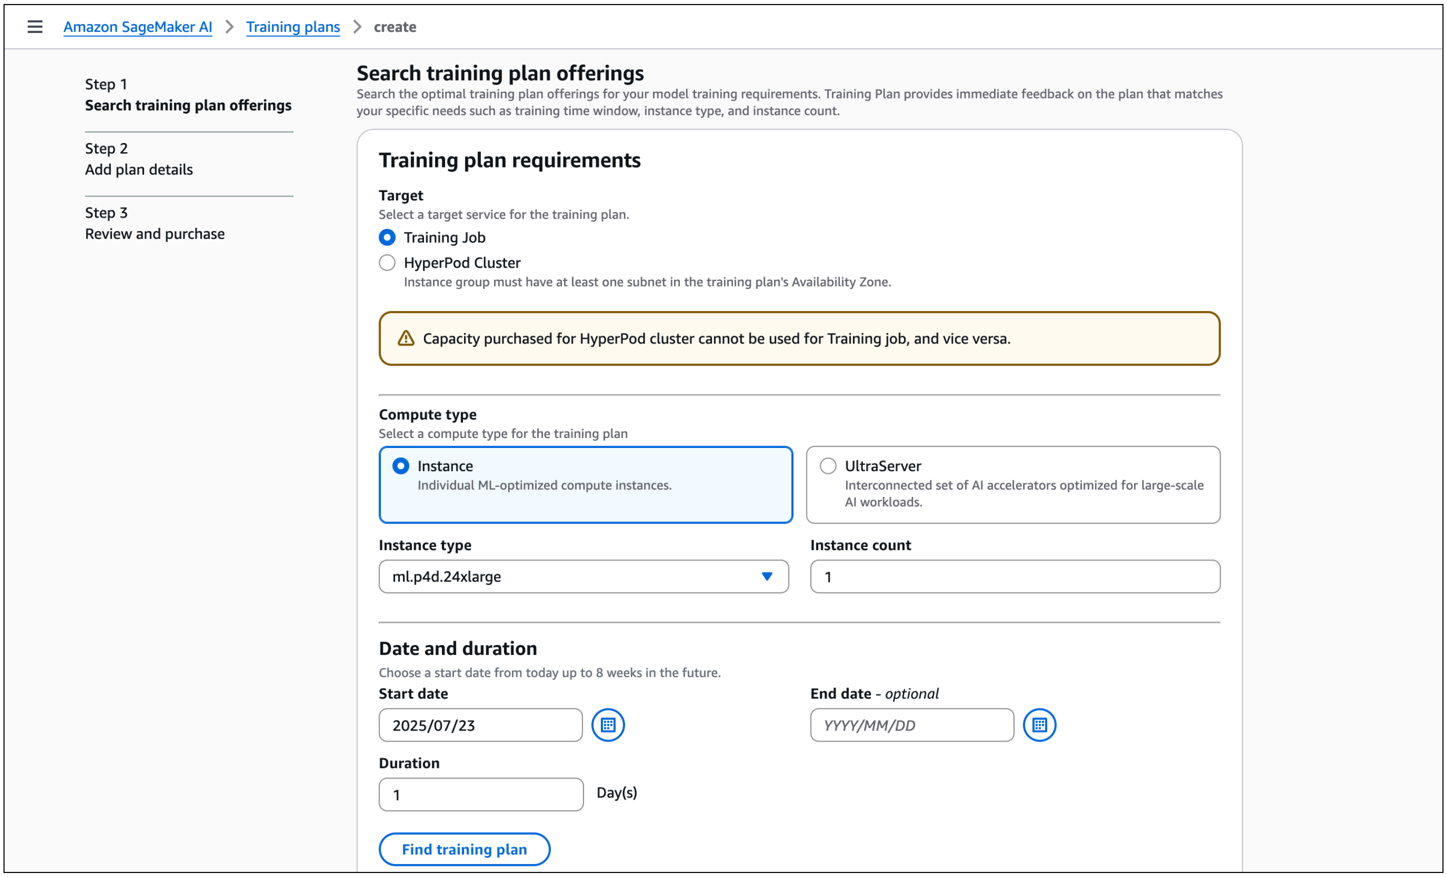
- [Reserve the best training plan]()
- [List training plans]()
- [View training plan details]()

Search training plan offerings

After you choose **Training Plans** in the left pane of the SageMaker AI console, and then **Create training plan**, a **Find training plan** form opens up. This form allows you to specify your requirements and search for suitable training plan offerings.

Follow these steps to complete the form:

1. Identify your **Target**: Training plans are specific to their target resource. Specify whether you want to use a plan to run SageMaker training jobs or SageMaker HyperPod clusters.
2. For **Compute type**, you can choose between **Instance** or **UltraServer**. UltraServers are connect multiple Amazon EC2 instances using a low-latency, high-bandwidth accelerator interconnect. For more information, see Amazon EC2 UltraServers. To learn about how you can use UltraServers with SageMaker AI, see UltraServers in SageMaker AI.
3. Choose your preferred **Instance type** and **Instance count**: For available instance types in a given AWS Region, duration, and quantity options, see the section called "Supported instance types, AWS Regions, and pricing".
4. Define your time parameters: Choose your desired start and end dates, and specify the plan duration within this window.
5. Choose **Find training plans**.



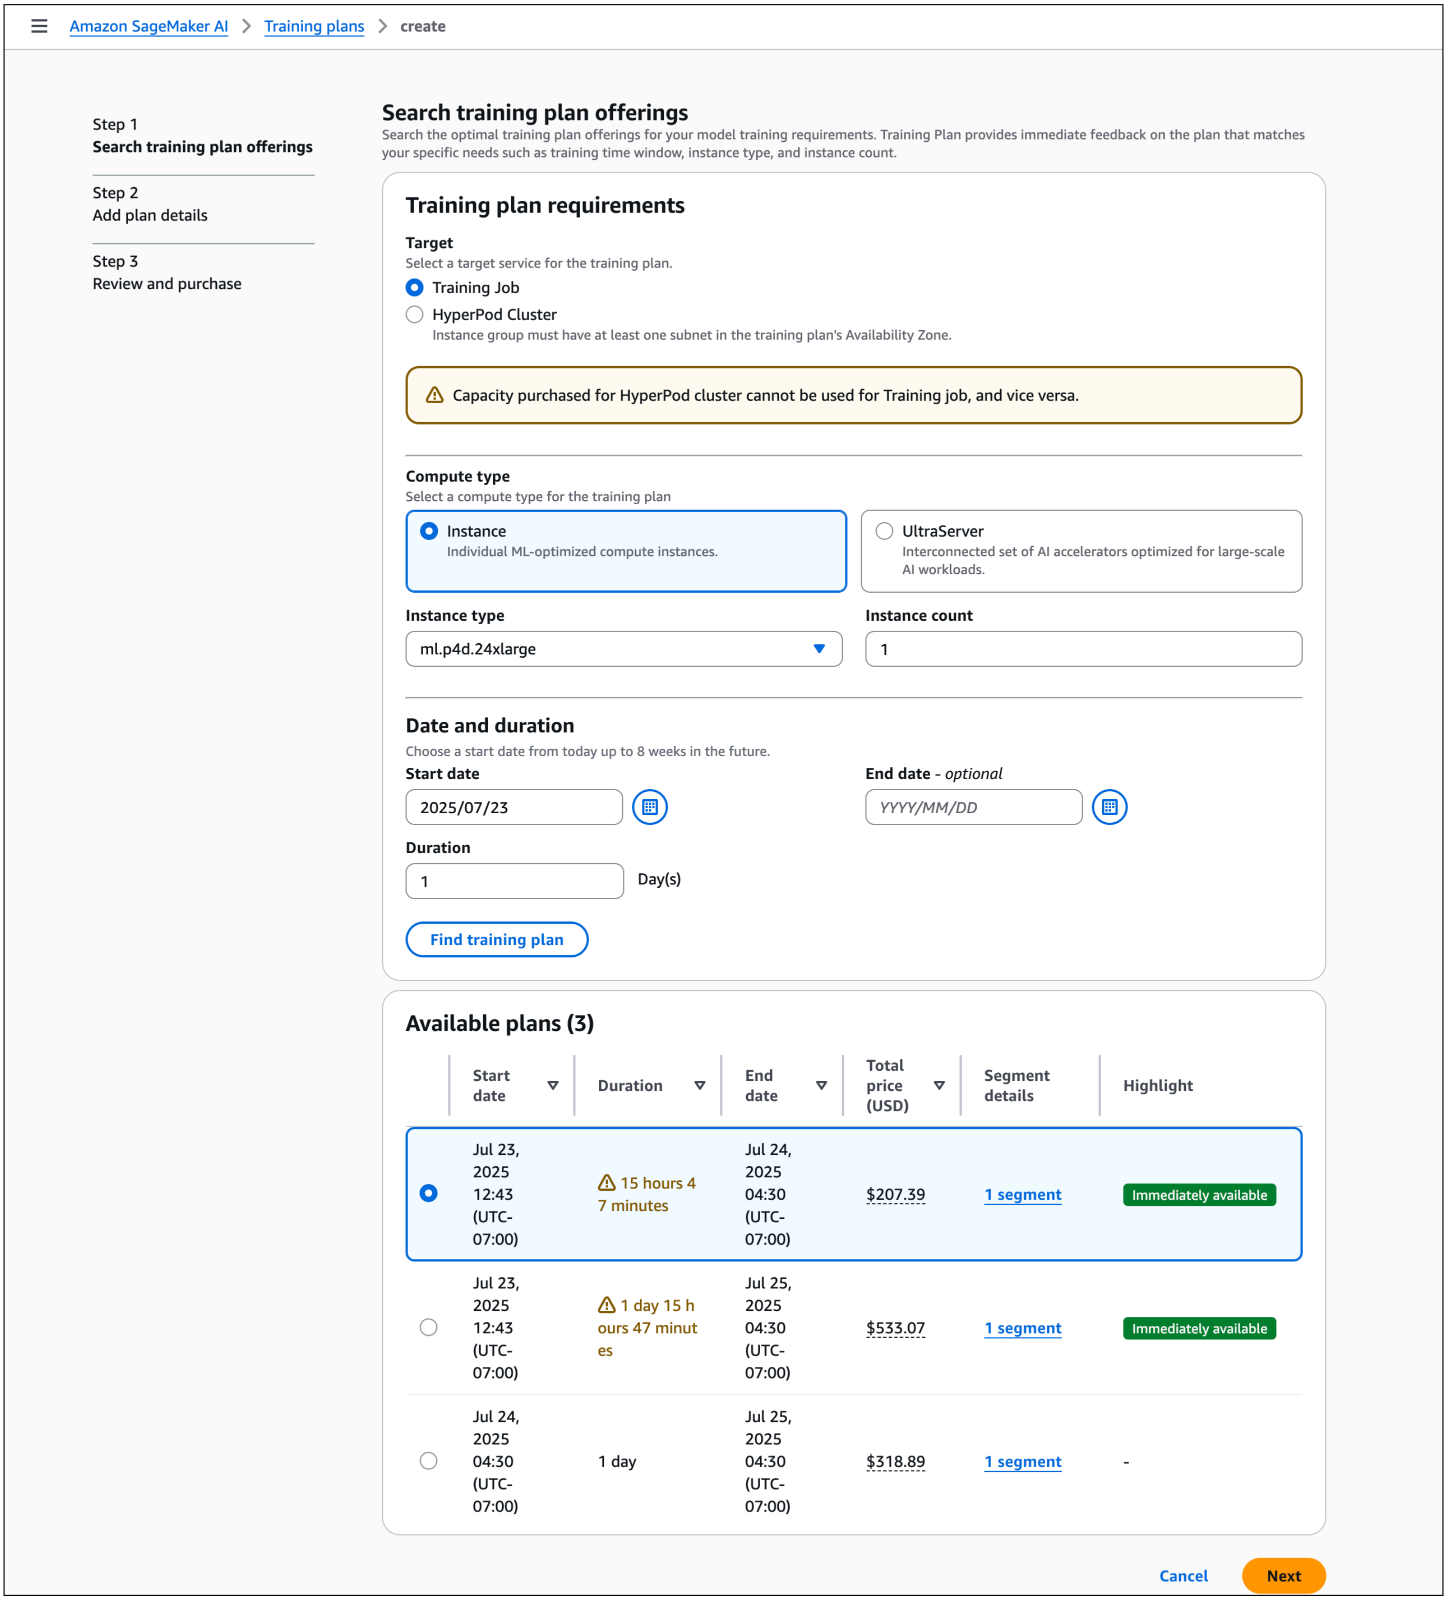
SageMaker training plans search for offerings that match your capacity requirements. When matches are found within your specified time frame, they appear at the bottom of the page. Each training plan offering includes the following details:

- Total plan duration
- Start and end dates
- Total upfront price:

  Hover over the price to view the detailed breakdown of instance hourly rate, instance count, and total hours
- Total number of plan segments

Clicking the segment detail link opens a modal view with segment-specific details:

- Duration
- Start and end dates
- Availability zone



If no suitable plans are found or the available plans don't meet your needs, adjust your search criteria by modifying the parameters in the **Training plans requirements** form. Once you find a suitable offering, select it and choose **Next** to continue to the plan reservation page. On this page, you can name your plan, and then review and confirm your selection before finalizing your reservation.

> **Note**
>
> Plans marked `Immediately available` will start within 30 minutes, provided payment is completed no less than 5 minutes before the scheduled start time.

Reserve the best training plan

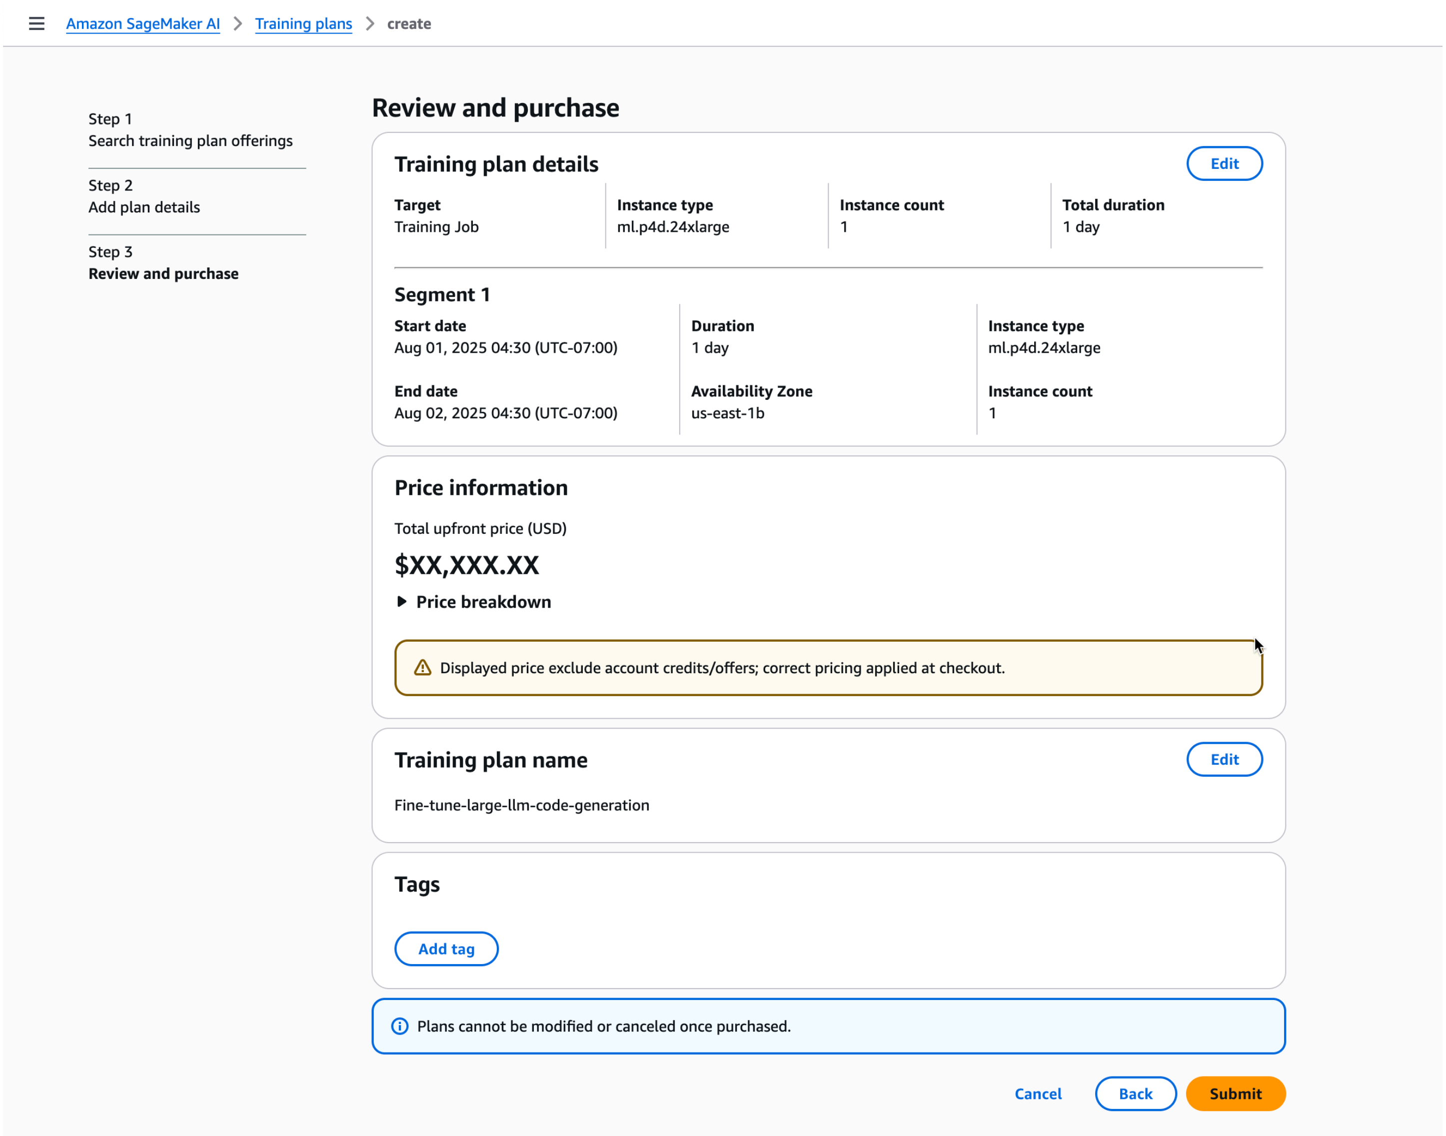
The search of a training plan has returned offerings that fit your capacity needs and budget.

1. Enter a name for your plan and then choose **Next**.
2. Review and **Submit** your purchase order.

> **Important**
>
> - Training plans cannot be modified once purchased.
> - Training plans cannot be shared across AWS accounts or within your AWS Organization.

After submitting your order

- The training plan initially appears as `Pending` in your training plan list.
- An invoice is generated automatically upon order receipt.
- The total payment is collected during the fulfillment process.
- Once payment is successfully processed, the plan status changes to `Scheduled` and the plan becomes available for use.

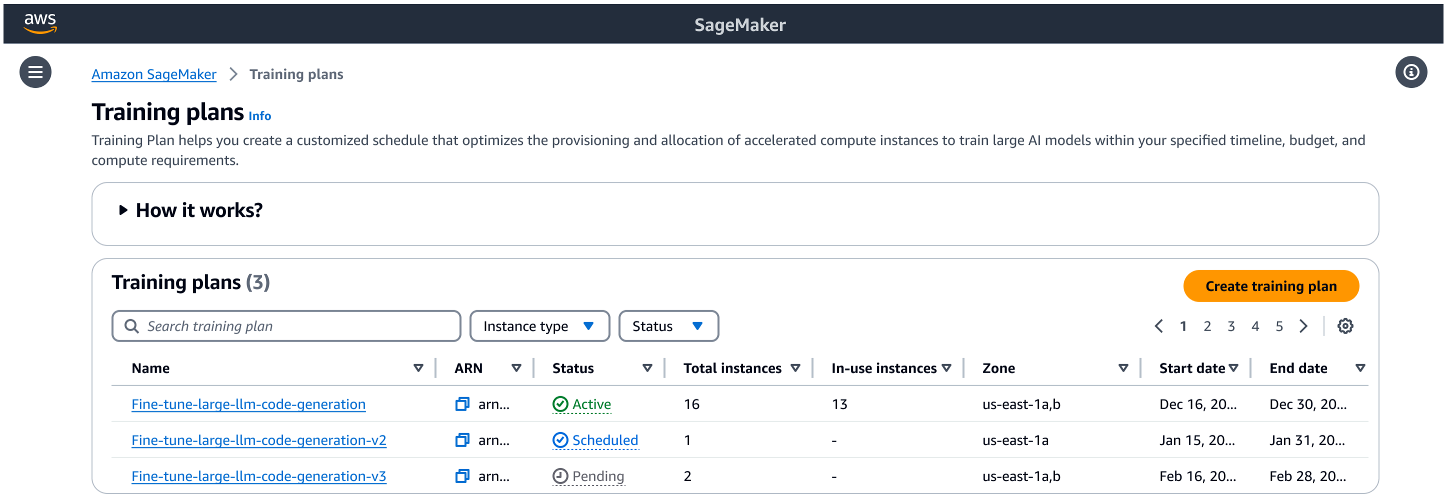


List training plans

To view your training plans:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Training Plans** in the left pane menu. This displays a list of all your training plans, including their names, status, target resource type, and other key details.

   After purchasing a plan, you are directed to this list. Newly created plans appear with a `Pending` status until payment is completed. The status is typically updated within a few minutes of payment processing.



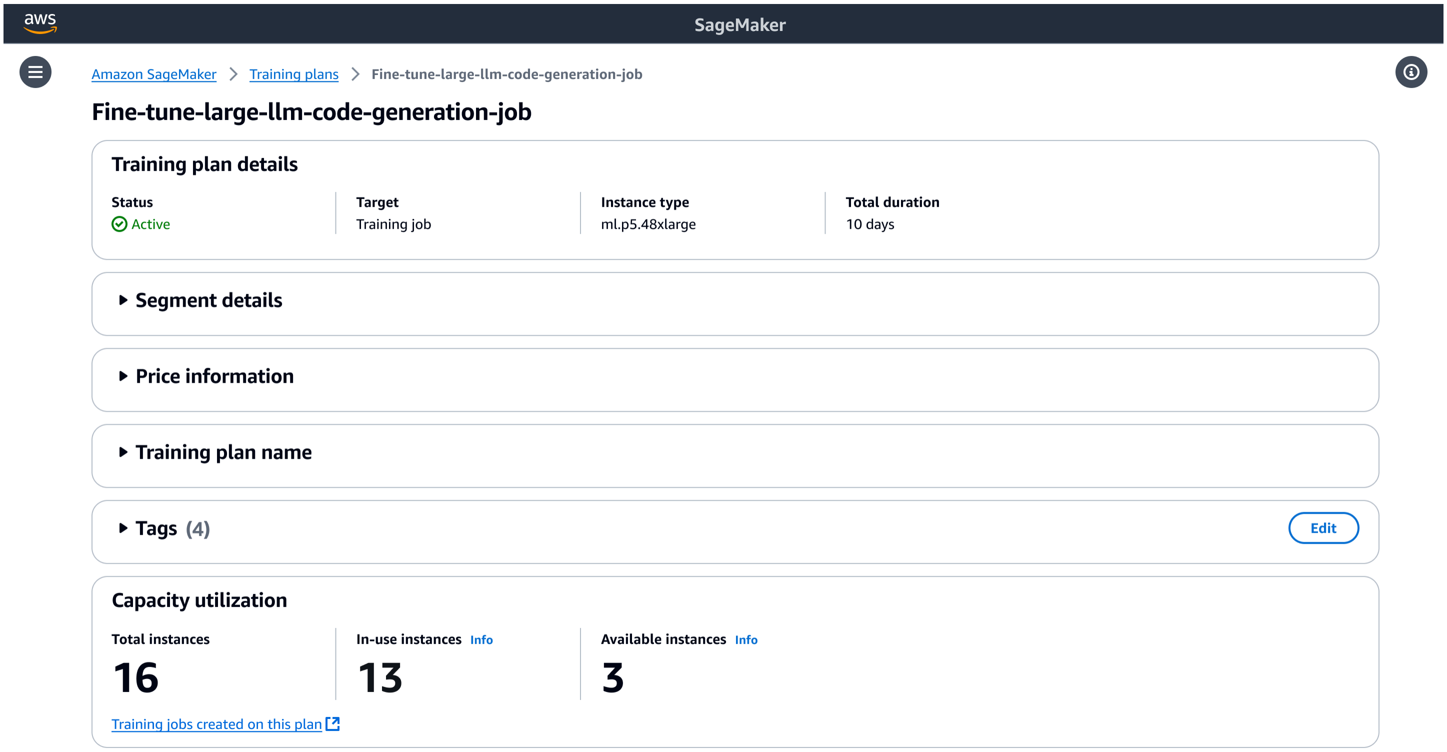
View training plan details

From the training plans list, follow a plan's name to view its details. Specifically, you can check your current capacity usage, and list your workloads in your plan's details page.

The details page shows:

- The training plan overview: Status, target, instance type, and duration.
- Expandable sections for segment details, pricing, plan name, and tags.
- Capacity utilization:
  - Total: The total number of instances reserved in this training plan.
  - In-use: The number of instances currently in use from this training plan.
  - Available instances: The number of instances currently available for use in this training plan.

At the bottom of the page, a link allows you to view either the training jobs or the list of SageMaker HyperPod cluster instance groups associated with this plan, depending on its target resource.



SageMaker training plans creation using the SageMaker API, or AWS CLI

SageMaker training plans support the programmatic creation of training plans through its API. You can interact with the training plans API using the AWS CLI or SageMaker SDKs.

SageMaker training plans's API actions provide a comprehensive workflow for managing training plans programmatically:

- **`SearchTrainingPlanOfferings`:** Enables users to query and discover available compute resources by specifying parameters like instance type, count, and desired time window. The API returns a ranked list of training plan offerings that best match the user's requirements.
- **`CreateTrainingPlan`:** Allows reservation of a specific training plan offering, transforming a potential compute capacity into scheduled reserved capacities with a unique training plan ARN.
- **`ListTrainingPlans`:** Provides a method to retrieve and review all existing training plans in a user's AWS account, with optional filtering and sorting capabilities.
- **`DescribeTrainingPlan`:** Offers detailed insights into a specific training plan, including its lifecycle stages from `Pending` to `Active` to `Expired`.

Search training plan offerings

To create a training plan, start by calling the `SearchTrainingPlanOfferings` API operation, passing your plan requirements (such as instance type, count, and desired time window) as input parameters. Training plans are specific to their target resource. Ensure that you specify which target resource the plan will be used for (`training-job` or `hyperpod-cluster`). The API returns a list of available offerings that match your requirements. If no suitable offerings are found, you may need to adjust your requirements and search again.

This API call retrieves the training plan offerings that best meet your capacity needs. Each `TrainingPlanOffering` returned in the response is identified by a unique offering ID. The first offering in the list represents the best match for your requirements. If no suitable training plan is available within your specified dates, the list is empty. Adjust your search criteria and look for a new set of offerings.

- Reservation durations are available in 1-day increments from 1 to 182 days.
- The reservation instance quantity options are 1, 2, 4, 8, 16, 32 or 64 instances.

To learn about the list of available instances supported by SageMaker training plans, see Supported instance types, AWS Regions, and pricing.

The following example uses an AWS CLI command to request training plan offerings with a specified instance type, count, and time information.

```
# List training plan offerings with instance type, instance count, duration in hours,
 start time after, and end time before.
aws sagemaker search-training-plan-offerings \
--target-resources "training-job" \
--instance-type "ml.p4d.24xlarge" \
--instance-count 1 \
--duration-hours 15 \
--start-time-after "1737484800"
```

```
--end-time-before "1737657600"
```

This JSON document is a sample response from the SageMaker training plans API. The response provides information about multiple available training plan offerings that match the specified capacity requirements. It includes three distinct offerings with varying durations, upfront fees, and start/end times, all using the same instance type and targeting training jobs.

```

                }
            ]
        }
    ]
}
```

The following is a sample command of how to use the AWS CLI to search for training plan offerings that include UltraServers.

```
aws sagemaker search-training-plan-offerings \
--ultra-server-type ml.c6i-32xlargesc \
--ultra-server-count 1 \
--duration-hours 24 \
--target-resources hyperpod-cluster
```

```
--start-time-after "1737484800" \
--end-time-before "1737657600"
```

```
{
    "TrainingPlanOfferings": [
        {
            "TrainingPlanOfferingId": "tpo-SHA-256-hash-value",
            "TargetResources": [
                "training-job"
            ],
            "RequestedStartTimeAfter": "2025-07-21T16:59:25.760000+00:00",
            "DurationHours": 24,
            "DurationMinutes": 0,
            "UpfrontFee": "0.24",
            "CurrencyCode": "USD",
            "ReservedCapacityOfferings": [
                {
                    "ReservedCapacityType": "UltraServer",
                    "UltraServerType": "ml.u-p6e-gb200x72",
                    "UltraServerCount": 1,
                    "InstanceType": "ml.p6e-gb200.36xlarge",
                    "InstanceCount": 18,
                    "AvailabilityZone": "us-east-2a",
                    "DurationHours": 24,
                    "DurationMinutes": 0,
                    "StartTime": "2025-07-22T11:30:00+00:00",
                    "EndTime": "2025-07-23T11:30:00+00:00"
                }
            ]
        }
    ]
}
```

The following sections define the mandatory and optional input request parameters for the `SearchTrainingPlanOfferings` API operation.

Required parameters

When calling the [`SearchTrainingPlanOfferings`]() API to list training plan offerings that meet your requirements, you must provide the following values:

- `TargetResources`: The target resources (`training-job` or `hyperpod-cluster`) for which the plan will be used. The default value is `training-job`. Training plans are specific to their target resource.
  - A training plan designed for SageMaker training jobs can only be used to schedule and run training jobs.
  - A training plan for HyperPod clusters can be used exclusively to provide compute resources to a cluster's instance group.
- `InstanceType`: The type of instance to provision. The `InstanceType` must be of a supported type.

  To learn about the list of available instances supported by SageMaker training plans, see Supported instance types, AWS Regions, and pricing.
- `InstanceCount`: The number of instances to provision. If the number of instances is greater than 1, it should be a power of 2.
- `DurationHour`: The total duration of your requested plan in hours. The `DurationHour` is rounded up to the nearest multiple of 24.

Optional parameters

The following sections provide details on some optional parameters that you can pass to your `SearchTrainingPlanOfferings` API request.

- `StartTimeAfter`: Specify the requested start time of the plan. The `StartTimeAfter` should be a `timestamp` or an `ISO 8601 date/time` value in the future.
- `EndTimeBefore`: Specify the requested end time of the plan in a `timestamp` or an `ISO 8601 date/time` format. The `EndTimeBefore` should be at least 24 hours after the start time .
- `UltraServerType` : Specify the type of UltraServer to search for. For more information about UltraServers, see UltraServers in SageMaker AI.
- `UltraServerCount`: Specify the number of UltraServers to search for.

Reserve the best training plan

After reviewing the available training plan offerings that best match your requirements, you can reserve a specific plan by calling the `CreateTrainingPlan` API operation. When created, the plan initially enters a `Pending` state and remains there until the reservation process is complete.

The response to the API call returns a training plan Amazon Resource Name (ARN). Make a note of this ARN for tracking and monitoring purposes later on. The training plan reservation is fulfilled asynchronously in the backend. The payment for the total amount is automatically collected as part of the fulfillment process. Once the payment transaction is completed and the requested reserved capacities are secured, the training plan is set to the `Scheduled` state, and is ready for scheduling.

> **Important**
>
> - Training plans cannot be modified once purchased.
> - Training plans cannot be shared across AWS accounts or within your AWS Organization.

The following example uses the an AWS CLI command to request a specific training plan, passing the plan ID as a parameter.

```
aws sagemaker create-training-plan \
--training-plan-offering-id "tpo-SHA-256-hash-value" \
--training-plan-name "name" \
```

This JSON document is a sample response from the SageMaker training plans API. The response contains the Amazon Resource Name (ARN) of the training plan that has been successfully created.

> **Note**
>
> The training plan remains in a `Pending` status until the fulfillment process is complete.

```
{
   "TrainingPlanArn":"arn:aws:sagemaker:us-east-1:123456789123:training-plan/large-
models-fine-tuning"
}
```

The following sections define the mandatory and optional input request parameters for the [CreateTrainingPlan](#) API operation.

Required parameters

When calling [CreateTrainingPlan](#) API to reserve a particular training plan, you must provide the following values:

- `TrainingPlanOfferingId`: The ID of the plan you are choosing. You can retrieve the ID of a plan offering in the response of your `SearchTrainingPlanOfferings` API call. Its format should start with `pto-*`.
- `TrainingPlanName`: The name of the plan you are creating.

List training plans

You can list all the training plans that have been created in your AWS account and Region by calling the `ListTrainingPlans` API.

The following example uses an AWS CLI command to retrieve the list of your training plans.

```
aws sagemaker list-training-plans \
--start-time-after "2024-09-26T00:00:01.000Z"
```

This JSON document is a sample response from the SageMaker training plans API. The response provides details about one training plan that has been successfully created and reserved.

```
{
   "TrainingPlanSummaries": [
      {
         "AvailableInstanceCount": 2,
         "CurrencyCode": "USD",

         "UpfrontFee": "xxxx.xx"
      }
   ]
}
```

The following sections provide details of some optional parameters that you can pass to your `ListTrainingPlans` API request.

Optional parameters

The following sections provide details on some optional parameters that you can pass to your `ListTrainingPlans` API request.

- `StartTimeAfter`: The start time of the actual time range of the listed plans, specified as a `timestamp` or an `ISO 8601 date/time`.
- `StartTimeBefore`: The end time of the actual time range of the listed plans, specified as a `timestamp` or an `ISO 8601 date/time`.
- `Filters`: Criteria used to filter the results, with up to 5 Name-Value pairs where "Name" is the name of a field of a TrainingPlanSummary and "Value" is the value to consider for the filter. For example `Name=Status,Value=Active`.

The following example uses an AWS CLI command to retrieve your list of training plans, using some of the optional parameters described above.

```
aws sagemaker list-training-plans --max-results 10 --sort-by StartTime --sort-order
 Descending --start-time-after 13000000 --filters Name=Status,Value=Active
```

View training plan details

To monitor the status or retrieve details of a training plan, you can use the `DescribeTrainingPlan` API. The API response includes a `Status` field, which reflects the current state of the training plan:

- If the plan purchase fails, the status is set to `Failed`.
- Upon successful payment, the status transitions from `Pending` to `Scheduled`, based on the plan's start date.
- When the plan reaches its start date, the status changes to `Active`.
- For plans with multiple discontinuous reserved capacities, the status reverts to `Scheduled` between active periods, until the start date of the next reserved capacity.
- After the plan's end date, the status becomes `Expired`.

Once the status is `Scheduled`, you can utilize the capacity reserved in the plan for your SageMaker training jobs or HyperPod cluster workloads.

Note

- Training jobs associated with the plan remain in `Pending` status until the plan becomes `Active`.
- For HyperPod clusters using a training plan for compute capacity, the instance group status appears as `InService` once created.

The following example uses an AWS CLI command to retrieve the details of a training plan by its name.

```
aws sagemaker describe-training-plan \
--training-plan-name "name"
```

This JSON document is a sample response from the SageMaker training plans API. This response provides details about a training plan that has been successfully created.

      }
```

The following sections define the mandatory input request parameter for the `DescribeTrainingPlan` API operation.

Required parameters

- `TrainingPlanName`: The name of the training plan you want to describe.

Training plans utilization for SageMaker training jobs

You can use a SageMaker training plans for your training jobs by specifying the plan of your choice when creating a training job.

> **Note**
>
> The training plan must be in the `Scheduled` or `Active` status to be used by a training job.

If the required capacity is not immediately available for a training job, the job waits until it becomes available, or until the `StoppingCondition` is met, or the job has been `Pending` for capacity for 2 days, whichever comes first. If the stopping condition is met, the job is stopped. If a job has been pending for 2 days, it is terminated with an `InsufficientCapacityError`.

> **Important**
>
> **Reserved Capacity termination process:** You have full access to all reserved instances until 30 minutes before the Reserved Capacity end time. When there are 30 minutes remaining in your Reserved Capacity, SageMaker training plans begin the process of terminating any running instances within that Reserved Capacity.
> To ensure you don't lose progress due to these terminations, we recommend checkpointing your training jobs.

Checkpoint your training job

When using SageMaker training plans for your SageMaker training jobs, ensure to implement checkpointing in your training script. This allows you to save your training progress before a Reserved Capacity expires. Checkpointing is especially important when working with reserved capacities, as it enables you to resume training from the last saved point if your job is interrupted between two reserved capacities or when your training plan reaches its end date.

To achieve this, you can use the `SAGEMAKER_CURRENT_CAPACITY_BLOCK_EXPIRATION_TIMESTAMP` environment variable. This variable helps determine when to initiate the checkpointing process. By incorporating this logic into your training script, you ensure that your model's progress is saved at appropriate intervals.

Here's an example of how you can implement this checkpointing logic in your Python training script:

```
import os
import time
from datetime import datetime, timedelta

def is_close_to_expiration(threshold_minutes=30):
    # Retrieve the expiration timestamp from the environment variable
    expiration_time_str = 
 os.environ.get('SAGEMAKER_CURRENT_CAPACITY_BLOCK_EXPIRATION_TIMESTAMP', '0')

    # If the timestamp is not set (default '0'), return False
    if expiration_time_str == '0':
        return False

    # Convert the timestamp string to a datetime object
    expiration_time = datetime.fromtimestamp(int(expiration_time_str))

    # Calculate the time difference between now and the expiration time
    time_difference = expiration_time - datetime.now()

    # Return True if we're within the threshold time of expiration
    return time_difference < timedelta(minutes=threshold_minutes)

def start_checkpointing():
    # Placeholder function for checkpointing logic
    print("Starting checkpointing process...")
    # TODO: Implement actual checkpointing logic here
    # For example:
    # - Save model state
    # - Save optimizer state
    # - Save current epoch and iteration numbers
    # - Save any other relevant training state

# Main training loop
num_epochs = 100
final_checkpointing_done = False
for epoch in range(num_epochs):
    # TODO: Replace this with your actual training code
    # For example:
    # - Load a batch of data
    # - Forward pass
```

```
    # - Calculate loss
    # - Backward pass
    # - Update model parameters

    # Check if we're close to capacity expiration and haven't done final checkpointing
    if not final_checkpointing_done and is_close_to_expiration():
        start_checkpointing()
        final_checkpointing_done = True

    # Simulate some training time (remove this in actual implementation)
    time.sleep(1)
print("Training completed.")
```

Note

- Training job provisioning follows a First-In-First-Out (FIFO) order, but a smaller cluster job created later might be assigned capacity before a larger cluster job created earlier, if the larger job cannot be fulfilled.
- SageMaker training managed warm-pool is compatible with SageMaker training plans. For cluster re-use, you must provide identical `TrainingPlanArn` values in subsequent `CreateTrainingJob` requests to reuse the same cluster.

Topics

- Create a training job using the SageMaker AI console
- Create a training job using the API, AWS CLI, SageMaker SDK

Create a training job using the SageMaker AI console

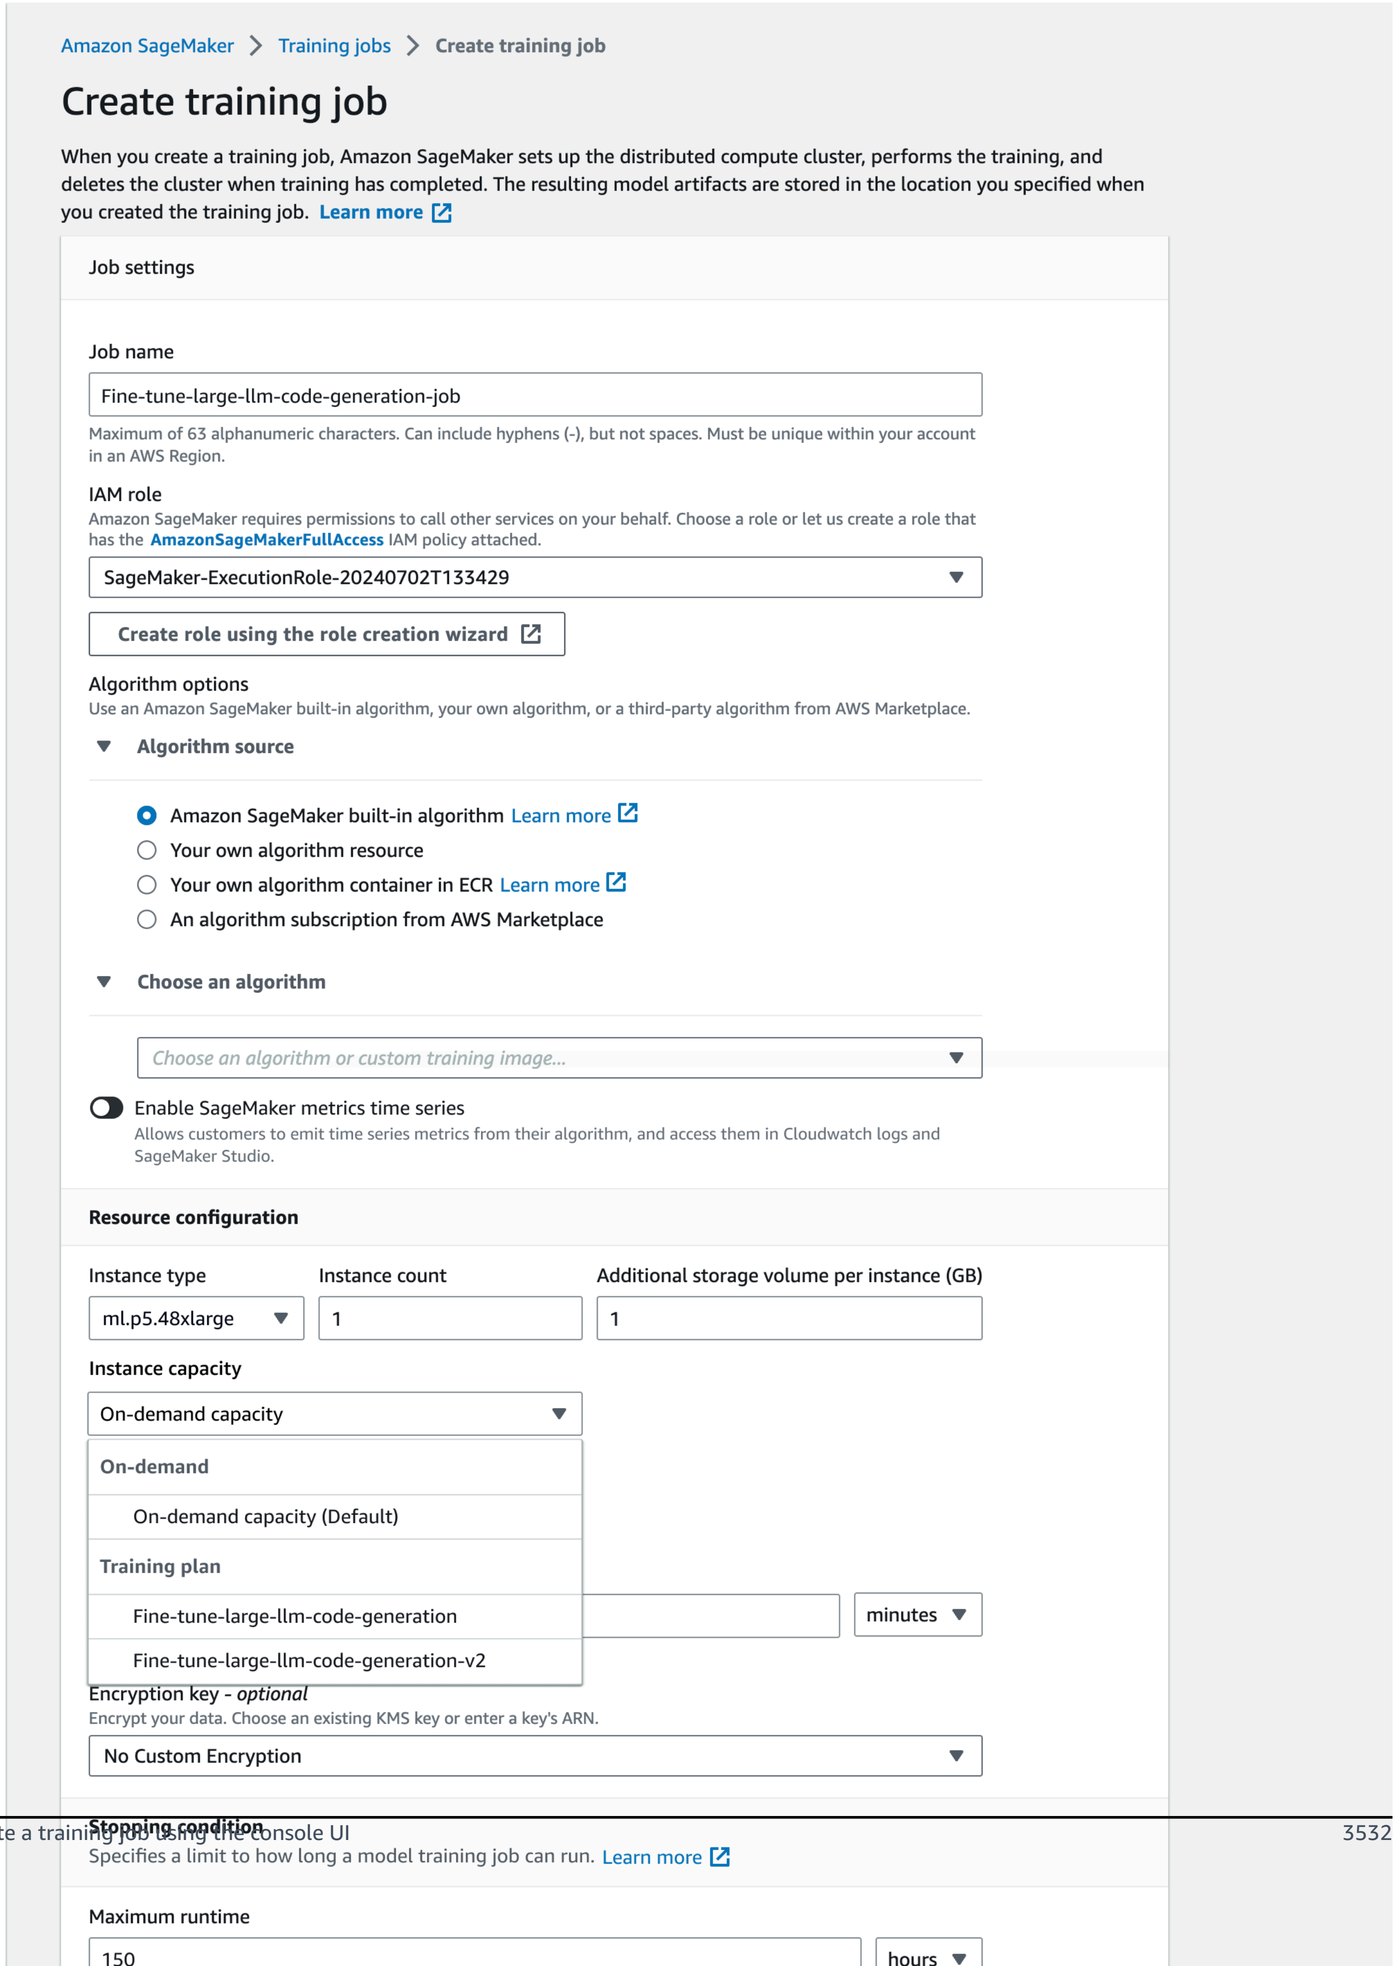
You can use a SageMaker training plans for your training jobs using the SageMaker AI UI. When creating a training job, the available plans are suggested to you if your instance choice and region matches the available plans.

To create a training job using a training plan's reserved capacity in the SageMaker console:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Training**, and then **Training jobs**.

3. Choose the **Create training job** button.
4. When configuring the resources for your training job, look for the **Instance capacity** section. If there are plans available that match your chosen instance type and region, they are displayed here. Select a training plan that aligns with your compute capacity needs.

   If no suitable plans are available, you can either adjust your instance type or region, or proceed without using a training plan.
5. After selecting a training plan (or choosing to proceed without one), complete the rest of your training job configuration and choose **Create training job** to start the process.



Amazon SageMaker > Training jobs > Create training job
Create training job
When you create a training job, Amazon SageMaker sets up the distributed compute cluster, performs the training, and deletes the cluster when training has completed. The resulting model artifacts are stored in the location you specified when you created the training job. Learn more
Job settings
Job name
Fine-tune-large-llm-code-generation-job
Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

hours

Review and launch your job. Your job starts running as soon as the training plan becomes `Active`, pending capacity.

Create a training job using the API, AWS CLI, SageMaker SDK

To use SageMaker training plans for your SageMaker training job, specify the `TrainingPlanArn` parameter of the desired plan in the `ResourceConfig` when calling the CreateTrainingJob API operation. You can use exactly one plan per job.

> **Important**
>
> The `InstanceType` field set in the `ResourceConfig` section of the `CreateTrainingJob` request must match the`InstanceType` of your training plan.

Run a training job on a plan using the CLI

The following example demonstrates how to create a SageMaker training job and associate it with a provided training plan using the `TrainingPlanArn` attribute in the `create-training-job` AWS CLI command.

For more information about how to create a training job using the AWS CLI CreateTrainingJob command, see create-training-job.

```
# Create a training job
aws sagemaker create-training-job \
  --training-job-name training-job-name \
  ...

  --resource-config '{
        "InstanceType": "ml.p5.48xlarge",
        "InstanceCount": 8,
        "VolumeSizeInGB": 10,
        "TrainingPlanArn": "training-plan-arn"
        }
    }' \
    ...
```

This AWS CLI example command creates a new training job in SageMaker AI passing a training plan in the `--resource-config` argument.

```
aws sagemaker create-training-job \
  --training-job-name job-name \
  --role-arn arn:aws:iam::123456789123:role/DataAndAPIAccessRole \
  --algorithm-specification '{"TrainingInputMode": "File","TrainingImage":
 "123456789123.dkr.ecr.us-east-1.amazonaws.com/algo-image:tag", "ContainerArguments":
 [" "]}' \
  --input-data-config '[{"ChannelName":"training","DataSource":
{"S3DataSource":{"S3DataType":"S3Prefix","S3Uri":"s3://bucketname/
input","S3DataDistributionType":"ShardedByS3Key"}}}]' \
  --output-data-config '{"S3OutputPath": "s3://bucketname/output"}' \
  --resource-config
 '{"VolumeSizeInGB":10,"InstanceCount":4,"InstanceType":"ml.p5.48xlarge",
 "TrainingJobArn" : "arn:aws:sagemaker:us-east-1:123456789123:training-job/plan-name"}'
 \
  --stopping-condition '{"MaxRuntimeInSeconds": 1800}' \
  --region us-east-1
```

After creating the training job, you can verify that it was properly assigned to the training plan by calling the `DescribeTrainingJob` API.

```
aws sagemaker describe-training-job --training-job-name training-job-name
```

Run a training job on a plan using the SageMaker AI Python SDK

Alternatively, you can create a training job associated with a training plan using the SageMaker Python SDK.

If you are using the SageMaker Python SDK from JupyterLab in Studio to create a training job, ensure that the execution role used by the space running your JupyterLab application has the required permissions to use SageMaker training plans. To learn about the required permissions to use SageMaker training plans, see the section called "IAM for SageMaker training plans".

The following example demonstrates how to create a SageMaker training job and associate it with a provided training plan using the `training_plan` attribute in the `Estimator` object when using the SageMaker Python SDK.

For more information on the SageMaker Estimator, see Use a SageMaker estimator to run a training job.

```
import sagemaker
```

```
import boto3
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

# Set up the session and SageMaker client
session = boto3.Session()
region = session.region_name
sagemaker_session = session.client('sagemaker')

# Get the execution role for the training job
role = get_execution_role()

# Define the input data configuration
trainingInput = TrainingInput(
    s3_data='s3://input-path',
    distribution='ShardedByS3Key',
    s3_data_type='S3Prefix'
)

estimator = Estimator(
    entry_point='train.py',
    image_uri="123456789123.dkr.ecr.{}.amazonaws.com/image:tag",
    role=role,
    instance_count=4,
    instance_type='ml.p5.48xlarge',
    training_plan="training-plan-arn",
    volume_size=20,
    max_run=3600,
    sagemaker_session=sagemaker_session,
    output_path="s3://output-path"
)

# Create the training job
estimator.fit(inputs=trainingInput, job_name=job_name)
```

After creating the training job, you can verify that it was properly assigned to the training plan by calling the `DescribeTrainingJob` API.

```
# Check job details
sagemaker_session.describe_training_job(TrainingJobName=job_name)
```

Training plans utilization for Amazon SageMaker HyperPod clusters

To use SageMaker training plans for your Amazon SageMaker HyperPod cluster, you specify the training plan you want to use at the cluster instance level when creating or updating your cluster.

Note

- The training plan must be in the `Scheduled` or `Active` status to be used by an HyperPod cluster.
- Ensure the cluster configuration aligns with the Availability Zone (AZ) specified in your training plan.

  For VPC setup, resource location, and security group configuration, refer to the section called "Setting up SageMaker HyperPod with a custom Amazon VPC" in the SageMaker HyperPod documentation.

  If setting up HyperPod with Amazon FSx for Lustre, learn about Region and AZ selection, review VPC configuration requirements, and understand AZ alignment best practices in the section called "(Optional) Setting up SageMaker HyperPod with Amazon FSx for Lustre".
- You can select a plan for each of your instance groups. However, we do not recommend using a training plan for the primary instance group of a cluster, as primary nodes require continuous, stable resources that don't align with the fixed duration and potentially discontinuous nature of training plan capacities.

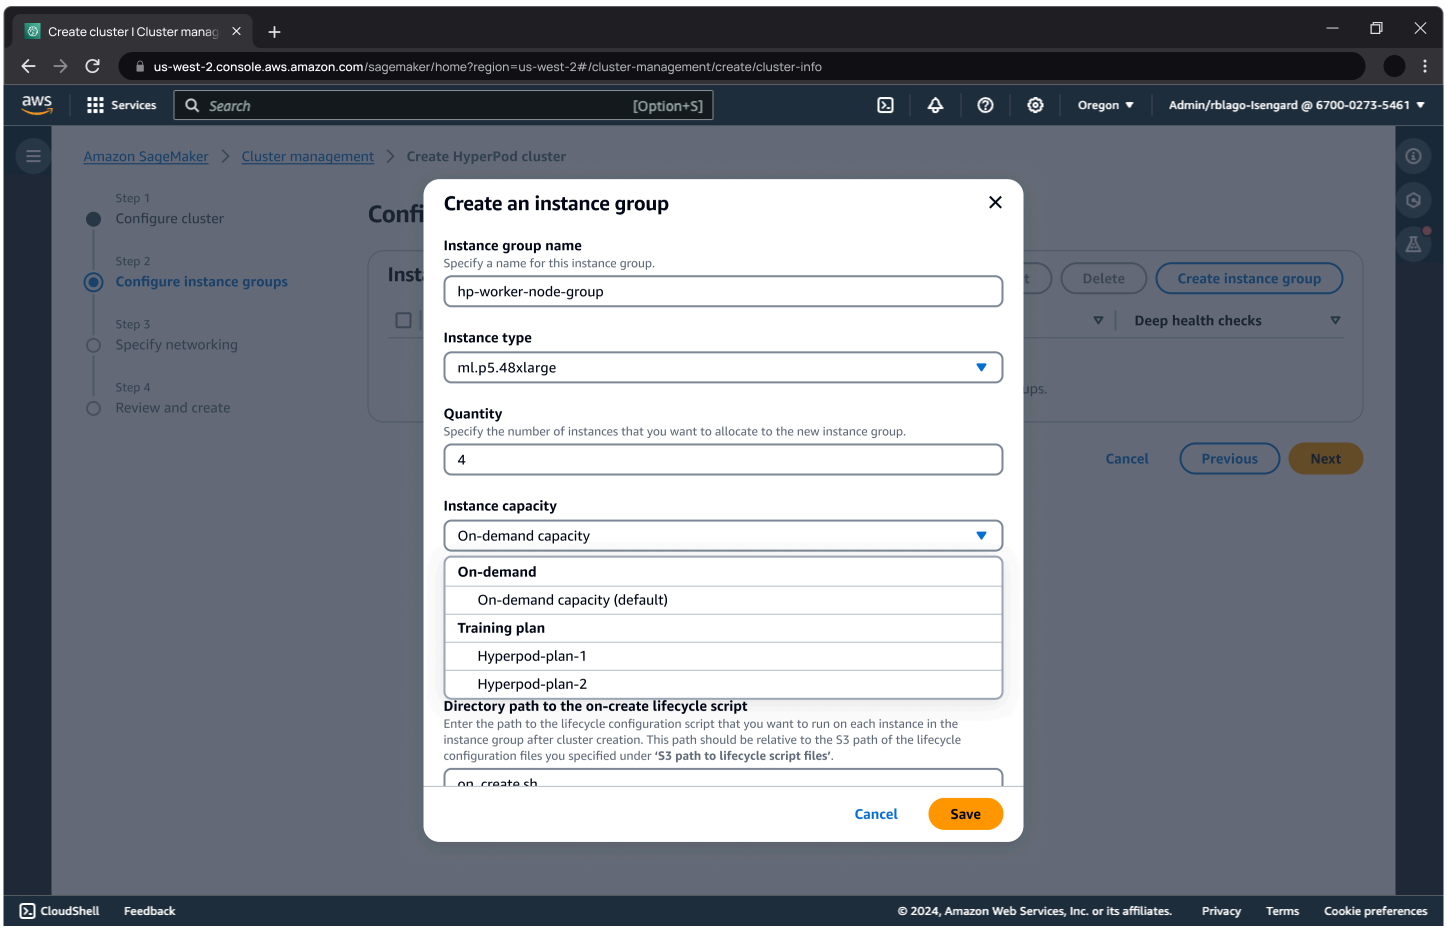
Topics

- Create a SageMaker HyperPod cluster on training plans using the SageMaker AI console
- Update a SageMaker HyperPod cluster on training plans using the SageMaker AI console
- Create a SageMaker HyperPod cluster on training plans using the SageMaker API, or AWS CLI
- Update a SageMaker HyperPod cluster on training plans using the SageMaker API, or AWS CLI

Create a SageMaker HyperPod cluster on training plans using the SageMaker AI console

To create an SageMaker HyperPod cluster using training plans from the SageMaker AI console UI, follow these steps:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Hyperpod**, and then **Create cluster**.
3. When configuring an instance group, you can select a plan that aligns with your compute capacity needs.

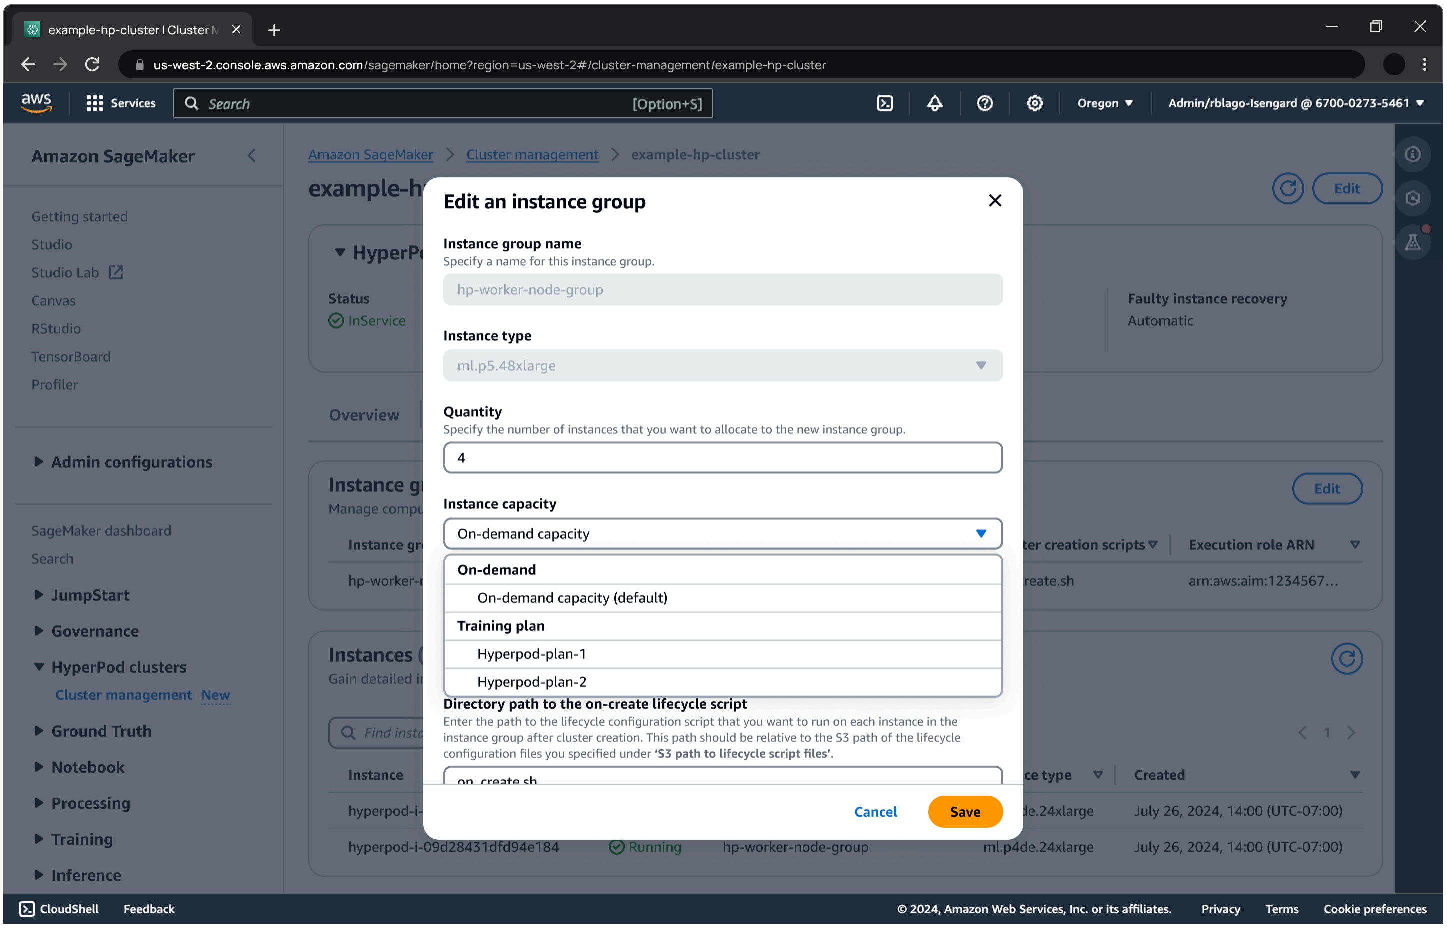


Review and create your cluster. Instance groups using a training plan scale up to the specified target instance count when the training plan becomes `Active`, subject to available capacity. Thirty minutes before each Reserved Capacity period ends, the instance group begins scaling down to zero instances. This scaled-down state persists until the next Reserved Capacity period begins or the plan ends. Throughout this process, an healthy instance group maintains an `InService` status after its initial creation, regardless of the current instance count.

Update a SageMaker HyperPod cluster on training plans using the SageMaker AI console

You can update, remove, or add a training plan to an existing SageMaker HyperPod cluster using the SageMaker AI console UI. To update the instance group of an SageMaker HyperPod cluster, follow these steps:

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Hyperpod**.
3. Navigate to the cluster's details page by following the hyperlink associated with the cluster name.
4. When configuring an instance group, you can update your plan to align with your new compute capacity needs.



Review and update your cluster.

Create a SageMaker HyperPod cluster on training plans using the SageMaker API, or AWS CLI

To use SageMaker training plans for your Amazon SageMaker HyperPod cluster, specify the ARN of the training plan you want to use in the `TrainingPlanArn` parameter of the `ClusterInstanceGroupSpecification` when calling the `CreateCluster` API operation.

Ensure that the subnet associated with the designated AZ of your plan is included in the `VPCConfig` of your cluster configuration. You can retrieve the `AvailabilityZone` of a training plan in the response of a DescribeTrainingPlan API call.

The following sample illustrates how to create a new SageMaker HyperPod cluster and provide an instance group with a training plan in the `--instance-groups` attribute of the `create-cluster` AWS CLI command.

```
# Create a cluster
```

```
aws sagemaker create-cluster \
  --cluster-name cluster-name \
  --instance-groups '[ \
        { \
            "InstanceCount": 1,\
            "InstanceGroupName": "controller-nodes",\
            "InstanceType": "ml.t3.xlarge",\
            "LifeCycleConfig": {"SourceS3Uri": source_s3_uri, "OnCreate": 
 "on_create.sh"},\
            "ExecutionRole": "arn:aws:iam::customer_account_id:role/execution_role",\
            "ThreadsPerCore": 1,\
        },\
        { \
            "InstanceCount": 2, \
            "InstanceGroupName": "worker-nodes",\
            "InstanceType": "p4d.24xlarge",\
            "LifeCycleConfig": {"SourceS3Uri": source_s3_uri, "OnCreate": 
 "on_create.sh"},\
            "ExecutionRole": "arn:aws:iam::customer_account_id}:role/execution_role}",\
            "ThreadsPerCore": 1,\
            "TrainingPlanArn": training_plan_arn,\
        }]'
```

For information about how to create an HyperPod cluster using the AWS CLI, see create-cluster.

After creating the cluster, you can verify that your instance group was properly assigned capacity from the training plan by calling the `DescribeCluster` API.

```
aws sagemaker describe-cluster --cluster-name cluster-name
```

Update a SageMaker HyperPod cluster on training plans using the SageMaker API, or AWS CLI

You can add, update, or remove a training plan by updating the instance group of an existing cluster using the `update-cluster` AWS CLI command. The following sample illustrates how to update a SageMaker HyperPod cluster and provide an instance group with a new training plan.

```
# Update a cluster
aws sagemaker update-cluster \
  --cluster-name cluster-name \
```

```
 --instance-groups '[ \
       { \
           "InstanceCount": 1,\
           "InstanceGroupName": "controller-nodes",\
           "InstanceType": "ml.t3.xlarge",\
           "LifeCycleConfig": {"SourceS3Uri": source_s3_uri, "OnCreate":
"on_create.sh"},\
           "ExecutionRole": "arn:aws:iam::customer_account_id:role/execution_role",\
           "ThreadsPerCore": 1,\
       },\
       { \
           "InstanceCount": 2, \
           "InstanceGroupName": "worker-nodes",\
           "InstanceType": "p4d.24xlarge",\
           "LifeCycleConfig": {"SourceS3Uri": source_s3_uri, "OnCreate":
"on_create.sh"},\
           "ExecutionRole": "arn:aws:iam::customer_account_id}:role/execution_role}",\
           "ThreadsPerCore": 1,\
           "TrainingPlanArn": training_plan_arn,\
       },\
       {\
           "InstanceCount": 1,\
           "InstanceGroupName": "worker-nodes-2",\
           "InstanceType": "p4d.24xlarge",\
           "LifeCycleConfig": {"SourceS3Uri": source_s3_uri, "OnCreate":
"on_create.sh"},\
           "ExecutionRole": "arn:aws:iam::customer_account_id:role/execution_role",\
           "ThreadsPerCore": 1,\
           "TrainingPlanArn": training_plan_arn,\
       }\
    ]'
```

View SageMaker training plans quotas using the AWS management console

> **Important**
>
> - For pricing information about SageMaker training plans, see the Amazon SageMaker Pricing page. Navigate to the **Amazon SageMaker HyperPod flexible training plans**

section under **On-Demand Pricing**. Choose your desired Region to view available instance types and their corresponding prices.

- Make sure that your Training Jobs or HyperPod service quotas allow a maximum number of instances per instance type that exceeds the number of instances specified in your plan.

You can view the current quotas and limits for SageMaker training plans using the AWS Management Console.

To search for a specific quota value:

1. Open the Service Quotas console.
2. In the left navigation pane, choose **AWS services**.
3. From the AWS services list, search for and select **Amazon SageMaker AI**.
4. In the **Service quotas** list, you can see the service quota name, applied value (if it's available), AWS default quota, and whether the quota value is adjustable.

To find specific quotas, you can use the search bar at the top of the **Service quotas** list. Type the `Limit Name` of the quota you are searching for. For example, to find the quota for the number of training plans per region, you would type **`training-plan-total_count`** in the search bar.

The following table outlines the quota limit names for SageMaker training plans.

SageMaker training plans quota limits

Limit Name	Display Name
training-plan-total_count	Number of training plans per Region
reserved-capacity-ml-p4d-24xlarge	Number of ml.p4d.24xlarge instances in reserved capacity across training plans per Region
reserved-capacity-ml-p5-48xlarge	Number of ml.p5.48xlarge instances in reserved capacity across training plans per Region

Limit Name	Display Name
reserved-capacity-ml-p5e-48xlarge	Number of ml.p5e.48xlarge instances in reserved capacity across training plans per Region
reserved-capacity-ml-p5en-48xlarge	Number of ml.p5en.48xlarge instances in reserved capacity across training plans per Region
reserved-capacity-ml-trn1-32xlarge	Number of ml-trn1-32xlarge instances in reserved capacity across training plans per Region
reserved-capacity-ml-trn2-48xlarge	Number of ml.trn2.48xlarge instances in reserved capacity across training plans per Region

If you need higher limits for your SageMaker training plans, you may be able to request a quota increase. The ability to increase a quota depends on whether it's adjustable, which you can see in the **Service quotas** console.

To request a quota increase:

1. Navigate to the specific quota in the **Service quotas** console.
2. If the quota is adjustable, you can request a quota increase at either the account level or resource level based on the value listed in the **Adjustability** column.
3. For **Increase quota value**, enter the new value. The new value must be greater than the current value.
4. Choose **Request**.
5. Quota increase requests are subject to review and approval by AWS. To view any pending or recently resolved requests in the console, navigate to the **Request history** tab from the service's details page, or choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is `Pending`. After the status changes to `Quota requested`, you see the case number with AWS Support. Choose the case number to open the ticket for your request.

To learn more about requesting a quota increase in general, see Requesting a quota increase in the *AWS Service Quotas User Guide*.

Release notes

See the following release notes to track the latest updates for SageMaker training plans.

Amazon SageMaker training plans Release Notes: December 04, 2024

New Features

- Launched Amazon SageMaker training plans at AWS re:Invent 2024.

Model training

The training stage of the full machine learning (ML) lifecycle spans from accessing your training dataset to generating a final model and selecting the best performing model for deployment. The following sections provide an overview of available SageMaker training features and resources with in-depth technical information for each.

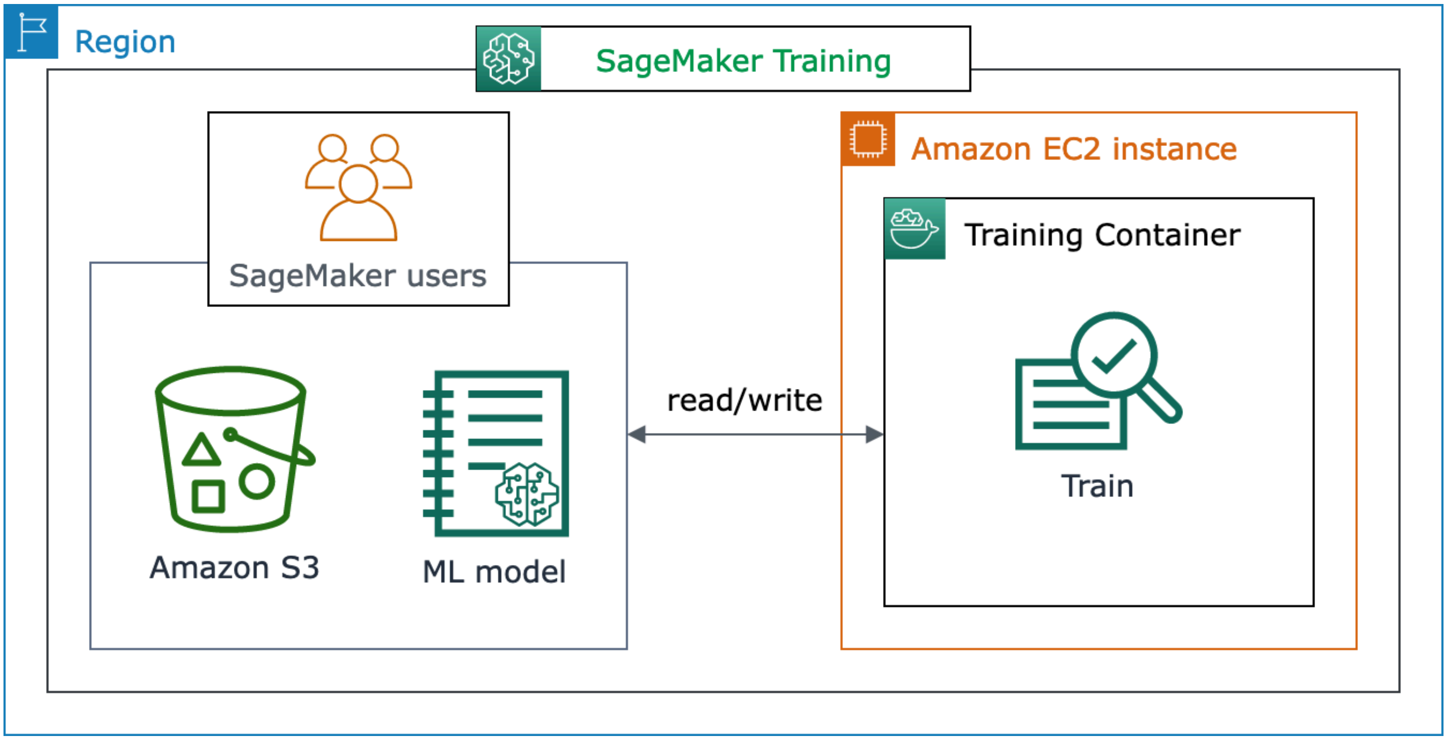
The basic architecture of SageMaker Training

If you're using SageMaker AI for the first time and want to find a quick ML solution to train a model on your dataset, consider using a no-code or low-code solution such as SageMaker Canvas, JumpStart within SageMaker Studio Classic, or SageMaker Autopilot.

For intermediate coding experiences, consider using a SageMaker Studio Classic notebook or SageMaker Notebook Instances. To get started, follow the instructions at the section called "Train a Model" of the SageMaker AI *Getting Started* guide. We recommend this for use cases in which you create your own model and training script using an ML framework.

The core of SageMaker AI jobs is the containerization of ML workloads and the capability of managing compute resources. The SageMaker Training platform takes care of the heavy lifting associated with setting up and managing infrastructure for ML training workloads. With SageMaker Training, you can focus on developing, training, and fine-tuning your model.

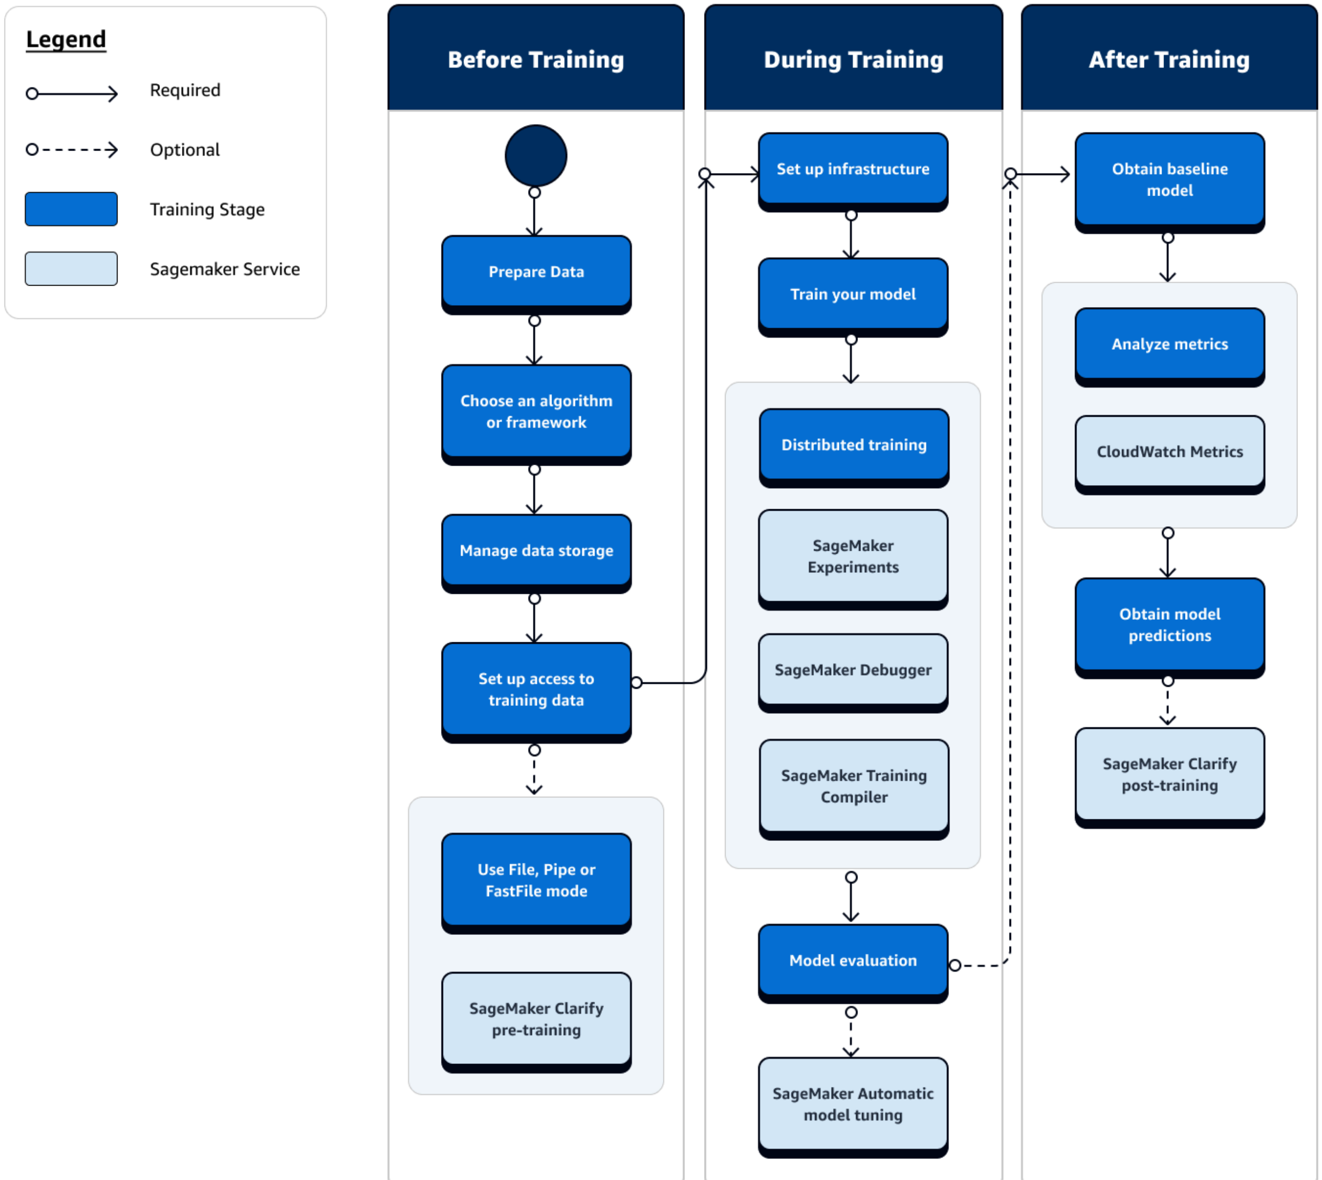
The following architecture diagram shows how SageMaker AI manages ML training jobs and provisions Amazon EC2 instances on behalf of SageMaker AI users. You as a SageMaker AI user can bring your own training dataset, saving it to Amazon S3. You can choose an ML model training from available SageMaker AI built-in algorithms, or bring your own training script with a model built with popular machine learning frameworks.



Full view of the SageMaker Training workflow and features

The full journey of ML training involves tasks beyond data ingestion to ML models, training models on compute instances, and obtaining model artifacts and outputs. You need to evaluate every phase of before, during, and after training to make sure your model is trained well to meet the target accuracy for your objectives.

The following flow chart shows a high-level overview of your actions (in blue boxes) and available SageMaker Training features (in light blue boxes) throughout the training phase of the ML lifecycle.



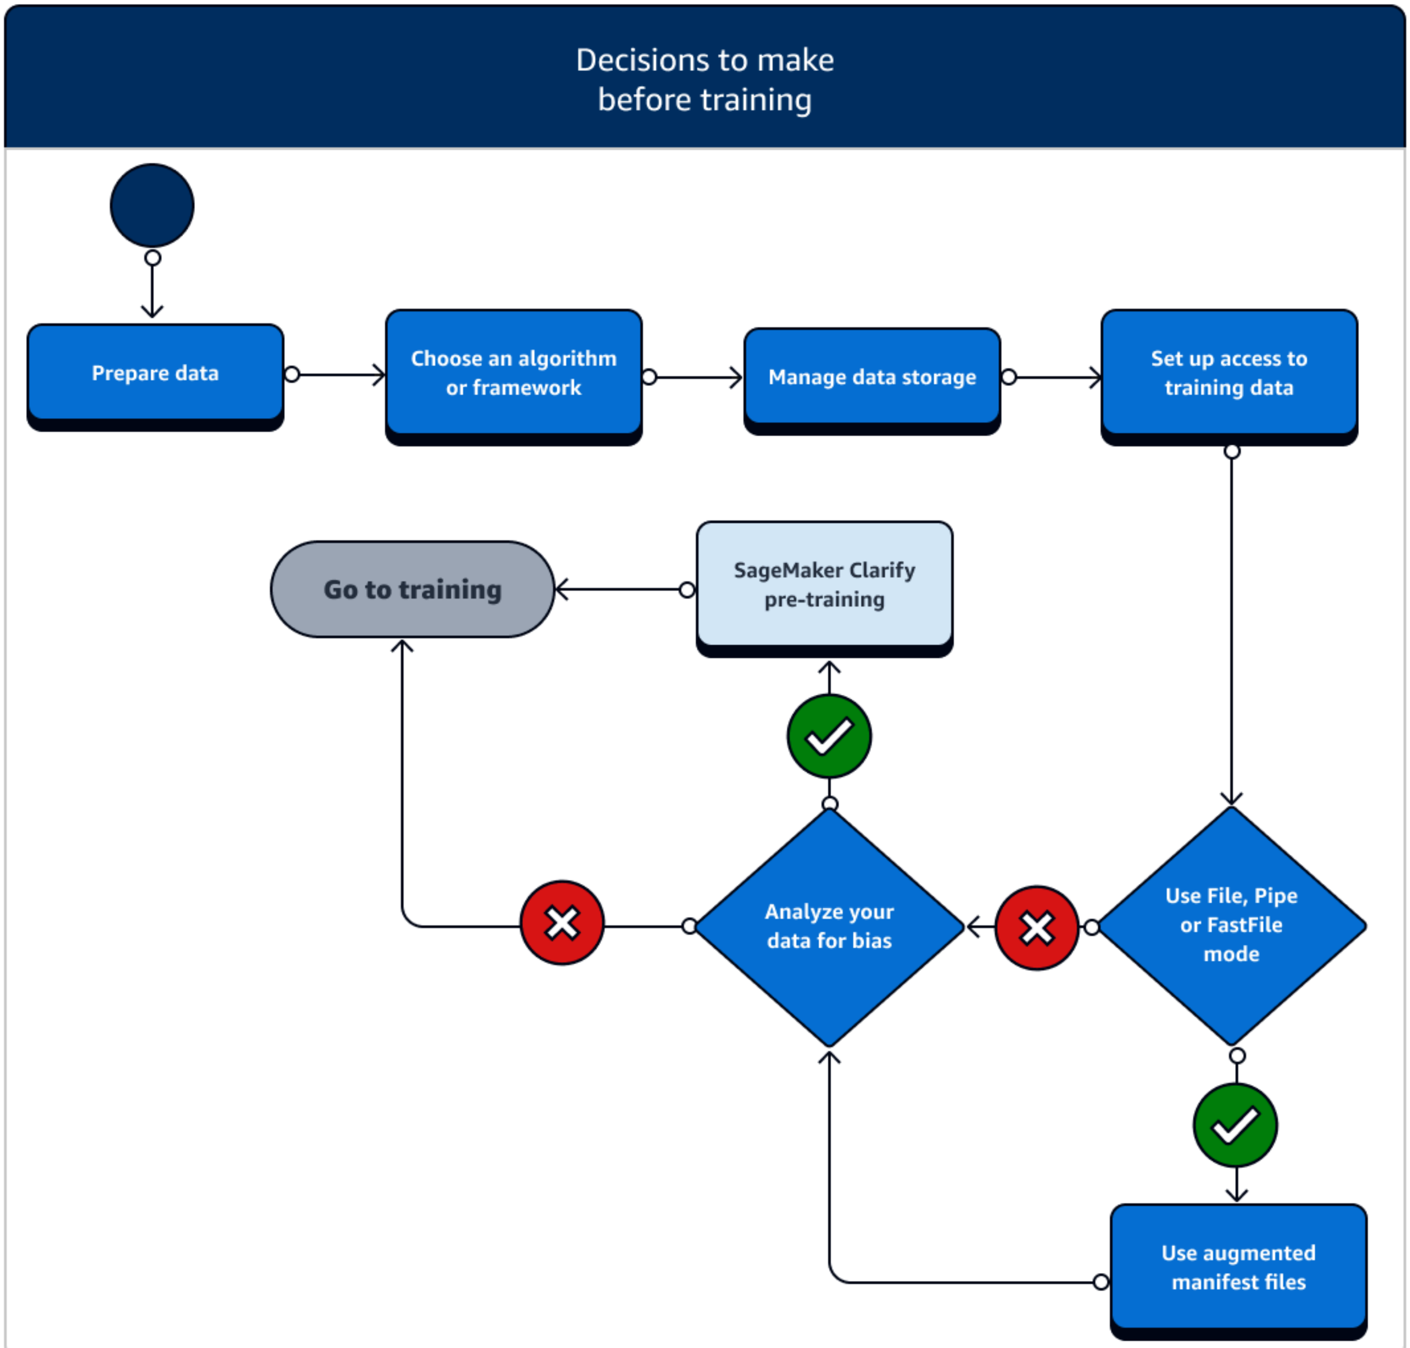
The following sections walk you through each phase of training depicted in the previous flow chart and useful features offered by SageMaker AI throughout the three sub-stages of the ML training.

Topics

- Before training
- During training
- After training

Before training

There are a number of scenarios of setting up data resources and access you need to consider before training. Refer to the following diagram and details of each before-training stage to get a sense of what decisions you need to make.



- **Prepare data:** Before training, you must have finished data cleaning and feature engineering during the data preparation stage. SageMaker AI has several labeling and feature engineering tools to help you. See Label Data, Prepare and Analyze Datasets, Process Data, and Create, Store, and Share Features for more information.

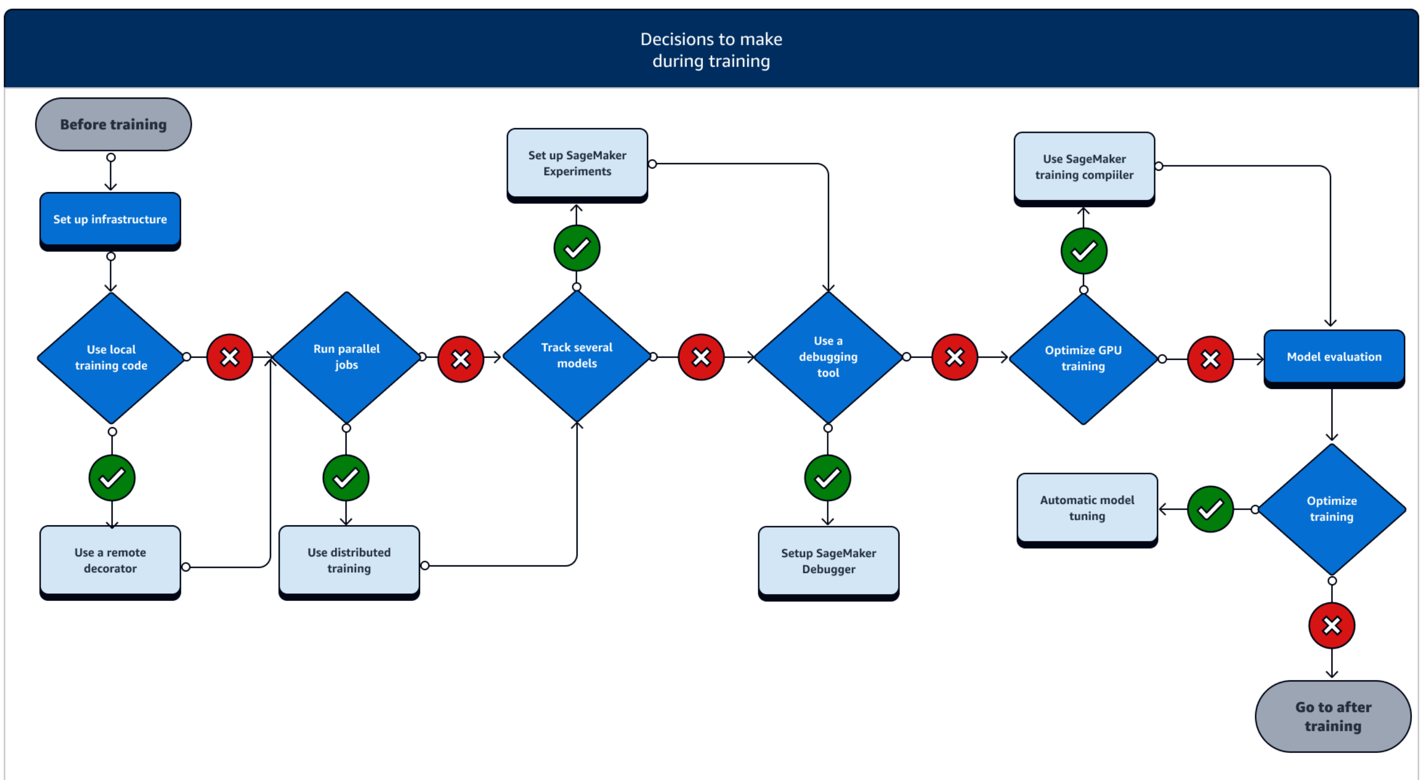
- **Choose an algorithm or framework:** Depending on how much customization you need, there are different options for algorithms and frameworks.
  - If you prefer a low-code implementation of a pre-built algorithm, use one of the built-in algorithms offered by SageMaker AI. For more information, see Choose an Algorithm.
  - If you need more flexibility to customize your model, run your training script using your preferred frameworks and toolkits within SageMaker AI. For more information, see ML Frameworks and Toolkits.
  - To extend pre-built SageMaker AI Docker images as the base image of your own container, see Use Pre-built SageMaker AI Docker images.
  - To bring your custom Docker container to SageMaker AI, see Adapting your own Docker container to work with SageMaker AI. You need to install the sagemaker-training-toolkit to your container.
- **Manage data storage:** Understand mapping between the data storage (such as Amazon S3, Amazon EFS, or Amazon FSx) and the training container that runs in the Amazon EC2 compute instance. SageMaker AI helps map the storage paths and local paths in the training container. You can also manually specify them. After mapping is done, consider using one of the data transmission modes: File, Pipe, and FastFile mode. To learn how SageMaker AI maps storage paths, see Training Storage Folders.
- **Set up access to training data:** Use Amazon SageMaker AI domain, a domain user profile, IAM, Amazon VPC, and AWS KMS to meet the requirements of the most security-sensitive organizations.
  - For account administration, see Amazon SageMaker AI domain.
  - For a complete reference about IAM policies and security, see Security in Amazon SageMaker AI.
- **Stream your input data:** SageMaker AI provides three data input modes, *File*, *Pipe*, and *FastFile*. The default input mode is File mode, which loads the entire dataset during initializing the training job. To learn about general best practices for streaming data from your data storage to the training container, see Access Training Data.

  In case of Pipe mode, you can also consider using an augmented manifest file to stream your data directly from Amazon Simple Storage Service (Amazon S3) and train your model. Using pipe mode reduces disk space because Amazon Elastic Block Store only needs to store your final model artifacts, rather than storing your full training dataset. For more information, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

- **Analyze your data for bias:** Before training, you can analyze your dataset and model for bias against a disfavored group so that you can check that your model learns an unbiased dataset using SageMaker Clarify.
- **Choose which SageMaker SDK to use:** There are two ways to launch a training job in SageMaker AI: using the high-level SageMaker AI Python SDK, or using the low-level SageMaker APIs for the SDK for Python (Boto3) or the AWS CLI. The SageMaker Python SDK abstracts the low-level SageMaker API to provide convenient tools. As aforementioned in the section called “The basic architecture of SageMaker Training”, you can also pursue no-code or minimal-code options using SageMaker Canvas, JumpStart within SageMaker Studio Classic, or SageMaker AI Autopilot.

During training

During training, you need to continuously improve training stability, training speed, training efficiency while scaling compute resources, cost optimization, and, most importantly, model performance. Read on for more information about during-training stages and relevant SageMaker Training features.



- **Set up infrastructure:** Choose the right instance type and infrastructure management tools for your use case. You can start from a small instance and scale up depending on your workload. For training a model on a tabular dataset, start with the smallest CPU instance of the C4 or C5 instance families. For training a large model for computer vision or natural language processing, start with the smallest GPU instance of the P2, P3, G4dn or G5 instance families. You can also mix different instance types in a cluster, or keep instances in warm pools using the following instance management tools offered by SageMaker AI. You can also use persistent cache to reduce latency and billable time on iterative training jobs over the latency reduction from warm pools alone. To learn more, see the following topics.
  - Running training jobs on a heterogeneous cluster
  - SageMaker AI Managed Warm Pools
  - Using persistent cache

  You must have sufficient quota to run a training job. If you run your training job on an instance where you have insufficient quota, you will receive a `ResourceLimitExceeded` error. To check the currently available quotas in your account, use your Service Quotas console. To learn how to request a quota increase, see Supported Regions and Quotas. Also, to find pricing information and available instance types depending on the AWS Regions, look up the tables in the Amazon SageMaker Pricing page.
- **Run a training job from a local code:** You can annotate your local code with a remote decorator to run your code as a SageMaker training job from inside Amazon SageMaker Studio Classic, an Amazon SageMaker notebook or from your local integrated development environment. For more information, see Run your local code as a SageMaker training job.
- **Track training jobs:** Monitor and track your training jobs using SageMaker Experiments, SageMaker Debugger, or Amazon CloudWatch. You can watch the model performance in terms of accuracy and convergence, and run comparative analysis of metrics between multiple training jobs by using SageMaker AI Experiments. You can watch the compute resource utilization rate by using SageMaker Debugger's profiling tools or Amazon CloudWatch. To learn more, see the following topics.
  - Manage Machine Learning with Amazon SageMaker Experiments
  - Profile Training Jobs Using Amazon SageMaker Debugger
  - Monitor and Analyze Using CloudWatch Metrics

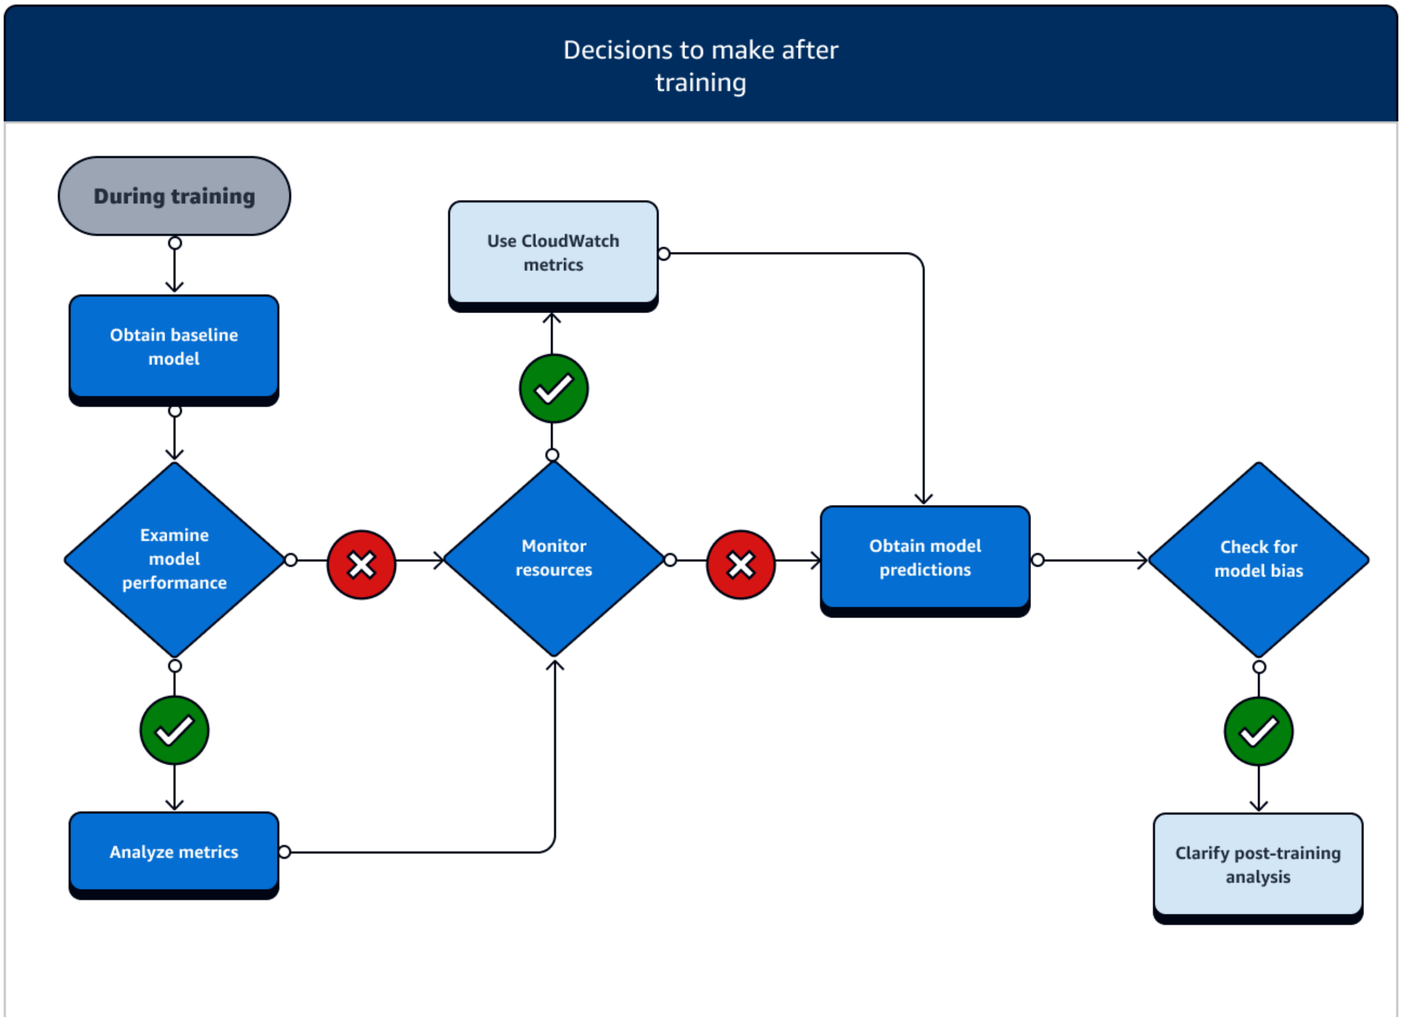
  Additionally, for deep learning tasks, use the Amazon SageMaker Debugger model debugging tools and built-in rules to identify more complex issues in model convergence and weight update processes.

- **Distributed training:** If your training job is going into a stable stage without breaking due to misconfiguration of the training infrastructure or out-of-memory issues, you might want to find more options to scale your job and run over an extended period of time for days and even months. When you're ready to scale up, consider distributed training. SageMaker AI provides various options for distributed computation from light ML workloads to heavy deep learning workloads.

  For deep learning tasks that involve training very large models on very large datasets, consider using one of the SageMaker AI distributed training strategies to scale up and achieve data parallelism, model parallelism, or a combination of the two. You can also use SageMaker Training Compiler for compiling and optimizing model graphs on GPU instances. These SageMaker AI features support deep learning frameworks such as PyTorch, TensorFlow, and Hugging Face Transformers.
- **Model hyperparameter tuning:** Tune your model hyperparameters using Automatic Model Tuning with SageMaker AI. SageMaker AI provides hyperparameter tuning methods such as grid search and Bayesian search, launching parallel hyperparameter tuning jobs with early-stopping functionality for non-improving hyperparameter tuning jobs.
- **Checkpointing and cost saving with Spot instances:** If training time is not a big concern, you might consider optimizing model training costs with managed Spot instances. Note that you must activate checkpointing for Spot training to keep restoring from intermittent job pauses due to Spot instance replacements. You can also use the checkpointing functionality to back up your models in case of unexpected training job termination. To learn more, see the following topics.
  - Managed Spot Training
  - Use Checkpoints

After training

After training, you obtain a final model artifact to use for model deployment and inference. There are additional actions involved in the after-training phase as shown in the following diagram.



- **Obtain baseline model:** After you have the model artifact, you can set it as a baseline model. Consider the following post-training actions and using SageMaker AI features before moving on to model deployment to production.
- **Examine model performance and check for bias:** Use Amazon CloudWatch Metrics and SageMaker Clarify for post-training bias to detect any bias in incoming data and model over time against the baseline. You need to evaluate your new data and model predictions against the new data regularly or in real time. Using these features, you can receive alerts about any acute changes or anomalies, as well as gradual changes or drifts in data and model.
- You can also use the Incremental Training functionality of SageMaker AI to load and update your model (or fine-tune) with an expanded dataset.
- You can register model training as a step in your SageMaker AI Pipeline or as part of other Workflow features offered by SageMaker AI in order to orchestrate the full ML lifecycle.

Train a Model with Amazon SageMaker

Amazon SageMaker Training is a fully managed machine learning (ML) service offered by SageMaker that helps you efficiently train a wide range of ML models at scale. The core of SageMaker AI jobs is the containerization of ML workloads and the capability of managing AWS compute resources. The SageMaker Training platform takes care of the heavy lifting associated with setting up and managing infrastructure for ML training workloads. With SageMaker Training, you can focus on developing, training, and fine-tuning your model. This page introduces three recommended ways to get started with training a model on SageMaker, followed by additional options you can consider.

Tip

For information about training foundation models for Generative AI, see Use SageMaker JumpStart foundation models in Amazon SageMaker Studio.

Choosing a feature within Amazon SageMaker Training

There are three main use cases for training ML models within SageMaker AI. This section describes those use cases, as well as the SageMaker AI features we recommend for each use case.

Whether you are training complex deep learning models or implementing smaller machine learning algorithms, SageMaker Training provides streamlined and cost-effective solutions that meet the requirements of your use cases.

Use cases

The following are the main uses cases for training ML models within SageMaker AI.

- **Use case 1**: Develop a machine learning model in a low-code or no-code environment.
- **Use case 2**: Use code to develop machine learning models with more flexibility and control.
- **Use case 3**: Develop machine learning models at scale with maximum flexibility and control.

Recommended features

The following table describes three common scenarios of training ML models and corresponding options to get started with SageMaker Training.

Descriptor	Use case 1	Use case 2	Use case 3
SageMaker AI feature	Build a model using Amazon SageMaker Canvas.	Train a model using one of the SageMaker AI built-in ML algorithms such as XGBoost or Task-Specific Models by SageMaker JumpStart with the SageMaker Python SDK.	Train a model at scale with maximum flexibility leveraging script mode or custom containers in SageMaker AI.
Description	Bring your data. SageMaker AI helps manage building ML models and setting up the training infrastructure and resources.	Bring your data and choose one of the built-in ML algorithms provided by SageMaker AI. Set up the model hyperparameters, output metrics, and basic infrastructure settings using the SageMaker Python SDK. The SageMaker Training platform helps provision the training infrastructure and resources.	Develop your own ML code and bring it as a script or a set of scripts to SageMaker AI. To learn more, see Distributed computing with SageMaker best practices. Additionally, you can bring your own Docker container. The SageMaker Training platform helps provision the training infrastructure and resources at scale based on your custom settings.
Optimized for	Low/no-code and UI-driven model development with quick experimentation with a training dataset. When you build a custom model an algorithm automatically selected based on your data. For advanced customization options like	Training ML models with high-level customization for hyperparameters, infrastructure settings, and the ability to directly use ML frameworks and entrypoint scripts for more flexibility. Use built-in algorithms, pre-trained models, and JumpStart	ML training workloads at scale, requiring multiple instances and maximum flexibility. See distributed computing with SageMaker best practices. SageMaker AI uses Docker images to host the training and serving of all models. You can use any

Descriptor	Use case 1	Use case 2	Use case 3
	algorithm selection, see advanced model building configurations.	models through the Amazon SageMaker Python SDK to develop ML models. For more information, see Low-code deployment with the JumpStart class.	SageMaker AI or external algorithms and use Docker containers to build models.
Considerations	Minimal flexibility to customize the model provided by Amazon SageMaker Canvas.	The SageMaker Python SDK provides a simplified interface and fewer configuration options compared to the low-level SageMaker Training API.	Requires knowledge of AWS infrastructure and distributed training options. See also Create your own training container using the SageMaker Training toolkit.
Recommended environment	Use Amazon SageMaker Canvas. To learn how to set it up, see Getting started with using SageMaker Canvas.	Use SageMaker AI JupyterLab within Amazon SageMaker Studio. To learn how to set it up, see Launch Amazon SageMaker Studio.	Use SageMaker JupyterLab within Amazon SageMaker Studio. To learn how to set it up, see Launch Amazon SageMaker Studio.

Additional options

SageMaker AI offers the following additional options for training ML models.

SageMaker AI features offering training capabilities

- **SageMaker JumpStart**: SageMaker JumpStart provides access to the SageMaker AI public model hub that contains the latest publicly available and proprietary foundation models (FMs). You can fine-tune, evaluate, and deploy these models within Amazon SageMaker Studio. SageMaker JumpStart streamlines the process of leveraging foundation models for your generative AI use-cases and allows you to create private model hubs to use foundation models while enforcing governance guardrails and ensuring that your organization can only access approved models. To get started with SageMaker JumpStart, see SageMaker JumpStart Foundation Models.

- **SageMaker HyperPod**: SageMaker HyperPod is a persistent cluster service for use cases that need resilient clusters for massive machine learning (ML) workloads and developing state-of-the-art foundation models (FMs). It accelerates development of such models by removing undifferentiated heavy-lifting involved in building and maintaining large-scale compute clusters powered by thousands of accelerators such as AWS Trainium or NVIDIA A100 and H100 Graphical Processing Units (GPUs). You can use workload manager software such as Slurm on HyperPod.

More features of SageMaker Training

- **Hyperparameter Tuning**: This SageMaker AI feature helps define a set of hyperparameters for a model and launch many training jobs on a dataset. Depending on the hyperparameter values, the model training performance might vary. This feature provides the best performing set of hyperparameters within the given range of hyperparameters you set to search through.
- **Distributed training**: Pre-train or fine-tune FMs built with PyTorch, NVIDIA CUDA, and other PyTorch-based frameworks. To efficiently utilize GPU instances, use the SageMaker AI distributed training libraries that offer collective communication operations and various model parallelism techniques such as expert parallelism and shared data parallelism that are optimized for AWS infrastructure.
- **Observability features**: Use the profiling and debugging functionalities of SageMaker Training to gain insights into model training workloads, model performance, and resource utilization. To learn more, see Debug and improve model performance and Profile and optimize computational performance.
- **Cost-saving and efficient instance options**: To optimize compute cost and efficiency for training instance provisioning, use Heterogeneous Cluster, Managed Spot instances, or Managed Warm Pools.

Types of Algorithms

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning
- Unsupervised learning
- Reinforcement learning

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics

- Choose an algorithm implementation
- Problem types for the basic machine learning paradigms
- Built-in algorithms and pretrained models in Amazon SageMaker
- Use Reinforcement Learning with Amazon SageMaker AI

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker AI supports three implementation options that require increasing levels of effort.

- **Pre-trained models** require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
- **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.
- If there is no built-in solution that works, try to develop one that uses **pre-made images for machine and deep learning frameworks** for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.
- If you need to run custom packages or use any code which isn't a part of a supported framework or available via PyPi, then you need to build **your own custom Docker image** that is configured to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

Topics

- Use a built-in algorithm
- Use script mode in a supported framework
- Use a custom Docker image

Algorithm implementation guidance

Implementation	Requires code	Pre-coded algorithms	Support for third party packages	Support for custom code	Level of effort
Built-in	No	Yes	No	No	Low
Scikit-learn	Yes	Yes	PyPi only	Yes	Medium
Spark ML	Yes	Yes	PyPi only	Yes	Medium
XGBoost (open source)	Yes	Yes	PyPi only	Yes	Medium
TensorFlow	Yes	No	PyPi only	Yes	Medium-high
PyTorch	Yes	No	PyPi only	Yes	Medium-high

Implementation	Requires code	Pre-coded algorithms	Support for third party packages	Support for custom code	Level of effort
MXNet	Yes	No	PyPi only	Yes	Medium-high
Chainer	Yes	No	PyPi only	Yes	Medium-high
Custom image	Yes	No	Yes, from any source	Yes	High

Use a built-in algorithm

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker AI's built-in algorithms. These built-in algorithms come with two major benefits.

- The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.
- The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker AI and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.

For more information on the built-in algorithms provided by SageMaker AI, see Built-in algorithms and pretrained models in Amazon SageMaker.

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker AI, see Parameters for Built-in Algorithms.

Use script mode in a supported framework

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker AI supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a `.py` extension. As the table above indicates, SageMaker AI supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework's image.

For more information on the frameworks supported by SageMaker AI, see Machine Learning Frameworks and Languages.

Use a custom Docker image

Amazon SageMaker AI's built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker AI uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker AI, see Docker containers for training and deploying models.

Problem types for the basic machine learning paradigms

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker AI provides to address these problem types, see Built-in algorithms and pretrained models in Amazon SageMaker.

Topics

- Supervised learning
- Unsupervised learning
- Reinforcement learning

Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a **classification problem**. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.
- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a **regression** problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker AI, see Supervised learning.

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.
- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.
- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.
- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker AI provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker AI, see Unsupervised learning.

Reinforcement learning

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker AI's frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker AI.

Built-in algorithms and pretrained models in Amazon SageMaker

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker, choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

Table: Mapping use cases to built-in algorithms

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Here a few examples out of the 15 problem types that can be addressed by the pre-trained models and pre-built solution templates provided by	Pre-trained models and pre-built solution templates	Image Classification Tabular Classification Tabular Regression Text Classification	Image, Text, Tabular	Popular models, including Mobilenet, YOLO, Faster R-CNN, BERT, lightGBM, and CatBoost For a list of pre-trained

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
SageMaker JumpStart: Question answering: chatbot that outputs an answer for a given question. Text analysis: analyze texts from models specific to an industry domain such as finance.		Object Detection Text Embedding Question Answering Sentence Pair Classification Image Embedding Named Entity Recognition Instance Segmentation Text Generation Text Summarization Semantic Segmentation Machine Translation		models available, see JumpStart Models. For a list of pre-built solution templates available, see JumpStart Solutions.

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Predict if an item belongs to a category: an email spam filter	Supervised learning	Binary/multi-class classification	Tabular	AutoGluon-Tabular, CatBoost, Factorization Machines Algorithm, K-Nearest Neighbors (k-NN) Algorithm, LightGBM, Linear Learner Algorithm, TabTransformer, XGBoost algorithm with Amazon SageMaker AI

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Predict a numeric/continuous value: estimate the value of a house		Regression	Tabular	AutoGluon-Tabular, CatBoost, Factorization Machines Algorithm, K-Nearest Neighbors (k-NN) Algorithm, LightGBM, Linear Learner Algorithm, TabTransformer, XGBoost algorithm with Amazon SageMaker AI
Based on historical data for a behavior, predict future behavior: predict sales on a new product based on previous sales data.		Time-series forecasting	Tabular	Use the SageMaker AI DeepAR forecasting algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Improve the data embedding s of the high-dimensional objects: identify duplicate support tickets or find the correct routing based on similarity of text in the tickets		Embeddings: convert high-dimensional objects into low-dimensional space.	Tabular	Object2Vec Algorithm
Drop those columns from a dataset that have a weak relation with the label/tar get variable: the color of a car when predicting its mileage.	Unsupervised learning	Feature engineering: dimensionality reduction	Tabular	Principal Component Analysis (PCA) Algorithm
Detect abnormal behavior in application: spot when an IoT sensor is sending abnormal readings		Anomaly detection	Tabular	Random Cut Forest (RCF) Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Protect your application from suspiciou s users: detect if an IP address accessing a service might be from a bad actor		IP anomaly detection	Tabular	IP Insights
Group similar objects/data together: find high-, medium-, and low-spend ing customers from their transaction histories		Clustering or grouping	Tabular	K-Means Algorithm
Organize a set of documents into topics (not known in advance): tag a document as belonging to a medical category based on the terms used in the document.		Topic modeling	Text	Latent Dirichlet Allocation (LDA) Algorithm, Neural Topic Model (NTM) Algorithm

Label/tag an image based on the content of the image: alerts about adult content in an image	Image processing	Image and multi-label classification	Image	Image Classification - MXNet
Classify something in an image using transfer learning.		Image classification	Image	Image Classification - TensorFlow
Detect people and objects in an image: police review a large photo gallery for a missing person		Object detection and classification	Image	Object Detection - MXNet, Object Detection - TensorFlow
Tag every pixel of an image individually with a category: self-driving cars prepare to identify objects in their way		Computer vision	Image	Semantic Segmentation Algorithm

For important information about the following items common to all of the built-in algorithms provided by SageMaker AI, see Parameters for Built-in Algorithms.

- Docker registry paths
- data formats
- recommended Amazon EC2 instance types
- CloudWatch logs

The following sections provide additional guidance for the Amazon SageMaker AI built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Types of Algorithms. Sections are also provided for the SageMaker AI built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained models and solution templates
- Supervised learning
- Unsupervised learning
- Textual analysis
- Image processing

Pre-trained models and solution templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types. These use the SageMaker SDK as well as Studio Classic. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart pretrained models.

Supervised learning

Amazon SageMaker AI provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- AutoGluon-Tabular—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.

- K-Nearest Neighbors (k-NN) Algorithm—a non-parametric method that uses the k nearest labeled points to assign a value. For classification, it is a label to a new data point. For regression, it is a predicted target value from the average of the k nearest points.
- LightGBM—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability. These two novel techniques are Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
- Linear Learner Algorithm—learns a linear function for regression or a linear threshold function for classification.
- TabTransformer—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- XGBoost algorithm with Amazon SageMaker AI—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker AI also provides several built-in supervised learning algorithms used for more specialized tasks during feature engineering and forecasting from time series data.

- Object2Vec Algorithm—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data. Even though it requires labeled data for training, this can occur without any explicit human annotation.
- Use the SageMaker AI DeepAR forecasting algorithm—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Unsupervised learning

Amazon SageMaker AI provides several built-in algorithms that can be used for a variety of unsupervised learning tasks. These tasks includes things like clustering, dimension reduction, pattern recognition, and anomaly detection.

- Principal Component Analysis (PCA) Algorithm—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.

- K-Means Algorithm—finds discrete groupings within data. This occurs where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- IP Insights—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- Random Cut Forest (RCF) Algorithm—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Textual analysis

SageMaker AI provides algorithms that are tailored to the analysis of textual documents. This includes text used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- BlazingText algorithm—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- Sequence-to-Sequence Algorithm—a supervised algorithm commonly used for neural machine translation.
- Latent Dirichlet Allocation (LDA) Algorithm—an algorithm suitable for determining topics in a set of documents. It is an *unsupervised algorithm*, which means that it doesn't use example data with answers during training.
- Neural Topic Model (NTM) Algorithm—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- Text Classification - TensorFlow—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

Image processing

SageMaker AI also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- Image Classification - MXNet—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Image Classification - TensorFlow—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.

- Semantic Segmentation Algorithm—provides a fine-grained, pixel-level approach to developing computer vision applications.
- Object Detection - MXNet—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- Object Detection - TensorFlow—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

Topics

Parameters for Built-in Algorithms

The following table lists parameters for each of the algorithms provided by Amazon SageMaker AI.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
AutoGluon-Tabular	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No	
BlazingText	train	File or Pipe	Text file (one sentence per line	CPU or GPU (single	No	

Algorithm name	Channel name	Training input mode	File type	Instance class	Paralleli zable
			with space-sep arated tokens)	instance only)	
CatBoost	training and (optional ly) validation	File	CSV	CPU (single instance only)	No
DeepAR Forecasti ng	train and (optional ly) test	File	JSON Lines or Parquet	CPU or GPU	Yes
Factoriza tion Machines	train and (optional ly) test	File or Pipe	recordIO-protobuf	CPU (GPU for dense data)	Yes
Image Classific ation - MXNet	train and validation, (optional ly) train_lst , validatio n_lst, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes
Image Classific ation - TensorFlo w	training and validation	File	image files (.jpg, .jpeg, or .png)	CPU or GPU	Yes (only across multiple GPUs on a single instance)

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
IP Insights	train and (optionally) validation	File	CSV	CPU or GPU	Yes
K-Means	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPUCommon (single GPU device on one or more instances)	No
K-Nearest-Neighbors (k-NN)	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU (single GPU device on one or more instances)	Yes
LDA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU (single instance only)	No
LightGBM	train/training and (optionally) validation	File	CSV	CPU	Yes

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
Linear Learner	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes
Neural Topic Model	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes
Object2Vec	train and (optionally) validation, test, or both	File	JSON Lines	CPU or GPU (single instance only)	No
Object Detection - MXNet	train and validation, (optionally) train_annotation, validation_annotation, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
Object Detection - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	GPU	Yes (only across multiple GPUs on a single instance)
PCA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes
Random Cut Forest	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU	Yes
Semantic Segmentation	train and validation, train_annotation, validation_annotation, and (optionally) label_map and model	File or Pipe	Image files	GPU (single instance only)	No
Seq2Seq Modeling	train, validation, and vocab	File	recordIO-protobuf	GPU (single instance only)	No

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
TabTransformer	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No
Text Classification - TensorFlow	training and validation	File	CSV	CPU or GPU	Yes (only across multiple GPUs on a single instance)
XGBoost (0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-21)	train and (optionally) validation	File or Pipe	CSV, LibSVM, or Parquet	CPU (or GPU for 1.2-1)	Yes

Algorithms that are *parallelizable* can be deployed on multiple compute instances for distributed training.

The following topics provide information about data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by Amazon SageMaker AI.

Note

To look up the Docker image URIs of the built-in algorithms managed by SageMaker AI, see Docker Registry Paths and Example Code.

Topics

Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data must go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker AI in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported `ContentType` values and the algorithms that use them:

ContentTypes for Built-in Algorithms

ContentType	Algorithm
application/x-image	Object Detection Algorithm, Semantic Segmentation
application/x-recordio	Object Detection Algorithm
application/x-recordio-protobuf	Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence
application/jsonlines	BlazingText, DeepAR
image/jpeg	Object Detection Algorithm, Semantic Segmentation
image/png	Object Detection Algorithm, Semantic Segmentation
text/csv	IP Insights, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, XGBoost
text/libsvm	XGBoost

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

Using Pipe Mode

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the `AlgorithmSpecification` for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker AI algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify **`text/csv`** as the `ContentType`. Amazon SageMaker AI requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case **'content_type=text/csv;label_size=0'**. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker AI built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker AI converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker AI protobuf format.

> **Note**
>
> For an example that shows how to convert the commonly used numPy array into the protobuf recordIO format, see *An Introduction to Factorization Machines with MNIST* .

```
syntax = "proto2";

 package aialgs.data;

 option java_package = "com.amazonaws.aialgorithms.proto";
 option java_outer_classname = "RecordProtos";

 // A sparse or dense rank-R tensor that stores data as doubles (float64).
 message Float32Tensor   {
     // Each value in the vector. If keys is empty, this is treated as a
     // dense vector.
     repeated float values = 1 [packed = true];

     // If key is not empty, the vector is treated as sparse, with
     // each key specifying the location of the value in the sparse vector.
     repeated uint64 keys = 2 [packed = true];

     // An optional shape that allows the vector to represent a matrix.
     // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
     // and keys[i] % 20 gives the column.
     // This also supports n-dimensonal tensors.
     // Note: If the tensor is sparse, you must specify this value.
```

```
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated double values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse, with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensonal tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated int32 values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For Exmple, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensonal tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
    repeated bytes value = 1;
```

```
    // If the content type of the data is known, stores it.
    // This allows for the possibility of using decoders for common formats
    // in the future.
    optional string content_type = 2;
}

message Value {
    oneof value {
        // The numbering assumes the possible use of:
        // - float16, float128
        // - int8, int16, int32
        Float32Tensor float32_tensor = 2;
        Float64Tensor float64_tensor = 3;
        Int32Tensor int32_tensor = 7;
        Bytes bytes = 9;
    }
}

message Record {
    // Map from the name of the feature to the value.
    //
    // For vectors and libsvm-like datasets,
    // a single feature with the name `values`
    // should be specified.
    map<string, Value> features = 1;

    // An optional set of labels for this record.
    // Similar to the features field above, the key used for
    // generic scalar / vector labels should be 'values'.
    map<string, Value> label = 2;

    // A unique identifier for this record in the dataset.
    //
    // Whilst not necessary, this allows better
    // debugging where there are data issues.
    //
    // This is not used by the algorithm directly.
    optional string uid = 3;

    // Textual metadata describing the record.
    //
    // This may include JSON-serialized information
    // about the source of the record.
    //
```

```
    // This is not used by the algorithm directly.
    optional string metadata = 4;

    // An optional serialized JSON object that allows per-record
    // hyper-parameters/configuration/other information to be set.
    //
    // The meaning/interpretation of this field is defined by
    // the algorithm author and may not be supported.
    //
    // This is used to pass additional inference configuration
    // when batch inference is used (e.g. types of scores to return).
    optional string configuration = 5;
}
```

After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker AI can access and that can be passed as part of `InputDataConfig` in `create_training_job`.

> **Note**
>
> For all Amazon SageMaker AI algorithms, the `ChannelName` in `InputDataConfig` must be set to `train`. Some algorithms also support a validation or test `input channels`. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

Trained Model Deserialization

Amazon SageMaker AI models are stored as model.tar.gz in the S3 bucket specified in `OutputDataConfig` `S3OutputPath` parameter of the `create_training_job` call. The S3 bucket must be in the same AWS Region as the notebook instance. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When `model.tar.gz` is untarred, it contains `model_algo-1`, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

Common data formats for inference

Amazon SageMaker AI algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use multiple AWS services to transform or preprocess records before running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

Topics

Convert data for inference request serialization

Content type options for Amazon SageMaker AI algorithm inference requests include: `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports `text/csv` from this list, but also supports `text/libsvm`.

For `text/csv`, the value for the Body argument to `invoke_endpoint` should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like `1.5,16.0,14,23.0`. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

`application/json` is more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```
let request = {
  // Instances might contain multiple rows that predictions are sought for.
```

```
  "instances": [
    {
      // Request and algorithm specific inference parameters.
      "configuration": {},
      // Data in the specific format required by the algorithm.
      "data": {
         "<field name>": dataElement
       }
    }
  ]
}
```

You have the following options for specifying the `dataElement`:

Protocol buffers equivalent

```
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}
```

Simple numeric vector

```
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": {
    "values": dataElement
  }
}
```

For multiple records

```
let request = {
  "instances": [
    // First instance.
    {
```

```
      "features": [ 1.5, 16.0, 14.0, 23.0 ]
    },
    // Second instance.
    {
      "features": [ -2.0, 100.2, 15.2, 9.2 ]
    }
  ]
}
```

Convert data for inference response deserialization

Amazon SageMaker AI algorithms return JSON in several layouts. At a high level, the structure is:

```
let response = {
  "predictions": [{
    // Fields in the response object are defined on a per algorithm-basis.
  }]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

Single-record inference

```
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

Multi-record inference

```
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
```

```
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

Multi-record inference with protobuf input

```
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker AI algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a collection of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the `jsonlines` response type by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

Common request formats for all algorithms

Most algorithms use many of the following inference request formats.

JSON request format

Content type: application/JSON

Dense format

```
let request =   {
    "instances":    [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}

let request =   {
    "instances":    [
        {
            "data": {
                "features": {
                    "values": [ 1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

Sparse format

```
{
 "instances": [
  {"data": {"features": {
     "keys": [26, 182, 232, 243, 431],
     "shape": [2000],
     "values": [1, 1, 1, 4, 1]
    }
   }
  },
  {"data": {"features": {
     "keys": [0, 182, 232, 243, 431],
     "shape": [2000],
     "values": [13, 1, 1, 4, 1]
    }
   }
  },
 ]
}
```

JSONLINES request format

Content type: application/JSONLINES

Dense format

A single record in dense format can be represented as either:

```
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } } }
```

Sparse Format

A single record in sparse format is represented as:

```
{"data": {"features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values":
 [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a collection of single-record representations, separated by newline characters:

```
{"data": {"features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } } }
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

CSV request format

Content type: text/CSV; label_size=0

> **Note**
>
> CSV support is not available for factorization machines.

RECORDIO request format

Content type: application/x-recordio-protobuf

Use batch transform with built-in algorithms

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. To do this, set the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the `SplitType` must be set based on the `ContentType` of the input data. Similarly, depending on the `Accept` field in the `CreateTransformJobRequest`, `AssembleWith` must be set accordingly. Use the following table to set these fields:

ContentType	Recommended SplitType
`application/x-recordio-protobuf`	`RecordIO`
`text/csv`	`Line`
`application/jsonlines`	`Line`
`application/json`	`None`
`application/x-image`	`None`
`image/*`	`None`

Accept	Recommended AssembleWith
`application/x-recordio-protobuf`	`None`
`application/json`	`None`
`application/jsonlines`	`Line`

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats
- Factorization Machines Response Formats
- IP Insights Inference Data Formats

- K-Means Response Formats
- k-NN Request and Response Formats
- Linear learner response formats
- NTM Response Formats
- Data Formats for Object2Vec Inference
- Encoder Embeddings for Object2Vec
- PCA Response Formats
- RCF Response Formats

Instance Types for Built-in Algorithms

Most Amazon SageMaker AI algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

To learn about the supported EC2 instances, see Instance details.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution. To get an automatic instance recommendation or conduct custom load tests, use Amazon SageMaker Inference Recommender.

For more information on SageMaker AI hardware specifications, see Amazon SageMaker AI ML Instance Types.

UltraServers

UltraServers connect multiple Amazon EC2 instances using a low-latency, high-bandwidth accelerator interconnect. They are built to handle large-scale AI/ML workloads that require significant processing power. For more information, see Amazon EC2 UltraServers. To get started with UltraServers, see Reserve training plans for your training jobs or HyperPod clusters.

To get started with UltraServers on Amazon SageMaker AI, create a training plan. Once your UltraServer is available in the training plan, create a training job with the AWS Management

Console, Amazon SageMaker AI API, or AWS CLI. Remember to specify the UltraServer instance type that you purchased in the training plan.

An UltraServer can run one or multiple jobs at a time. UltraServers groups instances together, which gives you some flexibility in terms of how to allocate your UltraServer capacity in your organization. As you configure your jobs, also remember your organization's data security guidelines, as instances in one UltraServer can access data for another job in another instance on the same UltraServer.

If you run into hardware failures in the UltraServer, SageMaker AI automatically tries to resolve the issue. As SageMaker AI investigates and resolves the issue, you might receive notifications and actions through AWS Health Events or AWS Support.

Once your training job finishes, SageMaker AI stops the instances, but they remain available in your training plan if the plan is still active. To keep an instance in an UltraServer running after a job finishes, you can use managed warm pools.

If your training plan has enough capacity, you can even run training jobs across multiple UltraServers. By default, each UltraServer comes with 18 instances, comprising of 17 instances and 1 spare instance. If you need more instances, you must buy more UltraServers. When creating a training job, you can configure how jobs are placed across UltraServers using the `InstancePlacementConfig` parameter.

If you don't configure job placement, SageMaker AI automatically allocates jobs to instances within your UltraServer. This default strategy is based on best effort that prioritizes filling all of the instances in a single UltraServer before using a different UltraServer. For example, if you request 14 instances and have 2 UltraServers in your training plan, SageMaker AI uses all of the instances in the first UltraServer. If you requested 20 instances and have 2 UltraServers in your training plan, SageMaker AI will will use all 17 instances in the first UltraServer and then use 3 from the second UltraServer. Instances within an UltraServer use NVLink to communicate, but individual UltraServers use Elastic Fabric Adapter (EFA), which might affect model training performance.

Logs for Built-in Algorithms

Amazon SageMaker AI algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose **CloudWatch**, choose **Logs**, and then choose the /aws/sagemaker/TrainingJobs **log group**. Each training job has one log stream per node on which it was trained. The log stream’s name begins with the value specified in the `TrainingJobName` parameter when the job was created.

> **Note**
>
> If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

Common Errors

If a training job fails, some details about the failure are provided by the `FailureReason` return value in the training job description, as follows:

```
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   From the CloudWatch Log

   ```
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was
   unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   FailureReason

   ```
   AlgorithmError: u'abc' is not valid under any of the given
   schemas\n\nFailed validating u'oneOf' in
   schema[u'properties'][u'feature_dim']:\n    {u'oneOf':
   [{u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},\n
   ```

```
{u'minimum': 1, u'type': u'integer'}]}\
```

FailureReason

```
[10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc'
is not valid under any of the given schemas
```

3. Inaccurate protobuf file format.

From the CloudWatch log

```
[10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
                   copy sequence with size 785 to array axis with dimension 784
```

Built-in SageMaker AI Algorithms for Tabular Data

Amazon SageMaker AI provides built-in algorithms that are tailored to the analysis of tabular data. Tabular data refers to any datasets that are organized in tables consisting of rows (observations) and columns (features). The built-in SageMaker AI algorithms for tabular data can be used for either classification or regression problems.

- AutoGluon-Tabular—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- K-Nearest Neighbors (k-NN) Algorithm—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- LightGBM—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
- Linear Learner Algorithm—learns a linear function for regression or a linear threshold function for classification.

- [TabTransformer](https://docs.aws.amazon.com)—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- XGBoost algorithm with Amazon SageMaker AI—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
AutoGluon-Tabular	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No
CatBoost	training and (optionally) validation	File	CSV	CPU (single instance only)	No
Factorization Machines	train and (optionally) test	File or Pipe	recordIO-protobuf	CPU (GPU for dense data)	Yes
K-Nearest-Neighbors (k-NN)	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU (single GPU device on one or more instances)	Yes
LightGBM	training and (optional	File	CSV	CPU (single	No

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
	ly) validation			instance only)	
Linear Learner	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes
TabTransformer	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No
XGBoost (0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-21)	train and (optionally) validation	File or Pipe	CSV, LibSVM, or Parquet	CPU (or GPU for 1.2-1)	Yes

AutoGluon-Tabular

AutoGluon-Tabular is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers. This page includes information about Amazon EC2 instance recommendations and sample notebooks for AutoGluon-Tabular.

How to use SageMaker AI AutoGluon-Tabular

You can use AutoGluon-Tabular as an Amazon SageMaker AI built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker AI `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker AI Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-classification-
ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
```

```
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "auto_stack"
] = "True"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
```

```
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples. Any S3 bucket used in these examples must be in the same AWS Region as the notebook instance used to run them.

- Tabular classification with Amazon SageMaker AI AutoGluon-Tabular algorithm
- Tabular regression with Amazon SageMaker AI AutoGluon-Tabular algorithm

Input and Output interface for the AutoGluon-Tabular algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains a CSV file. You can optionally include another subdirectory in the same location called `validation/` that also has a CSV file. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AI AutoGluon-Tabular uses the `autogluon.tabular.TabularPredictor` module to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker AI AutoGluon-Tabular with the AutoGluon framework

- Use the following Python code:

```
import tarfile
from autogluon.tabular import TabularPredictor

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = TabularPredictor.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm

SageMaker AI AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AI AutoGluon-Tabular currently does not support multi-GPU training.

AutoGluon-Tabular sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AI AutoGluon-Tabular algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker AI AutoGluon-Tabular algorithm	This notebook demonstrates the use of the Amazon SageMaker AI AutoGluon-Tabular algorithm to train and host a tabular classific ation model.
Tabular regression with Amazon SageMaker AI AutoGluon-Tabular algorithm	This notebook demonstrates the use of the Amazon SageMaker AI AutoGluon-Tabular algorithm to train and host a tabular regressio n model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are ensembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.

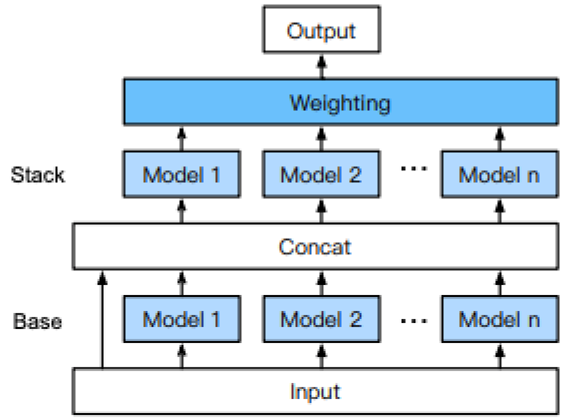

Figure 2. AutoGluon's multi-layer stacking strategy, shown here using two stacking layers and n types of base learners.

For more information, see *AutoGluon-Tabular: Robust and Accurate AutoML for Structured Data*.

AutoGluon-Tabular hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AI AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AI AutoGluon-Tabular algorithm is an implementation of the open-source AutoGluon-Tabular package.

> **Note**
>
> The default hyperparameters are based on example datasets in the AutoGluon-Tabular sample notebooks.

By default, the SageMaker AI AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on AutoGluon-Tabular hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
`eval_metric`	The evaluation metric for validation data. If `eval_metric` is set to the default `"auto"` value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • `"root_mean_squared_error"` for regression • `"roc_auc"` for binary classification • `"accuracy"` for multi-class classification Valid values: string, refer to the [AutoGluon documentation](#) for valid values. Default value: `"auto"`.
`presets`	List of preset configurations for various arguments in `fit()`. • `"best_quality"` : high predictive accuracy, slower inference times and higher disk usage • `"high_quality"` : high predictive accuracy and fast inference • `"good_quality"` : good predictive accuracy and very fast inference • `"medium_quality"` : medium predictive accuracy, very fast inference and training time • `"optimize_for_deployment"` : delete unused models and remove training artifacts • `"interpretable"` : fits only interpretable rule-based models from the `imodels` package For more details, see [AutoGluon Predictors](#). Valid values: string, any of the following: (`"best_quality"` , `"high_quality"` , `good_quality"` , `"medium_q`

Parameter Name	Description
	uality" ,"optimize_for_deployment" , or "interpretable"). Default value: "medium_quality" .
auto_stack	Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set auto_stack to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the num_bag_folds and num_stack _levels arguments based on dataset properties. Valid values: string, "True" or "False". Default value: "False".
num_bag_folds	Number of folds used for bagging of models. When num_bag_folds is equal to k, training time is roughly increased by a factor of k. Set num_bag_folds to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing num_bag_folds results in models with lower bias, but that are more prone to overfitti ng. One is an invalid value for this parameter, and will raise a ValueError . Values greater than 10 may produce diminishi ng returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing num_bag_f olds and instead increase num_bag_sets . Valid values: string, any integer between (and including) "0" and "10". Default value: "0".

Parameter Name	Description
`num_bag_sets`	Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to `num_bag_folds` * `num_bag_sets` . This parameter defaults to one if `time_limit` is not specified. This parameters is disabled if `num_bag_folds` is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [`1`, `20`]. Default value: `1`.
`num_stack_levels`	Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of `num_stack_levels` + 1. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a `ValueError` , `num_bag_folds` must be greater than or equal to 2. Valid values: float, range: [`0`, `3`]. Default value: `0`.
`refit_full`	Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors. Valid values: string, `"True"` or `"False"`. Default value: `"False"`.

Parameter Name	Description
`set_best_to_refit_full`	Whether or not to change the default model that the predictor uses for prediction. If `set_best_to_refit_full` is set to `"True"`, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by `refit_full`). Only valid if `refit_full` is set. Valid values: string, `"True"` or `"False"`. Default value: `"False"`.
`save_space`	Whether or note to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting `save_space` to `"True"` if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if `save_space` is set to `"True"`. Refer to the [`predictor.save_space()`] documentation for more details. Valid values: string, `"True"` or `"False"`. Default value: `"False"`.
`verbosity`	The verbosity of print messages. `verbosity` levels range from `0` to `4`, with higher levels corresponding to more detailed print statements. A `verbosity` of `0` suppresses warnings. Valid values: integer, any of the following: (`0`, `1`, `2`, `3`, or `4`). Default value: `2`.

Tuning an AutoGluon-Tabular model

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see AutoGluon-Tabular hyperparameters.

CatBoost

CatBoost is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms. This page includes information about Amazon EC2 instance recommendations and sample notebooks for CatBoost.

How to use SageMaker AI CatBoost

You can use CatBoost as an Amazon SageMaker AI built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

- **Use CatBoost as a built-in algorithm**

  Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker AI `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker AI Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "catboost-classification-model",
 "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters
```

```
# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "iterations"
] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AI LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker AI LightGBM and CatBoost algorithm

Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of CatBoost supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `training` or `validation` channels, the CatBoost algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AI CatBoost uses the `catboost.CatBoostClassifier` and `catboost.CatBoostRegressor` modules to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker AI CatBoost with `catboost`

- Use the following Python code:

```
import tarfile
from catboost import CatBoostClassifier

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)
```

```
# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the CatBoost algorithm

SageMaker AI CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

CatBoost sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AI CatBoost algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker AI LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker AI CatBoost algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker AI LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker AI CatBoost algorithm to train and host a tabular regression model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm

2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How the SageMaker AI XGBoost algorithm works. For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see *CatBoost: unbiased boosting with categorical features*.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AI CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AI CatBoost algorithm is an implementation of the open-source CatBoost package.

> **Note**
>
> The default hyperparameters are based on example datasets in the CatBoost sample notebooks.

By default, the SageMaker AI CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
iterations	The maximum number of trees that can be built. Valid values: integer, range: Positive integer. Default value: 500.
early_stopping_rounds	The training will stop if one metric of one validation data point does not improve in the last early_stopping_rounds round. If early_stopping_rounds is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: 5.
eval_metric	The evaluation metric for validation data. If eval_metric is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • "RMSE" for regression • "AUC" for binary classification • "MultiClass" for multi-class classification Valid values: string, refer to the CatBoost documentation for valid values. Default value: "auto".
learning_rate	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: (0.0, 1.0). Default value: 0.009.
depth	Depth of the tree.

Parameter Name	Description
	Valid values: integer, range: (1, 16). Default value: 6.
`l2_leaf_reg`	Coefficient for the L2 regularization term of the cost function. Valid values: integer, range: Positive integer. Default value: 3.
`random_strength`	The amount of randomness to use for scoring splits when the tree structure is selected. Use this parameter to avoid overfitti ng the model. Valid values: float, range: Positive floating point number. Default value: `1.0`.
`max_leaves`	The maximum number of leaves in the resulting tree. Can only be used with the `"Lossguide"` growing policy. Valid values: integer, range: [2, 64]. Default value: 31.
`rsm`	Random subspace method. The percentage of features to use at each split selection, when features are selected over again at random. Valid values: float, range: (`0.0`, `1.0`]. Default value: `1.0`.
`sampling_frequency`	Frequency to sample weights and objects when building trees. Valid values: string, either: (`"PerTreeLevel"` or `"PerTree"`). Default value: `"PerTreeLevel"` .

Parameter Name	Description
`min_data_in_leaf`	The minimum number of training samples in a leaf. CatBoost does not search for new splits in leaves with a sample count less than the specified value. Can only be used with the `"Lossguide"` and `"Depthwise"` growing policies. Valid values: integer, range: (1 or ∞). Default value: 1.
`bagging_temperature`	Defines the settings of the Bayesian bootstrap. Use the Bayesian bootstrap to assign random weights to objects. If `bagging_temperature` is set to `1.0`, then the weights are sampled from an exponential distribution. If `bagging_temperature` is set to `0.0`, then all weights are 1.0. Valid values: float, range: Non-negative float. Default value: `1.0`.
`boosting_type`	The boosting scheme. "Auto" means that the `boosting_type` is selected based on processing unit type, the number of objects in the training dataset, and the selected learning mode. Valid values: string, any of the following: (`"Auto"`, `"Ordered"`, `"Plain"`). Default value: `"Auto"`.
`scale_pos_weight`	The weight for positive class in binary classification. The value is used as a multiplier for the weights of objects from positive class. Valid values: float, range: Positive float. Default value: `1.0`.

Parameter Name	Description
max_bin	The number of splits for numerical features. "Auto" means that max_bin is selected based on the processing unit type and other parameters. For details, see the CatBoost documenta tion. Valid values: string, either: ("Auto" or string of integer from "1" to "65535" inclusively). Default value: "Auto".
grow_policy	The tree growing policy. Defines how to perform greedy tree construction. Valid values: string, any of the following: ("Symmetri cTree" , "Depthwise" , or "Lossguide"). Default value: "SymmetricTree" .
random_seed	The random seed used for training. Valid values: integer, range: Non-negative integer. Default value: 1.0.
thread_count	The number of threads to use during the training. If thread_count is -1, then the number of threads is equal to the number of processor cores. thread_count cannot be 0. Valid values: integer, either: (-1 or positive integer). Default value: -1.
verbose	The verbosity of print messages, with higher levels correspon ding to more detailed print statements. Valid values: integer, range: Positive integer. Default value: 1.

Tune a CatBoost model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning loss function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see CatBoost hyperparameters.

- A learning loss function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker AI console.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Evaluation metrics computed by the CatBoost algorithm

The SageMaker AI CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
`RMSE`	root mean square error	minimize	`"bestTest = ([0-9\\.]+)"`
`MAE`	mean absolute error	minimize	`"bestTest = ([0-9\\.]+)"`
`MedianAbsoluteError`	median absolute error	minimize	`"bestTest = ([0-9\\.]+)"`
`R2`	r2 score	maximize	`"bestTest = ([0-9\\.]+)"`
`Logloss`	binary cross entropy	maximize	`"bestTest = ([0-9\\.]+)"`
`Precision`	precision	maximize	`"bestTest = ([0-9\\.]+)"`
`Recall`	recall	maximize	`"bestTest = ([0-9\\.]+)"`
`F1`	f1 score	maximize	`"bestTest = ([0-9\\.]+)"`
`AUC`	auc score	maximize	`"bestTest = ([0-9\\.]+)"`

Metric Name	Description	Optimization Direction	Regex Pattern
`MultiClass`	multiclass cross entropy	maximize	`"bestTest = ([0-9\\.]+)"`
`Accuracy`	accuracy	maximize	`"bestTest = ([0-9\\.]+)"`
`BalancedAccuracy`	balanced accuracy	maximize	`"bestTest = ([0-9\\.]+)"`

Tunable CatBoost hyperparameters

Tune the CatBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the CatBoost evaluation metrics are: `learning_rate`, `depth`, `l2_leaf_reg`, and `random_strength`. For a list of all the CatBoost hyperparameters, see CatBoost hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
`depth`	IntegerParameterRanges	MinValue: 4, MaxValue: 10
`l2_leaf_reg`	IntegerParameterRanges	MinValue: 2, MaxValue: 10
`random_strength`	ContinuousParameterRanges	MinValue: 0, MaxValue: 10

Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

> **Note**
>
> The Amazon SageMaker AI implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics

- Input/Output Interface for the Factorization Machines Algorithm
- EC2 Instance Recommendation for the Factorization Machines Algorithm

- Factorization Machines Hyperparameters
- Tune a Factorization Machines Model
- Factorization Machines Response Formats

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the **test** channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For **training**, the Factorization Machines algorithm currently supports only the `recordIO-protobuf` format with `Float32` tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For **inference**, the Factorization Machines algorithm supports the `application/json` and `x-recordio-protobuf` formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either `0` or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker AI Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker AI Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. Example notebooks that use Factorization Machines algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function ŷ from a feature set x_i to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset (x_i,y_j) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

$$\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j>i} < v_i, v_j > x_i x_j$$

The three terms in this equation correspond respectively to the three components of the model:

- The w_0 term represents the global bias.
- The w_i linear terms model the strength of the i^{th} variable.
- The $<v_i,v_j>$ factorization terms model the pairwise interaction between the i^{th} and j^{th} variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see [Factorization Machines](https://www.csie.ntu.edu.tw/~b97053/paper/Rendle2010FM.pdf).

For regression tasks, the model is trained by minimizing the squared error between the model prediction $\hat{y}_n$ and the target value y_n. This is known as the square loss:

$$L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2$$

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

$$L = \frac{1}{N} \sum_n \left[y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n) \right]$$

where:

$$\hat{p}_n = \frac{1}{1 + e^{-\hat{y}_n}}$$

For more information about loss functions for classification, see Loss functions for classification.

Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Parameter Name	Description
`feature_dim`	The dimension of the input feature space. This could be very high with sparse input. **Required** Valid values: Positive integer. Suggested value range: [10000,10000000]
`num_factors`	The dimensionality of factorization. **Required** Valid values: Positive integer. Suggested value range: [2,1000], 64 typically generates good outcomes and is a good starting point.
`predictor_type`	The type of predictor. • `binary_classifier` : For binary classification tasks. • `regressor` : For regression tasks. **Required** Valid values: String: `binary_classifier` or `regressor`
`bias_init_method`	The initialization method for the bias term:

Parameter Name	Description
	`normal`: Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by `bias_init_sigma` . `uniform`: Initializes weights with random values uniformly sampled from a range specified by [-`bias_init_scale` , +`bias_init_scale`]. `constant`: Initializes the weights to a scalar value specified by `bias_init_value` . **Optional** Valid values: `uniform`, `normal`, or `constant` Default value: `normal`
`bias_init_scale`	Range for initialization of the bias term. Takes effect if `bias_init_method` is set to `uniform`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
`bias_init_sigma`	The standard deviation for initialization of the bias term. Takes effect if `bias_init_method` is set to `normal`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01

Parameter Name	Description
`bias_init_value`	The initial value of the bias term. Takes effect if `bias_init_method` is set to `constant`. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
`bias_lr`	The learning rate for the bias term. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.1
`bias_wd`	The weight decay for the bias term. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01
`clip_gradient`	Gradient clipping optimizer parameter. Clips the gradient by projecting onto the interval [-`clip_gradient` , +`clip_gradient`]. **Optional** Valid values: Float Default value: None

Parameter Name	Description
epochs	The number of training epochs to run. **Optional** Valid values: Positive integer Default value: 1
eps	Epsilon parameter to avoid division by 0. **Optional** Valid values: Float. Suggested value: small. Default value: None
factors_init_method	The initialization method for factorization terms: • `normal` Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by `factors_init_sigma` . • `uniform`: Initializes weights with random values uniformly sampled from a range specified by [-`factors_init_scale` , +`factors_init_scale`]. • `constant`: Initializes the weights to a scalar value specified by `factors_init_value` . **Optional** Valid values: `uniform`, `normal`, or `constant`. Default value: `normal`

Parameter Name	Description
`factors_init_scale`	The range for initialization of factorization terms. Takes effect if `factors_init_method` is set to `uniform`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
`factors_init_sigma`	The standard deviation for initialization of factorization terms. Takes effect if `factors_init_method` is set to `normal`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001
`factors_init_value`	The initial value of factorization terms. Takes effect if `factors_init_method` is set to `constant`. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
`factors_lr`	The learning rate for factorization terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.0001

Parameter Name	Description
`factors_wd`	The weight decay for factorization terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.00001
`linear_lr`	The learning rate for linear terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001
`linear_init_method`	The initialization method for linear terms: • `normal` Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by `linear_init_sigma` . • `uniform` Initializes weights with random values uniformly sampled from a range specified by [-`linear_init_scale` , +`linear_init_scale`]. • `constant` Initializes the weights to a scalar value specified by `linear_init_value` . **Optional** Valid values: `uniform`, `normal`, or `constant`. Default value: `normal`

Parameter Name	Description
`linear_init_scale`	Range for initialization of linear terms. Takes effect if `linear_init_method` is set to `uniform`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
`linear_init_sigma`	The standard deviation for initialization of linear terms. Takes effect if `linear_init_method` is set to `normal`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01
`linear_init_value`	The initial value of linear terms. Takes effect if `linear_init_method` is set to *constant*. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
`linear_wd`	The weight decay for linear terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001

Parameter Name	Description
`mini_batch_size`	The size of mini-batch used for training. **Optional** Valid values: Positive integer Default value: 1000
`rescale_grad`	Gradient rescaling optimizer parameter. If set, multiplies the gradient with `rescale_grad` before updating. Often choose to be 1.0/`batch_size` . **Optional** Valid values: Float Default value: None

Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a `test:rmse` regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
`test:rmse`	Root Mean Square Error	Minimize

The Factorization Machines algorithm reports three binary classification metrics, which are computed during training. When tuning the model for binary classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
`test:binary_classification_accuracy`	Accuracy	Maximize
`test:binary_classification_cross_entropy`	Cross Entropy	Minimize
`test:binary_f_beta`	Beta	Maximize

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: `uniform`, `normal`, and `constant`. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is `uniform`, then only the `scale` parameters are tunable. Specifically, if `bias_init_method==uniform`, then `bias_init_scale`, `linear_init_scale`, and `factors_init_scale` are tunable. Similarly, if the initialization method is `normal`, then only sigma parameters are tunable. If the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

Parameter Name	Parameter Type	Recommended Ranges	Dependency
bias_init_scale	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
bias_init_sigma	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
bias_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
bias_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
bias_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
epoch	IntegerParameterRange	MinValue: 1, MaxValue: 1000	None
factors_init_scale	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
factors_init_sigma	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
factors_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant

Parameter Name	Parameter Type	Recommended Ranges	Dependency
`factors_lr`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
`factors_wd`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512]	None
`linear_init_scale`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
`linear_init_sigma`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
`linear_init_value`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
`linear_lr`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
`linear_wd`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
`mini_batch_size`	IntegerParameterRange	MinValue: 100, MaxValue: 10000	None

Factorization Machines Response Formats

Amazon SageMaker AI provides several response formats for getting inference from the Factorization Machines model, such as JSON, JSONLINES, and RECORDIO, with specific structures for binary classification and regression tasks.

JSON Response Format

Binary classification

```
let response =   {
    "predictions":    [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
}
```

Regression

```
let response =   {
    "predictions":    [
        {
            "score": 0.4
        }
    ]
}
```

JSONLINES Response Format

Binary classification

```
{"score": 0.4, "predicted_label": 0}
```

Regression

```
{"score": 0.4}
```

RECORDIO Response Format

Binary classification

```
[
    Record = {
        features = {},
        label = {
            'score’: {
                keys: [],
                values: [0.4]  # float32
            },
```

```
            'predicted_label': {
                keys: [],
                values: [0.0]  # float32
            }
        }
    }
]
```

Regression

```
[
    Record = {
        features = {},
        label = {
            'score’: {
                keys: [],
                values: [0.4]  # float32
            }
        }
    }
]
```

K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker AI k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the *k* points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the *k* closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d >1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

Topics

Input/Output Interface for the k-NN Algorithm

SageMaker AI k-NN supports train and test data channels.

- Use a *train channel* for data that you want to sample and construct into the k-NN index.
- Use a *test channel* to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for `classifier`, mean-squared error (mse) for `regressor` for score.

For training inputs, k-NN supports `text/csv` and `application/x-recordio-protobuf` data formats. For input type `text/csv`, the first `label_size` columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference inputs, k-NN supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` data formats. The `text/csv` format accepts a `label_size` and encoding parameter. It assumes a `label_size` of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the `application/json` and `application/x-recordio-protobuf` data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the `application/jsonlines` data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines
```

```
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input for training, k-NN Request and Response Formats for inference, and the k-NN Sample Notebooks.

k-NN Sample Notebooks

For a sample notebook that uses the SageMaker AI k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype .

Use a Jupyter notebook instance to run the example in SageMaker AI. To learn how to create and open a Jupyter notebook instance in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI example notebooks. Find K-Nearest Neighbor notebooks in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How the k-NN Algorithm Works

The Amazon SageMaker AI k-nearest neighbors (k-NN) algorithm follows a multi-step training process which includes sampling the input data, performing dimension reduction, and building an index. The indexed data is then used during inference to efficiently find the k-nearest neighbors for a given data point and make predictions based on the neighboring labels or values.

Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size`parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample

50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The `fjlt` method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.

Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- model_algo-1: Contains the serialized index for computing the nearest neighbors.
- model_algo-1.labels: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- model_algo-1.json: Contains the JSON-formatted model metadata which stores the `k` and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change `k` to 10 or change `predictor_type` to *regressor*.

```
{
```

```
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {"type": "sign", "seed": 3, "target_dim": 10, "input_dim":
 20},
  "normalize": False,
  "version": "1.0"
}
```

EC2 Instance Recommendation for the k-NN Algorithm

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

k-NN Hyperparameters

The following table lists the hyperparameters that you can set for the Amazon SageMaker AI k-nearest neighbors (k-NN) algorithm.

Parameter Name	Description
`feature_dim`	The number of features in the input data. **Required** Valid values: positive integer.
`k`	The number of nearest neighbors. **Required** Valid values: positive integer
`predictor_type`	The type of inference to use on the data labels. **Required** Valid values: *classifier* for classification or *regressor* for regression.

Parameter Name	Description
`sample_size`	The number of data points to be sampled from the training data set. **Required** Valid values: positive integer
`dimension_reduction_target`	The target dimension to reduce to. **Required** when you specify the `dimension_reduction_type` parameter. Valid values: positive integer greater than 0 and less than `feature_dim` .
`dimension_reduction_type`	The type of dimension reduction method. **Optional** Valid values: *sign* for random projection or *fjlt* for the fast Johnson-Lindenstrauss transform. Default value: No dimension reduction
`faiss_index_ivf_nlists`	The number of centroids to construct in the index when `index_type` is *faiss.IVFFlat* or *faiss.IVFPQ*. **Optional** Valid values: positive integer Default value: *auto*, which resolves to `sqrt(sample_size)` .

Parameter Name	Description
`faiss_index_pq_m`	The number of vector sub-components to construct in the index when `index_type` is set to *faiss.IVFPQ*. The FaceBook AI Similarity Search (FAISS) library requires that the value of `faiss_index_pq_m` is a divisor of the data dimension. If `faiss_index_pq_m` is not a divisor of the data dimension, we increase the data dimension to smallest integer divisible by `faiss_index_pq_m`. If no dimension reduction is applied, the algorithm adds a padding of zeros. If dimension reduction is applied, the algorithm increase the value of the `dimension_reduction_target` hyper-parameter. **Optional** Valid values: One of the following positive integers: 1, 2, 3, 4, 8, 12, 16, 20, 24, 28, 32, 40, 48, 56, 64, 96
`index_metric`	The metric to measure the distance between points when finding nearest neighbors. When training with `index_type` set to `faiss.IVFPQ`, the `INNER_PRODUCT` distance and `COSINE` similarity are not supported. **Optional** Valid values: *L2* for Euclidean-distance, *INNER_PRODUCT* for inner-product distance, *COSINE* for cosine similarity. Default value: *L2*
`index_type`	The type of index. **Optional** Valid values: *faiss.Flat*, *faiss.IVFFlat*, *faiss.IVFPQ*. Default values: *faiss.Flat*

Parameter Name	Description
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: positive integer Default value: 5000

Tune a k-NN Model

The Amazon SageMaker AI k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- *classifier* specifies a classification task and computes `test:accuracy`
- *regressor* specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

Metric Name	Description	Optimization Direction
`test:accuracy`	When `predictor_type` is set to *classifier*, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).	Maximize
`test:mse`	When `predictor_type` is set to *regressor*, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.	Minimize

Tunable k-NN Hyperparameters

Tune the Amazon SageMaker AI k-nearest neighbor model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
k	IntegerParameterRanges	MinValue: 1, MaxValue: 1024
`sample_size`	IntegerParameterRanges	MinValue: 256, MaxValue: 20000000

Data Formats for k-NN Training Input

All Amazon SageMaker AI built-in algorithms adhere to the common input training formats described in [Common Data Formats - Training](). This topic contains a list of the available input formats for the SageMaker AI k-nearest-neighbor algorithm.

CSV Data Format

content-type: text/csv; label_size=1

```
4,1.2,1.3,9.6,20.3
```

The first `label_size` columns are interpreted as the label vector for that row.

RECORDIO Data Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {
            'values': {
                values: [1.2, 1.3, 9.6, 20.3]  # float32
            }
        },
        label = {
            'values': {
                values: [4]  # float32
            }
        }
    }
]

}
```

k-NN Request and Response Formats

All Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker AI k-nearest-neighbor algorithm.

INPUT: CSV Request Format

content-type: text/csv

```
1.2,1.3,9.6,20.3
```

This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

INPUT: JSON Request Format

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": [-3, -1, -4, 2]}}},
    {"features": [3.0, 0.1, 0.04, 0.002]}]
}
```

INPUT: JSONLINES Request Format

content-type: application/jsonlines

```
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}
```

INPUT: RECORDIO Request Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {
            'values': {
                values: [-3, -1, -4, 2]  # float32
            }
        },
        label = {}
    },
    Record = {
        features = {
            'values': {
                values: [3.0, 0.1, 0.04, 0.002]  # float32
            }
        },
        label = {}
    },
]
```

OUTPUT: JSON Response Format

accept: application/json

```
{
  "predictions": [
    {"predicted_label": 0.0},
    {"predicted_label": 2.0}
  ]
}
```

OUTPUT: JSONLINES Response Format

accept: application/jsonlines

```
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

OUTPUT: VERBOSE JSON Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

```
{
  "predictions": [
    {
        "predicted_label": 0.0,
        "distances": [3.11792408, 3.89746071, 6.32548437],
        "labels": [0.0, 1.0, 0.0]
    },
    {
        "predicted_label": 2.0,
        "distances": [1.08470316, 3.04917915, 5.25393973],
        "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

OUTPUT: RECORDIO-PROTOBUF Response Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [2.0]  # float32
            }
        }
    }
]
```

OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/x-recordio-protobuf; verbose=true

```
[
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            },
            'distances': {
                values: [3.11792408, 3.89746071, 6.32548437]  # float32
            },
            'labels': {
                values: [0.0, 1.0, 0.0]  # float32
            }
        }
    },
    Record = {
        features = {},
```

```
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            },
            'distances': {
                values: [1.08470316, 3.04917915, 5.25393973]  # float32
            },
            'labels': {
                values: [2.0, 2.0, 0.0]  # float32
            }
        }
    }
]
```

SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

```
[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse',
 0.013333333333333334)
```

For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy',
 0.98666666666666669)
```

LightGBM

LightGBM is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT. This page includes information about Amazon EC2 instance recommendations and sample notebooks for LightGBM.

How to use SageMaker AI LightGBM

You can use LightGBM as an Amazon SageMaker AI built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker AI `image_uris.retrieve` API (or the `get_image_uri` API if using [Amazon SageMaker Python SDK](https://sagemaker.readthedocs.io) version 2).

  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker AI Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "lightgbm-classification-model",
 "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
```

```
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "num_boost_round"
] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1, # for distributed training, specify an instance_count greater
 than 1
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)
```

```
# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "train": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AI LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker AI LightGBM and CatBoost algorithm

Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of LightGBM supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `train` and `validation` channels to provide your input data. Alternatively, you can use only the `train` channel.

> **Note**
>
> Both `train` and `training` are valid channel names for LightGBM training.

Use both the `train` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `train` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `train` or `validation` channels, the LightGBM algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `train` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `train` channel:

You can alternatively provide your input data by way of a single S3 path for the `train` channel. This S3 path should point to a directory with a subdirectory named `train/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AI LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker AI LightGBM with the JobLib module

- Use the following Python code:

```
import joblib
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = joblib.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the LightGBM algorithm

SageMaker AI LightGBM currently supports single-instance and multi-instance CPU training. For multi-instance CPU training (distributed training), specify an `instance_count` greater than 1 when you define your Estimator. For more information on distributed training with LightGBM, see [Amazon SageMaker AI LightGBM Distributed training using Dask](https://).

LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

LightGBM sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AI LightGBM algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker AI LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker AI LightGBM algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker AI LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker AI LightGBM algorithm to train and host a tabular regression model.
Amazon SageMaker AI LightGBM Distributed training using Dask	This notebook demonstrates distribut ed training with the Amazon SageMaker AI LightGBM algorithm using the Dask framework.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How LightGBM works

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How the SageMaker AI XGBoost algorithm works. For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see *LightGBM: A Highly Efficient Gradient Boosting Decision Tree*.

LightGBM hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AI LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AI LightGBM algorithm is an implementation of the open-source LightGBM package.

> **Note**
>
> The default hyperparameters are based on example datasets in the LightGBM sample notebooks.

By default, the SageMaker AI LightGBM algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The LightGBM algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error and the objective function is L2 loss. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric is multiclass cross entropy and the objective function is softmax. You can use the `metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
`num_boost_round`	The maximum number of boosting iterations. **Note:** Internally, LightGBM constructs `num_class * num_boost_round` trees for multi-class classification problems. Valid values: integer, range: Positive integer. Default value: `100`.
`early_stopping_rounds`	The training will stop if one metric of one validation data point does not improve in the last `early_stopping_rounds`

Parameter Name	Description
	round. If `early_stopping_rounds` is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: `10`.
`metric`	The evaluation metric for validation data. If `metric` is set to the default `"auto"` value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • `rmse` for regression • `binary_logloss` for binary classification • `multi_logloss` for multi-class classification Valid values: string, any of the following: (`"auto"`, `"rmse"`, `"l1"`, `"l2"`, `"huber"`, `"fair"`, `"binary_logloss"`, `"binary_error"`, `"auc"`, `"average_precision"`, `"multi_logloss"`, `"multi_error"`, `"auc_mu"`, or `"cross_entropy"`). Default value: `"auto"`.
`learning_rate`	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: (`0.0`, `1.0`). Default value: `0.1`.
`num_leaves`	The maximum number of leaves in one tree. Valid values: integer, range: (1, 131072). Default value: 64.

Parameter Name	Description
`feature_fraction`	A subset of features to be selected on each iteration (tree). Must be less than 1.0. Valid values: float, range: (`0.0`, `1.0`). Default value: `0.9`.
`bagging_fraction`	A subset of features similar to `feature_fraction` , but `bagging_fraction` randomly selects part of the data without resampling. Valid values: float, range: (`0.0`, `1.0`]. Default value: `0.9`.
`bagging_freq`	The frequency to perform bagging. At every `bagging_freq` iteration, LightGBM randomly selects a percentage of the data to use for the next `bagging_freq` iteration. This percentage is determined by the `bagging_fraction` hyperparameter. If `bagging_freq` is zero, then bagging is deactivated. Valid values: integer, range: Non-negative integer. Default value: `1`.
`max_depth`	The maximum depth for a tree model. This is used to deal with overfitting when the amount of data is small. If `max_depth` is less than or equal to zero, this means there is no limit for maximum depth. Valid values: integer. Default value: `6`.

Parameter Name	Description
`min_data_in_leaf`	The minimum amount of data in one leaf. Can be used to deal with overfitting. Valid values: integer, range: Non-negative integer. Default value: 3.
`max_delta_step`	Used to limit the max output of tree leaves. If `max_delta_step` is less than or equal to 0, then there is no constrain t. The final max output of leaves is `learning_rate * max_delta_step` . Valid values: float. Default value: `0.0`.
`lambda_l1`	L1 regularization. Valid values: float, range: Non-negative float. Default value: `0.0`.
`lambda_l2`	L2 regularization. Valid values: float, range: Non-negative float. Default value: `0.0`.
`boosting`	Boosting type Valid values: string, any of the following: (`"gbdt"`, `"rf"`, `"dart"`, or `"goss"`). Default value: `"gbdt"`.

Parameter Name	Description
`min_gain_to_split`	The minimum gain to perform a split. Can be used to speed up training. Valid values: integer, float: Non-negative float. Default value: `0.0`.
`scale_pos_weight`	The weight of the labels with positive class. Used only for binary classification tasks. `scale_pos_weight` cannot be used if `is_unbalance` is set to `"True"`. Valid values: float, range: Positive float. Default value: `1.0`.
`tree_learner`	Tree learner type. Valid values: string, any of the following: (`"serial"`, `"feature"` , `"data"`, or `"voting"`). Default value: `"serial"`.
`feature_fraction_bynode`	Selects a subset of random features on each tree node. For example, if `feature_fraction_bynode` is `0.8`, then 80% of features are selected. Can be used to deal with overfitting. Valid values: integer, range: (`0.0`, `1.0`]. Default value: `1.0`.
`is_unbalance`	Set to `"True"` if training data is unbalanced. Used only for binary classification tasks. `is_unbalance` cannot be used with `scale_pos_weight` . Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.

Parameter Name	Description
`max_bin`	The maximum number of bins used to bucket feature values. A small number of bins may reduce training accuracy, but may increase general performance. Can be used to deal with overfitting. Valid values: integer, range: (1, ∞). Default value: `255`.
`tweedie_variance_power`	Controls the variance of the Tweedie distribution. Set this closer to `2.0` to shift toward a gamma distribution. Set this closer to `1.0` to shift toward a Poisson distribution. Used only for regression tasks. Valid values: float, range: [`1.0`, `2.0`). Default value: `1.5`.
`num_threads`	Number of parallel threads used to run LightGBM. Value 0 means default number of threads in OpenMP. Valid values: integer, range: Non-negative integer. Default value: `0`.
`verbosity`	The verbosity of print messages. If the `verbosity` is less than `0`, then print messages only show fatal errors. If `verbosity` is set to `0`, then print messages include errors and warnings. If `verbosity` is 1, then print messages show more information. A `verbosity` greater than 1 shows the most information in print messages and can be used for debugging. Valid values: integer. Default value: 1.

Tune a LightGBM model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning objective function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see LightGBM hyperparameters.

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker AI console.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Evaluation metrics computed by the LightGBM algorithm

The SageMaker AI LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
`rmse`	root mean square error	minimize	`"rmse: ([0-9\\.]+)"`
`l1`	mean absolute error	minimize	`"l1: ([0-9\\.]+)"`
`l2`	mean squared error	minimize	`"l2: ([0-9\\.]+)"`
`huber`	huber loss	minimize	`"huber: ([0-9\\.]+)"`
`fair`	fair loss	minimize	`"fair: ([0-9\\.]+)"`
`binary_logloss`	binary cross entropy	maximize	`"binary_logloss: ([0-9\\.]+)"`
`binary_error`	binary error	minimize	`"binary_error: ([0-9\\.]+)"`
`auc`	AUC	maximize	`"auc: ([0-9\\.]+)"`
`average_precision`	average precision score	maximize	`"average_precision: ([0-9\\.]+)"`

Metric Name	Description	Optimization Direction	Regex Pattern
`multi_logloss`	multiclass cross entropy	maximize	`"multi_logloss: ([0-9\\.]+)"`
`multi_error`	multiclass error score	minimize	`"multi_error: ([0-9\\.]+)"`
`auc_mu`	AUC-mu	maximize	`"auc_mu: ([0-9\\.]+)"`
`cross_entropy`	cross entropy	minimize	`"cross_entropy: ([0-9\\.]+)"`

Tunable LightGBM hyperparameters

Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: `learning_rate`, `num_leaves`, `feature_fraction`, `bagging_fraction`, `bagging_freq`, `max_depth` and `min_data_in_leaf`. For a list of all the LightGBM hyperparameters, see LightGBM hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
`num_leaves`	IntegerParameterRanges	MinValue: 10, MaxValue: 100

Parameter Name	Parameter Type	Recommended Ranges
feature_fraction	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1.0
bagging_fraction	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1.0
bagging_freq	IntegerParameterRanges	MinValue: 0, MaxValue: 10
max_depth	IntegerParameterRanges	MinValue: 15, MaxValue: 100
min_data_in_leaf	IntegerParameterRanges	MinValue: 10, MaxValue: 200

Linear Learner Algorithm

Linear models are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples (*x*, *y*). *x* is a high-dimensional vector and *y* is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to `num_classes` - 1. For regression problems, *y* is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector *x* to an approximation of the label *y*.

The Amazon SageMaker AI linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker AI algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker AI linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker AI linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`. You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

Input/Output interface for the linear learner algorithm

The Amazon SageMaker AI linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the `S3DataDistributionType` should be `FullyReplicated`. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both `recordIO-wrapped protobuf` and CSV formats. For the `application/x-recordio-protobuf` input type, only Float32 tensors are supported. For the `text/csv` input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. **For regression** (predictor_type='regressor'), the score is the prediction produced by the model. **For classification** (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- **For binary classification**, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- **For multiclass classification**, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats. For more information on inference formats, and the Linear learner sample notebooks.

EC2 instance recommendation for the linear learner algorithm

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AI linear learner algorithm.

Notebook Title	Description
An Introduction with the MNIST dataset	Using the MNIST dataset, we train a binary classifier to predict a single digit.
How to Build a Multiclass Classifier?	Using UCI's Covertype dataset, we demonstra te how to train a multiclass classifier.
How to Build a Machine Learning (ML) Pipeline for Inference?	Using a Scikit-learn container, we demonstrate how to build an end-to-end ML pipeline.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker AI Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

> **Note**
>
> For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

> **Note**
>
> If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to `auto`, Amazon SageMaker AI will automatically calculate and set the value of that hyperparameter.

Parameter Name	Description
`num_classes`	The number of classes for the response variable. The algorithm assumes that classes are labeled `0`, ..., `num_classes - 1`. **Required** when `predictor_type` is `multiclass_classifier`. Otherwise, the algorithm ignores it. Valid values: Integers from 3 to 1,000,000
`predictor_type`	Specifies the type of target variable as a binary classification, multiclass classification, or regression. **Required** Valid values: `binary_classifier`, `multiclass_classifier`, or `regressor`
`accuracy_top_k`	When computing the top-k accuracy metric for multiclass classification, the value of *k*. If the model assigns one of the top-k scores to the true label, an example is scored as correct. **Optional** Valid values: Positive integers Default value: 3
`balance_multiclass_weights`	Specifies whether to use class weights, which give each class equal importance in the loss function. Used only when the `predictor_type` is `multiclass_classifier`. **Optional** Valid values: `true`, `false` Default value: `false`

Parameter Name	Description
beta_1	The exponential decay rate for first-moment estimates. Applies only when the optimizer value is adam. **Optional** Valid values: auto or floating-point value between 0 and 1.0 Default value: auto
beta_2	The exponential decay rate for second-moment estimates. Applies only when the optimizer value is adam. **Optional** Valid values: auto or floating-point integer between 0 and 1.0 Default value: auto
bias_lr_mult	Allows a different learning rate for the bias term. The actual learning rate for the bias is learning_rate * bias_lr_mult . **Optional** Valid values: auto or positive floating-point integer Default value: auto
bias_wd_mult	Allows different regularization for the bias term. The actual L2 regularization weight for the bias is wd * bias_wd_mult . By default, there is no regularization on the bias term. **Optional** Valid values: auto or non-negative floating-point integer Default value: auto

Parameter Name	Description
`binary_classifier_model_selection_criteria`	When `predictor_type` is set to `binary_classifier`, the model evaluation criteria for the validation dataset (or for the training dataset if you don't provide a validation dataset). Criteria include: • `accuracy`—The model with the highest accuracy. • `f_beta`—The model with the highest F1 score. The default is F1. • `precision_at_target_recall`—The model with the highest precision at a given recall target. • `recall_at_target_precision`—The model with the highest recall at a given precision target. • `loss_function`—The model with the lowest value of the loss function used in training. **Optional** Valid values: `accuracy`, `f_beta`, `precision_at_target_recall`, `recall_at_target_precision`, or `loss_function` Default value: `accuracy`

Parameter Name	Description
`early_stopping_patience`	If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for `binary_classifier_model_selection_criteria` . the metric is that value. Otherwise, the metric is the same as the value specified for the `loss` hyperparameter. The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the `loss` hyperparameter and is evaluated on the training data. To disable early stopping, set `early_stopping_patience` to a value greater than the value specified for `epochs`. **Optional** Valid values: Positive integer Default value: 3
`early_stopping_tolerance`	The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero. **Optional** Valid values: Positive floating-point integer Default value: 0.001
`epochs`	The maximum number of passes over the training data. **Optional** Valid values: Positive integer Default value: 15

Parameter Name	Description
`f_beta`	The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for `binary_classifier_model_selection_criteria` is `f_beta`. **Optional** Valid values: Positive floating-point integers Default value: 1.0
`feature_dim`	The number of features in the input data. **Optional** Valid values: `auto` or positive integer Default values: `auto`
`huber_delta`	The parameter for Huber loss. During training and metric evaluatio n, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta. **Optional** Valid values: Positive floating-point integer Default value: 1.0
`init_bias`	Initial weight for the bias term. **Optional** Valid values: Floating-point integer Default value: 0

Parameter Name	Description
`init_method`	Sets the initial distribution function used for model weights. Functions include: • `uniform`—Uniformly distributed between (-scale, +scale) • `normal`—Normal distribution, with mean 0 and sigma **Optional** Valid values: `uniform` or `normal` Default value: `uniform`
`init_scale`	Scales an initial uniform distribution for model weights. Applies only when the `init_method` hyperparameter is set to `uniform`. **Optional** Valid values: Positive floating-point integer Default value: 0.07
`init_sigma`	The initial standard deviation for the normal distribution. Applies only when the `init_method` hyperparameter is set to `normal`. **Optional** Valid values: Positive floating-point integer Default value: 0.01
`l1`	The L1 regularization parameter. If you don't want to use L1 regularization, set the value to 0. **Optional** Valid values: `auto` or non-negative float Default value: `auto`

Parameter Name	Description
learning_rate	The step size used by the optimizer for parameter updates. **Optional** Valid values: auto or positive floating-point integer Default value: auto, whose value depends on the optimizer chosen.
loss	Specifies the loss function. The available loss functions and their default values depend on the value of predictor_type : • If the predictor_type is set to regressor , the available options are auto, squared_loss , absolute_loss , eps_insensitive_squared_loss , eps_insensitive_absolute_loss , quantile_loss , and huber_loss . The default value for auto is squared_loss . • If the predictor_type is set to binary_classifier , the available options are auto,logistic, and hinge_loss . The default value for auto is logistic. • If the predictor_type is set to multiclass_classifier , the available options are auto and softmax_loss . The default value for auto is softmax_loss . Valid values: auto, logistic, squared_loss , absolute_loss , hinge_loss , eps_insensitive_squared_loss , eps_insensitive_absolute_loss , quantile_loss , or huber_loss **Optional** Default value: auto

Parameter Name	Description
loss_inse nsitivity	The parameter for the epsilon-insensitive loss type. During training and metric evaluation, any error smaller than this value is considered to be zero. **Optional** Valid values: Positive floating-point integer Default value: 0.01
lr_schedu ler_factor	For every `lr_scheduler_step` hyperparameter, the learning rate decreases by this quantity. Applies only when the `use_lr_sc heduler` hyperparameter is set to `true`. **Optional** Valid values: `auto` or positive floating-point integer between 0 and 1 Default value: `auto`
lr_schedu ler_minimum_lr	The learning rate never decreases to a value lower than the value set for `lr_scheduler_minimum_lr` . Applies only when the `use_lr_scheduler` hyperparameter is set to `true`. **Optional** Valid values: `auto` or positive floating-point integer Default values: `auto`
lr_scheduler_step	The number of steps between decreases of the learning rate. Applies only when the `use_lr_scheduler` hyperparameter is set to `true`. **Optional** Valid values: `auto` or positive integer Default value: `auto`

Parameter Name	Description
`margin`	The margin for the `hinge_loss` function. **Optional** Valid values: Positive floating-point integer Default value: 1.0
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: Positive integer Default value: 1000
`momentum`	The momentum of the `sgd` optimizer. **Optional** Valid values: `auto` or a floating-point integer between 0 and 1.0 Default value: `auto`
`normalize_data`	Normalizes the feature data before training. Data normalization shifts the data for each feature to have a mean of zero and scales it to have unit standard deviation. **Optional** Valid values: `auto`, `true`, or `false` Default value: `true`

Parameter Name	Description
`normalize_label`	Normalizes the label. Label normalization shifts the label to have a mean of zero and scales it to have unit standard deviation. The `auto` default value normalizes the label for regression problems but does not for classification problems. If you set the `normalize_label` hyperparameter to `true` for classification problems, the algorithm ignores it. **Optional** Valid values: `auto`, `true`, or `false` Default value: `auto`
`num_calibration_samples`	The number of observations from the validation dataset to use for model calibration (when finding the best threshold). **Optional** Valid values: `auto` or positive integer Default value: `auto`
`num_models`	The number of models to train in parallel. For the default, `auto`, the algorithm decides the number of parallel models to train. One model is trained according to the given training parameter (regularization, optimizer, loss), and the rest by close parameters. **Optional** Valid values: `auto` or positive integer Default values: `auto`

Parameter Name	Description
`num_point_for_scaler`	The number of data points to use for calculating normalization or unbiasing of terms. **Optional** Valid values: Positive integer Default value: 10,000
`optimizer`	The optimization algorithm to use. **Optional** Valid values: • `auto`—The default value. • `sgd`—Stochastic gradient descent. • `adam`—[Adaptive momentum estimation](https://arxiv.org/pdf/1412.6980.pdf). • `rmsprop`—A gradient-based optimization technique that uses a moving average of squared gradients to normalize the gradient. Default value: `auto`. The default setting for `auto` is `adam`.
`positive_example_weight_mult`	The weight assigned to positive examples when training a binary classifier. The weight of negative examples is fixed at 1. If you want the algorithm to choose a weight so that errors in classifying negative *vs.* positive examples have equal impact on training loss, specify `balanced`. If you want the algorithm to choose the weight that optimizes performance, specify `auto`. **Optional** Valid values: `balanced`, `auto`, or a positive floating-point integer Default value: 1.0

Parameter Name	Description
quantile	The quantile for quantile loss. For quantile q, the model attempts to produce predictions so that the value of true_label is greater than the prediction with probability q. **Optional** Valid values: Floating-point integer between 0 and 1 Default value: 0.5
target_precision	The target precision. If binary_classifier_model_selection_criteria is recall_at_target_precision , then precision is held at this value while recall is maximized. **Optional** Valid values: Floating-point integer between 0 and 1.0 Default value: 0.8
target_recall	The target recall. If binary_classifier_model_selection_criteria is precision_at_target_recall , then recall is held at this value while precision is maximized. **Optional** Valid values: Floating-point integer between 0 and 1.0 Default value: 0.8
unbias_data	Unbiases the features before training so that the mean is 0. By default data is unbiased as the use_bias hyperparameter is set to true. **Optional** Valid values: auto, true, or false Default value: auto

Parameter Name	Description
unbias_label	Unbiases labels before training so that the mean is 0. Applies to regression only if the use_bias hyperparameter is set to true. **Optional** Valid values: auto, true, or false Default value: auto
use_bias	Specifies whether the model should include a bias term, which is the intercept term in the linear equation. **Optional** Valid values: true or false Default value: true
use_lr_scheduler	Whether to use a scheduler for the learning rate. If you want to use a scheduler, specify true. **Optional** Valid values: true or false Default value: true
wd	The weight decay parameter, also known as the L2 regularization parameter. If you don't want to use L2 regularization, set the value to 0. **Optional** Valid values:auto or non-negative floating-point integer Default value: auto

Tune a linear learner model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

Metric Name	Description	Optimization Direction
`test:absolute_loss`	The absolute loss of the final model on the test dataset. This objective metric is only valid for regression.	Minimize
`test:binary_classification_accuracy`	The accuracy of the final model on the test dataset. This objective metric is only valid for binary classification.	Maximize
`test:binary_f_beta`	The F-beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall.	Maximize

Metric Name	Description	Optimization Direction
	This objective metric is only valid for binary classification.	
`test:dcg`	The discounted cumulative gain of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
`test:macro_f_beta`	The F-beta score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
`test:macro_precision`	The precision score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
`test:macro_recall`	The recall score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
`test:mse`	The mean square error of the final model on the test dataset. This objective metric is only valid for regression.	Minimize
`test:multiclass_accuracy`	The accuracy of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
`test:multiclass_top_k_accuracy`	The accuracy among the top k labels predicted on the test dataset. If you choose this metric as the objective, we recommend setting the value of k using the `accuracy_top_k` hyperparameter. This objective metric is only valid for multiclass classification.	Maximize

Metric Name	Description	Optimization Direction
`test:objective_loss`	The mean value of the objective loss function on the test dataset after the model is trained. By default, the loss is logistic loss for binary classification and squared loss for regression. To set the loss to other types, use the `loss` hyperparameter.	Minimize
`test:precision`	The precision of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the `binary_classifier_model_selection` hyperparameter to `precision_at_target_recall` and setting the value for the `target_recall` hyperparameter. This objective metric is only valid for binary classification.	Maximize
`test:recall`	The recall of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the `binary_classifier_model_selection` hyperparameter to `recall_at_target_precision` and setting the value for the `target_precision` hyperparameter. This objective metric is only valid for binary classification.	Maximize
`test:roc_auc_score`	The area under receiving operating characteristic curve (ROC curve) of the final model on the test dataset. This objective metric is only valid for binary classification.	Maximize

Metric Name	Description	Optimization Direction
validation:absolute_loss	The absolute loss of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize
validation:binary_classification_accuracy	The accuracy of the final model on the validation dataset. This objective metric is only valid for binary classification.	Maximize
validation:binary_f_beta	The F-beta score of the final model on the validation dataset. By default, the F-beta score is the F1 score, which is the harmonic mean of the `validation:precision` and `validation:recall` metrics. This objective metric is only valid for binary classification.	Maximize
validation:dcg	The discounted cumulative gain of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_f_beta	The F-beta score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_precision	The precision score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_recall	The recall score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:mse	The mean square error of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize

Metric Name	Description	Optimization Direction
validation:multiclass_accuracy	The accuracy of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:multiclass_top_k_accuracy	The accuracy among the top k labels predicted on the validation dataset. If you choose this metric as the objective, we recommend setting the value of k using the `accuracy_top_k` hyperparameter. This objective metric is only valid for multiclass classification.	Maximize
validation:objective_loss	The mean value of the objective loss function on the validation dataset every epoch. By default, the loss is logistic loss for binary classification and squared loss for regression. To set loss to other types, use the `loss` hyperparameter.	Minimize
validation:precision	The precision of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the `binary_classifier_model_selection` hyperparameter to `precision_at_target_recall` and setting the value for the `target_recall` hyperparameter. This objective metric is only valid for binary classification.	Maximize

Metric Name	Description	Optimization Direction
validation:recall	The recall of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the binary_classifier_model_selection hyperparameter to recall_at_target_precision and setting the value for the target_precision hyperparameter. This objective metric is only valid for binary classification.	Maximize
validation:rmse	The root mean square error of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize
validation:roc_auc_score	The area under receiving operating characteristic curve (ROC curve) of the final model on the validation dataset. This objective metric is only valid for binary classification.	Maximize

Tuning linear learner hyperparameters

You can tune a linear learner model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
wd	ContinuousParameterRanges	MinValue: 1e-7, MaxValue: 1
l1	ContinuousParameterRanges	MinValue: 1e-7, MaxValue: 1
learning_rate	ContinuousParameterRanges	MinValue: 1e-5, MaxValue: 1

Parameter Name	Parameter Type	Recommended Ranges
mini_batch_size	IntegerParameterRanges	MinValue: 100, MaxValue: 5000
use_bias	CategoricalParameterRanges	[True, False]
positive_example_weight_mult	ContinuousParameterRanges	MinValue: 1e-5, MaxValue: 1e5

Linear learner response formats

JSON response formats

All Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker AI linear learner algorithm.

Binary Classification

```
let response =   {
    "predictions":    [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
}
```

Multiclass Classification

```
let response =   {
    "predictions":    [
        {
            "score": [0.1, 0.2, 0.4, 0.3],
            "predicted_label": 2
        }
    ]
```

```
}
```

Regression

```
let response =   {
    "predictions":    [
        {
            "score": 0.4
        }
    ]
}
```

JSONLINES response formats

Binary Classification

```
{"score": 0.4, "predicted_label": 0}
```

Multiclass Classification

```
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

Regression

```
{"score": 0.4}
```

RECORDIO response formats

Binary Classification

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            },
            'predicted_label': {
                keys: [],
```

```
                values: [0.0]  # float32
            }
        }
    }
]
```

Multiclass Classification

```
[
    Record = {
    "features": [],
    "label":    {
            "score":  {
                    "values":   [0.1, 0.2, 0.3, 0.4]
            },
            "predicted_label":  {
                    "values":   [3]
            }
       },
    "uid":  "abc123",
    "metadata": "{created_at: '2017-06-03'}"
   }
]
```

Regression

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            }
        }
    }
]
```

TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability. This page includes information about Amazon EC2 instance recommendations and sample notebooks for TabTransformer.

How to use SageMaker AI TabTransformer

You can use TabTransformer as an Amazon SageMaker AI built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

- **Use TabTransformer as a built-in algorithm**

  Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker AI `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker AI Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-
tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)
```

```
# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "n_epochs"
] = "50"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")
```

```
# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AI TabTransformer algorithm
- Tabular regression with Amazon SageMaker AI TabTransformer algorithm

Input and Output interface for the TabTransformer algorithm

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
>
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the TabTransformer model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `training` or `validation` channels, the TabTransformer algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called validation/ that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named categorical_index.json in the same location as your data subdirectories.

Note

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the InstanceType) must be able to hold the training dataset.

Amazon EC2 instance recommendation for the TabTransformer algorithm

SageMaker AI TabTransformer supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AI TabTransformer currently does not support multi-GPU training.

TabTransformer sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AI TabTransformer algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker AI TabTransformer algorithm	This notebook demonstrates the use of the Amazon SageMaker AI TabTransformer algorithm to train and host a tabular classific ation model.
Tabular regression with Amazon SageMaker AI TabTransformer algorithm	This notebook demonstrates the use of the Amazon SageMaker AI TabTransformer algorithm to train and host a tabular regressio n model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How TabTransformer works

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.

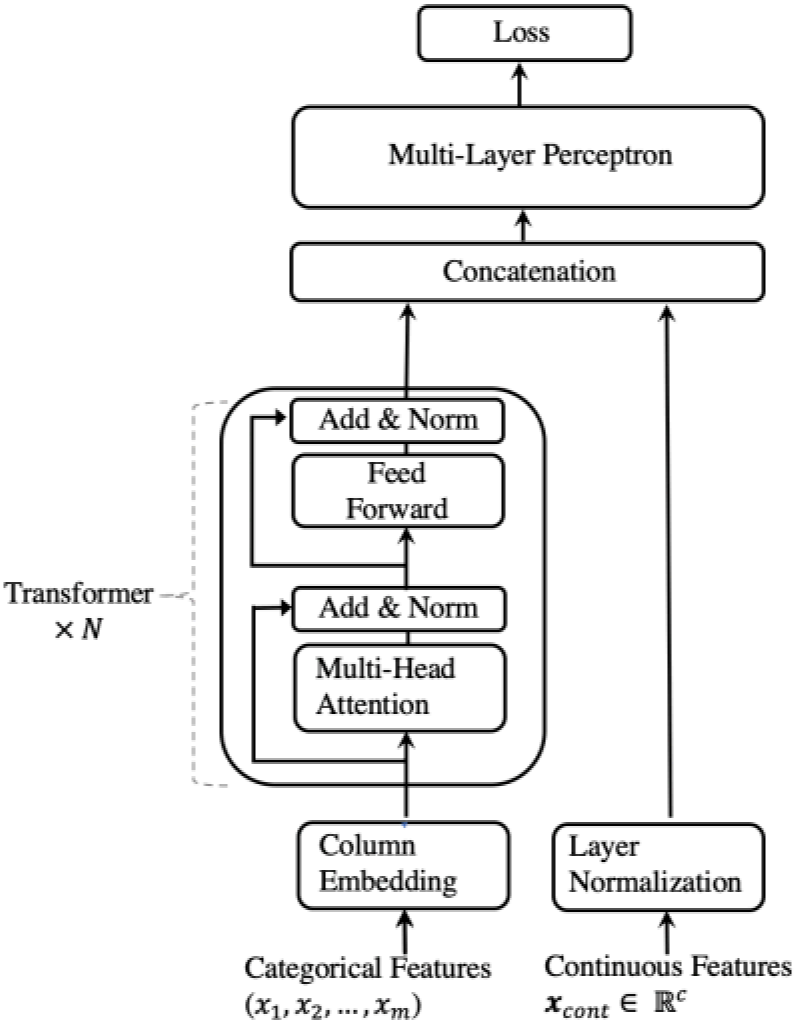

Figure 1: The architecture of TabTransformer.

For more information, see *TabTransformer: Tabular Data Modeling Using Contextual Embeddings*.

TabTransformer hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AI TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AI TabTransformer algorithm is an implementation of the open-source TabTransformer package.

> **Note**
>
> The default hyperparameters are based on example datasets in the TabTransformer sample notebooks.

The SageMaker AI TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is r square and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

> **Note**
>
> The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker AI TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

Parameter Name	Description
`n_epochs`	Number of epochs to train the deep neural network. Valid values: integer, range: Positive integer. Default value: 5.
`patience`	The training will stop if one metric of one validation data point does not improve in the last `patience` round. Valid values: integer, range: (2, `60`). Default value: `10`.

Parameter Name	Description
`learning_rate`	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: Positive floating point number. Default value: `0.001`.
`batch_size`	The number of examples propagated through the network. Valid values: integer, range: (1, `2048`). Default value: `256`.
`input_dim`	The dimension of embeddings to encode the categorical and/ or continuous columns. Valid values: string, any of the following: `"16"`, `"32"`, `"64"`, `"128"`, `"256"`, or `"512"`. Default value: `"32"`.
`n_blocks`	The number of Transformer encoder blocks. Valid values: integer, range: (`1`, `12`). Default value: `4`.
`attn_dropout`	Dropout rate applied to the Multi-Head Attention layers. Valid values: float, range: (`0`, `1`). Default value: `0.2`.

Parameter Name	Description
`mlp_dropout`	Dropout rate applied to the FeedForward network within the encoder layers and the final MLP layers on top of Transformer encoders. Valid values: float, range: (`0`, `1`). Default value: `0.1`.
`frac_shared_embed`	The fraction of embeddings shared by all the different categories for one particular column. Valid values: float, range: (`0`, `1`). Default value: `0.25`.

Tune a TabTransformer model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning objective function and evaluation metric are both automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see TabTransformer hyperparameters.

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for TabTransformer is only available from the Amazon SageMaker SDKs, not from the SageMaker AI console.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Evaluation metrics computed by the TabTransformer algorithm

The SageMaker AI TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
`r2`	r square	maximize	`"metrics={'r2': (\\S+)}"`
`f1_score`	binary cross entropy	maximize	`"metrics={'f1': (\\S+)}"`
`accuracy_score`	multiclass cross entropy	maximize	`"metrics={'accuracy': (\\S+)}"`

Tunable TabTransformer hyperparameters

Tune the TabTransformer model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the TabTransformer evaluation metrics are: `learning_rate`, `input_dim`, `n_blocks`, `attn_dropout`, `mlp_dropout`, and `frac_shared_embed`. For a list of all the TabTransformer hyperparameters, see TabTransformer hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
`input_dim`	CategoricalParameterRanges	[16, 32, 64, 128, 256, 512]
`n_blocks`	IntegerParameterRanges	MinValue: 1, MaxValue: 12
`attn_dropout`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.8
`mlp_dropout`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.8
`frac_shared_embed`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.5

XGBoost algorithm with Amazon SageMaker AI

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that tries to accurately predict a target variable by combining multiple estimates from a set of simpler models. The XGBoost algorithm performs well in machine learning competitions for the following reasons:

- Its robust handling of a variety of data types, relationships, distributions.
- The variety of hyperparameters that you can fine-tune.

You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm as either:

- A Amazon SageMaker AI built-in algorithm.
- A framework to run training scripts in your local environments.

This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an bigger set of metrics than the original versions. It provides an XGBoost `estimator` that runs a training script in a managed XGBoost environment. The current release of SageMaker AI XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, 1.5, and 1.7.

For more information about the Amazon SageMaker AI XGBoost algorithm, see the following blog posts:

- Introducing the open-source Amazon SageMaker AI XGBoost algorithm container
- Amazon SageMaker AI XGBoost now offers fully distributed GPU training

Supported versions

- Framework (open source) mode: 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1
- Algorithm mode: 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1

> **Warning**
>
> Due to required compute capacity, version 1.7-1 of SageMaker AI XGBoost is not compatible with GPU instances from the P2 instance family for training or inference.

> **Important**
>
> When you retrieve the SageMaker AI XGBoost image URI, do not use `:latest` or `:1` for the image URI tag. You must specify one of the Supported versions to choose the SageMaker AI-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker AI XGBoost containers, see Docker Registry Paths and Example Code. Then choose your AWS Region, and navigate to the **XGBoost (algorithm)** section.

> **Warning**
>
> The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. We highly recommend that you upgrade the XGBoost version to one of the newer versions.

> **Note**
>
> XGBoost v1.1 is not supported on SageMaker AI. XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker AI XGBoost 1.2-2 or later.

> **Note**
>
> You can use XGBoost v1.0-1, but it's not officially supported.

EC2 instance recommendation for the XGBoost algorithm

SageMaker AI XGBoost supports CPU and GPU training and inference. Instance recommendations depend on training and inference needs, as well as the version of the XGBoost algorithm. Choose one of the following options for more information:

- CPU training
- GPU training
- Distributed CPU training
- Distributed GPU training
- Inference

Training

The SageMaker AI XGBoost algorithm supports CPU and GPU training.

CPU training

SageMaker AI XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. It supports the use of disk space to handle data that does not fit into main memory. This is a result of the out-of-core feature available with the libsvm input mode. Even so, writing cache files onto disk slows the algorithm processing time.

GPU training

SageMaker AI XGBoost version 1.2-2 or later supports GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective.

SageMaker AI XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.

SageMaker AI XGBoost version 1.7-1 or later supports P3, G4dn, and G5 GPU instance families. Note that due to compute capacity requirements, version 1.7-1 or later does not support the P2 instance family.

To take advantage of GPU training:

- Specify the instance type as one of the GPU instances (for example, P3)
- Set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script

Distributed training

SageMaker AI XGBoost supports CPU and GPU instances for distributed training.

Distributed CPU training

To run CPU training on multiple instances, set the `instance_count` parameter for the estimator to a value greater than one. The input data must be divided between the total number of instances.

Divide input data across instances

Divide the input data using the following steps:

1. Break the input data down into smaller files. The number of files should be at least equal to the number of instances used for distributed training. Using multiple smaller files as opposed to one large file also decreases the data download time for the training job.
2. When creating your [TrainingInput](https://sagemaker.readthedocs.io/en/stable/api/utility/inputs.html), set the distribution parameter to `ShardedByS3Key`. With this, each instance gets approximately *1/n* of the number of files in S3 if there are *n* instances specified in the training job.

Distributed GPU training

You can use distributed training with either single-GPU or multi-GPU instances.

Distributed training with single-GPU instances

SageMaker AI XGBoost versions 1.2-2 through 1.3-1 only support single-GPU instance training. This means that even if you select a multi-GPU instance, only one GPU is used per instance.

You must divide your input data between the total number of instances if:

- You use XGBoost versions 1.2-2 through 1.3-1.
- You do not need to use multi-GPU instances.

For more information, see Divide input data across instances.

> **Note**
>
> Versions 1.2-2 through 1.3-1 of SageMaker AI XGBoost only use one GPU per instance even if you choose a multi-GPU instance.

Distributed training with multi-GPU instances

Starting with version 1.5-1, SageMaker AI XGBoost offers distributed GPU training with Dask. With Dask you can utilize all GPUs when using one or more multi-GPU instances. Dask also works when using single-GPU instances.

Train with Dask using the following steps:

1. Either omit the `distribution` parameter in your TrainingInput or set it to `FullyReplicated`.

2. When defining your hyperparameters, set `use_dask_gpu_training` to `"true"`.

> **Important**
>
> Distributed training with Dask only supports CSV and Parquet input formats. If you use other data formats such as LIBSVM or PROTOBUF, the training job fails.
> For Parquet data, ensure that the column names are saved as strings. Columns that have names of other data types will fail to load.

> **Important**
>
> Distributed training with Dask does not support pipe mode. If pipe mode is specified, the training job fails.

There are a few considerations to be aware of when training SageMaker AI XGBoost with Dask. Be sure to split your data into smaller files. Dask reads each Parquet file as a partition. There is a Dask worker for every GPU. As a result, the number of files should be greater than the total number of GPUs (instance count * number of GPUs per instance). Having a very large number of files can also degrade performance. For more information, see Dask Best Practices.

Variations in output

The specified `tree_method` hyperparameter determines the algorithm that is used for XGBoost training. The tree methods `approx`, `hist` and `gpu_hist` are all approximate methods and use sketching for quantile calculation. For more information, see Tree Methods in the XGBoost documentation. Sketching is an approximate algorithm. Therefore, you can expect variations in the model depending on factors such as the number of workers chosen for distributed training. The significance of the variation is data-dependent.

Inference

SageMaker AI XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see Amazon SageMaker AI ML Instance Types.

How to use SageMaker AI XGBoost

With SageMaker AI, you can use XGBoost as a built-in algorithm or framework. When XGBoost as a framework, you have more flexibility and access to more advanced scenarios because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK, and the input/output interface for the XGBoost algorithm. For information on how to use XGBoost from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

Topics

Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, SageMaker Python SDK provides the XGBoost API as a framework. This functions similarly to how SageMaker AI provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
        "max_depth":"5",
        "eta":"0.2",
        "gamma":"4",
        "min_child_weight":"6",
        "subsample":"0.7",
        "verbosity":"1",
        "objective":"reg:squarederror",
        "num_round":"50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
```

```
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker AI XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.7-1',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
 content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For an end-to-end example of using SageMaker AI XGBoost as a framework, see Regression with Amazon SageMaker AI XGBoost.

Use XGBoost as a built-in algorithm

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker AI `image_uris.retrieve` API. If using Amazon SageMaker Python SDK version 1, use the `get_image_uri` API. To make sure that the `image_uris.retrieve` API finds the correct URI, see Common parameters for built-in algorithms. Then look up `xgboost` from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, use the XGBoost container to construct an estimator using the SageMaker AI Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

> **Important**
>
> When you retrieve the SageMaker AI XGBoost image URI, do not use `:latest` or `:1` for the image URI tag. You must specify one of the [Supported versions](#) to choose the SageMaker AI-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker AI XGBoost containers, see [Docker Registry Paths and Example Code](#). Then choose your AWS Region, and navigate to the **XGBoost (algorithm)** section.

```
import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
        "max_depth":"5",
        "eta":"0.2",
        "gamma":"4",
        "min_child_weight":"6",
        "subsample":"0.7",
        "objective":"reg:squarederror",
        "num_round":"50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-
algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost
 container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.7-1")

# construct a SageMaker AI estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
```

```
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
 content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker AI XGBoost (Parquet input)

Input/Output interface for the XGBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of XGBoost supports the following data formats for training and inference:

- *text/libsvm* (default)
- *text/csv*
- *application/x-parquet*
- *application/x-recordio-protobuf*

Note

There are a few considerations to be aware of regarding training and inference input:

- For increased performance, we recommend using XGBoost with *File mode*, in which your data from Amazon S3 is stored on the training instance volumes.
- For training with columnar input, the algorithm assumes that the target variable (label) is the first column. For inference, the algorithm assumes that the input has no label column.
- For CSV data, the input should not have a header record.
- For LIBSVM training, the algorithm assumes that subsequent columns after the label column contain the zero-based index value pairs for features. So each row has the format: : <label> <index0>:<value0> <index1>:<value1>.
- For information on instance types and distributed training, see [EC2 instance recommendation for the XGBoost algorithm](#).

For CSV training input mode, the total memory available to the algorithm must be able to hold the training dataset. The total memory available is calculated as `Instance Count * the memory available in the InstanceType`. For libsvm training input mode, it's not required, but we recommend it.

For v1.3-1 and later, SageMaker AI XGBoost saves the model in the XGBoost internal binary format, using `Booster.save_model`. Previous versions use the Python pickle module to serialize/deserialize the model.

Note

Be mindful of versions when using an SageMaker AI XGBoost model in open source XGBoost. Versions 1.3-1 and later use the XGBoost internal binary format while previous versions use the Python pickle module.

To use a model trained with SageMaker AI XGBoost v1.3-1 or later in open source XGBoost

- Use the following Python code:

```
import xgboost as xgb

xgb_model = xgb.Booster()
xgb_model.load_model(model_file_path)
```

```
xgb_model.predict(dtest)
```

To use a model trained with previous versions of SageMaker AI XGBoost in open source XGBoost

- Use the following Python code:

```
import pickle as pkl
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker AI XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For *text/libsvm* input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For *text/csv* input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`).

XGBoost sample notebooks

The following list contains a variety of sample Jupyter notebooks that address different use cases of Amazon SageMaker AI XGBoost algorithm.

- How to Create a Custom XGBoost container – This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker AI Batch Transform.
- Regression with XGBoost using Parquet – This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.
- How to Train and Host a Multiclass Classification Model – This notebook shows how to use the MNIST dataset to train and host a multiclass classification model.

- How to train a Model for Customer Churn Prediction – This notebook shows you how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.
- An Introduction to Amazon SageMaker AI Managed Spot infrastructure for XGBoost Training – This notebook shows you how to use Spot Instances for training with a XGBoost Container.
- How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs – This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies using built-in debugging rules.

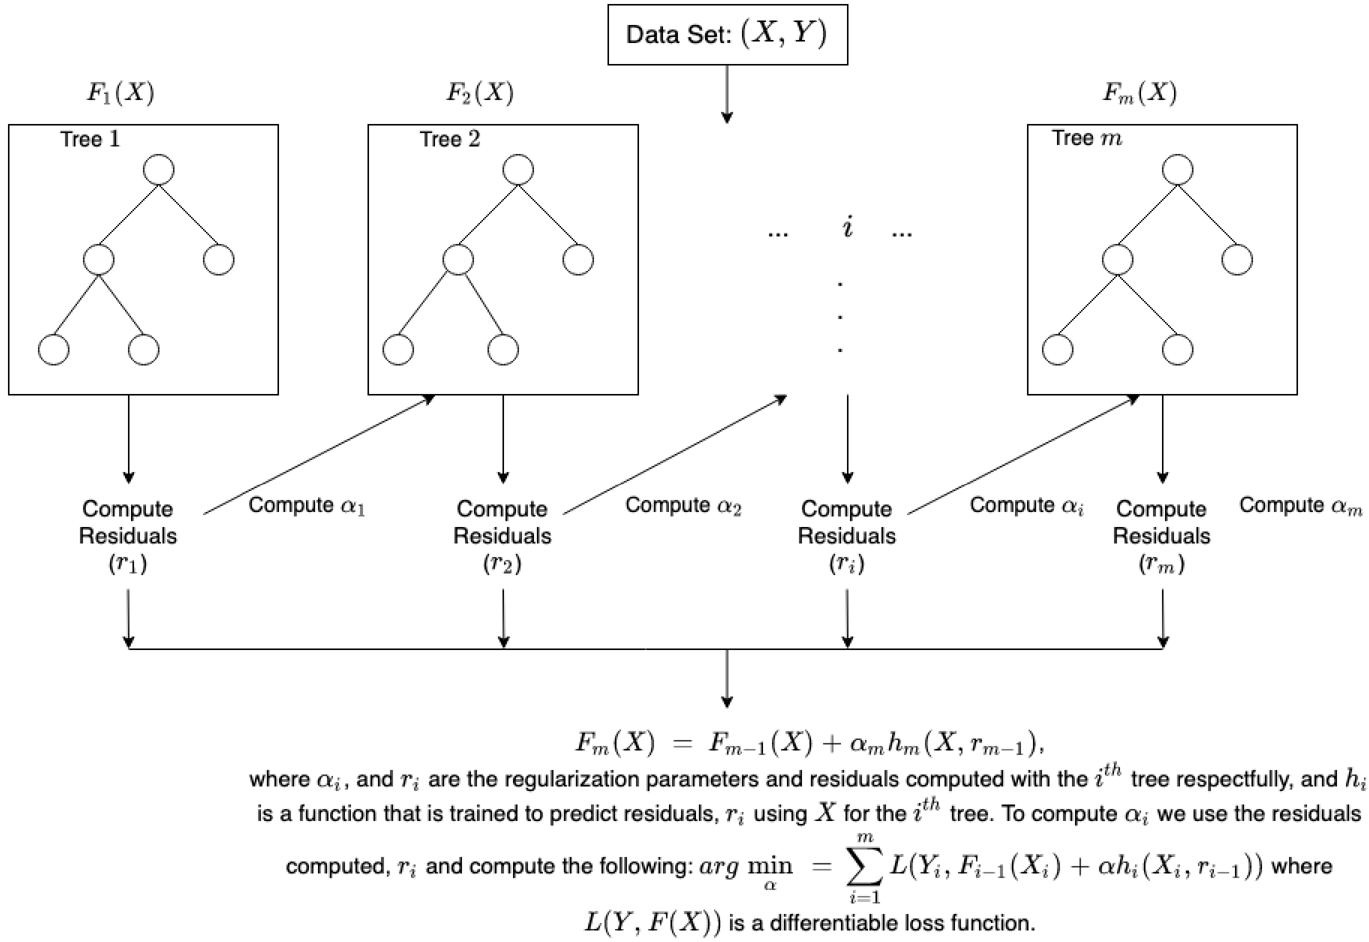
For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

How the SageMaker AI XGBoost algorithm works

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.



For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

XGBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AI XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker AI XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

Parameter Name	Description
`num_class`	The number of classes. **Required** if `objective` is set to *multi:softmax* or *multi:softprob*. Valid values: Integer.
`num_round`	The number of rounds to run the training. **Required** Valid values: Integer.
`alpha`	L1 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: Float. Default value: 0
`base_score`	The initial prediction score of all instances, global bias. **Optional** Valid values: Float. Default value: 0.5
`booster`	Which booster to use. The `gbtree` and `dart` values use a tree-based model, while `gblinear` uses a linear function. **Optional** Valid values: String. One of `"gbtree"`, `"gblinear"`, or `"dart"`. Default value: `"gbtree"`

Parameter Name	Description
`colsample_bylevel`	Subsample ratio of columns for each split, in each level. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`colsample_bynode`	Subsample ratio of columns from each node. **Optional** Valid values: Float. Range: (0,1]. Default value: 1
`colsample_bytree`	Subsample ratio of columns when constructing each tree. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`csv_weights`	When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights. **Optional** Valid values: 0 or 1 Default value: 0

Parameter Name	Description
`deterministic_histogram`	When this flag is enabled, XGBoost builds histogram on GPU deterministically. Used only if `tree_method` is set to `gpu_hist`. For a full list of valid inputs, please refer to XGBoost Parameters. **Optional** Valid values: String. Range: `"true"` or `"false"`. Default value: `"true"`
`early_stopping_rounds`	The model trains until the validation score stops improving. Validation error needs to decrease at least every `early_stopping_rounds` to continue training. SageMaker AI hosting uses the best model for inference. **Optional** Valid values: Integer. Default value: -
`eta`	Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The `eta` parameter actually shrinks the feature weights to make the boosting process more conservative. **Optional** Valid values: Float. Range: [0,1]. Default value: 0.3

Parameter Name	Description
`eval_metric`	Evaluation metrics for validation data. A default metric is assigned according to the objective: • `rmse`: for regression • `error`: for classification • `map`: for ranking For a list of valid inputs, see [XGBoost Learning Task Parameters](#). **Optional** Valid values: String. Default value: Default according to objective.
`gamma`	Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is. **Optional** Valid values: Float. Range: [0,∞). Default value: 0
`grow_policy`	Controls the way that new nodes are added to the tree. Currently supported only if `tree_method` is set to `hist`. **Optional** Valid values: String. Either `"depthwise"` or `"lossguide"`. Default value: `"depthwise"`

Parameter Name	Description
`interaction_constraints`	Specify groups of variables that are allowed to interact. **Optional** Valid values: Nested list of integers. Each integer represents a feature, and each nested list contains features that are allowed to interact e.g., [[1,2], [3,4,5]]. Default value: None
`lambda`	L2 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: Float. Default value: 1
`lambda_bias`	L2 regularization term on bias. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0
`max_bin`	Maximum number of discrete bins to bucket continuous features. Used only if `tree_method` is set to `hist`. **Optional** Valid values: Integer. Default value: 256

Parameter Name	Description
`max_delta_step`	Maximum delta step allowed for each tree's weight estimatio n. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update. **Optional** Valid values: Integer. Range: [0,∞). Default value: 0
`max_depth`	Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when `grow_policy` =`depth-wise` . **Optional** Valid values: Integer. Range: [0,∞) Default value: 6
`max_leaves`	Maximum number of nodes to be added. Relevant only if `grow_policy` is set to `lossguide` . **Optional** Valid values: Integer. Default value: 0

Parameter Name	Description
`min_child_weight`	Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than `min_child_weight` , the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is. **Optional** Valid values: Float. Range: [0,∞). Default value: 1
`monotone_constraints`	Specifies monotonicity constraints on any feature. **Optional** Valid values: Tuple of Integers. Valid integers: -1 (decreasing constraint), 0 (no constraint), 1 (increasing constraint). E.g., (0, 1): No constraint on first predictor, and an increasing constraint on the second. (-1, 1): Decreasing constraint on first predictor, and an increasing constraint on the second. Default value: (0, 0)
`normalize_type`	Type of normalization algorithm. **Optional** Valid values: Either *tree* or *forest*. Default value: *tree*

Parameter Name	Description
`nthread`	Number of parallel threads used to run *xgboost*. **Optional** Valid values: Integer. Default value: Maximum number of threads.
`objective`	Specifies the learning task and the corresponding learning objective. Examples: `reg:logistic` , `multi:softmax` , `reg:squarederror` . For a full list of valid inputs, refer to [XGBoost Learning Task Parameters](#). **Optional** Valid values: String Default value: `"reg:squarederror"`
`one_drop`	When this flag is enabled, at least one tree is always dropped during the dropout. **Optional** Valid values: 0 or 1 Default value: 0
`process_type`	The type of boosting process to run. **Optional** Valid values: String. Either `"default"` or `"update"`. Default value: `"default"`

Parameter Name	Description
`rate_drop`	The dropout rate that specifies the fraction of previous trees to drop during the dropout. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
`refresh_leaf`	This is a parameter of the 'refresh' updater plug-in. When set to `true` (1), tree leaves and tree node stats are updated. When set to `false`(0), only tree node stats are updated. **Optional** Valid values: 0/1 Default value: 1
`sample_type`	Type of sampling algorithm. **Optional** Valid values: Either `uniform` or `weighted`. Default value: `uniform`
`scale_pos_weight`	Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: `sum(negative cases)` / `sum(positive cases)`. **Optional** Valid values: float Default value: 1

Parameter Name	Description
`seed`	Random number seed. **Optional** Valid values: integer Default value: 0
`single_precision_histogram`	When this flag is enabled, XGBoost uses single precision to build histograms instead of double precision. Used only if `tree_method` is set to `hist` or `gpu_hist`. For a full list of valid inputs, please refer to [XGBoost Parameters](https://xgboost.readthedocs.io/en/release_1.0.0/parameter.html). **Optional** Valid values: String. Range: `"true"` or `"false"` Default value: `"false"`
`sketch_eps`	Used only for approximate greedy algorithm. This translates into O(1 / `sketch_eps`) number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy. **Optional** Valid values: Float, Range: [0, 1]. Default value: 0.03

Parameter Name	Description
`skip_drop`	Probability of skipping the dropout procedure during a boosting iteration. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
`subsample`	Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`tree_method`	The tree construction algorithm used in XGBoost. **Optional** Valid values: One of `auto`, `exact`, `approx`, `hist`, or `gpu_hist`. Default value: `auto`
`tweedie_variance_power`	Parameter that controls the variance of the Tweedie distribution. **Optional** Valid values: Float. Range: (1, 2). Default value: 1.5

Parameter Name	Description
`updater`	A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees. For a full list of valid inputs, please refer to [XGBoost Parameters](). **Optional** Valid values: comma-separated string. Default value: `grow_colmaker` , prune
`use_dask_gpu_training`	Set `use_dask_gpu_training` to `"true"` if you want to run distributed GPU training with Dask. Dask GPU training is only supported for versions 1.5-1 and later. Do not set this value to `"true"` for versions preceding 1.5-1. For more information, see [Distributed GPU training](). **Optional** Valid values: String. Range: `"true"` or `"false"` Default value: `"false"`
`verbosity`	Verbosity of printing messages. Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug). **Optional** Default value: 1

Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning `objective` function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

Note

Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker AI console.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters

Metric Name	Description	Optimization Direction
`validation:accuracy`	Classification rate, calculated as #(right)/#(all cases).	Maximize
`validation:auc`	Area under the curve.	Maximize
`validation:error`	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
`validation:f1`	Indicator of classification accuracy, calculated as the harmonic mean of precision and recall.	Maximize

Metric Name	Description	Optimization Direction
validation:logloss	Negative log-likelihood.	Minimize
validation:mae	Mean absolute error.	Minimize
validation:map	Mean average precision.	Maximize
validation:merror	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
validation:mlogloss	Negative log-likelihood for multiclass classification.	Minimize
validation:mse	Mean squared error.	Minimize
validation:ndcg	Normalized Discounted Cumulative Gain.	Maximize
validation:rmse	Root mean square error.	Minimize

Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
alpha	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
colsample_bylevel	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
colsample_bynode	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1

Parameter Name	Parameter Type	Recommended Ranges
colsample_bytree	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
eta	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
gamma	ContinuousParameterRanges	MinValue: 0, MaxValue: 5
lambda	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
max_delta_step	IntegerParameterRanges	[0, 10]
max_depth	IntegerParameterRanges	[0, 10]
min_child_weight	ContinuousParameterRanges	MinValue: 0, MaxValue: 120
num_round	IntegerParameterRanges	[1, 4000]
subsample	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker AI XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics

Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost `version` and `framework_version` parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.

Topics

- Upgrade SageMaker AI Python SDK Version 1.x to Version 2.x
- Change the image tag to 1.5-1
- Change Docker Image for Boto3
- Update Hyperparameters and Learning Objectives

Upgrade SageMaker AI Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must to upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrive`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.5-1',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
 content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.

```
{
    "AlgorithmSpecification":: {
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-
xgboost:1.5-1"
    }
    ...
}
```

If you using the SageMaker Python SDK to retrieve registry path, change the `version` parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

Update Hyperparameters and Learning Objectives

The silent parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          ...)
```

XGBoost Version 0.72

Important

The XGBoost 0.72 is deprecated by Amazon SageMaker AI. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with `:1` is for the old version.

SageMaker Python SDK v1

```
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri

xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
 repo_version="1")
```

SageMaker Python SDK v2

```
import boto3
from sagemaker import image_uris

xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name,
 "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions).

This previous release of the Amazon SageMaker AI XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost algorithm with Amazon SageMaker AI. They can use it as a SageMaker AI built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker AI implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are *text/libsvm* (default) or *text/csv*.
- For Inference ContentType, valid inputs are *text/libsvm* or (the default) *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.
>
> For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker AI algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the `InstanceType`) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker AI XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker AI XGBoost in open source XGBoost

- Use the following Python code:

```
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker AI XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For *text/libsvm* input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For *text/csv* input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`).

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker AI XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker AI XGBoost as a built-in algorithm to train and host a regression model, see [Regression with Amazon SageMaker AI XGBoost algorithm](). To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see [Amazon SageMaker notebook instances](). Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The topic modeling example notebooks using the XGBoost algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker AI XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker AI supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see [XGBoost Parameters]().

Parameter Name	Description
`num_class`	The number of classes. **Required** if `objective` is set to *multi:softmax* or *multi:sof tprob*. Valid values: integer
`num_round`	The number of rounds to run the training. **Required** Valid values: integer
`alpha`	L1 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: float Default value: 0
`base_score`	The initial prediction score of all instances, global bias. **Optional** Valid values: float Default value: 0.5
`booster`	Which booster to use. The `gbtree` and `dart` values use a tree-based model, while `gblinear` uses a linear function. **Optional** Valid values: String. One of `gbtree`, `gblinear`, or `dart`. Default value: `gbtree`
`colsample_bylevel`	Subsample ratio of columns for each split, in each level.

Parameter Name	Description
	Optional Valid values: Float. Range: [0,1]. Default value: 1
`colsample_bytree`	Subsample ratio of columns when constructing each tree. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`csv_weights`	When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights. **Optional** Valid values: 0 or 1 Default value: 0
`early_stopping_rounds`	The model trains until the validation score stops improving. Validation error needs to decrease at least every `early_stopping_rounds` to continue training. SageMaker AI hosting uses the best model for inference. **Optional** Valid values: integer Default value: -

Parameter Name	Description
eta	Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The eta parameter actually shrinks the feature weights to make the boosting process more conservative. **Optional** Valid values: Float. Range: [0,1]. Default value: 0.3
eval_metric	Evaluation metrics for validation data. A default metric is assigned according to the objective: • rmse: for regression • error: for classification • map: for ranking For a list of valid inputs, see XGBoost Parameters. **Optional** Valid values: string Default value: Default according to objective.
gamma	Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is. **Optional** Valid values: Float. Range: [0,∞). Default value: 0

Parameter Name	Description
`grow_policy`	Controls the way that new nodes are added to the tree. Currently supported only if `tree_method` is set to `hist`. **Optional** Valid values: String. Either `depthwise` or `lossguide` . Default value: `depthwise`
`lambda`	L2 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: float Default value: 1
`lambda_bias`	L2 regularization term on bias. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0
`max_bin`	Maximum number of discrete bins to bucket continuous features. Used only if `tree_method` is set to `hist`. **Optional** Valid values: integer Default value: 256

Parameter Name	Description
`max_delta_step`	Maximum delta step allowed for each tree's weight estimatio n. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update. **Optional** Valid values: Integer. Range: [0,∞). Default value: 0
`max_depth`	Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when `grow_policy` =`depth-wise` . **Optional** Valid values: Integer. Range: [0,∞) Default value: 6
`max_leaves`	Maximum number of nodes to be added. Relevant only if `grow_policy` is set to `lossguide` . **Optional** Valid values: integer Default value: 0

Parameter Name	Description
`min_child_weight`	Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than `min_child_weight` , the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is. **Optional** Valid values: Float. Range: [0,∞). Default value: 1
`normalize_type`	Type of normalization algorithm. **Optional** Valid values: Either *tree* or *forest*. Default value: *tree*
`nthread`	Number of parallel threads used to run *xgboost*. **Optional** Valid values: integer Default value: Maximum number of threads.

Parameter Name	Description
`objective`	Specifies the learning task and the corresponding learning objective. Examples: `reg:logistic` , `reg:softmax` , `multi:squarederror` . For a full list of valid inputs, refer to [XGBoost Parameters](). **Optional** Valid values: string Default value: `reg:squarederror`
`one_drop`	When this flag is enabled, at least one tree is always dropped during the dropout. **Optional** Valid values: 0 or 1 Default value: 0
`process_type`	The type of boosting process to run. **Optional** Valid values: String. Either `default` or `update`. Default value: `default`
`rate_drop`	The dropout rate that specifies the fraction of previous trees to drop during the dropout. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0

Parameter Name	Description
`refresh_leaf`	This is a parameter of the 'refresh' updater plug-in. When set to `true` (1), tree leaves and tree node stats are updated. When set to `false`(0), only tree node stats are updated. **Optional** Valid values: 0/1 Default value: 1
`sample_type`	Type of sampling algorithm. **Optional** Valid values: Either `uniform` or `weighted`. Default value: `uniform`
`scale_pos_weight`	Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: `sum(negative cases)` / `sum(positive cases)`. **Optional** Valid values: float Default value: 1
`seed`	Random number seed. **Optional** Valid values: integer Default value: 0

Parameter Name	Description
`silent`	0 means print running messages, 1 means silent mode. Valid values: 0 or 1 **Optional** Default value: 0
`sketch_eps`	Used only for approximate greedy algorithm. This translate s into O(1 / `sketch_eps`) number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy. **Optional** Valid values: Float, Range: [0, 1]. Default value: 0.03
`skip_drop`	Probability of skipping the dropout procedure during a boosting iteration. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
`subsample`	Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting. **Optional** Valid values: Float. Range: [0,1]. Default value: 1

Parameter Name	Description
`tree_method`	The tree construction algorithm used in XGBoost. **Optional** Valid values: One of `auto`, `exact`, `approx`, or `hist`. Default value: `auto`
`tweedie_variance_power`	Parameter that controls the variance of the Tweedie distribution. **Optional** Valid values: Float. Range: (1, 2). Default value: 1.5
`updater`	A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees. For a full list of valid inputs, please refer to [XGBoost Parameters](). **Optional** Valid values: comma-separated string. Default value: `grow_colmaker` , prune

Tune an XGBoost Release 0.72 Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning `objective` function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation

- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to [XGBoost Learning Task Parameters](#)

Metric Name	Description	Optimization Direction
`validation:auc`	Area under the curve.	Maximize
`validation:error`	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
`validation:logloss`	Negative log-likelihood.	Minimize
`validation:mae`	Mean absolute error.	Minimize
`validation:map`	Mean average precision.	Maximize
`validation:merror`	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
`validation:mlogloss`	Negative log-likelihood for multiclass classification.	Minimize
`validation:ndcg`	Normalized Discounted Cumulative Gain.	Maximize
`validation:rmse`	Root mean square error.	Minimize

Tunable XGBoost Release 0.72 Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
`alpha`	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
`colsample_bylevel`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
`colsample_bytree`	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
`eta`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
`gamma`	ContinuousParameterRanges	MinValue: 0, MaxValue: 5
`lambda`	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
`max_delta_step`	IntegerParameterRanges	[0, 10]
`max_depth`	IntegerParameterRanges	[0, 10]
`min_child_weight`	ContinuousParameterRanges	MinValue: 0, MaxValue: 120
`num_round`	IntegerParameterRanges	[1, 4000]
`subsample`	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

Built-in SageMaker AI Algorithms for Text Data

SageMaker AI provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- BlazingText algorithm—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- Latent Dirichlet Allocation (LDA) Algorithm—an algorithm suitable for determining topics in a set of documents. It is an *unsupervised algorithm*, which means that it doesn't use example data with answers during training.
- Neural Topic Model (NTM) Algorithm—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- Object2Vec Algorithm—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- Sequence-to-Sequence Algorithm—a supervised algorithm commonly used for neural machine translation.
- Text Classification - TensorFlow—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
BlazingText	train	File or Pipe	Text file (one sentence per line with space-separated tokens)	GPU (single instance only) or CPU	No	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
LDA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU (single instance only)	No
Neural Topic Model	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	GPU or CPU	Yes
Object2Vec	train and (optionally) validation, test, or both	File	JSON Lines	GPU or CPU (single instance only)	No
Seq2Seq Modeling	train, validation, and vocab	File	recordIO-protobuf	GPU (single instance only)	No
Text Classification - TensorFlow	training and validation	File	CSV	CPU or GPU	Yes (only across multiple GPUs on a single instance)

BlazingText algorithm

The Amazon SageMaker AI BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker AI BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.

- A `batch_skipgram` mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The `batch_skipgram` mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

Modes	Word2Vec (Unsupervised Learning)	Text Classification (Supervised Learning)

Single CPU instance	`cbow`
	
	`Skip-gram`
	
	`Batch Skip-gram`
		`supervised`

Single GPU instance (with 1 or more GPUs)	`cbow`
	
	`Skip-gram`
		`supervised` with one GPU

Multiple CPU instances	`Batch Skip-gram`	None

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

- Tune a BlazingText Model

Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the *train* channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For `supervised` mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string *__label__*. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time , intel says , despite all the linux hype , the
 open-source movement has yet to make a huge splash in the desktop market . that may be
 about to change , thanks to chipmaking giant intel corp .

__label__2  bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly as the indian skippers return to international cricket was short
 lived .
```

> **Note**
>
> The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

Supervised mode for CPU instances also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the `source` tag and the label can be specified using the `label` tag. Both `source` and `label` tags should be provided under the `AttributeNames` parameter value as specified in the request.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype",
 "label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype",
 "label": [1, 3]}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly", "label": [2, 4, 5]}
```

For more information on augmented manifest files, see Augmented Manifest Files for Training Jobs.

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of *vectors.txt*, which contains words-to-vectors mapping, and *vectors.bin*, a binary used by BlazingText for hosting, inference, or both. *vectors.txt* stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to `True`, an additional file, *eval.json*, is created. This file contains the similarity evaluation results (using Spearman’s rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

Sample JSON Request

Mime-type: `application/json`

```
{
"instances": ["word1", "word2", "word3"]
}
```

Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a *model.bin* file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

Sample JSON Request

Mime-type: `application/json`

```
{
 "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top *k* predictions, you can set *k* in the configuration, as follows:

```
{
 "instances": ["the movie was excellent", "i did not like the plot ."],
 "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}

if you need to pass the value of k for top-k, then you can do it in the following way:

{"source": "source_0", "k": 2}
{"source": "source_1", "k": 3}
```

The format for output follows:

```
accept: application/jsonlines

{"prob": [prob_1], "label": ["__label__1"]}
{"prob": [prob_1], "label": ["__label__1"]}

If you have passed the value of k to be more than 1, then response will be in this
 format:

{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (**.bin*) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```

#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz
```

```
#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

EC2 Instance Recommendation for the BlazingText Algorithm

For `cbow` and `skipgram` modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of `subwords` embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For `batch_skipgram` mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the `S3DataDistributionType` field of the [`S3DataSource`] object that you pass to [`CreateTrainingJob`] to `FullyReplicated`. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.

BlazingText Sample Notebooks

For a sample notebook that trains and deploys the SageMaker AI BlazingText algorithm to generate word vectors, see Learning Word2Vec Word Representations using BlazingText. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After creating and opening a notebook instance, choose the **SageMaker AI Examples** tab to see a list of all the SageMaker AI examples. The topic modeling example notebooks that use the Blazing Text are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

BlazingText Hyperparameters

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker AI.

Parameter Name	Description
`mode`	The Word2vec architecture used for training. **Required** Valid values: `batch_skipgram` , `skipgram`, or `cbow`
`batch_size`	The size of each batch when `mode` is set to `batch_skipgram` . Set to a number between 10 and 20. **Optional** Valid values: Positive integer Default value: 11
`buckets`	The number of hash buckets to use for subwords. **Optional** Valid values: positive integer Default value: 2000000
`epochs`	The number of complete passes through the training data. **Optional** Valid values: Positive integer Default value: 5
`evaluation`	Whether the trained model is evaluated using the WordSimilarity-353 Test. **Optional**

Parameter Name	Description
	Valid values: (Boolean) `True` or `False` Default value: `True`
`learning_rate`	The step size used for parameter updates. **Optional** Valid values: Positive float Default value: 0.05
`min_char`	The minimum number of characters to use for subwords/ character n-grams. **Optional** Valid values: positive integer Default value: 3
`min_count`	Words that appear less than `min_count` times are discarded. **Optional** Valid values: Non-negative integer Default value: 5
`max_char`	The maximum number of characters to use for subwords/ character n-grams **Optional** Valid values: positive integer Default value: 6

Parameter Name	Description
`negative_samples`	The number of negative samples for the negative sample sharing strategy. **Optional** Valid values: Positive integer Default value: 5
`sampling_threshold`	The threshold for the occurrence of words. Words that appear with higher frequency in the training data are randomly down-sampled. **Optional** Valid values: Positive fraction. The recommended range is (0, 1e-3] Default value: 0.0001
`subwords`	Whether to learn subword embeddings on not. **Optional** Valid values: (Boolean) `True` or `False` Default value: `False`
`vector_dim`	The dimension of the word vectors that the algorithm learns. **Optional** Valid values: Positive integer Default value: 100

Parameter Name	Description
`window_size`	The size of the context window. The context window is the number of words surrounding the target word used for training. **Optional** Valid values: Positive integer Default value: 5

Text Classification Hyperparameters

The following table lists the hyperparameters for the Text Classification training algorithm provided by Amazon SageMaker AI.

> **Note**
>
> Although some of the parameters are common between the Text Classification and Word2Vec modes, they might have different meanings depending on the context.

Parameter Name	Description
`mode`	The training mode. **Required** Valid values: `supervised`
`buckets`	The number of hash buckets to use for word n-grams. **Optional** Valid values: Positive integer Default value: 2000000

Parameter Name	Description
early_stopping	Whether to stop training if validation accuracy doesn't improve after a patience number of epochs. Note that a validation channel is required if early stopping is used. **Optional** Valid values: (Boolean) True or False Default value: False
epochs	The maximum number of complete passes through the training data. **Optional** Valid values: Positive integer Default value: 5
learning_rate	The step size used for parameter updates. **Optional** Valid values: Positive float Default value: 0.05
min_count	Words that appear less than min_count times are discarded. **Optional** Valid values: Non-negative integer Default value: 5

Parameter Name	Description
`min_epochs`	The minimum number of epochs to train before early stopping logic is invoked. **Optional** Valid values: Positive integer Default value: 5
`patience`	The number of epochs to wait before applying early stopping when no progress is made on the validation set. Used only when `early_stopping` is `True`. **Optional** Valid values: Positive integer Default value: 4
`vector_dim`	The dimension of the embedding layer. **Optional** Valid values: Positive integer Default value: 100
`word_ngrams`	The number of word n-gram features to use. **Optional** Valid values: Positive integer Default value: 2

Tune a BlazingText Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (`skipgram`, `cbow`, and `batch_skipgram` modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (`supervised` mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

Metric Name	Description	Optimization Direction
`train:mean_rho`	The mean rho (Spearman's rank correlation coefficient) on WS-353 word similarity datasets	Maximize
`validation:accuracy`	The classification accuracy on the user-specified validation dataset	Maximize

Tunable BlazingText Hyperparameters

Tunable Hyperparameters for the Word2Vec Algorithm

Tune an Amazon SageMaker AI BlazingText Word2Vec model with the following hyperparameters. The hyperparameters that have the greatest impact on Word2Vec objective metrics are: `mode`, `learning_rate`, `window_size`, `vector_dim`, and `negative_samples`.

Parameter Name	Parameter Type	Recommended Ranges or Values
batch_size	IntegerParameterRange	[8-32]
epochs	IntegerParameterRange	[5-15]
learning_rate	ContinuousParameterRange	MinValue: 0.005, MaxValue: 0.01
min_count	IntegerParameterRange	[0-100]
mode	CategoricalParameterRange	['batch_skipgram' , 'skipgram' , 'cbow']
negative_samples	IntegerParameterRange	[5-25]
sampling_threshold	ContinuousParameterRange	MinValue: 0.0001, MaxValue: 0.001
vector_dim	IntegerParameterRange	[32-300]
window_size	IntegerParameterRange	[1-10]

Tunable Hyperparameters for the Text Classification Algorithm

Tune an Amazon SageMaker AI BlazingText text classification model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges or Values
buckets	IntegerParameterRange	[1000000-10000000]
epochs	IntegerParameterRange	[5-15]

Parameter Name	Parameter Type	Recommended Ranges or Values
learning_rate	ContinuousParameterRange	MinValue: 0.005, MaxValue: 0.01
min_count	IntegerParameterRange	[0-100]
vector_dim	IntegerParameterRange	[32-300]
word_ngrams	IntegerParameterRange	[1-3]

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker AI Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat*, *sleep*, *play*, *meow*, and *bark*, LDA might produce topics like the following:

Topic	*eat*	*sleep*	*play*	*meow*	*bark*
Topic 1	0.1	0.3	0.2	0.4	0.0
Topic 2	0.2	0.1	0.4	0.0	0.3

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

Topics

Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on

CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

- Tune an LDA Model

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both `recordIO-wrapped-protobuf` (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to *number of records * vocabulary size*. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. LDA inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_mixture` vector for each observation.

Please see the LDA Sample Notebooks for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker AI Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker AI LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in

SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How LDA Works

Amazon SageMaker AI LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

> **Note**
>
> Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data. For more information, see Stemming and lemmatization.

An LDA model is defined by two parameters:

- α—A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- β—a collection of k topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture $\theta \sim \text{Dirichlet}(\alpha)$.

For each word in the document:

- Choose a topic z ~ Multinomial(θ)
- Choose the corresponding topic-word distribution β_z.
- Draw a word w ~ Multinomial(β_z).

When training the model, the goal is to find parameters α and β, which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker AI LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results**. The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable**. The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast**. Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a **V** x **V** x **V** tensor, which summarizes the moments of the documents in our corpus. **V** is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters α and β, which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this **V** x **V** x **V** tensor is prohibitively large to store in memory.
2. Instead, it uses a **V** x **V** moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension **V** x **k**. This matrix can be used to convert the **V** x **V** moment matrix into a **k** x **k** identity matrix. **k** is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller **k** x **k** x **k** tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the **V** x **V** x **V** tensor.
4. *Alternating Least Squares* is used to decompose the smaller **k** x *k* x **k** tensor. This provides a substantial improvement in memory consumption and speed. The parameters α and β can be found by “unwhitening” these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker AI LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

LDA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker AI. For more information, see How LDA Works.

Parameter Name	Description
`num_topics`	The number of topics for LDA to find within the data. **Required** Valid values: positive integer
`feature_dim`	The size of the vocabulary of the input document corpus. **Required** Valid values: positive integer
`mini_batch_size`	The total number of documents in the input document corpus. **Required** Valid values: positive integer
`alpha0`	Initial guess for the concentration parameter: the sum of the elements of the Dirichlet prior. Small values are more likely to generate sparse topic mixtures and large values (greater than 1.0) produce more uniform mixtures. **Optional** Valid values: Positive float Default value: 1.0
`max_restarts`	The number of restarts to perform during the Alternating Least Squares (ALS) spectral decomposition phase of the algorithm. Can be used to find better quality local minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive integer

Parameter Name	Description
	Default value: 10
`max_iterations`	The maximum number of iterations to perform during the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive integer Default value: 1000
`tol`	Target error tolerance for the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive float Default value: 1e-8

Tune an LDA Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`test:pwll`	Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.	Maximize

Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

Parameter Name	Parameter Type	Recommended Ranges
`alpha0`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 10
`num_topics`	IntegerParameterRanges	MinValue: 1, MaxValue: 150

Neural Topic Model (NTM) Algorithm

Amazon SageMaker AI NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker AI NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Topics

Input/Output Interface for the NTM Algorithm

Amazon SageMaker AI Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the `S3DataDistributionType` parameter for them to

`FullyReplicated`. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both `recordIO-wrapped-protobuf` (dense and sparse) and `CSV` file formats. For `CSV` format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The `ContentType` for the auxiliary channel is `text/plain`, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named `vocab.txt` and currently only UTF-8 encoding is supported.

For inference, `text/csv`, `application/json`, `application/jsonlines`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. NTM inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_weights` vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker AI Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats for inference and the NTM Sample Notebooks.

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference. NTM training supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker AI NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

NTM Hyperparameters

The following table lists the hyperparameters that you can set for the Amazon SageMaker AI Neural Topic Model (NTM) algorithm.

Parameter Name	Description
`feature_dim`	The vocabulary size of the dataset. **Required** Valid values: Positive integer (min: 1, max: 1,000,000)
`num_topics`	The number of required topics. **Required** Valid values: Positive integer (min: 2, max: 1000)
`batch_norm`	Whether to use batch normalization during training. **Optional** Valid values: *true* or *false* Default value: *false*
`clip_gradient`	The maximum magnitude for each gradient component. **Optional**

Parameter Name	Description
	Valid values: Float (min: 1e-3) Default value: Infinity
`encoder_layers`	The number of layers in the encoder and the output size of each layer. When set to *auto*, the algorithm uses two layers of sizes 3 x `num_topics` and 2 x `num_topics` respectively. **Optional** Valid values: Comma-separated list of positive integers or *auto* Default value: *auto*
`encoder_layers_activation`	The activation function to use in the encoder layers. **Optional** Valid values: • `sigmoid`: Sigmoid function • `tanh`: Hyperbolic tangent • `relu`: Rectified linear unit Default value: `sigmoid`
`epochs`	The maximum number of passes over the training data. **Optional** Valid values: Positive integer (min: 1) Default value: 50

Parameter Name	Description
`learning_rate`	The learning rate for the optimizer. **Optional** Valid values: Float (min: 1e-6, max: 1.0) Default value: 0.001
`mini_batch_size`	The number of examples in each mini batch. **Optional** Valid values: Positive integer (min: 1, max: 10000) Default value: 256
`num_patience_epochs`	The number of successive epochs over which early stopping criterion is evaluated. Early stopping is triggered when the change in the loss function drops below the specified `tolerance` within the last `num_patience_epochs` number of epochs. To disable early stopping, set `num_patience_epochs` to a value larger than `epochs`. **Optional** Valid values: Positive integer (min: 1) Default value: 3

Parameter Name	Description
optimizer	The optimizer to use for training. **Optional** Valid values: • sgd: Stochastic gradient descent • adam: Adaptive momentum estimation • adagrad: Adaptive gradient algorithm • adadelta: An adaptive learning rate algorithm • rmsprop: Root mean square propagation Default value: adadelta
rescale_gradient	The rescale factor for gradient. **Optional** Valid values: float (min: 1e-3, max: 1.0) Default value: 1.0
sub_sample	The fraction of the training data to sample for training per epoch. **Optional** Valid values: Float (min: 0.0, max: 1.0) Default value: 1.0

Parameter Name	Description
`tolerance`	The maximum relative change in the loss function. Early stopping is triggered when change in the loss function drops below this value within the last `num_patience_epochs` number of epochs. **Optional** Valid values: Float (min: 1e-6, max: 0.1) Default value: 0.001
`weight_decay`	The weight decay coefficient. Adds L2 regularization. **Optional** Valid values: Float (min: 0.0, max: 1.0) Default value: 0.0

Tune an NTM Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker AI NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. *Training loss* measures how well the model fits the training data. *Validation loss* measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which is has not been trained. Usually, it's preferable to have both losses be small.

However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

Metric Name	Description	Optimization Direction
`validation:total_loss`	Total Loss on validation set	Minimize

Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`encoder_layers_activation`	CategoricalParameterRanges	['sigmoid', 'tanh', 'relu']
`learning_rate`	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 0.1
`mini_batch_size`	IntegerParameterRanges	MinValue: 16, MaxValue:2048

Parameter Name	Parameter Type	Recommended Ranges
`optimizer`	CategoricalParameterRanges	['sgd', 'adam', 'adadelta']
`rescale_gradient`	ContinuousParameterRange	MinValue: 0.1, MaxValue: 1.0
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

NTM Response Formats

All Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker AI NTM algorithm.

JSON Response Format

```
{
    "predictions":    [
        {"topic_weights": [0.02, 0.1, 0,...]},
        {"topic_weights": [0.25, 0.067, 0,...]}
    ]
}
```

JSONLINES Response Format

```
{"topic_weights": [0.02, 0.1, 0,...]}
{"topic_weights": [0.25, 0.067, 0,...]}
```

RECORDIO Response Format

```
[
    Record = {
        features = {},
        label = {
            'topic_weights': {
```

```
                keys: [],
                values: [0.25, 0.067, 0, ...]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'topic_weights': {
                keys: [],
                values: [0.25, 0.067, 0, ...]  # float32
            }
        }
    }
]
```

Object2Vec Algorithm

The Amazon SageMaker AI Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker AI BlazingText algorithm. For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker AI Object2Vec.

Topics

- Data Formats for Object2Vec Training
- Data Formats for Object2Vec Inference
- Encoder Embeddings for Object2Vec

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

Input Data Type	Example
Sentence-sentence pairs	"A soccer game with multiple males playing." and "Some men are playing a sport."
Labels-sequence pairs	The genre tags of the movie "Titanic", such as "Romance" and "Drama", and its short description: "James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912."
Customer-customer pairs	The customer ID of Jane and customer ID of Jackie.
Product-product pairs	The product ID of football and product ID of basketball.
Item review user-item pairs	A user's ID and the items she has bought, such as apple, pear, and orange.

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single `integer-id`. For example, `[10]`.
- A sequences of discrete tokens, which is represented as a list of `integer-ids`. For example, `[0,12,10,13]`.

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the [the section called “GPU optimization: Classification or Regression”]() or [the section called “GPU optimization: Encoder Embeddings”]() inference network is loaded into GPU.

Object2Vec Sample Notebooks

How Object2Vec Works

When using the Amazon SageMaker AI Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training . To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

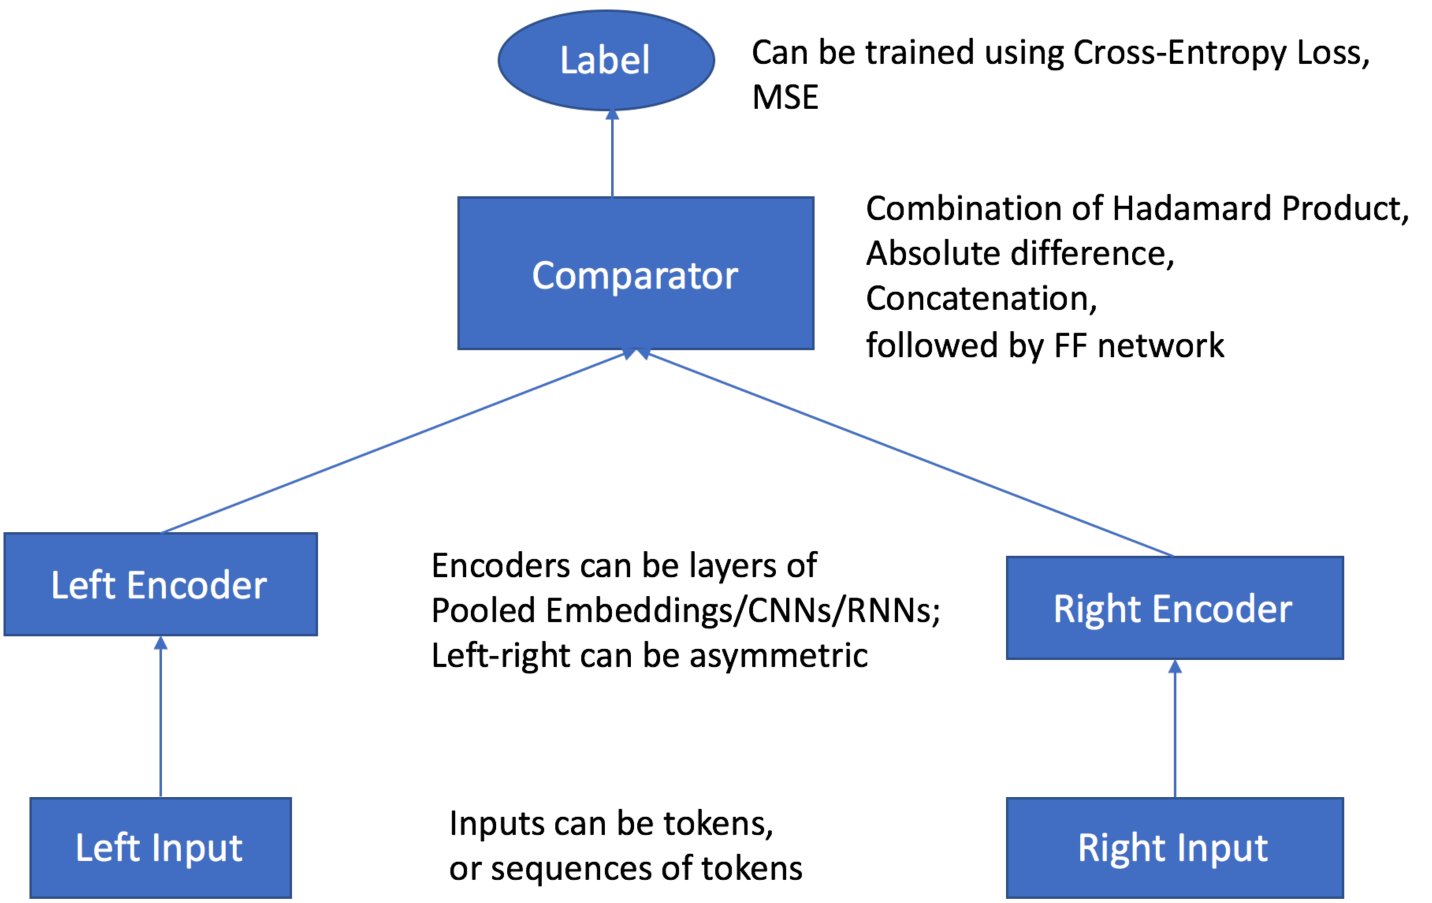
Step 2: Train a Model

The SageMaker AI Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.
- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the he `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.



Architecture of the Object2Vec Algorithm from Data Inputs to Scores

Step 3: Produce Inferences

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

Parameter Name	Description
`enc0_max_seq_len`	The maximum sequence length for the enc0 encoder. **Required** Valid values: 1 ≤ integer ≤ 5000
`enc0_vocab_size`	The vocabulary size of enc0 tokens. **Required** Valid values: 2 ≤ integer ≤ 3000000
`bucket_width`	The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter. **Optional** Valid values: 0 ≤ integer ≤ 100 Default value: 0 (no bucketing)
`comparator_list`	A list used to customize the way in which two embedding s are compared. The Object2Vec comparator operator layer

Parameter Name	Description
	takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvector s. The string values passed to the `comparator_list` and the order in which they are passed determine how these subvectors are assembled. For example, if `comparator_list="hadamard, concat"` , then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, `comparator_list="hadamard"` , then the comparator operator constructs the vector as the hadamard product of only two encodings. **Optional** Valid values: A string that contains any combination of the names of the three binary operators: `hadamard`, `concat`, or `abs_diff`. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows: • `hadamard`: Constructs a vector as the Hadamard (element-wise) product of two encodings. • `concat`: Constructs a vector as the concatenation of two encodings. • `abs_diff`: Constructs a vector as the absolute difference between two encodings. Default value: `"hadamard, concat, abs_diff"`

Parameter Name	Description
`dropout`	The dropout probability for network layers. *Dropout* is a form of regularization used in neural networks that reduces overfitti ng by trimming codependent neurons. **Optional** Valid values: 0.0 ≤ float ≤ 1.0 Default value: 0.0
`early_stopping_pat ience`	The number of consecutive epochs without improveme nt allowed before early stopping is applied. Improvement is defined by with the `early_stopping_tolerance` hyperparameter. **Optional** Valid values: 1 ≤ integer ≤ 5 Default value: 3
`early_stopping_tol erance`	The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the `early_stopping_patience` hyperparameter concludes. **Optional** Valid values: 0.000001 ≤ float ≤ 0.1 Default value: 0.01
`enc_dim`	The dimension of the output of the embedding layer. **Optional** Valid values: 4 ≤ integer ≤ 10000 Default value: 4096

Parameter Name	Description
`enc0_network`	The network model for the enc0 encoder. **Optional** Valid values: `hcnn`, `bilstm`, or `pooled_embedding` • `hcnn`: A hierarchical convolutional neural network. • `bilstm`: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks. • `pooled_embedding` : Averages the embeddings of all of the tokens in the input. Default value: `hcnn`
`enc0_cnn_filter_width`	The filter width of the convolutional neural network (CNN) enc0 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 9 Default value: 3
`enc0_freeze_pretrained_embedding`	Whether to freeze enc0 pretrained embedding weights. **Conditional** Valid values: `True` or `False` Default value: `True`

Parameter Name	Description
`enc0_layers`	The number of layers in the enc0 encoder. **Conditional** Valid values: `auto` or 1 ≤ integer ≤ 4 • For `hcnn`, `auto` means 4. • For `bilstm`, `auto` means 1. • For `pooled_embedding` , `auto` ignores the number of layers. Default value: `auto`
`enc0_pretrained_embedding_file`	The filename of the pretrained enc0 token embedding file in the auxiliary data channel. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
`enc0_token_embedding_dim`	The output dimension of the enc0 token embedding layer. **Conditional** Valid values: 2 ≤ integer ≤ 1000 Default value: 300

Parameter Name	Description
`enc0_vocab_file`	The vocabulary file for mapping pretrained enc0 token embedding vectors to numerical vocabulary IDs. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
`enc1_network`	The network model for the enc1 encoder. If you want the enc1 encoder to use the same network model as enc0, including the hyperparameter values, set the value to `enc0`. **Note** Even when the enc0 and enc1 encoder networks have symmetric architectures, you can't shared parameter values for these networks. **Optional** Valid values: `enc0`, `hcnn`, `bilstm`, or `pooled_embedding` • `enc0`: The network model for the enc0 encoder. • `hcnn`: A hierarchical convolutional neural network. • `bilstm`: A bidirectional LSTM, in which the signal propagate s backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks. • `pooled_embedding` : The averages of the embeddings of all of the tokens in the input. Default value: `enc0`

Parameter Name	Description
`enc1_cnn_filter_width`	The filter width of the CNN enc1 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 9 Default value: 3
`enc1_freeze_pretrained_embedding`	Whether to freeze enc1 pretrained embedding weights. **Conditional** Valid values: `True` or `False` Default value: `True`
`enc1_layers`	The number of layers in the enc1 encoder. **Conditional** Valid values: `auto` or 1 ≤ integer ≤ 4 • For `hcnn`, `auto` means 4. • For `bilstm`, `auto` means 1. • For `pooled_embedding` , `auto` ignores the number of layers. Default value: `auto`
`enc1_max_seq_len`	The maximum sequence length for the enc1 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 5000

Parameter Name	Description
enc1_pretrained_embedding_file	The name of the enc1 pretrained token embedding file in the auxiliary data channel. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
enc1_token_embedding_dim	The output dimension of the enc1 token embedding layer. **Conditional** Valid values: 2 ≤ integer ≤ 1000 Default value: 300
enc1_vocab_file	The vocabulary file for mapping pretrained enc1 token embeddings to vocabulary IDs. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
enc1_vocab_size	The vocabulary size of enc0 tokens. **Conditional** Valid values: 2 ≤ integer ≤ 3000000

Parameter Name	Description
`epochs`	The number of epochs to run for training. **Optional** Valid values: 1 ≤ integer ≤ 100 Default value: 30
`learning_rate`	The learning rate for training. **Optional** Valid values: 1.0E-6 ≤ float ≤ 1.0 Default value: 0.0004
`mini_batch_size`	The batch size that the dataset is split into for an `optimizer` during training. **Optional** Valid values: 1 ≤ integer ≤ 10000 Default value: 32
`mlp_activation`	The type of activation function for the multilayer perceptron (MLP) layer. **Optional** Valid values: `tanh`, `relu`, or `linear` • `tanh`: Hyperbolic tangent • `relu`: Rectified linear unit (ReLU) • `linear`: Linear function Default value: `linear`

Parameter Name	Description
`mlp_dim`	The dimension of the output from MLP layers. **Optional** Valid values: 2 ≤ integer ≤ 10000 Default value: 512
`mlp_layers`	The number of MLP layers in the network. **Optional** Valid values: 0 ≤ integer ≤ 10 Default value: 2
`negative_sampling_rate`	The ratio of negative samples, generated to assist in training the algorithm, to positive samples that are provided by users. Negative samples represent data that is unlikely to occur in reality and are labelled negatively for training. They facilitate training a model to discriminate between the positive samples observed and the negative samples that are not. To specify the ratio of negative samples to positive samples used for training, set the value to a positive integer. For example, if you train the algorithm on input data in which all of the samples are positive and set `negative_sampling_rate` to 2, the Object2Vec algorithm internally generates two negative samples per positive sample. If you don't want to generate or use negative samples during training, set the value to 0. **Optional** Valid values: 0 ≤ integer Default value: 0 (off)

Parameter Name	Description
`num_classes`	The number of classes for classification training. Amazon SageMaker AI ignores this hyperparameter for regression problems. **Optional** Valid values: 2 ≤ integer ≤ 30 Default value: 2
`optimizer`	The optimizer type. **Optional** Valid values: `adadelta`, `adagrad`, `adam`, `sgd`, or `rmsprop`. • `adadelta`: A per-dimension learning rate method for gradient descent • `adagrad`: The adaptive gradient algorithm • `adam`: The adaptive moment estimation algorithm • `sgd`: Stochastic gradient descent • `rmsprop`: Root mean square propagation Default value: `adam`
`output_layer`	The type of output layer where you specify that the task is regression or classification. **Optional** Valid values: `softmax` or `mean_squared_error` • `softmax`: The Softmax function used for classification. • `mean_squared_error` : The MSE used for regression. Default value: `softmax`

Parameter Name	Description
`tied_token_embedding_weight`	Whether to use a shared embedding layer for both encoders. If the inputs to both encoders use the same token-level units, use a shared token embedding layer. For example, for a collection of documents, if one encoder encodes sentences and another encodes whole documents, you can use a shared token embedding layer. That's because both sentences and documents are composed of word tokens from the same vocabulary. **Optional** Valid values: `True` or `False` Default value: `False`

Parameter Name	Description
`token_embedding_storage_type`	The mode of gradient update used during training: when the `dense` mode is used, the optimizer calculates the full gradient matrix for the token embedding layer even if most rows of the gradient are zero-valued. When `sparse` mode is used, the optimizer only stores rows of the gradient that are actually being used in the mini-batch. If you want the algorithm to perform lazy gradient updates, which calculate the gradients only in the non-zero rows and which speed up training, specify `row_sparse` . Setting the value to `row_sparse` constrains the values available for other hyperparameters, as follows: • The `optimizer` hyperparameter must be set to `adam`, `adagrad`, or `sgd`. Otherwise, the algorithm throws a `CustomerValueError` . • The algorithm automatically disables bucketing, setting the `bucket_width` hyperparameter to 0. **Optional** Valid values: `dense` or `row_sparse` Default value: `dense`
`weight_decay`	The weight decay parameter used for optimization. **Optional** Valid values: 0 ≤ float ≤ 10000 Default value: 0 (no decay)

Tune an Object2Vec Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
`test:mean_squared_error`	The Mean Square Error	Minimize
`validation:mean_squared_error`	The Mean Square Error	Minimize

Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
`test:accuracy`	Accuracy	Maximize
`test:cross_entropy`	Cross-entropy	Minimize

Metric Name	Description	Optimization Direction
validation:accuracy	Accuracy	Maximize
validation:cross_entropy	Cross-entropy	Minimize

Tunable Object2Vec Hyperparameters

You can tune the following hyperparameters for the Object2Vec algorithm.

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values
dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0
early_stopping_patience	IntegerParameterRange	MinValue: 1, MaxValue: 5
early_stopping_tolerance	ContinuousParameterRange	MinValue: 0.001, MaxValue: 0.1
enc_dim	IntegerParameterRange	MinValue: 4, MaxValue: 4096
enc0_cnn_filter_width	IntegerParameterRange	MinValue: 1, MaxValue: 5
enc0_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values
`enc0_token_embedding_dim`	IntegerParameterRange	MinValue: 5, MaxValue: 300
`enc1_cnn_filter_width`	IntegerParameterRange	MinValue: 1, MaxValue: 5

Data Formats for Object2Vec Training

When training with the Object2Vec algorithm, make sure that the input data in your request is in JSON Lines format, where each line represents a single data point.

Input: JSON Lines Request Format

Content-type: application/jsonlines

```
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80,
 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9,
 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The “in0” and “in1” are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field `"label"` can accept real valued inputs.

Data Formats for Object2Vec Inference

The following page describes the input request and output response formats for getting scoring inference from the Amazon SageMaker AI Object2Vec model.

GPU optimization: Classification or Regression

Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the classification/regression or the the section called “Output: Encoder Embeddings” inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify `INFERENCE_PREFERRED_MODE=classification`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```
transformer = o2v.transformer(instance_count=4,
                              instance_type="ml.p2.xlarge",
                              max_concurrent_transforms=2,
                              max_payload=1,  # 1MB
                              strategy='MultiRecord',
                              env={'INFERENCE_PREFERRED_MODE': 'classification'},  #
 only useful with GPU
                              output_path=output_s3_path)
```

Input: Classification or Regression Request Format

Content-type: application/json

```
{
  "instances" : [
    {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69,
 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},
    {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107,
 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},
    {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
  ]
}
```

Content-type: application/jsonlines

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821,
 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
 "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

For classification problems, the length of the scores vector corresponds to `num_classes`. For regression problems, the length is 1.

Output: Classification or Regression Response Format

Accept: application/json

```
{
    "predictions": [
        {
            "scores": [
                0.6533935070037842,
                0.07582679390907288,
                0.2707797586917877
            ]
        },
        {
            "scores": [
                0.026291321963071823,
                0.6577019095420837,
                0.31600672006607056
            ]
        }
    ]
}
```

Accept: application/jsonlines

```
{"scores":[0.195667684078216,0.395351558923721,0.408980727195739]}
{"scores":[0.251988261938095,0.258233487606048,0.489778339862823]}
{"scores":[0.280087798833847,0.368331134319305,0.351581096649169]}
```

In both the classification and regression formats, the scores apply to individual labels.

Encoder Embeddings for Object2Vec

The following page lists the input request and output response formats for getting encoder embedding inference from the Amazon SageMaker AI Object2Vec model.

GPU optimization: Encoder Embeddings

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the [the section called “Inference Formats: Scoring”](#) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFERENCE_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```
transformer = o2v.transformer(instance_count=4,
                              instance_type="ml.p2.xlarge",
                              max_concurrent_transforms=2,
                              max_payload=1,  # 1MB
                              strategy='MultiRecord',
                              env={'INFERENCE_PREFERRED_MODE': 'embedding'},  # only
 useful with GPU
                              output_path=output_s3_path)
```

Input: Encoder Embeddings

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{
  "instances" : [
    {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69,
 821, 4]},
    {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107,
 4]},
    {"in0": [774, 14, 21, 206]}
  ]
}
```

Content-type: application/jsonlines; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821,
 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: "`in0`" or "`in1`." The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

Output: Encoder Embeddings

Content-type: application/json

```
{
  "predictions": [
    {"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.00
    {"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.015
  ]
}
```

Content-type: application/jsonlines

```
{"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.00
{"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.015
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

Sequence-to-Sequence Algorithm

Amazon SageMaker AI Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker AI seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

Topics

- Tune a Sequence-to-Sequence Model

Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker AI seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- `train`: It should contain the training data (for example, the `train.rec` file generated by the preprocessing script).
- `validation`: It should contain the validation data (for example, the `val.rec` file generated by the preprocessing script).
- `vocab`: It should contain two vocabulary files (`vocab.src.json` and `vocab.trg.json`)

If the algorithm doesn't find data in any of these three channels, training results in an error.

Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the `application/json` format. Otherwise, use the `recordio-protobuf` format to work with the integer encoded data. Both modes support batching of input data. `application/json` format also allows you to visualize the attention matrix.

- `application/json`: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be `application/json`. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

  `configuration`: {`attention_matrix`: `true`}: Returns the attention matrix for the particular input sequence.

- `application/x-recordio-protobuf`: Expects the input in `recordio-protobuf` format and returns the output in `recordio-protobuf format`. Both content and accept types should be `applications/x-recordio-protobuf`. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be `application/jsonlines`. The format for input is as follows:

```
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the [Sequence-to-Sequence Sample Notebooks](#) .

EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm

The Amazon SageMaker AI seq2seq algorithm only supports on GPU instance types and can only train on a single machine. However, you can use instances with multiple GPUs. The seq2seq algorithm supports P2, P3, G4dn, and G5 GPU instance families.

Sequence-to-Sequence Sample Notebooks

For a sample notebook that shows how to use the SageMaker AI Sequence to Sequence algorithm to train a English-German translation model, see [Machine Translation English-German Example Using SageMaker AI Seq2Seq](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see [Amazon SageMaker notebook instances](#). Once you have created a notebook instance and opened it, select the **SageMaker AI**

Examples tab to see a list of all the SageMaker AI samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- An **embedding layer**. In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.
- An **encoder layer**. After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)
- A **decoder layer**. The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

Attention mechanism. The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

Sequence-to-Sequence Hyperparameters

The following table lists the hyperparameters that you can set when training with the Amazon SageMaker AI Sequence-to-Sequence (seq2seq) algorithm.

Parameter Name	Description
`batch_size`	Mini batch size for gradient descent. **Optional** Valid values: positive integer Default value: 64
`beam_size`	Length of the beam for beam search. Used during training for computing `bleu` and used during inference . **Optional** Valid values: positive integer Default value: 5
`bleu_sample_size`	Number of instances to pick from validation dataset to decode and compute `bleu` score during training. Set to -1 to use full validation set (if `bleu` is chosen as `optimized_metric`). **Optional** Valid values: integer Default value: 0
`bucket_width`	Returns (source,target) buckets up to (`max_seq_len_source` , `max_seq_len_target`). The longer side of the data uses steps of `bucket_width` while the shorter side uses steps scaled down by the average target/source length ratio. If one sided reaches its

Parameter Name	Description
	maximum length before the other, width of extra buckets on that side is fixed to that side of `max_len`. **Optional** Valid values: positive integer Default value: 10
`bucketing_enabled`	Set to `false` to disable bucketing, unroll to maximum length. **Optional** Valid values: `true` or `false` Default value: `true`
`checkpoint_frequency_num_batches`	Checkpoint and evaluate every x batches. This checkpointing hyperparameter is passed to the SageMaker AI's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker AI checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped. **Optional** Valid values: positive integer Default value: 1000

Parameter Name	Description
`checkpoint_threshold`	Maximum number of checkpoints model is allowed to not improve in `optimized_metric` on validatio n dataset before training is stopped. This checkpoin ting hyperparameter is passed to the SageMaker AI's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker AI checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped. **Optional** Valid values: positive integer Default value: 3
`clip_gradient`	Clip absolute gradient values greater than this. Set to negative to disable. **Optional** Valid values: float Default value: 1
`cnn_activation_type`	The `cnn` activation type to be used. **Optional** Valid values: String. One of `glu`, `relu`, `softrelu`, `sigmoid`, or `tanh`. Default value: `glu`

Parameter Name	Description
`cnn_hidden_dropout`	Dropout probability for dropout between convolutional layers. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
`cnn_kernel_width_decoder`	Kernel width for the `cnn` decoder. **Optional** Valid values: positive integer Default value: 5
`cnn_kernel_width_encoder`	Kernel width for the `cnn` encoder. **Optional** Valid values: positive integer Default value: 3
`cnn_num_hidden`	Number of `cnn` hidden units for encoder and decoder. **Optional** Valid values: positive integer Default value: 512
`decoder_type`	Decoder type. **Optional** Valid values: String. Either `rnn` or `cnn`. Default value: *rnn*

Parameter Name	Description
`embed_dropout_source`	Dropout probability for source side embeddings. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
`embed_dropout_target`	Dropout probability for target side embeddings. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
`encoder_type`	Encoder type. The `rnn` architecture is based on attention mechanism by Bahdanau et al. and *cnn* architecture is based on Gehring et al. **Optional** Valid values: String. Either `rnn` or `cnn`. Default value: `rnn`
`fixed_rate_lr_half_life`	Half life for learning rate in terms of number of checkpoints for `fixed_rate_` * schedulers. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
`learning_rate`	Initial learning rate. **Optional** Valid values: float Default value: 0.0003
`loss_type`	Loss function for training. **Optional** Valid values: String. `cross-entropy` Default value: `cross-entropy`
`lr_scheduler_type`	Learning rate scheduler type. `plateau_reduce` means reduce the learning rate whenever `optimized_metric` on `validation_accuracy` plateaus. `inv_t` is inverse time decay. `learning_rate` / (1+`decay_rate` *t) **Optional** Valid values: String. One of `plateau_reduce` , `fixed_rate_inv_t` , or `fixed_rate_inv_sqrt_t` . Default value: `plateau_reduce`
`max_num_batches`	Maximum number of updates/batches to process. -1 for infinite. **Optional** Valid values: integer Default value: -1

Parameter Name	Description
`max_num_epochs`	Maximum number of epochs to pass through training data before fitting is stopped. Training continues until this number of epochs even if validation accuracy is not improving if this parameter is passed. Ignored if not passed. **Optional** Valid values: Positive integer and less than or equal to max_num_epochs. Default value: none
`max_seq_len_source`	Maximum length for the source sequence length. Sequences longer than this length are truncated to this length. **Optional** Valid values: positive integer Default value: 100
`max_seq_len_target`	Maximum length for the target sequence length. Sequences longer than this length are truncated to this length. **Optional** Valid values: positive integer Default value: 100

Parameter Name	Description
`min_num_epochs`	Minimum number of epochs the training must run before it is stopped via `early_stopping` conditions. **Optional** Valid values: positive integer Default value: 0
`momentum`	Momentum constant used for `sgd`. Don't pass this parameter if you are using `adam` or `rmsprop`. **Optional** Valid values: float Default value: none
`num_embed_source`	Embedding size for source tokens. **Optional** Valid values: positive integer Default value: 512
`num_embed_target`	Embedding size for target tokens. **Optional** Valid values: positive integer Default value: 512

Parameter Name	Description
`num_layers_decoder`	Number of layers for Decoder *rnn* or *cnn*. **Optional** Valid values: positive integer Default value: 1
`num_layers_encoder`	Number of layers for Encoder `rnn` or `cnn`. **Optional** Valid values: positive integer Default value: 1
`optimized_metric`	Metrics to optimize with early stopping. **Optional** Valid values: String. One of `perplexity` , `accuracy`, or `bleu`. Default value: `perplexity`
`optimizer_type`	Optimizer to choose from. **Optional** Valid values: String. One of `adam`, `sgd`, or `rmsprop`. Default value: `adam`

Parameter Name	Description
plateau_reduce_lr_factor	Factor to multiply learning rate with (for plateau_reduce). **Optional** Valid values: float Default value: 0.5
plateau_reduce_lr_threshold	For plateau_reduce scheduler, multiply learning rate with reduce factor if optimized_metric didn't improve for this many checkpoints. **Optional** Valid values: positive integer Default value: 3
rnn_attention_in_upper_layers	Pass the attention to upper layers of *rnn*, like Google NMT paper. Only applicable if more than one layer is used. **Optional** Valid values: boolean (true or false) Default value: true
rnn_attention_num_hidden	Number of hidden units for attention layers. defaults to rnn_num_hidden . **Optional** Valid values: positive integer Default value: rnn_num_hidden

Parameter Name	Description
`rnn_attention_type`	Attention model for encoders. `mlp` refers to concat and bilinear refers to general from the Luong et al. paper. **Optional** Valid values: String. One of `dot`, `fixed`, `mlp`, or `bilinear`. Default value: `mlp`
`rnn_cell_type`	Specific type of `rnn` architecture. **Optional** Valid values: String. Either `lstm` or `gru`. Default value: `lstm`
`rnn_decoder_state_init`	How to initialize `rnn` decoder states from encoders. **Optional** Valid values: String. One of `last`, `avg`, or `zero`. Default value: `last`
`rnn_first_residual_layer`	First *rnn* layer to have a residual connection, only applicable if number of layers in encoder or decoder is more than 1. **Optional** Valid values: positive integer Default value: 2

Parameter Name	Description
`rnn_num_hidden`	The number of *rnn* hidden units for encoder and decoder. This must be a multiple of 2 because the algorithm uses bi-directional Long Term Short Term Memory (LSTM) by default. **Optional** Valid values: positive even integer Default value: 1024
`rnn_residual_connections`	Add residual connection to stacked *rnn*. Number of layers should be more than 1. **Optional** Valid values: boolean (`true` or `false`) Default value: `false`
`rnn_decoder_hidden_dropout`	Dropout probability for hidden state that combines the context with the *rnn* hidden state in the decoder. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
`training_metric`	Metrics to track on training on validation data. **Optional** Valid values: String. Either `perplexity` or `accuracy`. Default value: `perplexity`

Parameter Name	Description
`weight_decay`	Weight decay constant. **Optional** Valid values: float Default value: 0
`weight_init_scale`	Weight initialization scale (for `uniform` and `xavier` initialization). **Optional** Valid values: float Default value: 2.34
`weight_init_type`	Type of weight initialization. **Optional** Valid values: String. Either `uniform` or `xavier`. Default value: `xavier`
`xavier_factor_type`	Xavier factor type. **Optional** Valid values: String. One of `in`, `out`, or `avg`. Default value: `in`

Tune a Sequence-to-Sequence Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the Sequence-to-Sequence Algorithm

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

Metric Name	Description	Optimization Direction
`validation:accuracy`	Accuracy computed on the validation dataset.	Maximize
`validation:bleu`	Bleu score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the `bleu_sample_size` parameter to specify the subsample.	Maximize
`validation:perplexity`	Perplexity, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.	Minimize

Tunable Sequence-to-Sequence Hyperparameters

You can tune the following hyperparameters for the SageMaker AI Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective metrics are: `batch_size`, `optimizer_type`, `learning_rate`, `num_layers_encoder`, and `num_layers_decoder`.

Parameter Name	Parameter Type	Recommended Ranges
`num_layers_encoder`	IntegerParameterRange	[1-10]
`num_layers_decoder`	IntegerParameterRange	[1-10]
`batch_size`	CategoricalParameterRange	[16,32,64,128,256, 512,1024,2048]
`optimizer_type`	CategoricalParameterRange	['adam', 'sgd', 'rmsprop']
`weight_init_type`	CategoricalParameterRange	['xavier', 'uniform']
`weight_init_scale`	ContinuousParameterRange	For the xavier type: MinValue: 2.0, MaxValue: 3.0 For the uniform type: MinValue: -1.0, MaxValue: 1.0
`learning_rate`	ContinuousParameterRange	MinValue: 0.00005, MaxValue: 0.2
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.1
`momentum`	ContinuousParameterRange	MinValue: 0.5, MaxValue: 0.9
`clip_gradient`	ContinuousParameterRange	MinValue: 1.0, MaxValue: 5.0

Parameter Name	Parameter Type	Recommended Ranges
rnn_num_hidden	CategoricalParameterRange	Applicable only to recurrent neural networks (RNNs). [128,256,512,1024, 2048]
cnn_num_hidden	CategoricalParameterRange	Applicable only to convolutional neural networks (CNNs). [128,256,512,1024, 2048]
num_embed _source	IntegerParameterRange	[256-512]
num_embed _target	IntegerParameterRange	[256-512]
embed_dro pout_source	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
embed_dro pout_target	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
rnn_decod er_hidden _dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
cnn_hidde n_dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
lr_schedu ler_type	CategoricalParameterRange	['plateau_reduce', 'fixed_rate_inv_t', 'fixed_rate_inv_sq rt_t']

Parameter Name	Parameter Type	Recommended Ranges
`plateau_reduce_lr_factor`	ContinuousParameterRange	MinValue: 0.1, MaxValue: 0.5
`plateau_reduce_lr_threshold`	IntegerParameterRange	[1-5]
`fixed_rate_lr_half_life`	IntegerParameterRange	[10-30]

Text Classification - TensorFlow

The Amazon SageMaker AI Text Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of text data is not available. The text classification algorithm takes a text string as input and outputs a probability for each of the class labels. Training datasets must be in CSV format. This page includes information about Amazon EC2 instance recommendations and sample notebooks for Text Classification - TensorFlow.

How to use the SageMaker AI Text Classification - TensorFlow algorithm

You can use Text Classification - TensorFlow as an Amazon SageMaker AI built-in algorithm. The following section describes how to use Text Classification - TensorFlow with the SageMaker AI Python SDK. For information on how to use Text Classification - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

The Text Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Hub Models. Every pretrained model has a unique `model_id`. The following example uses BERT Base Uncased (`model_id`: `tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker AI Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Text Classification - TensorFlow Hyperparameters. Use these values to construct a SageMaker AI Estimator.

> **Note**
>
> Default hyperparameter values are different for different models. For example, for larger models, the default batch size is smaller.

This example uses the SST2 dataset, which contains positive and negative movie reviews. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset. Any S3 bucket used in a notebook must be in the same AWS Region as the notebook instance that accesses it.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2", "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
```

```
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/SST2/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tc-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_tc_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
```

```
tf_tc_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

Input and output interface for the Text Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset made up of text sentences with any number of classes. The pretrained model attaches a classification layer to the Text Embedding model and initializes the layer parameters to random values. The output dimension of the classification layer is determined based on the number of classes detected in the input data.

Be mindful of how to format your training data for input to the Text Classification - TensorFlow model.

- **Training data input format:** A directory containing a `data.csv` file. Each row of the first column should have integer class labels between 0 and the number of classes. Each row of the second column should have the corresponding text data.

The following is an example of an input CSV file. Note that the file should not have any header. The file should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing / is required.

```
|   |   |
|---|---|
|0 |hide new secretions from the parental units|
|0 |contains no wit , only labored gags|
|1 |that loves its characters and communicates something rather beautiful about human
 nature|
|...|...|
```

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker AI. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker AI Text Classification - TensorFlow model with another Text Classification - TensorFlow model trained in SageMaker AI.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model.

For more information on using incremental training with the SageMaker AI Text Classification - TensorFlow algorithm, see the [Introduction to JumpStart - Text Classification] sample notebook.

Inference with the Text Classification - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Text Classification training for inference. Any raw text formats for inference must be content type `application/x-text`.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Text Classification - TensorFlow model processes a single string per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
"labels": [label_0, label_1, label_2, ...],
"predicted_label": predicted_label}
```

If `accept` is set to `application/json`, then the model only outputs probabilities.

Amazon EC2 instance recommendation for the Text Classification - TensorFlow algorithm

The Text Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- `ml.p2.xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`

- `ml.p3.16xlarge`
- `ml.g4dn.xlarge`
- `ml.g4dn.16.xlarge`
- `ml.g5.xlarge`
- `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Text Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker AI Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Text Classification - TensorFlow Works

The Text Classification - TensorFlow algorithm takes text as classifies it into one of the output class labels. Deep learning networks such as BERT are highly accurate for text classification. There are also deep learning networks that are trained on large text datasets, such as TextNet, which has more than 11 million texts with about 11,000 categories. After a network is trained with TextNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific text classification tasks. The Amazon SageMaker AI Text Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a text classification layer is attached to the pretrained TensorFlow model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully connected layer with 2-norm regularization, and is initialized with random weights. You can change the hyperparameter values for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer.

You can fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Text Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	`model_id`	Source

Text Classification - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker AI built-in Object Detection - TensorFlow algorithm. See Tune a Text Classification - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
batch_size	The batch size for training. For training on instances with multiple GPUs, this batch size is used across the GPUs. Valid values: positive integer. Default value: 32.
beta_1	The beta1 for the "adam" and "adamw" optimizers. Represents the exponential decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0].

Parameter Name	Description
	Default value: `0.9`.
`beta_2`	The beta2 for the `"adam"` and `"adamw"` optimizers. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.999`.
`dropout_rate`	The dropout rate for the dropout layer in the top classification layer. Used only when `reinitialize_top_layer` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.2`
`early_stopping`	Set to `"True"` to use early stopping logic during training. If `"False"`, early stopping is not used. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`early_stopping_min_delta`	The minimum change needed to qualify as an improvement. An absolute change less than the value of `early_stopping_min_delta` does not qualify as improvement. Used only when `early_stopping` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0`.

Parameter Name	Description
`early_stopping_patience`	The number of epochs to continue training with no improvement. Used only when `early_stopping` is set to `"True"`. Valid values: positive integer. Default value: 5.
`epochs`	The number of training epochs. Valid values: positive integer. Default value: `10`.
`epsilon`	The epsilon for `"adam"`, `"rmsprop"` , `"adadelta"` , and `"adagrad"` optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `1e-7`.
`initial_accumulator_value`	The starting value for the accumulators, or the per-parameter momentum values, for the `"adagrad"` optimizer. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0001`.
`learning_rate`	The optimizer learning rate. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.001`.

Parameter Name	Description
`momentum`	The momentum for the `"sgd"` and `"nesterov"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.9`.
`optimizer`	The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: (`"adamw"`, `"adam"`, `"sgd"`, `"nesterov"` , `"rmsprop"` , `"adagrad"` , `"adadelta"`). Default value: `"adam"`.
`regularizers_l2`	The L2 regularization factor for the dense layer in the classification layer. Used only when `reinitialize_top_layer` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0001`.
`reinitialize_top_layer`	If set to `"Auto"`, the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to `"True"`. Valid values: string, any of the following: (`"Auto"`, `"True"` or `"False"`). Default value: `"Auto"`.

Parameter Name	Description
`rho`	The discounting factor for the gradient of the `"adadelta"` and `"rmsprop"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.95`.
`train_only_on_top_layer`	If `"True"`, only the top classification layer parameters are fine-tuned. If `"False"`, all model parameters are fine-tuned. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`validation_split_ratio`	The fraction of training data to randomly split to create validation data. Only used if validation data is not provided through the `validation` channel. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.2`.
`warmup_steps_fraction`	The fraction of the total number of gradient update steps, where the learning rate increases from 0 to the initial learning rate as a warm up. Only used with the `adamw` optimizer. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.1`.

Tune a Text Classification - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics computed by the Text Classification - TensorFlow algorithm

Refer to the following chart to find which metrics are computed by the Text Classification - TensorFlow algorithm.

Metric Name	Description	Optimization Direction	Regex Pattern
`validation:accuracy`	The ratio of the number of correct predictions to the total number of predictions made.	Maximize	`val_accuracy=([0-9\\.]+)`

Tunable Text Classification - TensorFlow hyperparameters

Tune a text classification model with the following hyperparameters. The hyperparameters that have the greatest impact on text classification objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adamw` or `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see Text Classification - TensorFlow Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`batch_size`	IntegerParameterRanges	MinValue: 4, MaxValue: 128
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999

Parameter Name	Parameter Type	Recommended Ranges
eps	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
learning_rate	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
momentum	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['adamw', 'adam', 'sgd', 'rmsprop', 'nesterov', 'adagrad', 'adadelta']
regularizers_l2	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
train_only_on_top_layer	CategoricalParameterRanges	['True', 'False']

Built-in SageMaker AI Algorithms for Time-Series Data

SageMaker AI provides algorithms that are tailored to the analysis of time-series data for forecasting product demand, server loads, webpage requests, and more.

- Use the SageMaker AI DeepAR forecasting algorithm—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
DeepAR Forecasting	train and (optionally) test	File	JSON Lines or Parquet	GPU or CPU	Yes

Use the SageMaker AI DeepAR forecasting algorithm

The Amazon SageMaker AI DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more `target` time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the `cat` field and a vector of dynamic (time-dependent) time series provided by the `dynamic_feat` field. SageMaker AI trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the `context_length` hyperparameter. To control how far in the future predictions can be made, use the `prediction_length` hyperparameter. For more information, see [How the DeepAR Algorithm Works](#).

Topics

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required `train` channel describes the training dataset. The optional `test` channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named *_SUCCESS*. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (`.json`, `.json.gz`, or `.parquet`) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the `content_type` parameter of the s3_input class.

The records in your input files should contain the following fields:

- `start`—A string with the format `YYYY-MM-DD HH:MM:SS`. The start timestamp can't contain time zone information.
- `target`—An array of floating-point values or integers that represent the time series. You can encode missing values as `null` literals, or as `"NaN"` strings in JSON, or as `nan` floating-point values in Parquet.

- `dynamic_feat` (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated `target` value plus `prediction_length`. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated `dynamic_feat` might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```
{"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]}
```

- `cat` (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the `embedding_dimension` hyperparameter. For more information, see DeepAR Hyperparameters.

If you use a JSON file, it must be in JSON Lines format. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
 "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3],
 "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
 [[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, `"start"` can be the `datetime` type. You can compress Parquet files using gzip (`gzip`) or the Snappy compression library (`snappy`).

If the algorithm is trained without `cat` and `dynamic_feat` fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the `cat` and `dynamic_feat` feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding `cat` features. For example, if the `target` time series represents the demand of clothing items, you can associate a two-dimensional `cat` vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with `cat` values that are combinations of the `cat` values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the `start` field correctly. The algorithm uses the `start` timestamp to derive the internal features.
- If you use categorical features (`cat`), all time series must have the same number of categorical features. If the dataset contains the `cat` field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, `cardinality` is `"auto"`. If the dataset contains the `cat` field, but you don't want to use it, you can disable it by setting `cardinality` to `""`. If a model was trained using a `cat` feature, you must include it for inference.
- If your dataset contains the `dynamic_feat` field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the `dynamic_feat` field should have the same length as the `target`. If the dataset contains the `dynamic_feat` field, but you don't want to use it, disable it by setting(`num_dynamic_feat` to `""`). If the model was trained with the `dynamic_feat` field, you must provide this field for

inference. In addition, each of the features has to have the length of the provided target plus the `prediction_length`. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

$$\mathrm{RMSE} = \sqrt{\frac{1}{nT}\sum_{i,t}\left(\hat{y}_{i,t} - y_{i,t}\right)^2}$$

$y_{i,t}$ is the true value of time series *i* at the time *t*. $\hat{y}_{i,t}$ is the mean prediction. The sum is over all *n* time series in the test set and over the last T time points for each time series, where T corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see [DeepAR Hyperparameters](#).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range [0, 1], the weighted quantile loss is defined as follows:

$$\mathrm{wQuantileLoss}[\tau] = 2\frac{\sum_{i,t} Q_{i,t}^{(\tau)}}{\sum_{i,t} |y_{i,t}|}, \quad \text{with} \quad Q_{i,t}^{(\tau)} = \begin{cases} (1-\tau)|q_{i,t}^{(\tau)} - y_{i,t}| & \text{if } q_{i,t}^{(\tau)} > y_{i,t} \\ \tau|q_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}$$

$q_{i,t}^{(\tau)}$ is the τ-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see [DeepAR Hyperparameters](#).

For inference, DeepAR accepts JSON format and the following fields:

- `"instances"`, which includes one or more time series in JSON Lines format
- A name of `"configuration"`, which includes parameters for generating the forecast

For more information, see [DeepAR Inference Formats](#).

Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.

- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholds the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see [Tune a DeepAR Model](#).
- Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use `5min` instead of `1min`.
- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.
- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for `context_length`, `prediction_length`, `num_cells`, `num_layers`, or `mini_batch_size` can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker AI DeepAR algorithm and how to deploy the trained model for performing inferences, see [DeepAR demo on electricity dataset](), which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker AI, see [Amazon SageMaker notebook instances](). After creating and opening a notebook instance, choose the **SageMaker AI Examples** tab to see a list of all of the SageMaker AI examples. To open a notebook, choose its **Use** tab, and choose **Create copy**.

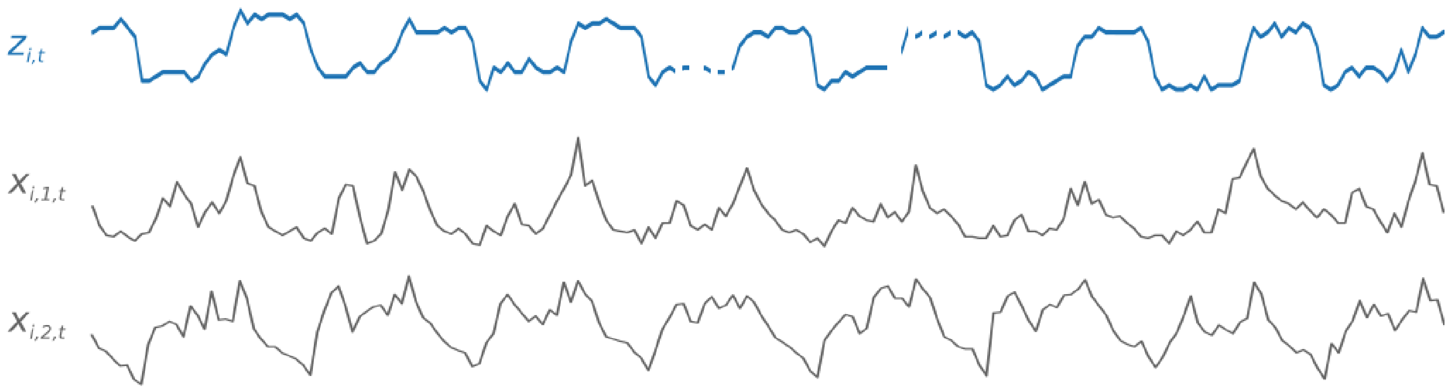
For more information about the Amazon SageMaker AI DeepAR algorithm, see the following blog posts:

- [Now available in Amazon SageMaker AI: DeepAR algorithm for more accurate time series forecasting]()
- [Deep demand forecasting with Amazon SageMaker AI]()

How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see [Input/Output Interface for the DeepAR Algorithm]().

For example, the following is an element of a training set indexed by *i* which consists of a target time series, $Z_{i,t}$, and two associated feature time series, $X_{i,1,t}$ and $X_{i,2,t}$:

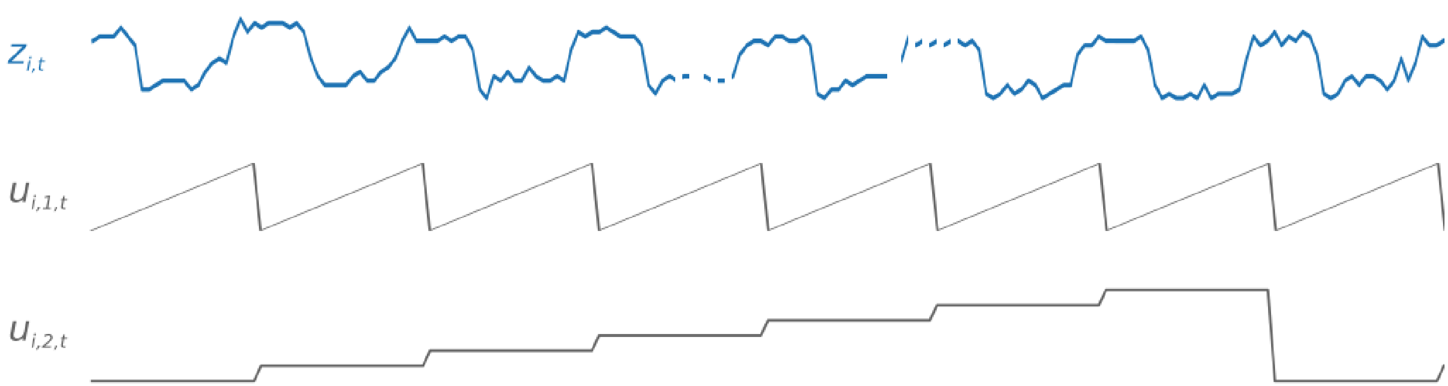


The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

How Feature Time Series Work in the DeepAR Algorithm

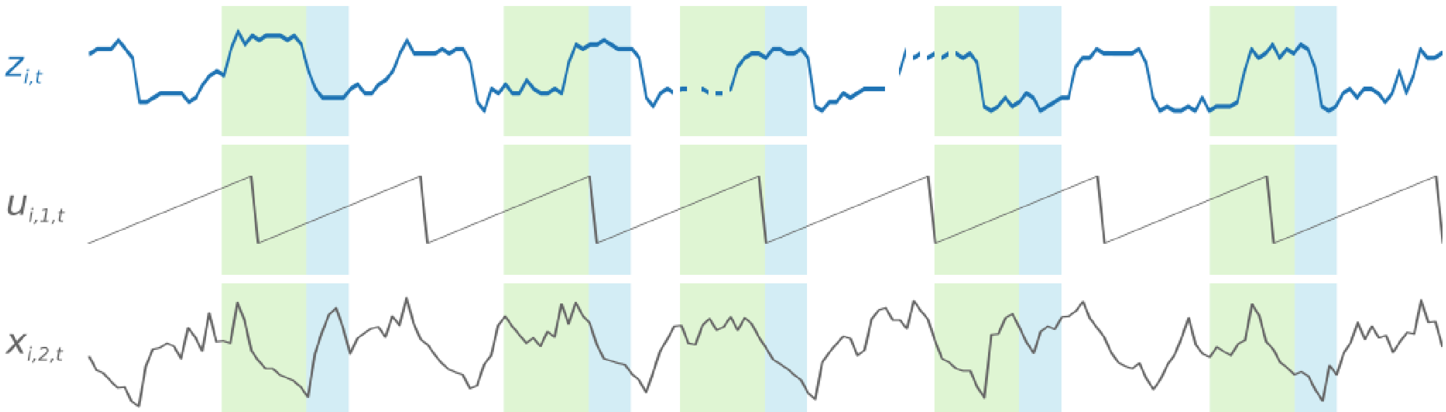
To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.



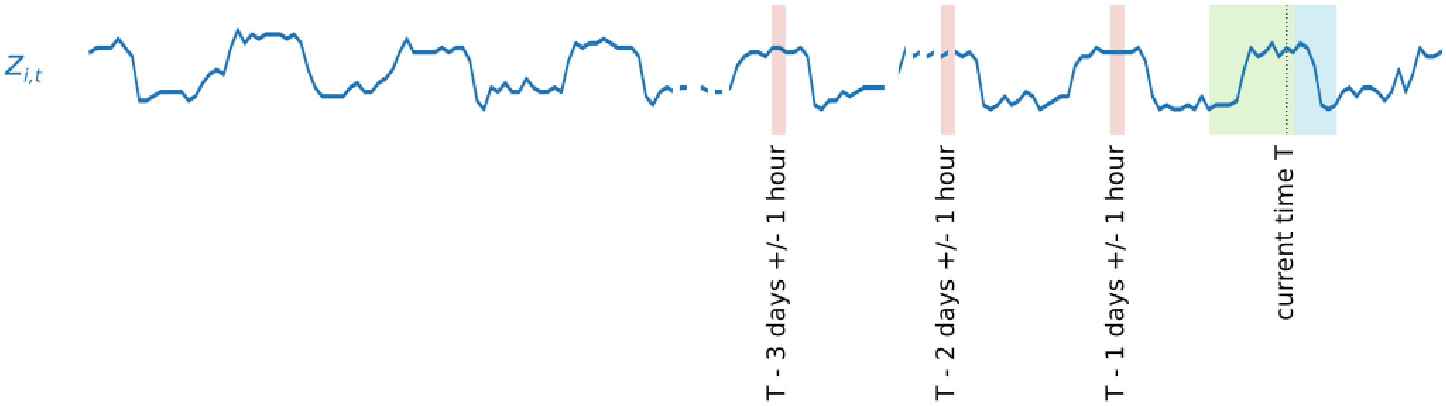
The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

Frequency of the Time Series	Derived Features
`Minute`	`minute-of-hour` , `hour-of-day` , `day-of-week` , `day-of-month` , `day-of-year`
`Hour`	`hour-of-day` , `day-of-week` , `day-of-month` , `day-of-year`
`Day`	`day-of-week` , `day-of-month` , `day-of-year`
`Week`	`day-of-month` , `week-of-year`
`Month`	month-of-year

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The `context_length` hyperparameter controls how far in the past the network can see, and the `prediction_length` hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element *i*. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.



To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, *t* = *T*, the model exposes the $z_{i,t}$ values, which occurred approximately one, two, and three days in the past.



For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next `prediction_length` values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

DeepAR Hyperparameters

The following table lists the hyperparameters that you can set when training with the Amazon SageMaker AI DeepAR forecasting algorithm.

Parameter Name	Description
`context_length`	The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the `prediction_length` . The model also receives lagged inputs from the target, so `context_length` can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For

Parameter Name	Description
	example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. **Required** Valid values: Positive integer
`epochs`	The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also `early_stopping_patience`. Typical values range from 10 to 1000. **Required** Valid values: Positive integer
`prediction_length`	The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can't generate longer forecasts. The `prediction_length` is fixed when a model is trained and it cannot be changed later. **Required** Valid values: Positive integer

Parameter Name	Description
`time_freq`	The granularity of the time series in the dataset. Use `time_freq` to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, `5min` specifies a frequency of 5 minutes. • *M*: monthly • *W*: weekly • *D*: daily • *H*: hourly • *min*: every minute **Required** Valid values: An integer followed by *M*, *W*, *D*, *H*, or *min*. For example, `5min`.

Parameter Name	Description
`cardinality`	When using the categorical features (`cat`), `cardinality` is an array specifying the number of categories (groups) per categorical feature. Set this to `auto` to infer the cardinality from the data. The `auto` mode also works when no categoric al features are used in the dataset. This is the recommended setting for the parameter. Set cardinality to `ignore` to force DeepAR to not use categoric al features, even it they are present in the data. To perform additional data validation, it is possible to explicitl y set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3]. For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR. **Optional** Valid values: `auto`, `ignore`, array of positive integers, empty string, or Default value: `auto`
`dropout_rate`	The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2. **Optional** Valid values: float Default value: 0.1

Parameter Name	Description
`early_stopping_patience`	If this parameter is set, training stops when no progress is made within the specified number of `epochs`. The model that has the lowest loss is returned as the final model. **Optional** Valid values: integer
`embedding_dimension`	Size of embedding vector learned per categorical feature (same value is used for all categorical features). The DeepAR model can learn group-level time series patterns when a categorical grouping feature is provided. To do this, the model learns an embedding vector of size `embedding_dimension` for each group, capturing the common properties of all time series in the group. A larger `embedding_dimension` allows the model to capture more complex patterns. However, because increasing the `embedding_dimension` increases the number of parameters in the model, more training data is required to accurately learn these parameters. Typical values for this parameter are between 10-100. **Optional** Valid values: positive integer Default value: 10
`learning_rate`	The learning rate used in training. Typical values range from 1e-4 to 1e-1. **Optional** Valid values: float Default value: 1e-3

Parameter Name	Description
`likelihood`	The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected: • *gaussian*: Use for real-valued data. • *beta*: Use for real-valued targets between 0 and 1 inclusive. • *negative-binomial*: Use for count data (non-negative integers). • *student-T*: An alternative for real-valued data that works well for bursty data. • *deterministic-L1*: A loss function that does not estimate uncertainty and only learns a point forecast. **Optional** Valid values: One of *gaussian*, *beta*, *negative-binomial*, *student-T*, or *deterministic-L1*. Default value: `student-T`
`mini_batch_size`	The size of mini-batches used during training. Typical values range from 32 to 512. **Optional** Valid values: positive integer Default value: 128

Parameter Name	Description
`num_cells`	The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100. **Optional** Valid values: positive integer Default value: 40
`num_dynamic_feat`	The number of `dynamic_feat` provided in the data. Set this to `auto` to infer the number of dynamic features from the data. The `auto` mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter. To force DeepAR to not use dynamic features, even it they are present in the data, set `num_dynamic_feat` to `ignore`. To perform additional data validation, it is possible to explicitl y set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2. **Optional** Valid values: `auto`, `ignore`, positive integer, or empty string Default value: `auto`

Parameter Name	Description
`num_eval_samples`	The number of samples that are used per time-series when calculating test accuracy metrics. This parameter does not have any influence on the training or the final model. In particular, the model can be queried with a different number of samples. This parameter only affects the reported accuracy scores on the test channel after training. Smaller values result in faster evaluation, but then the evaluation scores are typically worse and more uncertain. When evaluating with higher quantiles, for example 0.95, it may be important to increase the number of evaluation samples. **Optional** Valid values: integer Default value: 100
`num_layers`	The number of hidden layers in the RNN. Typical values range from 1 to 4. **Optional** Valid values: positive integer Default value: 2
`test_quantiles`	Quantiles for which to calculate quantile loss on the test channel. **Optional** Valid values: array of floats Default value: [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9]

Tune a DeepAR Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see Best Practices for Using the DeepAR Algorithm.

Metric Name	Description	Optimization Direction
`test:RMSE`	The root mean square error between the forecast and the actual target computed on the test set.	Minimize
`test:mean_wQuantileLoss`	The average overall quantile losses computed on the test set. To control which quantiles are used, set the `test_quantiles` hyperparameter.	Minimize
`train:final_loss`	The training negative log-likelihood loss averaged over the last training epoch for the model.	Minimize

Tunable Hyperparameters for the DeepAR Algorithm

Tune a DeepAR model with the following hyperparameters. The hyperparameters that have the greatest impact, listed in order from the most to least impactful, on DeepAR objective metrics are: `epochs`, `context_length`, `mini_batch_size`, `learning_rate`, and `num_cells`.

Parameter Name	Parameter Type	Recommended Ranges
`epochs`	`IntegerParameterRanges`	MinValue: 1, MaxValue: 1000
`context_length`	`IntegerParameterRanges`	MinValue: 1, MaxValue: 200
`mini_batch_size`	`IntegerParameterRanges`	MinValue: 32, MaxValue: 1028
`learning_rate`	`ContinuousParameterRange`	MinValue: 1e-5, MaxValue: 1e-1
`num_cells`	`IntegerParameterRanges`	MinValue: 30, MaxValue: 200
`num_layers`	`IntegerParameterRanges`	MinValue: 1, MaxValue: 8
`dropout_rate`	`ContinuousParameterRange`	MinValue: 0.00, MaxValue: 0.2
`embedding_dimension`	`IntegerParameterRanges`	MinValue: 1, MaxValue: 50

DeepAR Inference Formats

The following page describes the request and response formats for inference with the Amazon SageMaker AI DeepAR model.

DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat`values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```
{
    "instances": [
        {
            "start": "2009-11-01 00:00:00",
            "target": [4.0, 10.0, "NaN", 100.0, 113.0],
            "cat": [0, 1],
            "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
        },
        {
            "start": "2012-01-30",
            "target": [1.0],
            "cat": [2, 1],
            "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
        },
        {
            "start": "1999-01-30",
            "target": [2.0, 1.0],
            "cat": [1, 3],
            "dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
        }
    ],
    "configuration": {
         "num_samples": 50,
         "output_types": ["mean", "quantiles", "samples"],
         "quantiles": ["0.5", "0.9"]
    }
}
```

The `configuration` field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are `"mean"` `"quantiles"` and `"samples"`. If you specify `"quantiles"`, each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify `"samples"`, the model also returns the raw samples used to calculate the other outputs.

DeepAR JSON Response Formats

The following is the format of a response, where `[...]` are arrays of numbers:

```
{
    "predictions": [
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        }
    ]
}
```

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable `MODEL_SERVER_WORKERS` For example, by setting `MODEL_SERVER_WORKERS=1`) when calling the SageMaker AI [`CreateModel`]() API.

Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see Input/Output Interface for the DeepAR Algorithm. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
 "dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3],
 "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
 [[1.3, 0.4]]}
```

Note

When creating the transformation job with `CreateTransformJob`, set the `BatchStrategy` value to `SingleRecord` and set the `SplitType` value in the `TransformInput` configuration to `Line`, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the `cat` and the `dynamic_feat` fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the `cat` and the `dynamic_feat` fields.
- The corresponding `cardinality` and `num_dynamic_feat` values used in the training job are not set to `""`.

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using an environment variable named `DEEPAR_INFERENCE_CONFIG`. The value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment, the inference container uses the following default:

```
{
    "num_samples": 100,
    "output_types": ["mean", "quantiles"],
    "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]
}
```

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the TransformInput configuration of the SageMaker AI CreateTransformJob request clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all JSON objects on the same line.

For example, here is a SageMaker AI CreateTransformJob request for a DeepAR job with a custom DEEPAR_INFERENCE_CONFIG:

```
{
   "BatchStrategy": "SingleRecord",
   "Environment": {
      "DEEPAR_INFERENCE_CONFIG" : "{ \"num_samples\": 200, \"output_types\": [\"mean
\"] }",
      ...
   },
   "TransformInput": {
      "SplitType": "Line",
      ...
   },
   "TransformOutput": {
      "AssembleWith": "Line",
      ...
   },
   ...
}
```

Unsupervised Built-in SageMaker AI Algorithms

Amazon SageMaker AI provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- IP Insights—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- K-Means Algorithm—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- Principal Component Analysis (PCA) Algorithm—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- Random Cut Forest (RCF) Algorithm—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
IP Insights	train and (optionally) validation	File	CSV	CPU or GPU	Yes
K-Means	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPUCommon (single GPU device on one or more instances)	No

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
PCA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	GPU or CPU	Yes
Random Cut Forest	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU	Yes

IP Insights

Amazon SageMaker AI IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker AI IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker AI IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker AI IP Insights algorithm can also learn vector representations of IP addresses, known as *embeddings*. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

Topics

Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker AI IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in `text/csv` format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats.

Inference

For inference, IP Insights supports `text/csv`, `application/json`, and `application/jsonlines` data content types. For more information about the common data formats for inference provided by SageMaker AI, see Common data formats for inference. IP Insights inference returns output formatted as either `application/json` or `application/jsonlines`. Each record in the output data contains the corresponding `dot_product` (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats.

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker AI IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances. IP Insights supports P2, P3, G4dn, and G5 GPU families.

GPU Instances for the IP Insights Algorithm

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the `mini_batch_size` is divided equally into the number of GPUs used. You may want to increase the value of the `mini_batch_size` to compensate for this.

CPU Instances for the IP Insights Algorithm

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: `vector_dim` and `num_entity_vectors`. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for `vector_dim` in the first column range from 32 to 2048 and the values for `num_entity_vectors` in the first row range from 10,000 to 50,000,000.

vector_dim \ num_entity_vectors.	**10,000**	**50,000**	**100,000**	**500,000**	**1,000,000**	**5,000,000**	**10,000,000**	**50,000,000**
32	ml.m5.large	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.xlarge`	`ml.m5.2xlarge`	`ml.m5.4xlarge`
64	ml.m5.large	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.2xlarge`	`ml.m5.2xlarge`	
128	ml.m5.large	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.2xlarge`	`ml.m5.4xlarge`	
256	ml.m5.large	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.xlarge`	`ml.m5.4xlarge`		
512	ml.m5.large	`ml.m5.large`	`ml.m5.large`	`ml.m5.large`	`ml.m5.2xlarge`			

vector_dim \ num_entity_vectors.	10,000	50,000	100,000	500,000	1,000,000	5,000,000	10,000,000	50,000,000
1024	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.4xlarge			
2048	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.xlarge				

The values for the `mini_batch_size`, `num_ip_encoder_layers`, `random_negative_sampling_rate`, and `shuffled_negative_sampling_rate` hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker AI IP Insights algorithm and perform inferences with it, see [An Introduction to the SageMaker AIIP Insights Algorithm](). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see [Amazon SageMaker notebook instances](). After creating a notebook instance, choose the **SageMaker AI Examples** tab to see a list of all the SageMaker AI examples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How IP Insights Works

Amazon SageMaker AI IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of *collisions*, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see [Feature Hashing for Large Scale Multitask Learning](). For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the *cross entropy*, also known as the *log loss*, defined as follows:

$$L = \frac{1}{N} \sum_{n} \left[y_n \log p_n + (1 - y_n) \log (1 - p_n) \right]$$

y_n is the label that indicates whether the sample is from the real distribution governing observed data (y_n=1) or from the distribution generating negative samples (y_n=0). p_n is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the `random_negative_sampling_rate` and `shuffled_negative_sampling_rate` hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a *score*, S_n , that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log\left(\frac{P_{real}(n)}{P_{neg}(n)}\right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, p_n, to use in the cross entropy minimization, where:

$$p_n = \frac{1}{1 + e^{-S_n}}$$

IP Insights Hyperparameters

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker AI IP Insights algorithm.

Parameter Name	Description
`num_entity_vectors`	The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers.

Parameter Name	Description
	Required Valid values: 1 ≤ positive integer ≤ 250,000,000
`vector_dim`	The size of embedding vectors to represent entities and IP addresses. The larger the value, the more informati on that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommend ed value is 128. **Required** Valid values: 4 ≤ positive integer ≤ 4096
`batch_metrics_publish_interval`	The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). **Optional** Valid values: positive integer ≥ 1 Default value: 1,000

Parameter Name	Description
`epochs`	The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100. **Optional** Valid values: positive integer ≥ 1 Default value: 10
`learning_rate`	The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from 1e-4 to 1e-1. **Optional** Valid values: 1e-6 ≤ float ≤ 10.0 Default value: 0.001

Parameter Name	Description
`mini_batch_size`	The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the `mini_batch_size`, the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large `mini_batch_size`, the training is more likely to converge to a poor local minimum and perform relatively worse for inference. **Optional** Valid values: 1 ≤ positive integer ≤ 500000 Default value: 10,000
`num_ip_encoder_layers`	The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting. **Optional** Valid values: 0 ≤ positive integer ≤ 100 Default value: 1

Parameter Name	Description
`random_negative_sampling_rate`	The number of random negative samples, R, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates R random IP addresses for each input account in the mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500. **Optional** Valid values: 0 ≤ positive integer ≤ 500 Default value: 1
`shuffled_negative_sampling_rate`	The number of shuffled negative samples, S, to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates S negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500. **Optional** Valid values: 0 ≤ positive integer ≤ 500 Default value: 1

Parameter Name	Description
`weight_decay`	The weight decay coefficient. This parameter adds an L2 regularization factor that is required to prevent the model from overfitting the training data. **Optional** Valid values: 0.0 ≤ float ≤ 10.0 Default value: 0.00001

Tune an IP Insights Model

Automatic model tuning, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker AI IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model , which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This `validation:discriminator_auc` metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a `validation:discriminator_auc` metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

Metric Name	Description	Optimization Direction
validation:discriminator_auc	Area under the receiver operating characteristic curve on the validation dataset. The validation dataset is not labeled. Area Under the Curve (AUC) is a metric that describes the model's ability to discriminate validation data points from randomly generated data points.	Maximize

Tunable IP Insights Hyperparameters

You can tune the following hyperparameters for the SageMaker AI IP Insights algorithm.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRange	MinValue: 1, MaxValue: 100
learning_rate	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 0.1
mini_batch_size	IntegerParameterRanges	MinValue: 100, MaxValue: 50000
num_entity_vectors	IntegerParameterRanges	MinValue: 10000, MaxValue: 1000000
num_ip_encoder_layers	IntegerParameterRanges	MinValue: 1, MaxValue: 10
random_negative_sampling_rate	IntegerParameterRanges	MinValue: 0, MaxValue: 10

Parameter Name	Parameter Type	Recommended Ranges
`shuffled_negative_sampling_rate`	IntegerParameterRanges	MinValue: 0, MaxValue: 10
`vector_dim`	IntegerParameterRanges	MinValue: 8, MaxValue: 256
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

Topics

- IP Insights Training Data Formats
- IP Insights Inference Data Formats

IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker AI built-in algorithms adhere to the common input training format described in Common Data Formats for Training. However, the SageMaker AI IP Insights algorithm currently supports only the CSV data input format.

IP Insights Training Data Input Formats

INPUT: CSV

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in Common data formats for inference. However, the SageMaker AI IP Insights algorithm does not currently support RecordIO format.

IP Insights Input Request Formats

INPUT: CSV Format

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

INPUT: JSON Format

JSON data can be provided in different formats. IP Insights follows the common SageMaker AI formats. For more information about inference formats, see Common data formats for inference.

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},
    {"features": ["entity_id_2", "10.10.1.2"]}
  ]
}
```

INPUT: JSONLINES Format

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker AI inference formats, see Common data formats for inference. For more information on running batch transform jobs, see Batch transform for inference with Amazon SageMaker AI.

content-type: application/jsonlines

```
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},
{"features": ["entity_id_2", "10.10.1.2"]}]
```

IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker AI IP Insights algorithm is the `dot_product` between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The `dot_product` is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the `dot_product` for anomaly detection, see the An Introduction to the SageMaker AIIP Insights Algorithm.

accept: application/json

```
{
  "predictions": [
    {"dot_product": 0.0},
    {"dot_product": 2.0}
  ]
}
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter `verbose=True` to the Accept heading. You can use the `entity_embedding` and `ip_embedding` for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

accept: application/json;verbose=True

```
{
  "predictions": [
    {
        "dot_product": 0.0,
        "entity_embedding": [1.0, 0.0, 0.0],
        "ip_embedding": [0.0, 1.0, 0.0]
    },
```

```
    {
        "dot_product": 2.0,
        "entity_embedding": [1.0, 0.0, 1.0],
        "ip_embedding": [1.0, 0.0, 1.0]
    }
  ]
}
```

OUTPUT: JSONLINES Response Format

accept: application/jsonlines

```
{"dot_product": 0.0}
{"dot_product": 2.0}
```

accept: application/jsonlines; verbose=True

```
{"dot_product": 0.0, "entity_embedding": [1.0, 0.0, 0.0], "ip_embedding": [0.0, 1.0,
 0.0]}
{"dot_product": 2.0, "entity_embedding": [1.0, 0.0, 1.0], "ip_embedding": [1.0, 0.0,
 1.0]}
```

K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker AI uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker AI is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker AI streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see [Web-scale k-means Clustering](https://dl.acm.org/doi/10.1145/1772690.1772862).

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The *n* attributes in each row represent a point in *n*-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker AI, see How K-Means Clustering Works.

Topics

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the *train* channel (recommended `S3DataDistributionType=ShardedByS3Key`), with an optional *test* channel (recommended `S3DataDistributionType=FullyReplicated`) to score the data on. Both `recordIO-wrapped-protobuf` and `CSV` formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` are supported. k-means returns a `closest_cluster` label and the `distance_to_cluster` for each observation.

For more information on input and output file formats, see K-Means Response Formats for inference and the K-Means Sample Notebooks. The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to single-GPU instances (such as ml.g4dn.xlarge) because only one GPU is used per instance. The k-means algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

K-Means Sample Notebooks

For a sample notebook that uses the SageMaker AI K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker AI. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, click on its **Use** tab and select **Create copy**.

How K-Means Clustering Works

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the *n*-dimensional space (where *n* is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points (*t, h*) in 2-dimensional space.

> **Note**
>
> Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used. For more information, see Unsupervised learning.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters (*k*) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, …, 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space (x,y). To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

> **Note**
>
> Amazon SageMaker AI uses a customized version of the algorithm where, instead of specifying that the algorithm create *k* clusters, you might choose to improve model accuracy by specifying extra cluster centers *(K = k*x)*. However, the algorithm ultimately reduces these to *k* clusters.

In SageMaker AI, you specify the number of clusters when creating a training job. For more information, see [`CreateTrainingJob`](). In the request body, you add the `HyperParameters` string map to specify the `k` and `extra_center_factor` strings.

The following is a summary of how k-means works for model training in SageMaker AI:

1. It determines the initial *K* cluster centers.

   > **Note**
   >
   > In the following topics, *K* clusters refer to *k * x*, where you specify *k* and *x* when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to *k* (if the data scientist specified the creation of *k*x* clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the `HyperParameters` string map.

Topics

- Step 1: Determine the Initial Cluster Centers
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers
- Step 3: Reduce the Clusters from K to k

Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker AI, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose *K* observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.
- The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
     - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the *K* cluster centers.

To train a model in SageMaker AI, you create a training job. In the request, you provide configuration information by specifying the following `HyperParameters` string maps:

- To specify the number of clusters to create, add the `k` string.
- For greater accuracy, add the optional `extra_center_factor` string.

- To specify the strategy that you want to use to determine the initial cluster centers, add the `init_method` string and set its value to `random` or `k-means++`.

For more information about the SageMaker AI k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the *K* cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   > **Note**
   >
   > When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.

   a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

   b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

      For example, consider the following clusters:

      Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

      Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

      Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

```
p1 = proportion of points assigned to c1 = 25/(100+25)
p2 = proportion of points assigned to c2 = 40/(150+40)
p3 = proportion of points assigned to c3 = 5/(450+5)
```

c. Compute the center of the new points added to each cluster:

```
d1 = center of the new points added to cluster 1
d2 = center of the new points added to cluster 2
d3 = center of the new points added to cluster 3
```

d. Compute the weighted average to find the updated cluster centers as follows:

```
Center of cluster 1 = ((1 - p1) * center of cluster 1) + (p1 * d1)
Center of cluster 2 = ((1 - p2) * center of cluster 2) + (p2 * d2)
Center of cluster 3 = ((1 - p3) * center of cluster 3) + (p3 * d3)
```

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.
3. For more information about mini-batch *k*-means, see Web-scale k-means Clustering).

Step 3: Reduce the Clusters from *K* to *k*

If the algorithm created *K* clusters—*(K = k*x)* where *x* is greater than 1—then it reduces the *K* clusters to *k* clusters. (For more information, see `extra_center_factor` in the preceding discussion.) It does this by applying Lloyd's method with `kmeans++` initialization to the *K* cluster centers. For more information about Lloyd's method, see k-means clustering.

K-Means Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker AI. For more information about how k-means clustering works, see How K-Means Clustering Works.

Parameter Name	Description
`feature_dim`	The number of features in the input data. **Required**

Parameter Name	Description
	Valid values: Positive integer
`k`	The number of required clusters. **Required** Valid values: Positive integer
`epochs`	The number of passes done over the training data. **Optional** Valid values: Positive integer Default value: 1
`eval_metrics`	A JSON list of metric types used to report a score for the model. Allowed values are `msd` for Means Square Deviation and `ssd` for Sum of Square Distance. If test data is provided, the score is reported for each of the metrics requested. **Optional** Valid values: Either `[\"msd\"]` or `[\"ssd\"]` or `[\"msd\",\"ssd\"]` . Default value: `[\"msd\"]`
`extra_center_factor`	The algorithm creates K centers = `num_clusters * extra_center_factor` as it runs and reduces the number of centers from K to `k` when finalizing the model. **Optional** Valid values: Either a positive integer or `auto`. Default value: `auto`

Parameter Name	Description
`half_life_time_size`	Used to determine the weight given to an observation when computing a cluster mean. This weight decays exponentially as more points are observed. When a point is first observed, it is assigned a weight of 1 when computing the cluster mean. The decay constant for the exponential decay function is chosen so that after observing `half_life_time_size` points, its weight is 1/2. If set to 0, there is no decay. **Optional** Valid values: Non-negative integer Default value: 0
`init_method`	Method by which the algorithm chooses the initial cluster centers. The standard k-means approach chooses them at random. An alternative k-means++ method chooses the first cluster center at random. Then it spreads out the position of the remaining initial clusters by weighting the selection of centers with a probability distribution that is proportional to the square of the distance of the remaining data points from existing centers. **Optional** Valid values: Either `random` or `kmeans++`. Default value: `random`
`local_lloyd_init_method`	The initialization method for Lloyd's expectation-maximization (EM) procedure used to build the final model containing `k` centers. **Optional** Valid values: Either `random` or `kmeans++`. Default value: `kmeans++`

Parameter Name	Description
`local_lloyd_max_iter`	The maximum number of iterations for Lloyd's expectation-maximization (EM) procedure used to build the final model containing k centers. **Optional** Valid values: Positive integer Default value: 300
`local_lloyd_num_trials`	The number of times the Lloyd's expectation-maximization (EM) procedure with the least loss is run when building the final model containing k centers. **Optional** Valid values: Either a positive integer or `auto`. Default value: `auto`
`local_lloyd_tol`	The tolerance for change in loss for early stopping of Lloyd's expectation-maximization (EM) procedure used to build the final model containing k centers. **Optional** Valid values: Float. Range in [0, 1]. Default value: 0.0001
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: Positive integer Default value: 5000

Tune a K-Means Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker AI k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the K-Means Algorithm

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

Metric Name	Description	Optimization Direction
`test:msd`	Mean squared distances between each record in the test set and the closest center of the model.	Minimize
`test:ssd`	Sum of the squared distances between each record in the test set and the closest center of the model.	Minimize

Tunable K-Means Hyperparameters

Tune the Amazon SageMaker AI k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are:

mini_batch_size, extra_center_factor, and init_method. Tuning the hyperparameter epochs generally results in minor improvements.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRanges	MinValue: 1, MaxValue:10
extra_center_factor	IntegerParameterRanges	MinValue: 4, MaxValue:10
init_method	CategoricalParameterRanges	['kmeans++', 'random']
mini_batch_size	IntegerParameterRanges	MinValue: 3000, MaxValue:15000

K-Means Response Formats

All SageMaker AI built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker AI k-means algorithm.

JSON Response Format

```
{
    "predictions": [
        {
            "closest_cluster": 1.0,
            "distance_to_cluster": 3.0,
        },
        {
            "closest_cluster": 2.0,
            "distance_to_cluster": 5.0,
        },

        ....
    ]
}
```

JSONLINES Response Format

```
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

RECORDIO Response Format

```
[
    Record = {
        features = {},
        label = {
            'closest_cluster': {
                keys: [],
                values: [1.0, 2.0]  # float32
            },
            'distance_to_cluster': {
                keys: [],
                values: [3.0, 5.0]  # float32
            },
        }
    }
]
```

CSV Response Format

The first value in each line corresponds to `closest_cluster`.

The second value in each line corresponds to `distance_to_cluster`.

```
1.0,3.0
2.0,5.0
```

Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called *components*, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker AI, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

Topics

Input/Output Interface for the PCA Algorithm

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both `recordIO-wrapped-protobuf` and `CSV` formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, PCA supports `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Results are returned in either `application/json` or `application/x-recordio-protobuf` format with a vector of "projections."

For more information on input and output file formats, see PCA Response Formats for inference and the PCA Sample Notebooks.

EC2 Instance Recommendation for the PCA Algorithm

PCA supports CPU and GPU instances for training and inference. Which instance type is most performant depends heavily on the specifics of the input data. For GPU instances, PCA supports P2, P3, G4dn, and G5.

PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker AI Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called *components*, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows

$x_1, \dots, x_n$

each of dimension 1 * d, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

Modes

The Amazon SageMaker AI PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm's last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

Mode 1: Regular

The workers jointly compute both

$\sum x_i^T x_i$

and

$\sum x_i$

.

> **Note**
>
> Because
>
> x_i
>
> are 1 * d row vectors,
>
> $x_i^T x_i$
>
> is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as

$\sum x_i^T x_i - (1/n) (\sum x_i)^T \sum x_i$

, and its top `num_components` singular vectors form the model.

> **Note**
>
> If `subtract_mean` is `False`, we avoid computing and subtracting
>
> $\sum x_i$
>
> .

Use this algorithm when the dimension d of the vectors is small enough so that

d^2

can fit in memory.

Mode 2: Randomized

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch

X_t

of dimension `b * d`, we randomly initialize a `(num_components + extra_components) * b` matrix that we multiply by each mini-batch, to create a `(num_components + extra_components) * d` matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final `(num_components + extra_components) * d` matrix. The top right `num_components` singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let

ℓ

`= num_components + extra_components`. Given a mini-batch

X_t

of dimension `b * d`, the worker draws a random matrix

H_t

of dimension

$\ell * b$

. Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is `+-1` or a *FJLT* (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes

$H_t X_t$

and maintains

$B = \sum H_t X_t$

. The worker also maintains

h^T

, the sum of columns of

$H_1, \ldots, H_T$

(T being the total number of mini-batches), and `s`, the sum of all input rows. After processing the entire shard of data, the worker sends the server `B`, `h`, `s`, and `n` (the number of input rows).

Denote the different inputs to the server as

B^1, h^1, s^1, n^1

The server computes B, h, s, n the sums of the respective inputs. It then computes

$C = B - (1/n)h^T s$

, and finds its singular value decomposition. The top-right singular vectors and singular values of C are used as the approximate solution to the problem.

PCA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker AI. For more information about how PCA works, see How PCA Works.

Parameter Name	Description
`feature_dim`	Input dimension. **Required** Valid values: positive integer
`mini_batch_size`	Number of rows in a mini-batch. **Required** Valid values: positive integer
`num_components`	The number of principal components to compute. **Required** Valid values: positive integer
`algorithm_mode`	Mode for computing the principal components. **Optional** Valid values: *regular* or *randomized* Default value: *regular*

Parameter Name	Description
`extra_components`	As the value increases, the solution becomes more accurate but the runtime and memory consumption increase linearly. The default, -1, means the maximum of 10 and `num_components`. Valid for *randomized* mode only. **Optional** Valid values: Non-negative integer or -1 Default value: -1
`subtract_mean`	Indicates whether the data should be unbiased both during training and at inference. **Optional** Valid values: One of *true* or *false* Default value: *true*

PCA Response Formats

All Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker AI PCA algorithm.

JSON Response Format

Accept—application/json

```
{
    "projections": [
        {
            "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
        },
        {
            "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
        },
        ....
```

```
    ]
}
```

JSONLINES Response Format

Accept—application/jsonlines

```
{ "projection": [1.0, 2.0, 3.0, 4.0, 5.0] }
{ "projection": [6.0, 7.0, 8.0, 9.0, 0.0] }
```

RECORDIO Response Format

Accept—application/x-recordio-protobuf

```
[
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    },
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    }
]
```

Random Cut Forest (RCF) Algorithm

Amazon SageMaker AI Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker AI RCF scales well with respect to number of features, data set size, and number of instances.

- RCF Response Formats

Input/Output Interface for the RCF Algorithm

Amazon SageMaker AI Random Cut Forest supports the `train` and `test` data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either `application/x-recordio-protobuf` or `text/csv` formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV

The train channel only supports `S3DataDistributionType=ShardedByS3Key` and the test channel only supports `S3DataDistributionType=FullyReplicated`. The following example specifies the S3 distribution type for the train channel using the Amazon SageMaker Python SDK.

Note

The `sagemaker.inputs.s3_input` method was renamed to `sagemaker.inputs.TrainingInput` in SageMaker Python SDK v2.

```
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.TrainingInput(
     s3_data=s3_training_data_location,
     content_type='text/csv;label_size=0',
     distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, `AmazonSageMakerFullAccess` and `AmazonEC2ContainerRegistryFullAccess`. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger then the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the `S3DataSource` for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the Parameters for Built-in Algorithms documentation for more information. RCF inference returns `application/x-recordio-protobuf` or `application/json` formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats for inference and the RCF Sample Notebooks.

Instance Recommendations for the RCF Algorithm

For training, we recommend the `ml.m4`, `ml.c4`, and `ml.c5` instance families. For inference we recommend using a `ml.c5.xl` instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

RCF Sample Notebooks

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker AI Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, click on its **Use** tab and select **Create copy**.

For a blog post on using the RCF algorithm, see Use the built-in Amazon SageMaker AI Random Cut Forest algorithm for anomaly detection.

How RCF Works

Amazon SageMaker AI Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size K from N total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw K elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

[Reservoir sampling](https://en.wikipedia.org/wiki/Reservoir_sampling) is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1, \ldots, S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when N is not known *a priori*. If only one sample is requested, such as when $K = 1$, the algorithm is like this:

Algorithm: Reservoir Sampling

- Input: dataset or data stream $S = \{S_1, \ldots, S_N\}$
- Initialize the random sample $X = S_1$
- For each observed sample $S_n, n = 2, \ldots, N$:
  - Pick a uniform random number $\xi \in [0, 1]$
  - If $\xi < 1/n$

  - Set

    $X = S_n$

- Return

  X

This algorithm selects a random sample such that

$P(X = S_n) = 1/N$

for all

$n = 1, \ldots, N$

.

When

$K > 1$

the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

Train a RCF Model and Produce Inferences

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

Figure: A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.

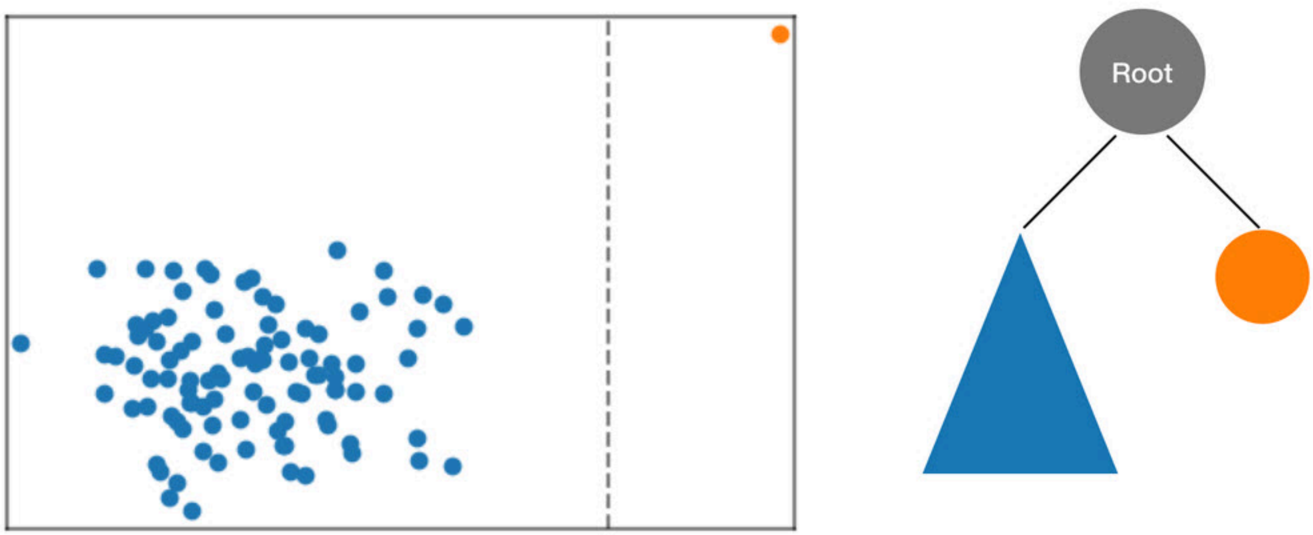

Figure: A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that `1/num_samples_per_tree` approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies 1/256 or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

RCF Hyperparameters

In the [`CreateTrainingJob`] request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker AI RCF algorithm. For more information, including recommendations on how to choose hyperparameters, see [How RCF Works].

Parameter Name	Description
`feature_dim`	The number of features in the data set. (If you use the Random Cut Forest estimator, this value is calculated for you and need not be specified.) **Required** Valid values: Positive integer (min: 1, max: 10000)
`eval_metrics`	A list of metrics used to score a labeled test data set. The following metrics can be selected for output: • `accuracy` - returns fraction of correct predictions. • `precision_recall_fscore` - returns the positive and negative precision, recall, and F1-scores. **Optional** Valid values: a list with possible values taken from `accuracy` or `precision_recall_fscore` . Default value: Both `accuracy`, `precision_recall_fscore` are calculated.
`num_samples_per_tree`	Number of random samples given to each tree from the training data set. **Optional** Valid values: Positive integer (min: 1, max: 2048) Default value: 256
`num_trees`	Number of trees in the forest. **Optional** Valid values: Positive integer (min: 50, max: 1000)

Parameter Name	Description
	Default value: 100

Tune an RCF Model

Automatic model tuning, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker AI RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test data points and then labels the data points as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Automatic model tuning with SageMaker AI.

Metrics Computed by the RCF Algorithm

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`test:f1`	F1-score on the test dataset, based on the difference between calculated labels and actual labels.	Maximize

Tunable RCF Hyperparameters

You can tune a RCF model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`num_samples_per_tree`	IntegerParameterRanges	MinValue: 1, MaxValue:2048
`num_trees`	IntegerParameterRanges	MinValue: 50, MaxValue:1000

RCF Response Formats

All Amazon SageMaker AI built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](). Note that SageMaker AI Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker AI RCF algorithm.

JSON Response Format

ACCEPT: application/json.

```
{

    "scores":    [

        {"score": 0.02},

        {"score": 0.25}

    ]

```

```
    }
```

JSONLINES Response Format

ACCEPT: application/jsonlines.

```
{"score": 0.02},
{"score": 0.25}
```

RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```
    [

         Record = {

             features = {},

             label = {

                 'score': {

                     keys: [],

                     values: [0.25]  # float32

                 }
```

```
    }

},

Record = {

    features = {},

    label = {

        'score': {

            keys: [],

            values: [0.23]  # float32

        }

    }

}
```

Built-in SageMaker AI Algorithms for Computer Vision

SageMaker AI provides image processing algorithms that are used for image classification, object detection, and computer vision.

- Image Classification - MXNet—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Image Classification - TensorFlow—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Object Detection - MXNet—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- Object Detection - TensorFlow—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.
- Semantic Segmentation Algorithm—provides a fine-grained, pixel-level approach to developing computer vision applications.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
Image Classification - MXNet	train and validation, (optionally) train_lst, validation_lst, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
Image Classification - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	CPU or GPU	Yes (only across multiple GPUs on a single instance)
Object Detection	train and validation, (optionally) train_annotation, validation_annotation, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes
Object Detection - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	GPU	Yes (only across multiple GPUs on a single instance)

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
Semantic Segmentation	train and validation, train_annotation, validation_annotation, and (optionally) label_map and model	File or Pipe	Image files	GPU (single instance only)	No

Image Classification - MXNet

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available

The recommended input format for the Amazon SageMaker AI image classification algorithms is Apache MXNet [RecordIO](). However, you can also use raw images in .jpg or .png format. Refer to [this discussion]() for a broad overview of efficient data preparation and loading for machine learning systems.

> **Note**
>
> To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker AI algorithms.

Topics

Input/Output Interface for the Image Classification Algorithm

The SageMaker AI Image Classification algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode, and supports the RecordIO (`application/x-recordio`) content type for training in pipe mode. However, you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the `S3DataDistributionType` of the `S3DataSource` to `FullyReplicated`. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports `image/png`, `image/jpeg`, and `application/x-image` for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (`.rec`) file in the `train` channel and one RecordIO file in the `validation` channel. Set the content type for both channels to `application/x-recordio`.

Train with Image Format

If you use the Image format for training, specify `train`, `validation`, `train_lst`, and `validation_lst` channels as values for the `InputDataConfig` parameter of the [`CreateTrainingJob`] request. Specify the individual image data (`.jpg` or `.png` files) for the `train` and `validation` channels. Specify one `.lst` file in each of the `train_lst` and `validation_lst` channels. Set the content type for all four channels to `application/x-image`.

> **Note**
>
> SageMaker AI reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A `.lst` file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a `.lst` file:

```
5       1   your_image_directory/train_img_dog1.jpg
1000    0   your_image_directory/train_img_cat1.jpg
22      1   your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in `s3://<your_bucket>/train/class_dog`, `s3://<your_bucket>/train/class_cat`, and so on, specify the path for your `train` channel as `s3://<your_bucket>/train`, which is the top-level directory for your data. In the `.lst` file, specify the relative path for an individual file named `train_image_dog1.jpg` in the `class_dog` class directory as `class_dog/train_image_dog1.jpg`. You can also store all your image files under one subdirectory inside the `train` directory. In that case, use that subdirectory for the relative path. For example, `s3://<your_bucket>/train/your_image_directory`.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the [CreateTrainingJob](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_CreateTrainingJob.html) request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in [JSON Lines](http://jsonlines.org/) format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ["source-ref", "class"]. The corresponding label value is "0" for the first image and “1” for the second image:

```
{"source-ref":"s3://image/filename1.jpg", "class":"0"}
{"source-ref":"s3://image/filename2.jpg", "class":"1", "class-metadata": {"class-name":
 "cat", "type" : "groundtruth/image-classification"}}
```

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

```
{"image-ref": "s3://amzn-s3-demo-bucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://amzn-s3-demo-bucket/sample02/image2.jpg", "class": "[0, 0, 1]"}
```

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data point. The previous example would instead look like this:

```
{"image-ref": "s3://amzn-s3-demo-bucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://amzn-s3-demo-bucket/sample02/image2.jpg", "class": "[2]"}
```

The multi-hot format is the default, but can be explicitly set in the content type with the `label-format` parameter: `"application/x-recordio; label-format=multi-hot"`. The class-id format, which is the format outputted by GroundTruth, must be set explicitly: `"application/x-recordio; label-format=class-id"`.
