For more information on augmented manifest files, see [Augmented Manifest Files for Training Jobs](#).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker AI. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker AI image classification models can be seeded only with another built-in image classification model trained in SageMaker AI.

To use a pretrained model, in the [`CreateTrainingJob`](#) request, specify the `ChannelName` as "model" in the `InputDataConfig` parameter. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the `num_layers`, `image_shape` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker AI. You can use either RecordIO or image formats for input data.

Inference with the Image Classification Algorithm

The generated models can be hosted for inference and support encoded `.jpg` and `.png` image formats as `image/png, image/jpeg`, and `application/x-image` content-type. The input image is resized automatically. The output is the probability values for all classes encoded in JSON format, or in [JSON Lines text format](#) for batch transform. The image classification model processes a single image per request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a response in JSON Lines format:

```
accept: application/jsonlines

 {"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances referenced in the introduction.

EC2 Instance Recommendation for the Image Classification Algorithm

For image classification, we support P2, P3, G4dn, and G5 instances. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. Both CPU (such as C4) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker AI image classification algorithm, see Build and Register an MXNet Image Classification Model via SageMaker Pipelines. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The example image classification notebooks are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet, DenseNet, Inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker AI can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker AI built-in Image Classification algorithm. See Tune an Image Classification Model for information on image classification hyperparameter tuning.

Parameter Name	Description
`num_classes`	Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm for details on how to work with multi-label classification with augmented manifest files. **Required** Valid values: positive integer
`num_training_samples`	Number of training examples in the input dataset. If there is a mismatch between this value and the number of samples in the training set, then the behavior of the `lr_scheduler_step` parameter is undefined and distributed training accuracy might be affected. **Required** Valid values: positive integer
`augmentation_type`	Data augmentation type. The input images can be augmented in multiple ways as specified below. • `crop`: Randomly crop the image and flip the image horizontally • `crop_color` : In addition to 'crop', three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the

Parameter Name	Description
	corresponding Hue-Saturation-Lightness channels respectively • `crop_color_transform` : In addition to `crop_color` , random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25. **Optional** Valid values: `crop`, `crop_color` , or `crop_color_transform` . Default value: no default value
`beta_1`	The beta1 for `adam`, that is the exponential decay rate for the first moment estimates. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
`beta_2`	The beta2 for `adam`, that is the exponential decay rate for the second moment estimates. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.999

Parameter Name	Description
`checkpoint_frequency`	Period to store model parameters (in number of epochs). Note that all checkpoint files are saved as part of the final model file "model.tar.gz" and uploaded to S3 to the specified model location. This increases the size of the model file proportionally to the number of checkpoints saved during training. **Optional** Valid values: positive integer no greater than `epochs`. Default value: no default value (Save checkpoint at the epoch that has the best validation accuracy)
`early_stopping`	`True` to use early stopping logic during training. `False` not to use it. **Optional** Valid values: `True` or `False` Default value: `False`
`early_stopping_min_epochs`	The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when `early_stopping = True`. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
`early_stopping_patience`	The number of epochs to wait before ending training if no improvement is made in the relevant metric. It is used only when `early_stopping` = `True`. **Optional** Valid values: positive integer Default value: 5
`early_stopping_tolerance`	Relative tolerance to measure an improvement in accuracy validation metric. If the ratio of the improvement in accuracy divided by the previous best accuracy is smaller than the `early_stopping_tolerance` value set, early stopping considers there is no improvement. It is used only when `early_stopping` = `True`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
`epochs`	Number of training epochs. **Optional** Valid values: positive integer Default value: 30
`eps`	The epsilon for `adam` and `rmsprop`. It is usually set to a small value to avoid division by 0. **Optional** Valid values: float. Range in [0, 1]. Default value: 1e-8

Parameter Name	Description
`gamma`	The gamma for `rmsprop`, the decay factor for the moving average of the squared gradient. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
`image_shape`	The input image dimensions, which is the same size as the input layer of the network. The format is defined as '`num_channels` , height, width'. The image dimension can take on any value as the network can handle varied dimension s of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3,224,224'. This is similar to the ImageNet dataset. For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter `augmentation_type` is set, random crop is taken; otherwise, central crop is taken. At inference, input images are resized to the `image_shape` that was used during training. Aspect ratio is not preserved, and images are not cropped. **Optional** Valid values: string Default value: ‘3,224,224’

Parameter Name	Description
`kv_store`	Weight update synchronization mode during distributed training. The weight updates can be updated either synchrono usly or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See distributed training in MXNet for more details. This parameter is not applicable to single machine training. • `dist_sync` : The gradients are synchronized after every batch with all the workers. With `dist_sync` , batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then `dist_sync` behaves like local with batch size n*b • `dist_async` : Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed. **Optional** Valid values: `dist_sync` or `dist_async` Default value: no default value
`learning_rate`	Initial learning rate. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.1

Parameter Name	Description
lr_scheduler_factor	The ratio to reduce learning rate used in conjunction with the lr_scheduler_step parameter, defined as lr_new = lr_old * lr_scheduler_factor . **Optional** Valid values: float. Range in [0, 1]. Default value: 0.1
lr_scheduler_step	The epochs at which to reduce the learning rate. As explained in the lr_scheduler_factor parameter, the learning rate is reduced by lr_scheduler_factor at these epochs. For example, if the value is set to "10, 20", then the learning rate is reduced by lr_scheduler_factor after 10th epoch and again by lr_scheduler_factor after 20th epoch. The epochs are delimited by ",". **Optional** Valid values: string Default value: no default value
mini_batch_size	The batch size for training. In a single-machine multi-GPU setting, each GPU handles mini_batch_size /num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size *number of machines. See MXNet docs for more details. **Optional** Valid values: positive integer Default value: 32

Parameter Name	Description
`momentum`	The momentum for `sgd` and `nag`, ignored for other optimizers. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
`multi_label`	Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged. **Optional** Valid values: 0 or 1 Default value: 0
`num_layers`	Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200]. **Optional** Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110] Default value: 152

Parameter Name	Description
optimizer	The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API. **Optional** Valid values: One of sgd, adam, rmsprop, or nag. • sgd: Stochastic gradient descent • adam: Adaptive momentum estimation • rmsprop: Root mean square propagation • nag: Nesterov accelerated gradient Default value: sgd
precision_dtype	The precision of the weights used for training. The algorithm can use either single precision (float32) or half precision (float16) for the weights. Using half-precision for weights results in reduced memory consumption. **Optional** Valid values: float32 or float16 Default value: float32

Parameter Name	Description
`resize`	The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of `image_shape` to prevent training failure. **Required** when using image content types **Optional** when using the RecordIO content type Valid values: positive integer Default value: no default value
`top_k`	Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported. **Optional** Valid values: positive integer larger than 1. Default value: no default value
`use_pretrained_model`	Flag to use pre-trained model for training. If set to 1, then the pretrained model with the corresponding number of layers is loaded and used for training. Only the top FC layer are reinitial ized with random weights. Otherwise, the network is trained from scratch. **Optional** Valid values: 0 or 1 Default value: 0

Parameter Name	Description
`use_weighted_loss`	Flag to use weighted cross-entropy loss for multi-label classification (used only when `multi_label` = 1), where the weights are calculated based on the distribution of classes. **Optional** Valid values: 0 or 1 Default value: 0
`weight_decay`	The coefficient weight decay for `sgd` and `nag`, ignored for other optimizers. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.0001

Tune an Image Classification Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
validation:accuracy	The ratio of the number of correct predictions to the total number of predictions made.	Maximize

Tunable Image Classification Hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `mini_batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `weight_decay`, `beta_1`, `beta_2`, `eps`, and `gamma`, based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the `optimizer`.

For more information about which hyperparameters are used in each optimizer, see [Image Classification Hyperparameters](#).

Parameter Name	Parameter Type	Recommended Ranges
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`eps`	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
`gamma`	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 0.999
`learning_rate`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
`mini_batch_size`	IntegerParameterRanges	MinValue: 8, MaxValue: 512

Parameter Name	Parameter Type	Recommended Ranges
`momentum`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
`optimizer`	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'nag']
`weight_decay`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999

Image Classification - TensorFlow

The Amazon SageMaker Image Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The image classification algorithm takes an image as input and outputs a probability for each provided class label. Training datasets must consist of images in .jpg, .jpeg, or .png format. This page includes information about Amazon EC2 instance recommendations and sample notebooks for Image Classification - TensorFlow.

Topics

How to use the SageMaker Image Classification - TensorFlow algorithm

You can use Image Classification - TensorFlow as an Amazon SageMaker AI built-in algorithm. The following section describes how to use Image Classification - TensorFlow with the SageMaker AI

Python SDK. For information on how to use Image Classification - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

The Image Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow Hub models. For a list of all available pretrained models, see TensorFlow Hub Models. Every pretrained model has a unique `model_id`. The following example uses MobileNet V2 1.00 224 (`model_id`: `tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker AI Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Image Classification - TensorFlow Hyperparameters. Use these values to construct a SageMaker AI Estimator.

> **Note**
>
> Default hyperparameter values are different for different models. For larger models, the default batch size is smaller and the `train_only_top_layer` hyperparameter is set to `"True"`.

This example uses the `tf_flowers` dataset, which contains five classes of flower images. We pre-downloaded the dataset from TensorFlow under the Apache 2.0 license and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-ic-imagenet-mobilenet-v2-100-224-
classification-4", "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta
```

```
# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")

# Retrieve the default hyper-parameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# The sample training data is available in the following S3 bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tf_flowers/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-ic-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create SageMaker Estimator instance
tf_ic_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Use S3 path of the training data to launch SageMaker TrainingJob
tf_ic_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

Input and output interface for the Image Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Image Classification - TensorFlow model.

- **Training data input format:** Your training data should be a directory with as many subdirectories as the number of classes. Each subdirectory should contain images belonging to that class in .jpg, .jpeg, or .png format.

The following is an example of an input directory structure. This example dataset has two classes: `roses` and `dandelion`. The image files in each class folder can have any name. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing / is required.

```
input_directory
    |--roses
        |--abc.jpg
        |--def.jpg
    |--dandelion
        |--ghi.jpg
        |--jkl.jpg
```

Trained models output label mapping files that map class folder names to the indices in the list of output class probabilities. This mapping is in alphabetical order. For example, in the preceding example, the dandelion class is index 0 and the roses class is index 1.

After training, you have a fine-tuned model that you can further train using incremental training or deploy for inference. The Image Classification - TensorFlow algorithm automatically adds a pre-processing and post-processing signature to the fine-tuned model so that it can take in images as input and return class probabilities. The file mapping class indices to class labels is saved along with the models.

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker AI. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker Image Classification - TensorFlow model with another Image Classification - TensorFlow model trained in SageMaker AI.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For an example of incremental training with the SageMaker AI Image Classification - TensorFlow algorithm, see the [Introduction to SageMaker TensorFlow - Image Classification]() sample notebook.

Inference with the Image Classification - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Image Classification training for inference. Any input image for inference must be in `.jpg`, `.jpeg`, or `.png` format and be content type `application/x-image`. The Image Classification - TensorFlow algorithm resizes input images automatically.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Image Classification - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

 {"probabilities": [prob_0, prob_1, prob_2, ...],
  "labels":        [label_0, label_1, label_2, ...],
  "predicted_label": predicted_label}
```

If `accept` is set to `application/json`, then the model only outputs probabilities. For more information on training and inference with the Image Classification - TensorFlow algorithm, see the [Introduction to SageMaker TensorFlow - Image Classification]() sample notebook.

Amazon EC2 instance recommendation for the Image Classification - TensorFlow algorithm

The Image Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- `ml.p2.xlarge`

- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.16xlarge`
- `ml.g4dn.xlarge`
- `ml.g4dn.16.xlarge`
- `ml.g5.xlarge`
- `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

Image Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Image Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Image Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Image Classification - TensorFlow Works

The Image Classification - TensorFlow algorithm takes an image as input and classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for image classification. There are also deep learning networks that are trained on large image datasets, such as ImageNet, which has over 11 million images and almost 11,000 classes. After a network is trained with ImageNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific classification tasks. The Amazon SageMaker Image Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a classification layer is attached to the pretrained TensorFlow Hub model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully-connected layer with 2-norm regularizer that is initialized with random weights. The model has hyperparameters for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Image Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	model_id	Source

Image Classification - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker AI built-in Image Classification - TensorFlow algorithm. See Tune an Image Classification - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
`augmentation`	Set to `"True"` to apply `augmentation_random_flip` , `augmentation_random_rotation` , and `augmentation_random_zoom` to the training data. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`augmentation_random_flip`	Indicates which flip mode to use for data augmentation when `augmentation` is set to `"True"`. For more information, see RandomFlip in the TensorFlow documentation. Valid values: string, any of the following: (`"horizontal_and_vertical"` , `"vertical"` , or `"None"`). Default value: `"horizontal_and_vertical"` .
`augmentation_random_rotation`	Indicates how much rotation to use for data augmentation when `augmentation` is set to `"True"`. Values represent a fraction of 2π. Positive values rotate counterclockwise while negative values rotate clockwise. `0` means no rotation. For more information, see RandomRotation in the TensorFlow documentation. Valid values: float, range: [`-1.0`, `1.0`]. Default value: `0.2`.
`augmentation_random_zoom`	Indicates how much vertical zoom to use for data augmentation when `augmentation` is set to `"True"`. Positive values zoom out while negative values zoom in. `0` means no zoom. For more information, see RandomZoom in the TensorFlow documentation. Valid values: float, range: [`-1.0`, `1.0`]. Default value: `0.1`.

Parameter Name	Description
`batch_size`	The batch size for training. For training on instances with multiple GPUs, this batch size is used across the GPUs. Valid values: positive integer. Default value: `32`.
`beta_1`	The beta1 for the `"adam"` optimizer. Represents the exponenti al decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.9`.
`beta_2`	The beta2 for the `"adam"` optimizer. Represents the exponenti al decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.999`.
`binary_mode`	When `binary_mode` is set to `"True"`, the model returns a single probability number for the positive class and can use additional `eval_metric` options. Use only for binary classific ation problems. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`dropout_rate`	The dropout rate for the dropout layer in the top classification layer. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.2`

Parameter Name	Description
early_stopping	Set to "True" to use early stopping logic during training. If "False", early stopping is not used. Valid values: string, either: ("True" or "False"). Default value: "False".
early_stopping_min_delta	The minimum change needed to qualify as an improvement. An absolute change less than the value of early_stopping_min_delta does not qualify as improvement. Used only when early_stopping is set to "True". Valid values: float, range: [0.0, 1.0]. Default value: 0.0.
early_stopping_patience	The number of epochs to continue training with no improvement. Used only when early_stopping is set to "True". Valid values: positive integer. Default value: 5.
epochs	The number of training epochs. Valid values: positive integer. Default value: 3.
epsilon	The epsilon for "adam", "rmsprop" , "adadelta" , and "adagrad" optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 1e-7.

Parameter Name	Description
`eval_metric`	If `binary_mode` is set to `"False"`, `eval_metric` can only be `"accuracy"`. If `binary_mode` is `"True"`, select any of the valid values. For more information, see Metrics in the TensorFlow documentation. Valid values: string, any of the following: (`"accuracy"`, `"precision"`, `"recall"`, `"auc"`, or `"prc"`). Default value: `"accuracy"`.
`image_resize_interpolation`	Indicates interpolation method used when resizing images. For more information, see image.resize in the TensorFlow documentation. Valid values: string, any of the following: (`"bilinear"`, `"nearest"`, `"bicubic"`, `"area"`, `"lanczos3"`, `"lanczos5"`, `"gaussian"`, or `"mitchellcubic"`). Default value: `"bilinear"`.
`initial_accumulator_value`	The starting value for the accumulators, or the per-parameter momentum values, for the `"adagrad"` optimizer. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0001`.
`label_smoothing`	Indicates how much to relax the confidence on label values. For example, if `label_smoothing` is `0.1`, then non-target labels are `0.1/num_classes` and target labels are `0.9+0.1/num_classes`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.1`.

Parameter Name	Description
`learning_rate`	The optimizer learning rate. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.001`.
`momentum`	The momentum for `"sgd"`, `"nesterov"` , and `"rmsprop"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.9`.
`optimizer`	The optimizer type. For more information, see [Optimizers]() in the TensorFlow documentation. Valid values: string, any of the following: (`"adam"`, `"sgd"`, `"nesterov"` , `"rmsprop"` , `"adagrad"` , `"adadelta"`). Default value: `"adam"`.
`regularizers_l2`	The L2 regularization factor for the dense layer in the classific ation layer. Valid values: float, range: [`0.0`, `1.0`]. Default value: `.0001`.
`reinitialize_top_l ayer`	If set to `"Auto"`, the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to `"True"`. Valid values: string, any of the following: (`"Auto"`, `"True"` or `"False"`). Default value: `"Auto"`.

Parameter Name	Description
`rho`	The discounting factor for the gradient of the `"adadelta"` and `"rmsprop"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.95`.
`train_only_top_layer`	If `"True"`, only the top classification layer parameters are fine-tuned. If `"False"`, all model parameters are fine-tuned. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.

Tune an Image Classification - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics computed by the Image Classification - TensorFlow algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`validation:accuracy`	The ratio of the number of correct predictions to the total number of predictions made.	Maximize

Tunable Image Classification - TensorFlow hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see [Image Classification - TensorFlow Hyperparameters](#).

Parameter Name	Parameter Type	Recommended Ranges
`batch_size`	IntegerParameterRanges	MinValue: 8, MaxValue: 512
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`eps`	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
`learning_rate`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
`momentum`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
`optimizer`	CategoricalParameterRanges	['sgd', ‘adam’, ‘rmsprop’, 'nesterov', 'adagrad', 'adadelta']
`regularizers_l2`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999

Parameter Name	Parameter Type	Recommended Ranges
`train_only_top_layer`	ContinuousParameterRanges	['True', 'False']

Object Detection - MXNet

The Amazon SageMaker AI Object Detection - MXNet algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

Input/Output Interface for the Object Detection Algorithm

The SageMaker AI Object Detection algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode and supports RecordIO (`application/x-recordio`) for training in pipe mode. However you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker AI object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only `application/x-image` for inference.

> **Note**
>
> To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker AI algorithms.

See the Object Detection Sample Notebooks for more details on data formats.

Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to `application/x-recordio`. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify `train`, `validation`, `train_annotation`, and `validation_annotation` channels as values for the `InputDataConfig` parameter of `CreateTrainingJob` request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the `train_annotation` and `validation_annotation` channels. Set the content type for all four channels to `image/png` or `image/jpeg` based on the image type. You can also use the content type `application/x-image` when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```
{
   "file": "your_image_directory/sample_image1.jpg",
   "image_size": [
      {
         "width": 500,
         "height": 400,
```

```
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
            "top": 134,
            "width": 61,
            "height": 128
        },
        {
            "class_id": 0,
            "left": 161,
            "top": 250,
            "width": 79,
            "height": 143
        },
        {
            "class_id": 1,
            "left": 101,
            "top": 185,
            "width": 42,
            "height": 130
        }
    ],
    "categories": [
        {
            "class_id": 0,
            "name": "dog"
        },
        {
            "class_id": 1,
            "name": "cat"
        }
    ]
}
```

Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://*your_bucket*/train/sample_image and s3://*your_bucket*/train_annotation, specify the path for your train and train_annotation channels as s3://*your_bucket*/train and s3://*your_bucket*/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The `"image_size"` property specifies the overall image dimensions. The SageMaker AI object detection algorithm currently only supports 3-channel images. The `"annotations"` property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a `"class_id"` index and by four bounding box coordinates (`"left"`, `"top"`, `"width"`, `"height"`). The `"left"` (x-coordinate) and `"top"` (y-coordinate) values represent the upper-left corner of the bounding box. The `"width"` (x-coordinate) and `"height"` (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The `"categories"` property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The `"categories"` property is optional for the annotation .json file

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the [`CreateTrainingJob`](#) request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in [JSON Lines](#) format in which each line represents one sample. The images are specified using the `'source-ref'` tag that points to the S3 location of the image. The annotations are provided under the `"AttributeNames"` parameter value as specified in the [`CreateTrainingJob`](#) request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the `"AttributeNames` are contained in the list `["source-ref", "bounding-box"]`:

```
{"source-ref": "s3://your_bucket/image1.jpg", "bounding-box":{"image_size":[{ "width":
 500, "height": 400, "depth":3}], "annotations":[{"class_id": 0, "left": 111, "top":
 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width":
 80, "height": 50}]}, "bounding-box-metadata":{"class-map":{"0": "dog", "5": "horse"},
 "type": "groundtruth/object-detection"}}
{"source-ref": "s3://your_bucket/image2.jpg", "bounding-box":{"image_size":[{ "width":
 400, "height": 300, "depth":3}], "annotations":[{"class_id": 1, "left": 100, "top":
 120, "width": 43, "height": 78}]}, "bounding-box-metadata":{"class-map":{"1": "cat"},
 "type": "groundtruth/object-detection"}}
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see [Augmented Manifest Files for Training Jobs](#).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker AI. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker AI object detection models can be seeded only with another built-in object detection model trained in SageMaker AI.

To use a pretrained model, in the [CreateTrainingJob](#) request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker AI. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see [Use Incremental Training in Amazon SageMaker AI](#).

EC2 Instance Recommendation for the Object Detection Algorithm

The object detection algorithm supports P2, P3, G4dn, and G5 GPU instance families. We recommend using GPU instances with more memory for training with large batch sizes. You can run the object detection algorithm on multi-GPU and mult-machine settings for distributed training.

You can use both CPU (such as C5 and M5) and GPU (such as P3 and G4dn) instances for inference.

Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker AI Object Detection algorithm to train and host a model on the

Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see Amazon SageMaker AI Object Detection for Bird Species. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. Once you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The object detection example notebook using the Object Detection algorithm is located in the **Introduction to Amazon Algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

For more information about the Amazon SageMaker AI Object Detection algorithm, see the following blog posts:

- Training the Amazon SageMaker AI object detection model and running it on AWS IoT Greengrass – Part 1 of 3: Preparing training data
- Training the Amazon SageMaker AI object detection model and running it on AWS IoT Greengrass – Part 2 of 3: Training a custom object detection model
- Training the Amazon SageMaker AI object detection model and running it on AWS IoT Greengrass – Part 3 of 3: Deploying to the edge

How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker AI Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker AI supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker AI for training the object detection algorithm. For more information about how object training works, see How Object Detection Works.

Parameter Name	Description
`num_classes`	The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. **Required** Valid values: positive integer
`num_training_samples`	The number of training examples in the input dataset. **Note** If there is a mismatch between this value and the number of samples in the training set, then the behavior of the `lr_scheduler_step` parameter will be undefined and distributed training accuracy may be affected. **Required** Valid values: positive integer
`base_network`	The base network architecture to use. **Optional** Valid values: 'vgg-16' or 'resnet-50' Default value: 'vgg-16'

Parameter Name	Description
early_stopping	True to use early stopping logic during training. False not to use it. **Optional** Valid values: True or False Default value: False
early_stopping_min_epochs	The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when early_stopping = True. **Optional** Valid values: positive integer Default value: 10
early_stopping_patience	The number of epochs to wait before ending training if no improvement, as defined by the early_stopping_tolerance hyperparameter, is made in the relevant metric. It is used only when early_stopping = True. **Optional** Valid values: positive integer Default value: 5

Parameter Name	Description
`early_stopping_tolerance`	The tolerance value that the relative improvement in `validation:mAP` , the mean average precision (mAP), is required to exceed to avoid early stopping. If the ratio of the change in the mAP divided by the previous best mAP is smaller than the `early_stopping_tolerance` value set, early stopping considers that there is no improvement. It is used only when `early_stopping` = `True`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
`image_shape`	The image size for input images. We rescale the input image to a square image with this size. We recommend using 300 and 512 for better performance. **Optional** Valid values: positive integer ≥300 Default: 300
`epochs`	The number of training epochs. **Optional** Valid values: positive integer Default: 30

Parameter Name	Description
`freeze_layer_pattern`	The regular expression (regex) for freezing layers in the base network. For example, if we set `freeze_layer_pattern = "^(conv1_|conv2_).*"` , then any layers with a name that contains `"conv1_"` or `"conv2_"` are frozen, which means that the weights for these layers are not updated during training. The layer names can be found in the network symbol files [vgg16-symbol.json]() and [resnet-50-symbol.json](). Freezing a layer means that its weights can not be modified further. This can reduce training time significantly in exchange for modest losses in accuracy. This technique is commonly used in transfer learning where the lower layers in the base network do not need to be retrained. **Optional** Valid values: string Default: No layers frozen.

Parameter Name	Description
`kv_store`	The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details. **Note** This parameter is not applicable to single machine training. **Optional** Valid values: `'dist_sync'` or `'dist_async'` • `'dist_sync'` : The gradients are synchronized after every batch with all the workers. With `'dist_sync'` , batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b. • `'dist_async'` : Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed. Default: -

Parameter Name	Description
`label_width`	The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the `label_width` should be no smaller than (10*5 + header information length). The header information length is usually 2. We recommend using a slightly larger `label_width` for the training, such as 60 for this example. **Optional** Valid values: Positive integer large enough to accommodate the largest annotation information length in the data. Default: 350
`learning_rate`	The initial learning rate. **Optional** Valid values: float in (0, 1] Default: 0.001
`lr_scheduler_factor`	The ratio to reduce learning rate. Used in conjunction with the `lr_scheduler_step` parameter defined as `lr_new` = `lr_old` * `lr_scheduler_factor` . **Optional** Valid values: float in (0, 1) Default: 0.1

Parameter Name	Description
`lr_scheduler_step`	The epochs at which to reduce the learning rate. The learning rate is reduced by `lr_scheduler_factor` at epochs listed in a comma-delimited string: "epoch1, epoch2, ...". For example, if the value is set to "10, 20" and the `lr_scheduler_factor` is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch. **Optional** Valid values: string Default: empty string
`mini_batch_size`	The batch size for training. In a single-machine multi-gpu setting, each GPU handles `mini_batch_size` /`num_gpu` training samples. For the multi-machine training in `dist_sync` mode, the actual batch size is `mini_batch_size` *number of machines. A large `mini_batch_size` usually leads to faster training, but it may cause out of memory problem. The memory usage is related to `mini_batch_size`, `image_shape`, and `base_network` architecture. For example, on a single p3.2xlarge instance, the largest `mini_batch_size` without an out of memory error is 32 with the base_network set to "resnet-50" and an `image_shape` of 300. With the same instance, you can use 64 as the `mini_batch_size` with the base network `vgg-16` and an `image_shape` of 300. **Optional** Valid values: positive integer Default: 32

Parameter Name	Description
`momentum`	The momentum for `sgd`. Ignored for other optimizers. **Optional** Valid values: float in (0, 1] Default: 0.9
`nms_threshold`	The non-maximum suppression threshold. **Optional** Valid values: float in (0, 1] Default: 0.45
`optimizer`	The optimizer types. For details on optimizer values, see [MXNet's API](#). **Optional** Valid values: ['sgd', 'adam', 'rmsprop', 'adadelta'] Default: 'sgd'
`overlap_threshold`	The evaluation overlap threshold. **Optional** Valid values: float in (0, 1] Default: 0.5

Parameter Name	Description
`use_pretrained_model`	Indicates whether to use a pre-trained model for training. If set to 1, then the pre-trained model with corresponding architect ure is loaded and used for training. Otherwise, the network is trained from scratch. **Optional** Valid values: 0 or 1 Default: 1
`weight_decay`	The weight decay coefficient for `sgd` and `rmsprop`. Ignored for other optimizers. **Optional** Valid values: float in (0, 1) Default: 0.0005

Tune an Object Detection Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: `validation:mAP`. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`validation:mAP`	Mean Average Precision (mAP) computed on the validation set.	Maximize

Tunable Object Detection Hyperparameters

Tune the Amazon SageMaker AI object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on the object detection objective metric are: `mini_batch_size`, `learning_rate`, and `optimizer`.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRange	MinValue: 1e-6, MaxValue: 0.5
`mini_batch_size`	IntegerParameterRanges	MinValue: 8, MaxValue: 64
`momentum`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999
`optimizer`	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'adadelta']
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999

Object Detection Request and Response Formats

The following page describes the inference request and response formats for the Amazon SageMaker AI Object Detection - MXNet model.

Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with `image/jpeg` and `image/png` content-types.

Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```
{"prediction":[
  [4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636,
 0.7110607028007507, 0.9345266819000244],
  [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895,
 0.827075183391571, 0.9712159633636475],
  [4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486,
 0.6318609714508057, 0.5967587828636169],
  [8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051,
 0.8985623121261597],
  [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702,
 0.39093565940856934, 0.9574796557426453]
]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide examples of scripts that use a threshold to remove low confidence detections and to plot bounding boxes on the original images.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id,
 confidence_score, xmin, ymin, xmax, ymax]]}
```

For more details on training and inference, see the Object Detection Sample Notebooks.

Object Detection - TensorFlow

The Amazon SageMaker AI Object Detection - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Model Garden. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The object detection algorithm takes an image as input and outputs a list of bounding boxes. Training datasets must consist of images in `.jpg`, `.jpeg`, or `.png` format. This page includes information about Amazon EC2 instance recommendations and sample notebooks for Object Detection - TensorFlow.

How to use the SageMaker AI Object Detection - TensorFlow algorithm

You can use Object Detection - TensorFlow as an Amazon SageMaker AI built-in algorithm. The following section describes how to use Object Detection - TensorFlow with the SageMaker AI Python SDK. For information on how to use Object Detection - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart pretrained models.

The Object Detection - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see

TensorFlow Models. Every pretrained model has a unique `model_id`. The following example uses ResNet50 (`model_id`: `tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker AI Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Object Detection - TensorFlow Hyperparameters. Use these values to construct a SageMaker AI Estimator.

Note

Default hyperparameter values are different for different models. For example, for larger models, the default number of epochs is smaller.

This example uses the PennFudanPed dataset, which contains images of pedestrians in the street. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8",
 "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")
```

```
# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/PennFudanPed_COCO_format/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-od-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_od_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
tf_od_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker AI Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Input and output interface for the Object Detection - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Object Detection - TensorFlow model.

- **Training data input format:** Your training data should be a directory with an `images` subdirectory and an `annotations.json` file.

The following is an example of an input directory structure. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing `/` is required.

```
input_directory
    |--images
        |--abc.png
        |--def.png
    |--annotations.json
```

The `annotations.json` file should contain information for bounding boxes and their class labels in the form of a dictionary `"images"` and `"annotations"` keys. The value for the `"images"` key should be a list of dictionaries. There should be one dictionary for each image with the following information: `{"file_name": image_name, "height": height, "width": width, "id": image_id}`. The value for the `"annotations"` key should also be a list of dictionaries. There should be one dictionary for each bounding box with the following information: `{"image_id": image_id, "bbox": [xmin, ymin, xmax, ymax], "category_id": bbox_label}`.

After training, a label mapping file and trained model are saved to your Amazon S3 bucket.

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker AI. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker AI Object Detection - TensorFlow model with another Object Detection - TensorFlow model trained in SageMaker AI.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For more information about how to use incremental training with the SageMaker AI Object Detection - TensorFlow, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Inference with the Object Detection - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Object Detection training for inference. Any input image for inference must be in `.jpg`, `.jpeg`, or `.png` format and be content type `application/x-image`. The Object Detection - TensorFlow algorithm resizes input images automatically.

Running inference results in bounding boxes, predicted classes, and the scores of each prediction encoded in JSON format. The Object Detection - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

{"normalized_boxes":[[xmin1, xmax1, ymin1, ymax1],....],
    "classes":[classidx1, class_idx2,...],
    "scores":[score_1, score_2,...],
    "labels": [label1, label2, ...],
    "tensorflow_model_output":<original output of the model>}
```

If `accept` is set to `application/json`, then the model only outputs normalized boxes, classes, and scores.

Amazon EC2 instance recommendation for the Object Detection - TensorFlow algorithm

The Object Detection - TensorFlow algorithm supports all GPU instances for training, including:

- `ml.p2.xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.16xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2 or P3) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Object Detection - TensorFlow sample notebooks

For more information about how to use the SageMaker AI Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, select the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Object Detection - TensorFlow Works

The Object Detection - TensorFlow algorithm takes an image as input and predicts bounding boxes and object labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for object detection. There are also deep learning networks that are trained on large image datasets, such as Common Objects in Context (COCO), which has 328,000 images. After a network is trained with COCO data, you can then fine-tune the network on a dataset with a particular focus to perform more specific object detection tasks. The Amazon SageMaker AI Object Detection - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Model Garden.

According to the number of class labels in your training data, an object detection layer is attached to the pretrained TensorFlow model of your choice. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Models

The following pretrained models are available to use for transfer learning with the Object Detection - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	model_id	Source
ResNet50 V1 FPN 640	tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8	TensorFlow Model Garden link

Object Detection - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker AI built-in Object Detection - TensorFlow algorithm. See Tune an Object Detection - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
batch_size	The batch size for training.

Parameter Name	Description
	Valid values: positive integer. Default value: 3.
`beta_1`	The beta1 for the `"adam"` optimizer. Represents the exponenti al decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.9`.
`beta_2`	The beta2 for the `"adam"` optimizer. Represents the exponenti al decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.999`.
`early_stopping`	Set to `"True"` to use early stopping logic during training. If `"False"`, early stopping is not used. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`early_stopping_min _delta`	The minimum change needed to qualify as an improveme nt. An absolute change less than the value of `early_sto pping_min_delta` does not qualify as improvement. Used only when `early_stopping` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0`.

Parameter Name	Description
`early_stopping_patience`	The number of epochs to continue training with no improvement. Used only when `early_stopping` is set to `"True"`. Valid values: positive integer. Default value: 5.
`epochs`	The number of training epochs. Valid values: positive integer. Default value: 5 for smaller models, 1 for larger models.
`epsilon`	The epsilon for `"adam"`, `"rmsprop"` , `"adadelta"` , and `"adagrad"` optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `1e-7`.
`initial_accumulator_value`	The starting value for the accumulators, or the per-parameter momentum values, for the `"adagrad"` optimizer. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.1`.
`learning_rate`	The optimizer learning rate. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.001`.

Parameter Name	Description
`momentum`	The momentum for the `"sgd"` and `"nesterov"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.9`.
`optimizer`	The optimizer type. For more information, see [Optimizers](#) in the TensorFlow documentation. Valid values: string, any of the following: (`"adam"`, `"sgd"`, `"nesterov"` , `"rmsprop"` , `"adagrad"` , `"adadelta"`). Default value: `"adam"`.
`reinitialize_top_layer`	If set to `"Auto"`, the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to `"True"`. Valid values: string, any of the following: (`"Auto"`, `"True"` or `"False"`). Default value: `"Auto"`.
`rho`	The discounting factor for the gradient of the `"adadelta"` and `"rmsprop"` optimizers. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.95`.
`train_only_on_top_layer`	If `"True"`, only the top classification layer parameters are fine-tuned. If `"False"`, all model parameters are fine-tuned. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.

Tune an Object Detection - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Automatic model tuning with SageMaker AI](#).

Metrics computed by the Object Detection - TensorFlow algorithm

Refer to the following chart to find which metrics are computed by the Object Detection - TensorFlow algorithm.

Metric Name	Description	Optimization Direction	Regex Pattern
`validation:localization_loss`	The localization loss for box prediction.	Minimize	`Val_localization=([0-9\\.]+)`

Tunable Object Detection - TensorFlow hyperparameters

Tune an object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on object detection objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see [Object Detection - TensorFlow Hyperparameters](#).

Parameter Name	Parameter Type	Recommended Ranges
batch_size	IntegerParameterRanges	MinValue: 8, MaxValue: 512
beta_1	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
beta_2	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
eps	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
learning_rate	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
momentum	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['sgd', ‘adam’, ‘rmsprop’, 'nesterov', 'adagrad', 'adadelta']
regularizers_l2	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
train_only_on_top_layer	CategoricalParameterRanges	['True', 'False']
initial_accumulator_value	CategoricalParameterRanges	MinValue: 0.0, MaxValue: 0.999

Semantic Segmentation Algorithm

The SageMaker AI semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker AI Image Classification - MXNet is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection - MXNet is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a *segmentation mask*. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker AI semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm , Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The *backbone* (or *encoder*)—A network that produces reliable activation maps of features.
- The *decoder*—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker AI hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

Topics

- Semantic Segmentation Sample Notebooks

Semantic Segmentation Sample Notebooks

For a sample Jupyter notebook that uses the SageMaker AI semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances.

To see a list of all of the SageMaker AI samples, create and open a notebook instance, and choose the **SageMaker AI Examples** tab. The example semantic segmentation notebooks are located under **Introduction to Amazon algorithms**. To open a notebook, choose its **Use** tab, and choose **Create copy**.

Input/Output Interface for the Semantic Segmentation Algorithm

SageMaker AI semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker AI semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for `train` and one for `validation` using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (`application/x-image`) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an `image/jpeg` content type.

How Training Works

The training data is split into four directories: `train`, `train_annotation`, `validation`, and `validation_annotation`. There is a channel for each of these directories. The dataset also expected to have one `label_map.json` file per channel for `train_annotation` and `validation_annotation` respectively. If you don't provide these JSON files, SageMaker AI provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
    |
    |- train
                 |
                 | - 0000.jpg
                 | - coffee.jpg
    |- validation
                 |
                 | - 00a0.jpg
                 | - bananna.jpg
    |- train_annotation
                 |
                 | - 0000.png
                 | - coffee.png
    |- validation_annotation
                 |
                 | - 00a0.png
                 | - bananna.png
    |- label_map
                 | - train_label_map.json
                 | - validation_label_map.json
```

Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the `train_annotation` and `validation_annotation` directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The `train`, `train_annotation`, `validation`, and `validation_annotation` channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the [Python Image Library documentation](). We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the *label map*. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don't provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
```

```
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker AI semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn't convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```

The following example shows how this `"scale"` value is used to rescale the `encoded_label` values of the input annotation image when they are mapped to the `mapped_label` values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a `label_map` file:

```
{
    "map": {
        "0": 5,
        "1": 0,
        "2": 2
    }
}
```

This label mapping for this example is:

```
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the `label_map` channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in [JSON Lines](http://jsonlines.org/) format, as described in the `CreateTrainingJob` request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references `["source-ref", "city-streets-ref"]`. These names must have `-ref` appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be `"RecordIO"` and value of the `ContentType` parameter must be `application/x-recordio`.

```
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see Augmented Manifest Files for Training Jobs.

Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker AI. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker AI Semantic Segmentation.

To use your own pre-trained model, specify the `ChannelName` as "model" in the `InputDataConfig` for the `CreateTrainingJob` request. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The `backbone`, `algorithm`, `crop_size`, and `num_classes` input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker AI outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see Use Incremental Training in Amazon SageMaker AI.

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an `AcceptType` that denotes the type of output required. The endpoint takes JPEG images with an `image/jpeg` content type. If you request an `AcceptType` of `image/png`, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of`application/x-recordio-protobuf`, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker AI semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2, P3, G4dn, or G5 instances in single machine configurations.

For inference, you can use either CPU instances (such as C5 and M5) and GPU instances (such as P3 and G4dn) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker AI ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker AI semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the `AlgorithmName` of the `CreateTrainingJob` request.

Network Architecture Hyperparameters

Parameter Name	Description
`backbone`	The backbone to use for the algorithm's encoder component. **Optional**

Parameter Name	Description
	Valid values: `resnet-50` , `resnet-101` Default value: `resnet-50`
`use_pretrained_model`	Whether a pretrained model is to be used for the backbone. **Optional** Valid values: `True`, `False` Default value: `True`
`algorithm`	The algorithm to use for semantic segmentation. **Optional** Valid values: • `fcn`: Fully-Convolutional Network (FCN) algorithm • `psp`: Pyramid Scene Parsing (PSP) algorithm • `deeplab`: DeepLab V3 algorithm Default value: `fcn`

Data Hyperparameters

Parameter Name	Description
`num_classes`	The number of classes to segment. **Required** Valid values: 2 ≤ positive integer ≤ 254
`num_training_samples`	The number of samples in the training data. The algorithm uses this value to set up the learning rate scheduler. **Required**

Parameter Name	Description
	Valid values: positive integer
`base_size`	Defines how images are rescaled before cropping. Images are rescaled such that the long size length is set to `base_size` multiplied by a random number from 0.5 to 2.0, and the short size is computed to preserve the aspect ratio. **Optional** Valid values: positive integer > 16 Default value: 520
`crop_size`	The image size for input during training. We randomly rescale the input image based on `base_size` , and then take a random square crop with side length equal to `crop_size` . The `crop_size` will be automatically rounded up to multiples of 8. **Optional** Valid values: positive integer > 16 Default value: 240

Training Hyperparameters

Parameter Name	Description
`early_stopping`	Whether to use early stopping logic during training. **Optional** Valid values: `True`, `False` Default value: `False`
`early_stopping_min_epochs`	The minimum number of epochs that must be run.

Parameter Name	Description
	Optional Valid values: integer Default value: 5
`early_stopping_patience`	The number of epochs that meet the tolerance for lower performance before the algorithm enforces an early stop. **Optional** Valid values: integer Default value: 4
`early_stopping_tolerance`	If the relative improvement of the score of the training job, the mIOU, is smaller than this value, early stopping considers the epoch as not improved. This is used only when `early_stopping = True`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
`epochs`	The number of epochs with which to train. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
`gamma1`	The decay factor for the moving average of the squared gradient for `rmsprop`. Used only for `rmsprop`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.9
`gamma2`	The momentum factor for `rmsprop`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.9
`learning_rate`	The initial learning rate. **Optional** Valid values: 0 < float ≤ 1 Default value: 0.001

Parameter Name	Description
`lr_scheduler`	The shape of the learning rate schedule that controls its decrease over time. **Optional** Valid values: • `step`: A stepwise decay, where the learning rate is reduced (multiplied) by the `lr_scheduler_factor` after epochs specified by `lr_scheduler_step` . • `poly`: A smooth decay using a polynomial function. • `cosine`: A smooth decay using a cosine function. Default value: `poly`
`lr_scheduler_factor`	If `lr_scheduler` is set to `step`, the ratio by which to reduce (multipy) the `learning_rate` after each of the epochs specified by the `lr_scheduler_step` . Otherwise, ignored. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.1
`lr_scheduler_step`	A comma delimited list of the epochs after which the `learning_rate` is reduced (multiplied) by an `lr_scheduler_factor` . For example, if the value is set to `"10, 20"`, then the `learning-rate` is reduced by `lr_scheduler_factor` after the 10th epoch and again by this factor after 20th epoch. **Conditionally Required** if `lr_scheduler` is set to `step`. Otherwise , ignored. Valid values: string Default value: (No default, as the value is required when used.)

Parameter Name	Description
mini_batch_size	The batch size for training. Using a large mini_batch_size usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the mini_batch_size and image_shape parameters, and the backbone architecture. **Optional** Valid values: positive integer Default value: 16
momentum	The momentum for the sgd optimizer. When you use other optimizers, the semantic segmentation algorithm ignores this parameter. **Optional** Valid values: 0 < float ≤ 1 Default value: 0.9
optimizer	The type of optimizer. For more information about an optimizer, choose the appropriate link: • adam: Adaptive momentum estimation • adagrad: Adaptive gradient descent • nag: Nesterov accelerated gradient • rmsprop: Root mean square propagation • sgd: Stochastic gradient descent **Optional** Valid values: adam, adagrad, nag, rmsprop, sgd Default value: sgd

Parameter Name	Description
syncbn	If set to `True`, the batch normalization mean and variance are computed over all the samples processed across the GPUs. **Optional** Valid values: `True`, `False` Default value: `False`
validation_mini_batch_size	The batch size for validation. A large `mini_batch_size` usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the `mini_batch_size` and `image_shape` parameters, and the backbone architecture. • To score the validation on the entire image without cropping the images, set this parameter to 1. Use this option if you want to measure performance on the entire image as a whole. **Note** Setting the `validation_mini_batch_size` parameter to 1 causes the algorithm to create a new network model for every image. This might slow validation and training. • To crop images to the size specified in the `crop_size` parameter, even during evaluation, set this parameter to a value greater than 1. **Optional** Valid values: positive integer Default value: 16

Parameter Name	Description
`weight_decay`	The weight decay coefficient for the `sgd` optimizer. When you use other optimizers, the algorithm ignores this parameter. **Optional** Valid values: 0 < float < 1 Default value: 0.0001

Tuning a Semantic Segmentation Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

Metric Name	Description	Optimization Direction
`validation:mIOU`	The area of the intersection of the predicted segmentation and the ground truth divided by the area of union between them for images in the validation set. Also known as the Jaccard Index.	Maximize
`validation:pixel_accuracy`	The percentage of pixels that are correctly classified in images from the validation set.	Maximize

Tunable Semantic Segmentation Hyperparameters

You can tune the following hyperparameters for the semantic segmentation algorithm.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 1e-1
`mini_batch_size`	IntegerParameterRanges	MinValue: 1, MaxValue: 128
`momentum`	ContinuousParameterRange	MinValue: 0.9, MaxValue: 0.999
`optimzer`	CategoricalParameterRanges	['sgd', 'adam', 'adadelta']
`weight_decay`	ContinuousParameterRange	MinValue: 1e-5, MaxValue: 1e-3

Use Reinforcement Learning with Amazon SageMaker AI

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent’s current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Topics

Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles.

Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a *policy*.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

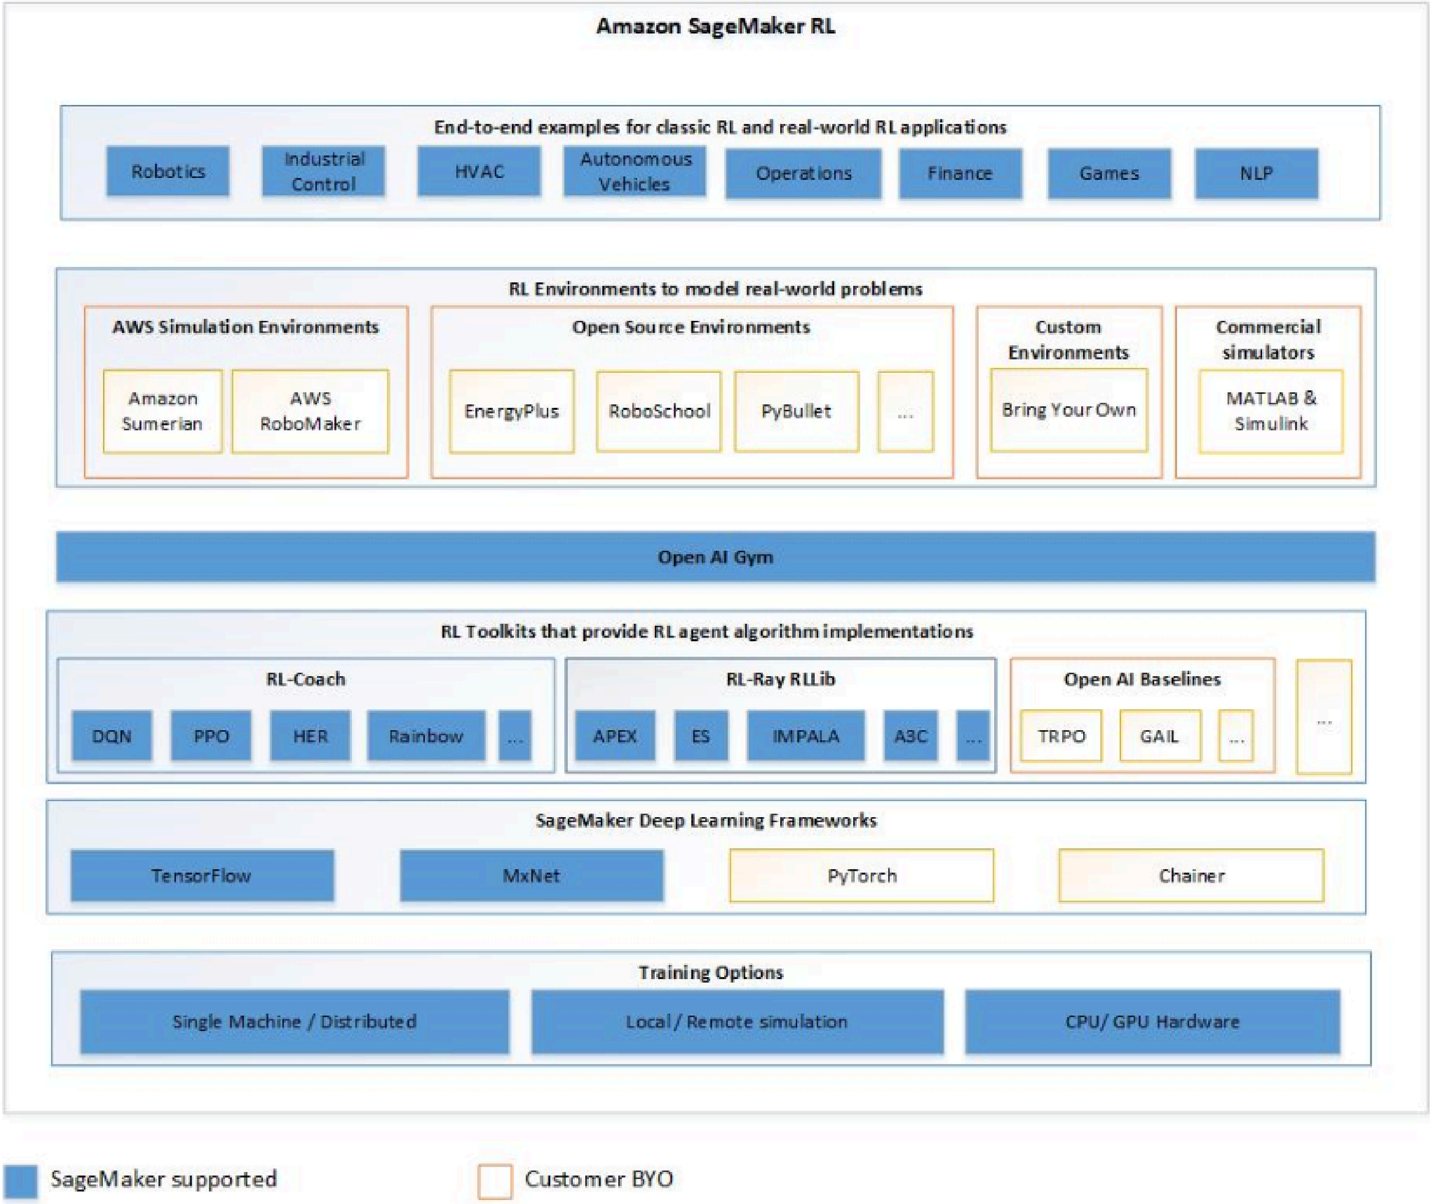
Typically, training in RL consists of many *episodes*. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.

Key Features of Amazon SageMaker AI RL

To train RL models in SageMaker AI RL, use the following components:

- A deep learning (DL) framework. Currently, SageMaker AI supports RL in TensorFlow and Apache MXNet.
- An RL toolkit. An RL toolkit manages the interaction between the agent and the environment and provides a wide selection of state of the art RL algorithms. SageMaker AI supports the Intel Coach and Ray RLlib toolkits. For information about Intel Coach, see https://nervanasystems.github.io/coach/. For information about Ray RLlib, see https://ray.readthedocs.io/en/latest/rllib.html.
- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker AI.

The following diagram shows the RL components that are supported in SageMaker AI RL.



Reinforcement Learning Sample Notebooks

For complete code examples, see the reinforcement learning sample notebooks in the SageMaker AI Examples repository.

Sample RL Workflow Using Amazon SageMaker AI RL

The following example describes the steps for developing RL models using Amazon SageMaker AI RL.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending

on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:

a. **Objective**—Scale instance capacity so that it matches the desired load profile.

b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.

c. **State**—The current load, number of failed jobs, and number of active machines.

d. **Action**—Remove, add, or keep the same number of instances.

e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker AI training job. In your training code, import the environment files and the preset files, and then define the `main()` function.

5. **Train the RL Model**—Use the SageMaker AI `RLEstimator` in the [Amazon SageMaker Python SDK](https://sagemaker.readthedocs.io) to start an RL training job. If you are using local mode, the training job runs on the notebook instance. When you use SageMaker AI for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker AI training.

   The `RLEstimator` requires the following information as parameters.

   a. The source directory where the environment, presets, and training code are uploaded.

   b. The path to the training script.

   c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.

   d. The training parameters, such as the instance count, job name, and S3 path for output.

e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker AI notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch,. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

> **Note**
>
> If you train in local mode, you can't visualize metrics in CloudWatch.

7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker AI training mode, you need to upload the data to S3 first.

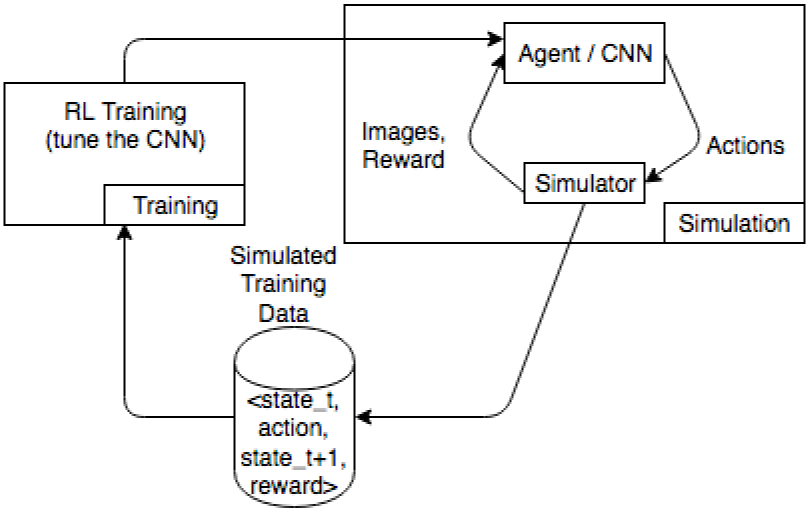
8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker AI containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker AI, see Using RL with the SageMaker Python SDK.

RL Environments in Amazon SageMaker AI

Amazon SageMaker AI RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.



The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form `state_t`, `action`, `state_t+1`, and `reward_t+1`. Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

Topics

- Use OpenAI Gym Interface for Environments in SageMaker AI RL
- Use Open-Source Environments
- Use Commercial Environments

Use OpenAI Gym Interface for Environments in SageMaker AI RL

To use OpenAI Gym environments in SageMaker AI RL, use the following API elements. For more information about OpenAI Gym, see Gym Documentation.

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()`

returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.

- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an `info` dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.

Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker AI RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker AI examples repository show how to build a custom container to use with SageMaker AI RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker AI RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker AI RL

Amazon SageMaker AI RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker AI RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker AI examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker AI examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker AI examples repository. This is useful if the simulation environment is light-weight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker AI examples repository.

Hyperparameter Tuning with Amazon SageMaker AI RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker AI RL. The Roboschool example in the sample notebooks in the SageMaker AI examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Run your local code as a SageMaker training job

You can run your local machine learning (ML) Python code as a large single-node Amazon SageMaker training job or as multiple parallel jobs. You can do this by annotating your code with an @remote decorator, as shown in the following code example. Distributed training (across multiple instances) are not supported with remote functions.

```
@remote(**settings)
def divide(x, y):
    return x / y
```

The SageMaker Python SDK will automatically translate your existing workspace environment and any associated data processing code and datasets into a SageMaker training job that runs on the SageMaker training platform. You can also activate a persistent cache feature, which will further reduce job start latency by caching previously downloaded dependency packages. This reduction in job latency is greater than the reduction in latency from using SageMaker AI managed warm pools alone. For more information, see Using persistent cache.

Note

Distributed training jobs are not supported by remote functions.

The following sections show how to annotate your local ML code with an @remote decorator and tailor your experience for your use case. This includes customizing your environment and integrating with SageMaker Experiments.

Topics

- Configuration file
- Customize your runtime environment
- Container image compatibility
- Logging parameters and metrics with Amazon SageMaker Experiments
- Using modular code with the @remote decorator
- Private repository for runtime dependencies
- Example notebooks

Set up your environment

Choose one of the following three options to set up your environment.

Run your code from Amazon SageMaker Studio Classic

You can annotate and run your local ML code from SageMaker Studio Classic by creating a SageMaker Notebook and attaching any image available on SageMaker Studio Classic image. The following instructions help you create a SageMaker Notebook, install the SageMaker Python SDK, and annotate your code with the decorator.

1. Create a SageMaker Notebook and attach an image in SageMaker Studio Classic as follows:
    a. Follow the instructions in Launch Amazon SageMaker Studio Classic in the *Amazon SageMaker AI Developer Guide*.
    b. Select **Studio** from the left navigation pane. This opens a new window.
    c. In the **Get Started** dialog box, select a user profile from the down arrow. This opens a new window.
    d. Select **Open Studio Classic**.
    e. Select **Open Launcher** from the main working area. This opens a new page.
    f. Select **Create notebook** from the main working area.
    g. Select **Base Python 3.0** from the down arrow next to **Image** in the **Change environment** dialog box.

       The @remote decorator automatically detects the image attached to the SageMaker Studio Classic notebook and uses it to run the SageMaker training job. If `image_uri` is specified either as an argument in the decorator or in the configuration file, then the value specified in `image_uri` will be used instead of the detected image.

For more information about how to create a notebook in SageMaker Studio Classic, see the **Create a Notebook from the File Menu** section in [Create or Open an Amazon SageMaker Studio Classic Notebook](#).

For a list of available images, see [Supported Docker images](#).

2. Install the SageMaker Python SDK.

   To annotate your code with the @remote function inside a SageMaker Studio Classic Notebook, you must have the SageMaker Python SDK installed. Install the SageMaker Python SDK, as shown in the following code example.

   ```
   !pip install sagemaker
   ```

3. Use @remote decorator to run functions in a SageMaker training job.

   To run your local ML code, first create a dependencies file to instruct SageMaker AI where to locate your local code. To do so, follow these steps:

   a. From the SageMaker Studio Classic Launcher main working area, in **Utilities and files**, choose **Text file**. This opens a new tab with a text file called `untitled.txt.`

      For more information about the SageMaker Studio Classic user interface (UI), see [Amazon SageMaker Studio Classic UI Overview](#).

   b. Rename `untitled.txt` to `requirements.txt`.

   c. Add all the dependencies required for the code along with the SageMaker AI library to `requirements.txt`.

      A minimal code example for `requirements.txt` for the example `divide` function is provided in the following section, as follows.

      ```
      sagemaker
      ```

   d. Run your code with the remote decorator by passing the dependencies file, as follows.

      ```
      from sagemaker.remote_function import remote

      @remote(instance_type="ml.m5.xlarge", dependencies='./requirements.txt')
      def divide(x, y):
          return x / y
      ```

```
divide(2, 3.0)
```

For additional code examples, see the sample notebook quick_start.ipynb.

If you're already running a SageMaker Studio Classic notebook, and you install the Python SDK as instructed in **2. Install the SageMaker Python SDK**, you must restart your kernel. For more information, see Use the SageMaker Studio Classic Notebook Toolbar in the *Amazon SageMaker AI Developer Guide*.

Run your code from an Amazon SageMaker notebook

You can annotate your local ML code from a SageMaker notebook instance. The following instructions show how to create a notebook instance with a custom kernel, install the SageMaker Python SDK, and annotate your code with the decorator.

1. Create a notebook instance with a custom `conda` kernel.

   You can annotate your local ML code with an @remote decorator to use inside of a SageMaker training job. First you must create and customize a SageMaker notebook instance to use a kernel with Python version 3.7 or higher, up to 3.10.x. To do so, follow these steps:

   a. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.

   b. In the left navigation panel, choose **Notebook** to expand its options.

   c. Choose **Notebook Instances** from the expanded options.

   d. Choose the **Create Notebook Instance** button. This opens a new page.

   e. For **Notebook instance name**, enter a name with a maximum of 63 characters and no spaces. Valid characters: **A-Z**, **a-z**, **0-9**, and **.:+=@ _%-** (hyphen).

   f. In the **Notebook instance settings** dialog box, expand the right arrow next to **Additional Configuration**.

   g. Under **Lifecycle configuration - optional**, expand the down arrow and select **Create a new lifecycle configuration**. This opens a new dialog box.

   h. Under **Name**, enter a name for your configuration setting.

   i. In the **Scripts** dialog box, in the **Start notebook** tab, replace the existing contents of the text box with the following script.

   ```
   #!/bin/bash
   ```

```
set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda/
source "$WORKING_DIR/miniconda/bin/activate"
for env in $WORKING_DIR/miniconda/envs/*; do
    BASENAME=$(basename "$env")
    source activate "$BASENAME"
    python -m ipykernel install --user --name "$BASENAME" --display-name "Custom
 ($BASENAME)"
done
EOF

echo "Restarting the Jupyter server.."
# restart command is dependent on current running Amazon Linux and JupyterLab
CURR_VERSION_AL=$(cat /etc/system-release)
CURR_VERSION_JS=$(jupyter --version)

if [[ $CURR_VERSION_JS == *$"jupyter_core     : 4.9.1"* ]] && [[ $CURR_VERSION_AL
 == *$" release 2018"* ]]; then
 sudo initctl restart jupyter-server --no-wait
else
 sudo systemctl --no-block restart jupyter-server.service
fi
```

j. In the **Scripts** dialog box, in the **Create notebook** tab, replace the existing contents of the text box with the following script.

```
#!/bin/bash

set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
# Install a separate conda installation via Miniconda
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda
mkdir -p "$WORKING_DIR"
wget https://repo.anaconda.com/miniconda/Miniconda3-4.6.14-Linux-x86_64.sh -O
 "$WORKING_DIR/miniconda.sh"
bash "$WORKING_DIR/miniconda.sh" -b -u -p "$WORKING_DIR/miniconda"
rm -rf "$WORKING_DIR/miniconda.sh"
# Create a custom conda environment
```

```
source "$WORKING_DIR/miniconda/bin/activate"
KERNEL_NAME="custom_python310"
PYTHON="3.10"
conda create --yes --name "$KERNEL_NAME" python="$PYTHON" pip
conda activate "$KERNEL_NAME"
pip install --quiet ipykernel
# Customize these lines as necessary to install the required packages
EOF
```

k. Choose the **Create configuration** button on the bottom right of the window.

l. Choose the **Create notebook instance** button on the bottom right of the window.

m. Wait for the notebook instance **Status** to change from **Pending** to **InService**.

2. Create a Jupyter notebook in the notebook instance.

   The following instructions show how to create a Jupyter notebook using Python 3.10 in your newly created SageMaker instance.

   a. After the notebook instance **Status** from the previous step is **InService**, do the following:

      i. Select **Open Jupyter** under **Actions** in the row containing your newly created notebook instance **Name**. This opens a new Jupyter server.

   b. In the Jupyter server, select **New** from the top right menu.

   c. From the down arrow, select **conda_custom_python310**. This creates a new Jupyter notebook that uses a Python 3.10 kernel. This new Jupyter notebook can now be used similarly to a local Jupyter notebook.

3. Install the SageMaker Python SDK.

   After your virtual environment is running, install the SageMaker Python SDK by using the following code example.

```
!pip install sagemaker
```

4. Use an @remote decorator to run functions in a SageMaker training job.

   When you annotate your local ML code with an @remote decorator inside the SageMaker notebook, SageMaker training will automatically interpret the function of your code and run it as a SageMaker training job. Set up your notebook by doing the following:

   a. Select the kernel name in the notebook menu from the SageMaker notebook instance that you created in step 1, **Create a SageMaker Notebook instance with a custom kernel**.

For more information, see Change an Image or a Kernel.

b. From the down arrow, choose the a custom conda kernel that uses a version of Python that is 3.7 or higher.

   As an example, selecting conda_custom_python310 chooses the kernel for Python 3.10.

c. Choose **Select**.

d. Wait for the kernel's status to show as idle, which indicates that the kernel has started.

e. In the Jupyter Server Home, select **New** from the top right menu.

f. Next to the down arrow, select **Text file**. This creates a new text file called untitled.txt.

g. Rename untitled.txt to requirements.txt and add any dependencies required for the code along with sagemaker.

h. Run your code with the remote decorator by passing the dependencies file as shown below.

```
from sagemaker.remote_function import remote

@remote(instance_type="ml.m5.xlarge", dependencies='./requirements.txt')
def divide(x, y):
    return x / y

divide(2, 3.0)
```

See the sample notebook quick_start.ipnyb for additional code examples.

Run your code from within your local IDE

You can annotate your local ML code with an @remote decorator inside your preferred local IDE. The following steps show the necessary prerequisites, how to install the Python SDK, and how to annotate your code with the @remote decorator.

1. Install prerequisites by setting up the AWS Command Line Interface (AWS CLI) and creating a role, as follows:
   - Onboard to a SageMaker AI domain following the instructions in the **AWS CLI Prerequisites** section of Set Up Amazon SageMaker AI Prerequisites.
   - Create an IAM role following the **Create execution role** section of SageMaker AI Roles.
2. Create a virtual environment by using either PyCharm or conda and using Python version 3.7 or higher, up to 3.10.x.

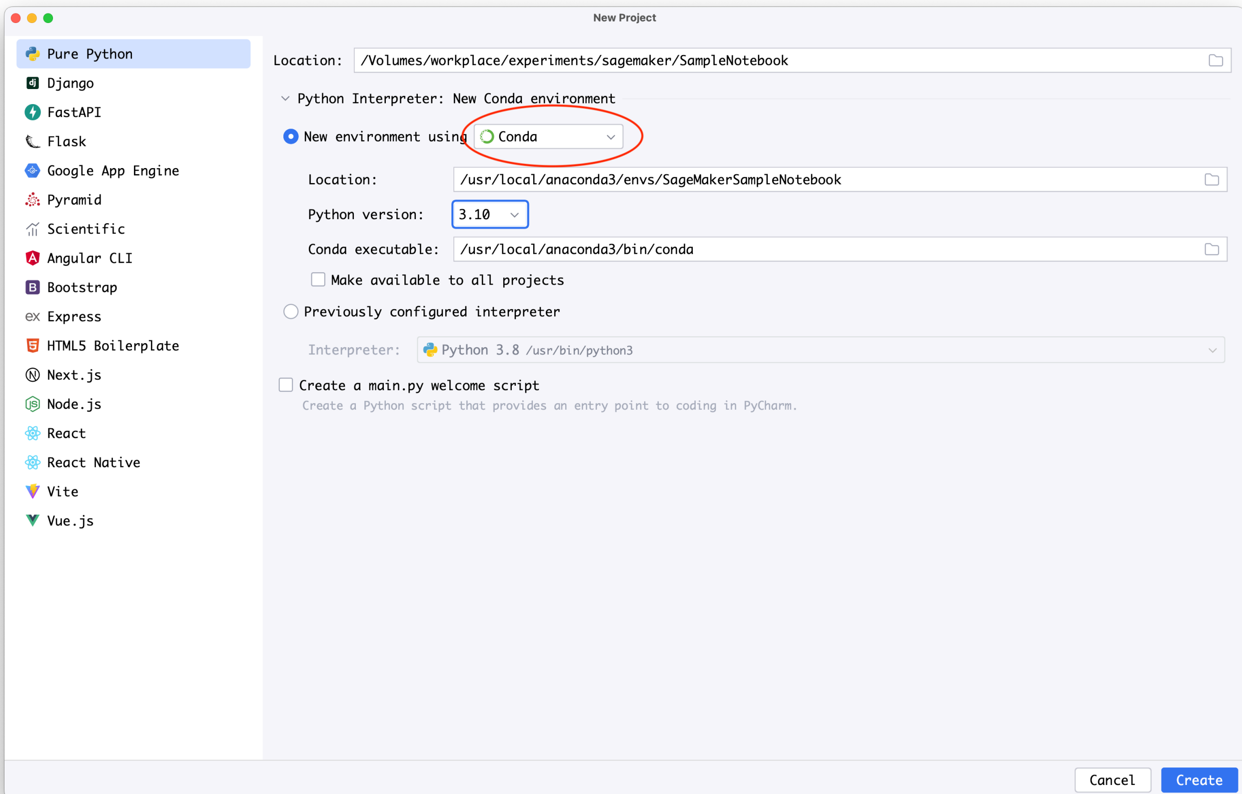
- Set up a virtual environment using PyCharm as follows:

  a. Select **File** from the main menu.

  b. Choose **New Project**.

  c. Choose **Conda** from the down arrow under **New environment using**.

  d. In the field for **Python version** use the down arrow to select a version of Python that is 3.7 or above. You can go up to 3.10.x from the list.



- If you have Anaconda installed, you can set up a virtual environment using conda, as follows:

  - Open an Anaconda prompt terminal interface.

  - Create and activate a new conda environment using a Python version of 3.7 or higher, up to 3.10x. The following code example shows how to create a conda environment using Python version 3.10.

```
conda create -n sagemaker_jobs_quick_start python=3.10 pip
conda activate sagemaker_jobs_quick_start
```

3. Install the SageMaker Python SDK.

To package your code from your preferred IDE, you must have a virtual environment set up using Python 3.7 or higher, up to 3.10x. You also need a compatible container image. Install the SageMaker Python SDK using the following code example.

```
pip install sagemaker
```

4. Wrap your code inside the @remote decorator. The SageMaker Python SDK will automatically interpret the function of your code and run it as a SageMaker training job. The following code examples show how to import the necessary libraries, set up a SageMaker session, and annotate a function with the @remote decorator.

   You can run your code by either providing the dependencies needed directly, or by using dependencies from the active `conda` environment.

   - To provide the dependencies directly, do the following:
     - Create a `requirements.txt` file in the working directory that the code resides in.
     - Add all of the dependencies required for the code along with the SageMaker library. The following section provides a minimal code example for `requirements.txt` for the example `divide` function.

       ```
       sagemaker
       ```

     - Run your code with the @remote decorator by passing the dependencies file. In the following code example, replace `The IAM role name` with an AWS Identity and Access Management (IAM) role ARN that you would like SageMaker to use to run your job.

       ```
       import boto3
       import sagemaker
       from sagemaker.remote_function import remote

       sm_session =
        sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
       settings = dict(
           sagemaker_session=sm_session,
           role=<The IAM role name>,
           instance_type="ml.m5.xlarge",
           dependencies='./requirements.txt'
       )

       @remote(**settings)
       ```

```
def divide(x, y):
    return x / y

if __name__ == "__main__":
    print(divide(2, 3.0))
```

- To use dependencies from the active `conda` environment, use the value `auto_capture` for the `dependencies` parameter, as shown in the following.

```
import boto3
import sagemaker
from sagemaker.remote_function import remote

sm_session = sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
settings = dict(
    sagemaker_session=sm_session,
    role=<The IAM role name>,
    instance_type="ml.m5.xlarge",
    dependencies="auto_capture"
)

@remote(**settings)
def divide(x, y):
    return x / y

if __name__ == "__main__":
    print(divide(2, 3.0))
```

> **Note**
>
> You can also implement the previous code inside a Jupyter notebook. PyCharm Professional Edition supports Jupyter natively. For more guidance, see [Jupyter notebook support](#) in PyCharm's documentation.

Invoke a remote function

To invoke a function inside the @remote decorator, use either of the following methods:

- Use an @remote decorator to invoke a function.
- Use the `RemoteExecutor` API to invoke a function.

If you use the @remote decorator method to invoke a function, the training job will wait for the function to complete before starting a new task. However, if you use the `RemoteExecutor` API, you can run more than one job in parallel. The following sections show both ways of invoking a function.

Use an @remote decorator to invoke a function

You can use the @remote decorator to annotate a function. SageMaker AI will transform the code inside the decorator into a SageMaker training job. The training job will then invoke the function inside the decorator and wait for the job to complete. The following code example shows how to import the required libraries, start a SageMaker AI instance, and annotate a matrix multiplication with the @remote decorator.

```
from sagemaker.remote_function import remote
import numpy as np

@remote(instance_type="ml.m5.large")
def matrix_multiply(a, b):
    return np.matmul(a, b)

a = np.array([[1, 0],
             [0, 1]])
b = np.array([1, 2])

assert (matrix_multiply(a, b) == np.array([1,2])).all()
```

The decorator is defined as follows.

```
def remote(
    *,
    **kwarg):
        ...
```

When you invoke a decorated function, SageMaker Python SDK loads any exceptions raised by an error into local memory. In the following code example, the first call to the divide function completes successfully and the result is loaded into local memory. In the second call to the divide function, the code returns an error and this error is loaded into local memory.

```
from sagemaker.remote_function import remote
import pytest

@remote()
def divide(a, b):
    return a/b

# the underlying job is completed successfully
# and the function return is loaded
assert divide(10, 5) == 2

# the underlying job fails with "AlgorithmError"
# and the function exception is loaded into local memory
with pytest.raises(ZeroDivisionError):
    divide(10, 0)
```

> **Note**
>
> The decorated function is run as a remote job. If the thread is interrupted, the underlying job will not be stopped.

How to change the value of a local variable

The decorator function is run on a remote machine. Changing a non-local variable or input arguments inside a decorated function will not change the local value.

In the following code example, a list and a dict are appended inside the decorator function. This does not change when the decorator function is invoked.

```
a = []

@remote
def func():
    a.append(1)

# when func is invoked, a in the local memory is not modified
func()
func()

# a stays as []
```

```
a = {}
@remote
def func(a):
    # append new values to the input dictionary
    a["key-2"] = "value-2"

a = {"key": "value"}
func(a)

# a stays as {"key": "value"}
```

To change the value of a local variable declared inside of a decorator function, return the variable from the function. The following code example shows that the value of a local variable is changed when it is returned from the function.

```
a = {"key-1": "value-1"}

@remote
def func(a):
    a["key-2"] = "value-2"
    return a

a = func(a)

-> {"key-1": "value-1", "key-2": "value-2"}
```

Data serialization and deserialization

When you invoke a remote function, SageMaker AI automatically serializes your function arguments during the input and output stages. Function arguments and returns are serialized using cloudpickle. SageMaker AI supports serializing the following Python objects and functions.

- Built-in Python objects including dicts, lists, floats, ints, strings, boolean values and tuples
- Numpy arrays
- Pandas Dataframes
- Scikit-learn datasets and estimators
- PyTorch models
- TensorFlow models
- The Booster class for XGBoost

The following can be used with some limitations.

- Dask DataFrames
- The XGBoost Dmatrix class
- TensorFlow datasets and subclasses
- PyTorch models

The following section contains best practices for using the previous Python classes with some limitations in your remote function, information about where SageMaker AI stores your serialized data and how to manage access to it.

Best practices for Python classes with limited support for remote data serialization

You can use the Python classes listed in this section with limitations. The next sections discuss best practices for how to use the following Python classes.

- Dask DataFrames
- The XGBoost DMatric class
- TensorFlow datasets and subclasses
- PyTorch models

Best practices for Dask

Dask is an open-source library used for parallel computing in Python. This section shows the following.

- How to pass a Dask DataFrame into your remote function
- How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

How to pass a Dask DataFrame into your remote function

Dask DataFrames are often used to process large datasets because they can hold datasets that require more memory than is available. This is because a Dask DataFrame does not load your local data into memory. If you pass a Dask DataFrame as a function argument to your remote function, Dask may pass a reference to the data in your local disk or cloud storage, instead of the data itself. The following code shows an example of passing a Dask DataFrame inside your remote function that will operate on an empty DataFrame.

```
#Do not pass a Dask DataFrame  to your remote function as follows
def clean(df: dask.DataFrame ):
    cleaned = df[] \ ...
```

Dask will load the data from the Dask DataFrame into memory only when you use the DataFrame . If you want to use a Dask DataFrame inside a remote function, provide the path to the data . Then Dask will read the dataset directly from the data path that you specify when the code runs.

The following code example shows how to use a Dask DataFrame inside the remote function `clean`. In the code example, `raw_data_path` is passed to clean instead of the Dask DataFrame. When the code runs, the dataset is read directly from the location of an Amazon S3 bucket specified in `raw_data_path`. Then the `persist` function keeps the dataset in memory to facilitate the subsequent `random_split` function and written back to the output data path in an S3 bucket using Dask DataFrame API functions.

```
import dask.dataframe as dd

@remote(
   instance_type='ml.m5.24xlarge',
   volume_size=300,
   keep_alive_period_in_seconds=600)
#pass the data path to your remote function rather than the Dask DataFrame  itself
def clean(raw_data_path: str, output_data_path: str: split_ratio: list[float]):
    df = dd.read_parquet(raw_data_path) #pass the path to your DataFrame
    cleaned = df[(df.column_a >= 1) & (df.column_a < 5)]\
        .drop(['column_b', 'column_c'], axis=1)\
        .persist() #keep the data in memory to facilitate the following random_split
 operation

    train_df, test_df = cleaned.random_split(split_ratio, random_state=10)

    train_df.to_parquet(os.path.join(output_data_path, 'train')
    test_df.to_parquet(os.path.join(output_data_path, 'test'))

clean("s3://amzn-s3-demo-bucket/raw/", "s3://amzn-s3-demo-bucket/cleaned/",
 split_ratio=[0.7, 0.3])
```

How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

Summary statistics from a Dask DataFrame can be converted into a Pandas DataFrame by invoking the `compute` method as shown in the following example code. In the example, the S3 bucket contains a large Dask DataFrame that cannot fit into memory or into a Pandas dataframe. In the following example, a remote function scans the data set and returns a Dask DataFrame containing the output statistics from `describe` to a Pandas DataFrame.

```
executor = RemoteExecutor(
    instance_type='ml.m5.24xlarge',
    volume_size=300,
    keep_alive_period_in_seconds=600)

future = executor.submit(lambda: dd.read_parquet("s3://amzn-s3-demo-bucket/
raw/").describe().compute())

future.result()
```

Best practices for the XGBoost DMatric class

DMatrix is an internal data structure used by XGBoost to load data. A DMatrix object can't be pickled in order to move easily between compute sessions. Directly passing DMatrix instances will fail with a `SerializationError`.

How to pass a data object to your remote function and train with XGBoost

To convert a Pandas DataFrame into a DMatrix instance and use it for training in your remote function, pass it directly to the remote function as shown in the following code example.

```
import xgboost as xgb

@remote
def train(df, params):
    #Convert a pandas dataframe into a DMatrix DataFrame and use it for training
    dtrain = DMatrix(df)
    return xgb.train(dtrain, params)
```

Best practices for TensorFlow datasets and sub-classes

TensorFlow datasets and subclasses are internal objects used by TensorFlow to load data during training. TensorFlow datasets and subclasses can't be pickled in order to move easily between compute sessions. Directly passing Tensorflow datasets or subclasses will fail with a `SerializationError`. Use the Tensorflow I/O APIs to load data from the storage, as shown in the following code example.

```
import tensorflow as tf
import tensorflow_io as tfio

@remote
def train(data_path: str, params):

    dataset = tf.data.TextLineDataset(tf.data.Dataset.list_files(f"{data_path}/*.txt"))
    ...

train("s3://amzn-s3-demo-bucket/data", {})
```

Best practices for PyTorch models

PyTorch models are serializable and can be passed between your local environment and remote function. If your local environment and remote environment have different device types, such as (GPUs and CPUs), you cannot return a trained model to your local environment. For example, if the following code is developed in a local environment without GPUs but run in an instance with GPUs, returning the trained model directly will lead to a `DeserializationError`.

```
# Do not return a model trained on GPUs to a CPU-only environment as follows

@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu") # a device without GPU capabilities

    model = Net().to(device)

    # train the model
    ...

    return model

model = train(...) #returns a DeserializationError if run on a device with GPU
```

To return a model trained in a GPU environment to one that contains only CPU capabilities, use the PyTorch model I/O APIs directly as shown in the code example below.

```
import s3fs
```

```
model_path = "s3://amzn-s3-demo-bucket/folder/"

@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu")

    model = Net().to(device)

    # train the model
    ...

    fs = s3fs.FileSystem()
    with fs.open(os.path.join(model_path, 'model.pt'), 'wb') as file:
        torch.save(model.state_dict(), file) #this writes the model in a device-
agnostic way (CPU vs GPU)

train(...) #use the model to train on either CPUs or GPUs

model = Net()
fs = s3fs.FileSystem()with fs.open(os.path.join(model_path, 'model.pt'), 'rb') as file:
    model.load_state_dict(torch.load(file, map_location=torch.device('cpu')))
```

Where SageMaker AI stores your serialized data

When you invoke a remote function, SageMaker AI automatically serializes your function arguments and return values during the input and output stages. This serialized data is stored under a root directory in your S3 bucket. You specify the root directory, `<s3_root_uri>`, in a configuration file. The parameter `job_name` is automatically generated for you.

Under the root directory, SageMaker AI creates a `<job_name>` folder, which holds your current work directory, serialized function, the arguments for your serialized function, results and any exceptions that arose from invoking the serialized function.

Under `<job_name>`, the directory `workdir` contains a zipped archive of your current working directory. The zipped archive includes any Python files in your working directory and the `requirements.txt` file, which specifies any dependencies needed to run your remote function.

The following is an example of the folder structure under an S3 bucket that you specify in your configuration file.

```
<s3_root_uri>/ # specified by s3_root_uri or S3RootUri
    <job_name>/ #automatically generated for you
        workdir/workspace.zip # archive of the current working directory (workdir)
        function/ # serialized function
        arguments/ # serialized function arguments
        results/ # returned output from the serialized function including the model
        exception/ # any exceptions from invoking the serialized function
```

The root directory that you specify in your S3 bucket is not meant for long term storage. The serialized data are tightly tied to the Python version and machine learning (ML) framework version that were used during serialization. If you upgrade the Python version or ML framework, you may not be able to use your serialized data. Instead, do the following.

- Store your model and model artifacts in a format that is agnostic to your Python version and ML framework.
- If you upgrade your Python or ML framework, access your model results from your long-term storage.

Important

To delete your serialized data after a specified amount of time, set a lifetime configuration on your S3 bucket.

Note

Files that are serialized with the Python pickle module can be less portable than other data formats including CSV, Parquet and JSON. Be wary of loading pickled files from unknown sources.

For more information about what to include in a configuration file for a remote function, see Configuration File.

Access to your serialized data

Administrators can provide settings for your serialized data, including its location and any encryption settings in a configuration file. By default, the serialized data are encrypted with an AWS Key Management Service (AWS KMS) Key. Administrators can also restrict access to the root directory that you specify in your configuration file with a bucket policy. The configuration file can be shared and used across projects and jobs. For more information, see Configuration File.

Use the `RemoteExecutor` API to invoke a function

You can use the `RemoteExecutor` API to invoke a function. SageMaker AI Python SDK will transform the code inside the `RemoteExecutor` call into a SageMaker AI training job. The training job will then invoke the function as an asynchronous operation and return a future. If you use the `RemoteExecutor` API, you can run more than one training job in parallel. For more information about futures in Python, see Futures.

The following code example shows how to import the required libraries, define a function, start a SageMaker AI instance, and use the API to submit a request to run 2 jobs in parallel.

```
from sagemaker.remote_function import RemoteExecutor

def matrix_multiply(a, b):
    return np.matmul(a, b)

a = np.array([[1, 0],
             [0, 1]])
b = np.array([1, 2])

with RemoteExecutor(max_parallel_job=2, instance_type="ml.m5.large") as e:
    future = e.submit(matrix_multiply, a, b)

assert (future.result() == np.array([1,2])).all()
```

The `RemoteExecutor` class is an implementation of the concurrent.futures.Executor library.

The following code example shows how to define a function and call it using the `RemoteExecutorAPI`. In this example, the `RemoteExecutor` will submit 4 jobs in total, but only 2 in parallel. The last two jobs will reuse the clusters with minimal overhead.

```
from sagemaker.remote_function.client import RemoteExecutor
```

```
def divide(a, b):
    return a/b

with RemoteExecutor(max_parallel_job=2, keep_alive_period_in_seconds=60) as e:
    futures = [e.submit(divide, a, 2) for a in [3, 5, 7, 9]]

for future in futures:
    print(future.result())
```

The `max_parallel_job` parameter only serves as a rate limiting mechanism without optimizing compute resource allocation. In the previous code example, `RemoteExecutor` doesn't reserve compute resources for the two parallel jobs before any jobs are submitted. For more information about `max_parallel_job` or other parameters for the @remote decorator, see Remote function classes and methods specification.

Future class for the `RemoteExecutor` API

A future class is a public class that represents the return function from the training job when it is invoked asynchronously. The future class implements the concurrent.futures.Future class. This class can be used to do operations on the underlying job and load data into memory.

Configuration file

The Amazon SageMaker Python SDK supports setting of default values for AWS infrastructure primitive types. After administrators configure these defaults, they are automatically passed when SageMaker Python SDK calls supported APIs. The arguments for the decorator function can be put inside of configuration files. This is so that you can separate settings that are related to the infrastructure from the code base. For more information about parameters and arguments for the remote function and methods, see Remote function classes and methods specification.

You can set infrastructure settings for the network configuration, IAM roles, Amazon S3 folder for input, output data, and tags inside the configuration file. The configuration file can be used when invoking a function using either the @remote decorator or the `RemoteExecutor` API.

An example configuration file that defines the dependencies, resources, and other arguments follows. This example configuration file is used to invoke a function that is initiated either using the @remote decorator or the RemoteExecutor API.

```
SchemaVersion: '1.0'
SageMaker:
```

```
  PythonSDK:
    Modules:
      RemoteFunction:
        Dependencies: 'path/to/requirements.txt'
        EnableInterContainerTrafficEncryption: true
        EnvironmentVariables: {'EnvVarKey': 'EnvVarValue'}
        ImageUri: '366666666666.dkr.ecr.us-west-2.amazonaws.com/my-image:latest'
        IncludeLocalWorkDir: true
        CustomFileFilter:
          IgnoreNamePatterns:
          - "*.ipynb"
          - "data"
        InstanceType: 'ml.m5.large'
        JobCondaEnvironment: 'your_conda_env'
        PreExecutionCommands:
            - 'command_1'
            - 'command_2'
        PreExecutionScript: 'path/to/script.sh'
        RoleArn: 'arn:aws:iam::366666666666:role/MyRole'
        S3KmsKeyId: 'yourkmskeyid'
        S3RootUri: 's3://amzn-s3-demo-bucket/my-project'
        VpcConfig:
            SecurityGroupIds:
            - 'sg123'
            Subnets:
            - 'subnet-1234'
        Tags: [{'Key': 'yourTagKey', 'Value':'yourTagValue'}]
        VolumeKmsKeyId: 'yourkmskeyid'
```

The @remote decorator and `RemoteExecutor` will look for `Dependencies` in the following configuration files:

- An admin-defined configuration file.
- A user-defined configuration file.

The default locations for these configuration files depend on, and are relative to, your environment. The following code example returns the default location of your admin and user configuration files. These commands must be run in the same environment where you're using the SageMaker Python SDK.

```
import os
```

```
from platformdirs import site_config_dir, user_config_dir

#Prints the location of the admin config file
print(os.path.join(site_config_dir("sagemaker"), "config.yaml"))

#Prints the location of the user config file
print(os.path.join(user_config_dir("sagemaker"), "config.yaml"))
```

You can override the default locations of these files by setting the `SAGEMAKER_ADMIN_CONFIG_OVERRIDE` and `SAGEMAKER_USER_CONFIG_OVERRIDE` environment variables for the admin-defined and user-defined configuration file paths, respectively.

If a key exists in both the admin-defined and user-defined configuration files, the value in the user-defined file will be used.

Customize your runtime environment

You can customize your runtime environment to use your preferred local integrated development environments (IDEs), SageMaker notebooks, or SageMaker Studio Classic notebooks to write your ML code. SageMaker AI will help package and submit your functions and its dependencies as a SageMaker training job. This allows you to access the capacity of the SageMaker training server to run your training jobs.

Both the remote decorator and the `RemoteExecutor` methods to invoke a function allow users to define and customize their runtime environment. You can use either a `requirements.txt` file or a conda environment YAML file.

To customize a runtime environment using both a conda environment YAML file and a `requirements.txt` file, refer to the following code example.

```
# specify a conda environment inside a yaml file
@remote(instance_type="ml.m5.large",
        image_uri = "my_base_python:latest",
        dependencies = "./environment.yml")
def matrix_multiply(a, b):
    return np.matmul(a, b)

# use a requirements.txt file to import dependencies
@remote(instance_type="ml.m5.large",
        image_uri = "my_base_python:latest",
        dependencies = './requirements.txt')
def matrix_multiply(a, b):
```

```
    return np.matmul(a, b)
```

Alternatively, you can set `dependencies` to `auto_capture` to let the SageMaker Python SDK capture the installed dependencies in the active conda environment. The following are required for `auto_capture` to work reliably:

- You must have an active conda environment. We recommend not using the `base` conda environment for remote jobs so that you can reduce potential dependency conflicts. Not using the `base` conda environment also allows for faster environment setup in the remote job.
- You must not have any dependencies installed using pip with a value for the parameter `--extra-index-url`.
- You must not have any dependency conflicts between packages installed with conda and packages installed with pip in the local development environment.
- Your local development environment must not contain operating system-specific dependencies that are not compatible with Linux.

In case `auto_capture` does not work, we recommend that you pass in your dependencies as a requirement.txt or conda environment.yaml file, as described in the first coding example in this section.

Container image compatibility

The following table shows a list of SageMaker training images that are compatible with the @remote decorator.

Name	Python Version	Image URI - CPU	Image URI - GPU
Data Science	3.7(py37)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.

Name	Python Version	Image URI - CPU	Image URI - GPU
Data Science 2.0	3.8(py38)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.
Data Science 3.0	3.10(py310)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.
Base Python 2.0	3.8(py38)	Python SDK selects this image when it detects that development environment is using Python 3.8 runtime. Otherwise Python SDK automatic ally selects this image when used as SageMaker Studio Classic Notebook kernel image	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.

Name	Python Version	Image URI - CPU	Image URI - GPU
Base Python 3.0	3.10(py310)	Python SDK selects this image when it detects that development environment is using Python 3.8 runtime. Otherwise Python SDK automatically selects this image when used as SageMaker Studio Classic Notebook kernel image	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as Studio Classic Notebook kernel image.

Note

To run jobs locally using AWS Deep Learning Containers (DLC) images, use the image URIs found in the DLC documentation. The DLC images do not support the `auto_capture` value for dependencies.

Jobs with SageMaker AI Distribution in SageMaker Studio run in a container as a non-root user named `sagemaker-user`. This user needs full permission to access `/opt/ml` and `/tmp`. Grant this permission by adding `sudo chmod -R 777 /opt/ml /tmp` to the `pre_execution_commands` list, as shown in the following snippet:

```
@remote(pre_execution_commands=["sudo chmod -R 777 /opt/ml /tmp"])
def func():
    pass
```

You can also run remote functions with your custom images. For compatibility with remote functions, custom images should be built with Python version 3.7.x-3.10.x. The following is a minimal Dockerfile example showing you how to use a Docker image with Python 3.10.

```
FROM python:3.10
```

```
#... Rest of the Dockerfile
```

To create conda environments in your image and use it to run jobs, set the environment variable SAGEMAKER_JOB_CONDA_ENV to the conda environment name. If your image has the SAGEMAKER_JOB_CONDA_ENV value set, the remote function cannot create a new conda environment during the training job runtime. Refer to the following Dockerfile example that uses a conda environment with Python version 3.10.

```
FROM continuumio/miniconda3:4.12.0

ENV SHELL=/bin/bash \
    CONDA_DIR=/opt/conda \
    SAGEMAKER_JOB_CONDA_ENV=sagemaker-job-env

RUN conda create -n $SAGEMAKER_JOB_CONDA_ENV \
   && conda install -n $SAGEMAKER_JOB_CONDA_ENV python=3.10 -y \
   && conda clean --all -f -y \
```

For SageMaker AI to use [mamba](https://mamba.readthedocs.io/) to manage your Python virtual environment in the container image, install the [mamba toolkit from miniforge](https://github.com/conda-forge/miniforge). To use mamba, add the following code example to your Dockerfile. Then, SageMaker AI will detect the mamba availability at runtime and use it instead of conda.

```
#Mamba Installation
RUN curl -L -O "https://github.com/conda-forge/miniforge/releases/latest/download/
Mambaforge-Linux-x86_64.sh" \
    && bash Mambaforge-Linux-x86_64.sh -b -p "/opt/conda"  \
    && /opt/conda/bin/conda init bash
```

Using a custom conda channel on an Amazon S3 bucket is not compatible with mamba when using a remote function. If you choose to use mamba, make sure you are not using a custom conda channel on Amazon S3. For more information, see the **Prerequisites** section under **Custom conda repository using Amazon S3**.

The following is a complete Dockerfile example showing how to create a compatible Docker image.

```
FROM python:3.10

RUN apt-get update -y \
    # Needed for awscli to work
    # See: https://github.com/aws/aws-cli/issues/1957#issuecomment-687455928
```

```
    && apt-get install -y groff unzip curl \
    && pip install --upgrade \
        'boto3>1.0<2' \
        'awscli>1.0<2' \
        'ipykernel>6.0.0<7.0.0' \
#Use ipykernel with --sys-prefix flag, so that the absolute path to
    #/usr/local/share/jupyter/kernels/python3/kernel.json python is used
    # in kernelspec.json file
    && python -m ipykernel install --sys-prefix

#Install Mamba
RUN curl -L -O "https://github.com/conda-forge/miniforge/releases/latest/download/
Mambaforge-Linux-x86_64.sh" \
    && bash Mambaforge-Linux-x86_64.sh -b -p "/opt/conda"  \
    && /opt/conda/bin/conda init bash

#cleanup
RUN apt-get clean \
    && rm -rf /var/lib/apt/lists/* \
    && rm -rf ${HOME}/.cache/pip \
    && rm Mambaforge-Linux-x86_64.sh

ENV SHELL=/bin/bash \
    PATH=$PATH:/opt/conda/bin
```

The resulting image from running the previous Dockerfile example can also be used as a SageMaker Studio Classic kernel image.

Logging parameters and metrics with Amazon SageMaker Experiments

This guide show how to log parameters and metrics with Amazon SageMaker Experiments. A SageMaker AI experiment consists of runs, and each run consists of all the inputs, parameters, configurations and results for a single model training interaction.

You can log parameters and metrics from a remote function using either the @remote decorator or the `RemoteExecutor` API.

To log parameters and metrics from a remote function, choose one of the following methods:

- Instantiate a SageMaker AI experiment run inside a remote function using Run from the SageMaker Experiments library. For more information, see Create an Amazon SageMaker AI Experiment.

- Use the `load_run` function inside a remote function from the SageMaker AI Experiments library. This will load a Run instance that is declared outside of the remote function.

The following sections show how to create and track lineage with SageMaker AI experiment runs by using the previous listed methods. The sections also describe cases that are not supported by SageMaker training.

Use the @remote decorator to integrate with SageMaker Experiments

You can either instantiate an experiment in SageMaker AI, or load a current SageMaker AI experiment from inside a remote function. The following sections show you show to use either method.

Create an experiment with SageMaker Experiments

You can create an experiment run in SageMaker AI experiment. To do this you pass your experiment name, run name, and other parameters into your remote function.

The following code example imports the name of your experiment, the name of the run, and the parameters to log during each run. The parameters `param_1` and `param_2` are logged over time inside a training loop. Common parameters may include batch size or epochs. In this example, the metrics `metric_a` and `metric_b` are logged for a run over time inside a training loop. Other common metrics may include `accuracy` or `loss`.

```
from sagemaker.remote_function import remote
from sagemaker.experiments.run import Run

# Define your remote function
@remote
def train(value_1, value_2, exp_name, run_name):
    ...
    ...
    #Creates the experiment
    with Run(
        experiment_name=exp_name,
        run_name=run_name,
    ) as run:
        ...
        #Define values for the parameters to log
        run.log_parameter("param_1", value_1)
```

```
        run.log_parameter("param_2", value_2)
        ...
        #Define metrics to log
        run.log_metric("metric_a", 0.5)
        run.log_metric("metric_b", 0.1)

# Invoke your remote function
train(1.0, 2.0, "my-exp-name", "my-run-name")
```

Load current SageMaker Experiments with a job initiated by the @remote decorator

Use the `load_run()` function from the SageMaker Experiments library to load the current run object from the run context. You can also use the `load_run()` function within your remote function. Load the run object initialized locally by the `with` statement on the run object as shown in the following code example.

```
from sagemaker.experiments.run import Run, load_run

# Define your remote function
@remote
def train(value_1, value_2):
    ...
    ...
    with load_run() as run:
        run.log_metric("metric_a", value_1)
        run.log_metric("metric_b", value_2)

# Invoke your remote function
with Run(
    experiment_name="my-exp-name",
    run_name="my-run-name",
) as run:
    train(0.5, 1.0)
```

Load a current experiment run within a job initiated with the `RemoteExecutor` API

You can also load a current SageMaker AI experiment run if your jobs were initiated with the `RemoteExecutor` API. The following code example shows how to use `RemoteExecutor` API with the SageMaker Experiments `load_run` function. You do this to load a current SageMaker AI experiment run and capture metrics in the job submitted by `RemoteExecutor`.

```
from sagemaker.experiments.run import Run, load_run

def square(x):
    with load_run() as run:
        result = x * x
        run.log_metric("result", result)
    return result

with RemoteExecutor(
    max_parallel_job=2,
    instance_type="ml.m5.large"
) as e:
    with Run(
        experiment_name="my-exp-name",
        run_name="my-run-name",
    ):
        future_1 = e.submit(square, 2)
```

Unsupported uses for SageMaker Experiments while annotating your code with an @remote decorator

SageMaker AI does not support passing a Run type object to an @remote function or using global Run objects. The following examples show code that will throw a `SerializationError`.

The following code example attempts to pass a Run type object to an @remote decorator, and it generates an error.

```
@remote
def func(run: Run):
    run.log_metrics("metric_a", 1.0)

with Run(...) as run:
    func(run) ---> SerializationError caused by NotImplementedError
```

The following code example attempts to use a global `run` object instantiated outside of the remote function. In the code example, the `train()` function is defined inside the `with Run` context, referencing a global run object from within. When `train()` is called, it generates an error.

```
with Run(...) as run:
    @remote
    def train(metric_1, value_1, metric_2, value_2):
        run.log_parameter(metric_1, value_1)
        run.log_parameter(metric_2, value_2)

    train("p1", 1.0, "p2", 0.5) ---> SerializationError caused by NotImplementedError
```

Using modular code with the @remote decorator

You can organize your code into modules for ease of workspace management during development and still use the @remote function to invoke a function. You can also replicate the local modules from your development environment to the remote job environment. To do so, set the parameter `include_local_workdir` to `True`, as shown in the following code example.

```
@remote(
  include_local_workdir=True,
)
```

> **Note**
>
> The @remote decorator and parameter must appear in the main file, rather than in any of the dependent files.

When `include_local_workdir` is set to `True`, SageMaker AI packages all of the Python scripts while maintaining the directory structure in the process' current directory. It also makes the dependencies available in the job's working directory.

For example, suppose your Python script which processes the MNIST dataset is divided into a `main.py` script and a dependent `pytorch_mnist.py` script. `main.py` calls the dependent script. Also, the `main.py` script contains code to import the dependency as shown.

```
from mnist_impl.pytorch_mnist import ...
```

The `main.py` file must also contain the `@remote` decorator, and it must set the `include_local_workdir` parameter to `True`.

The `include_local_workdir` parameter by default includes all the Python scripts in the directory. You can customize which files you want to upload to the job by using this parameter in conjunction with the `custom_file_filter` parameter. You can either pass a function that filters job dependencies to be uploaded to S3, or a `CustomFileFilter` object that specifies the local directories and files to ignore in the remote function. You can use `custom_file_filter` only if `include_local_workdir` is set to `True`—otherwise the parameter is ignored.

The following example uses `CustomFileFilter` to ignore all notebook files and folders or files named `data` when uploading files to S3.

```
@remote(
   include_local_workdir=True,
   custom_file_filter=CustomFileFilter(
      ignore_pattern_names=[ # files or directories to ignore
        "*.ipynb", # all notebook files
        "data", # folter or file named data
      ]
   )
)
```

The following example demonstrates how you can package an entire workspace.

```
@remote(
   include_local_workdir=True,
   custom_file_filter=CustomFileFilter(
      ignore_pattern_names=[] # package whole workspace
   )
)
```

The following example shows how you can use a function to filter files.

```
import os

def my_filter(path: str, files: List[str]) -> List[str]:
    to_ignore = []
   for file in files:
       if file.endswith(".txt") or file.endswith(".ipynb"):
           to_ignore.append(file)
   return to_ignore

@remote(
```

```
    include_local_workdir=True,
    custom_file_filter=my_filter
)
```

Best practices in structuring your working directory

The following best practices suggest how you can organize your directory structure while using the `@remote` decorator in your modular code.

- Put the @remote decorator in a file that resides at the root level directory of the workspace.
- Structure the local modules at the root level.

The following example image shows the recommended directory structure. In this example structure, the `main.py` script is located at the root level directory.

```
.
### config.yaml
### data/
### main.py <----------------- @remote used here
### mnist_impl
# ### __pycache__/
# # ### pytorch_mnist.cpython-310.pyc
# ### pytorch_mnist.py <-------- dependency of main.py
### requirements.txt
```

The following example image shows a directory structure that will result in inconsistent behavior when it is used to annotate your code with an @remote decorator.

In this example structure, the `main.py` script that contains the @remote decorator is **not** located at the root level directory. The following structure is **NOT** recommended.

```
.
### config.yaml
### entrypoint
# ### data
# ### main.py <----------------- @remote used here
### mnist_impl
# ### __pycache__
# # ### pytorch_mnist.cpython-310.pyc
# ### pytorch_mnist.py <-------- dependency of main.py
```

```
### requirements.txt
```

Private repository for runtime dependencies

You can use pre-execution commands or script to configure a dependency manager like pip or conda in your job environment. To achieve network isolation, use either of these options to redirect your dependency managers to access your private repositories and run remote functions within a VPC. The pre-execution commands or script will run before your remote function runs. You can define them with the @remote decorator, the `RemoteExecutor` API, or within a configuration file.

The following sections show you how to access a private Python Package Index (PyPI) repository managed with AWS CodeArtifact. The sections also show how to access a custom conda channel hosted on Amazon Simple Storage Service (Amazon S3).

How to use a custom PyPI repository managed with AWS CodeArtifact

To use CodeArtifact to manage a custom PyPI repository, the following prerequisites are required:

- Your private PyPI repository should already have been created. You can utilize AWS CodeArtifact to create and manage your private package repositories. To learn more about CodeArtifact, see the CodeArtifact User Guide.
- Your VPC should have access to your CodeArtifact repository. To allow a connection from your VPC to your CodeArtifact repository, you must do the following:
  - Create VPC endpoints for CodeArtifact.
  - Create an Amazon S3 gateway endpoint for your VPC, which allows CodeArtifact to store package assets.

The following pre-execution command example shows how to configure pip in the SageMaker AI training job to point to your CodeArtifact repository. For more information, see Configure and use pip with CodeArtifact.

```
# use a requirements.txt file to import dependencies
@remote(
    instance_type="ml.m5.large"
    image_uri = "my_base_python:latest",
    dependencies = './requirements.txt',
    pre_execution_commands=[
```

```
        "aws codeartifact login --tool pip --domain my-org --domain-owner
 <000000000000> --repository my-codeartifact-python-repo --endpoint-url https://vpce-
xxxxx.api.codeartifact.us-east-1.vpce.amazonaws.com"
    ]
)
def matrix_multiply(a, b):
    return np.matmul(a, b)
```

How to use a custom conda channel hosted on Amazon S3

To use Amazon S3 to manage a custom conda repository, the following prerequisites are required:

- Your private conda channel must already be set up in your Amazon S3 bucket, and all dependent packages must be indexed and uploaded to your Amazon S3 bucket. For instructions on how to index your conda packages, see Creating custom channels.
- Your VPC should have access to the Amazon S3 bucket. For more information, see Endpoints for Amazon S3.
- The base conda environment in your job image should have `boto3` installed. To check your environment, enter the following in your Anaconda prompt to check that `boto3` appears in the resulting generated list.

  ```
  conda list -n base
  ```
- You job image should be installed with conda, not mamba. To check your environment, ensure that the previous code prompt does not return `mamba`.

The following pre-execution commands example shows how to configure conda in the SageMaker training job to point to your private channel on Amazon S3 The pre-execution commands removes the defaults channel and adds custom channels to a `.condarc` conda configuration file.

```
# specify your dependencies inside a conda yaml file
@remote(
    instance_type="ml.m5.large"
    image_uri = "my_base_python:latest",
    dependencies = "./environment.yml",
    pre_execution_commands=[
        "conda config --remove channels 'defaults'"
        "conda config --add channels 's3://my_bucket/my-conda-repository/conda-
forge/'",
```

```
        "conda config --add channels 's3://my_bucket/my-conda-repository/main/'"
    ]
)
def matrix_multiply(a, b):
    return np.matmul(a, b)
```

Example notebooks

You can transform a training code in an existing workspace environment and any associated data processing code and datasets into a SageMaker training job. The following notebooks show you how to customize your environment, job settings, and more for an image classification problem, using the XGBoost algorithm and Hugging Face.

The quick_start notebook contains the following code examples:

- How to customize your job settings with a configuration file.
- How to invoke Python functions as jobs, asynchronously.
- How to customize the job runtime environment by bringing in additional dependencies.
- How to use local dependencies with the @remote function method.

The following notebooks provide additional code examples for different ML problems types and implementations.

- To see code examples to use the @remote decorator for an image classification problem, open the pytorch_mnist.ipynb notebook. This classification problem recognizes handwritten digits using the Modified National Institute of Standards and Technology (MNIST) sample dataset.
- To see code examples for using the @remote decorator for the previous image classification problem with a script, see the Pytorch MNIST sample script, train.py.
- To see how the XGBoost algorithm implemented with an @remote decorator: Open the xgboost_abalone.ipynb notebook.
- To see how Hugging Face is integrated with an @remote decorator: Open the huggingface.ipynb notebook.

Accelerate generative AI development using managed MLflow on Amazon SageMaker AI

Fully managed MLflow 3.0 on Amazon SageMaker AI enables you to accelerate generative AI by making it easier to track experiments and monitor performance of models and AI applications using a single tool.

Generative AI development with MLflow 3.0

As customers across industries accelerate their generative AI development, they require capabilities to track experiments, observe behavior, and evaluate performance of models and AI applications. Data scientists and developers lack tools for analyzing the performance of models and AI applications from experimentation to production, making it hard to root cause and resolve issues. Teams spend more time integrating tools than improving their models or generative AI applications.

Training or fine-tuning generative AI and machine learning is an iterative process that requires experimenting with various combinations of data, algorithms, and parameters, while observing their impact on model accuracy. The iterative nature of experimentation results in numerous model training runs and versions, making it challenging to track the best performing models and their configurations. The complexity of managing and comparing iterative training runs increases with GenAI, where experimentation involves not only fine-tuning models but also exploring creative and diverse outputs. Researchers must adjust hyperparameters, select suitable model architectures, and curate diverse datasets to optimize both the quality and creativity of the generated content. Evaluating generative AI models requires both quantitative and qualitative metrics, adding another layer of complexity to the experimentation process. Experimentation tracking capabilities in MLflow 3.0 on Amazon SageMaker AI enables you to track, organize, view, analyze, and compare iterative ML experimentation to gain comparative insights and register and deploy your best performing models.

Tracing capabilities in fully managed MLflow 3.0 enables you to record the inputs, outputs, and metadata at every step of a generative AI application, helping you to quickly identify the source of bugs or unexpected behaviors. By maintaining records of each model and application version, fully managed MLflow 3.0 offers traceability to connect AI responses to their source components, allowing you to quickly trace an issue directly to the specific code, data, or parameters that generated it. This dramatically reduces troubleshooting time and enables teams to focus more on innovation.

MLflow integrations

Use MLflow while training and evaluating models to find the best candidates for your use case. You can compare model performance, parameters, and metrics across experiments in the MLflow UI, keep track of your best models in the MLflow Model Registry, automatically register them as a SageMaker AI model, and deploy registered models to SageMaker AI endpoints.

Amazon SageMaker AI with MLflow

Use MLflow to track and manage the experimentation phase of the machine learning (ML) lifecycle with AWS integrations for model development, management, deployment, and tracking.

Amazon SageMaker Studio

Create and manage tracking servers, run notebooks to create experiments, and access the MLflow UI to view and compare experiment runs all through Studio.

SageMaker Model Registry

Manage model versions and catalog models for production by automatically registering models from MLflow Model Registry to SageMaker Model Registry. For more information, see Automatically register SageMaker AI models with SageMaker Model Registry.

SageMaker AI Inference

Prepare your best models for deployment on a SageMaker AI endpoint using `ModelBuilder`. For more information, see Deploy MLflow models with `ModelBuilder`.

AWS Identity and Access Management

Configure access to MLflow using role-based access control (RBAC) with IAM. Write IAM identity policies to authorize the MLflow APIs that can be called by a client of an MLflow tracking server. All MLflow REST APIs are represented as IAM actions under the `sagemaker-mlflow` service prefix. For more information, see Set up IAM permissions for MLflow.

AWS CloudTrail

View logs in AWS CloudTrail to help you enable operational and risk auditing, governance, and compliance of your AWS account. For more information, see AWS CloudTrail logs.

Amazon EventBridge

Automate the model review and deployment lifecycle using MLflow events captured by Amazon EventBridge. For more information, see Amazon EventBridge events.

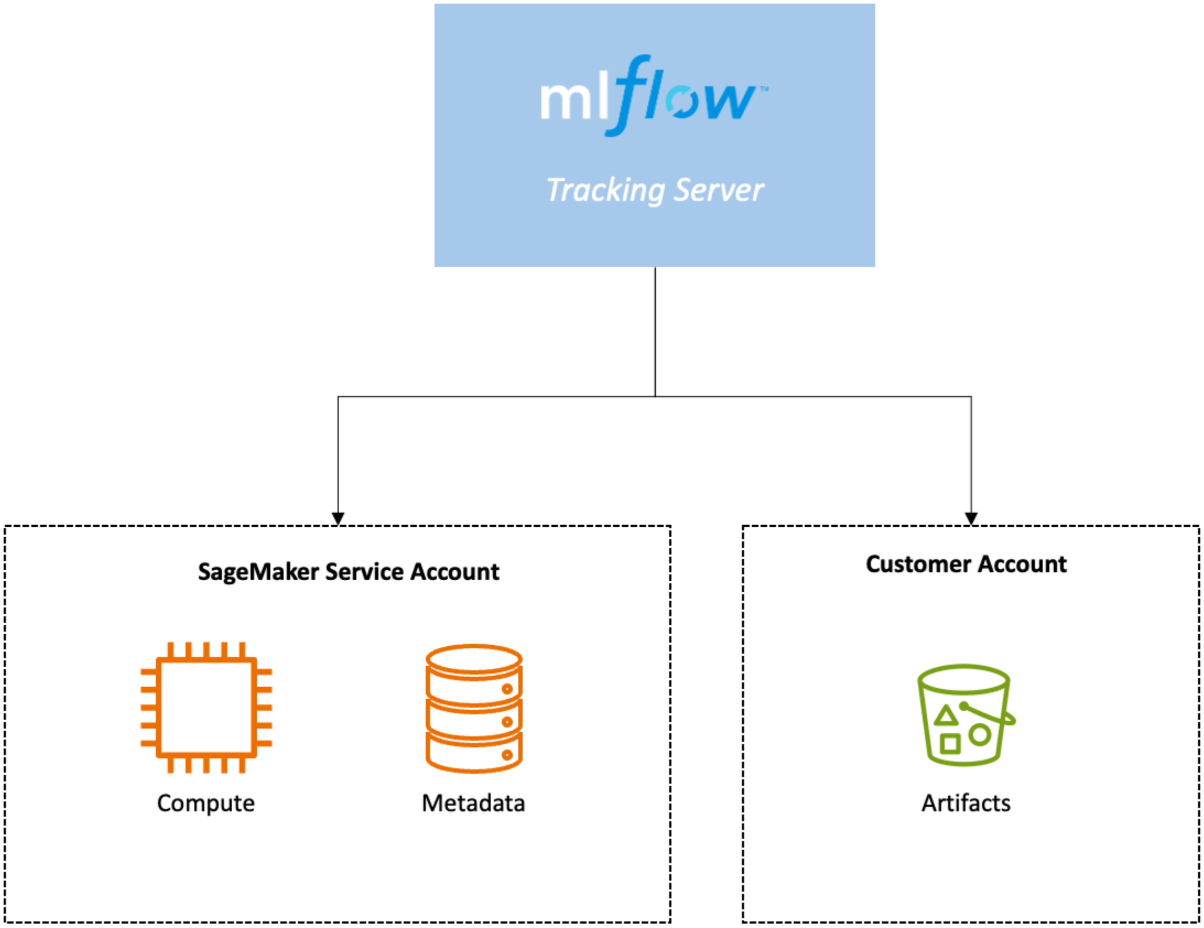
Supported AWS Regions

Amazon SageMaker AI with MLflow is generally available in all AWS commercial Regions where Amazon SageMaker Studio is available, except the China Regions and AWS GovCloud (US) Regions. SageMaker AI with MLflow is available using only the AWS CLI in the Europe (Zurich), Asia Pacific (Hyderabad), Asia Pacific (Melbourne), and Canada West (Calgary) AWS Regions.

Tracking servers are launched in a single availability zone within their specified Region.

How it works

An MLflow Tracking Server has three main components: compute, backend metadata storage, and artifact storage. The compute that hosts the tracking server and the backend metadata storage are securely hosted in the SageMaker AI service account. The artifact storage lives in an Amazon S3 bucket in your own AWS account.



A tracking server has an ARN. You can use this ARN to connect the MLflow SDK to your Tracking Server and start logging your training runs to MLflow.

Read on for more information about the following key concepts:

- Backend metadata storage
- Artifact storage
- MLflow Tracking Server sizes
- Tracking server versions
- AWS CloudTrail logs
- Amazon EventBridge events

Backend metadata storage

When you create an MLflow Tracking Server, a backend store, which persists various metadata for each Run, such as run ID, start and end times, parameters, and metrics, is automatically configured within the SageMaker AI service account and fully managed for you.

Artifact storage

To provide MLflow with persistent storage for metadata for each run, such as model weights, images, model files, and data files for your experiment runs, you must create an artifact store using Amazon S3. The artifact store must be set up within your AWS account and you must explicitly give MLflow access to Amazon S3 in order to access your artifact store. For more information, see Artifact Stores in the MLflow documentation.

MLflow Tracking Server sizes

You can optionally specify the size of your tracking server in the Studio UI or with the AWS CLI parameter `--tracking-server-size`. You can choose between `"Small"`, `"Medium"`, and `"Large"`. The default MLflow tracking server configuration size is `"Small"`. You can choose a size depending on the projected use of the tracking server such as the volume of data logged, number of users, and frequency of use.

We recommend using a small tracking server for teams of up to 25 users, a medium tracking server for teams of up to 50 users, and a large tracking server for teams of up to 100 users. We assume that all users will make concurrent requests to your MLflow Tracking Server to make these recommendations. You should select the tracking server size based on your expected usage pattern and the TPS (Transactions Per Second) supported by each tracking server.

> **Note**
>
> The nature of your workload and the type of requests that you make to the tracking server dictate the TPS you see.

Tracking server size	Sustained TPS	Burst TPS
Small	Up to 25	Up to 50
Medium	Up to 50	Up to 100

Tracking server size	Sustained TPS	Burst TPS
Large	Up to 100	Up to 200

Tracking server versions

The following MLflow versions are available to use with SageMaker AI:

MLflow version	Python version
MLflow 3.0 (latest version)	Python 3.9 or later
MLflow 2.16	Python 3.8 or later
MLflow 2.13	Python 3.8 or later

The latest version of the tracking server has the latest features, security patches, and bug fixes. When you create a new tracking server, we recommend using the latest version. For more information about creating a tracking server, see MLflow Tracking Servers.

MLflow tracking servers use semantic versioning. Versions are in the following format: *major-version*.*minor-version*.*patch-version*.

The latest features, such as new UI elements and API functionality, are in the minor-version.

AWS CloudTrail logs

AWS CloudTrail automatically logs activity related to your MLflow Tracking Server. The following control plane API calls are logged in CloudTrail:

- CreateMlflowTrackingServer
- DescribeMlflowTrackingServer
- UpdateMlflowTrackingServer
- DeleteMlflowTrackingServer
- ListMlflowTrackingServers
- CreatePresignedMlflowTrackingServer

- StartMlflowTrackingServer
- StopMlflowTrackingServer

AWS CloudTrail also automatically logs activity related to your MLflow data plane. The following data plane API calls are logged in CloudTrail. For event names, add the prefix `Mlflow` (for example, `MlflowCreateExperiment`).

- CreateExperiment
- CreateModelVersion
- CreateRegisteredModel
- CreateRun
- DeleteExperiment
- DeleteModelVersion
- DeleteModelVersionTag
- DeleteRegisteredModel
- DeleteRegisteredModelAlias
- DeleteRegisteredModelTag
- DeleteRun
- DeleteTag
- GetDownloadURIForModelVersionArtifacts
- GetExperiment
- GetExperimentByName
- GetLatestModelVersions
- GetMetricHistory
- GetModelVersion
- GetModelVersionByAlias
- GetRegisteredModel
- GetRun
- ListArtifacts
- LogBatch

- LogInputs
- LogMetric
- LogModel
- LogParam
- RenameRegisteredModel
- RestoreExperiment
- RestoreRun
- SearchExperiments
- SearchModelVersions
- SearchRegisteredModels
- SearchRuns
- SetExperimentTag
- SetModelVersionTag
- SetRegisteredModelAlias
- SetRegisteredModelTag
- SetTag
- TransitionModelVersionStage
- UpdateExperiment
- UpdateModelVersion
- UpdateRegisteredModel
- UpdateRun
- FinalizeLoggedModel
- GetLoggedModel
- DeleteLoggedModel
- SearchLoggedModels
- SetLoggedModelTags
- DeleteLoggedModelTag
- ListLoggedModelArtifacts
- LogLoggedModelParams

- LogOutputs

For more information about CloudTrail, see the *AWS CloudTrail User Guide*.

Amazon EventBridge events

Use EventBridge to route events from using MLflow with SageMaker AI to consumer applications across your organization. The following events are emitted to EventBridge:

- "SageMaker Tracking Server Creating"
- "SageMaker Tracking Server Created“
- "SageMaker Tracking Server Create Failed"
- "SageMaker Tracking Server Updating"
- "SageMaker Tracking Server Updated"
- "SageMaker Tracking Server Update Failed"
- "SageMaker Tracking Server Deleting"
- "SageMaker Tracking Server Deleted"
- "SageMaker Tracking Server Delete Failed"
- "SageMaker Tracking Server Starting"
- "SageMaker Tracking Server Started"
- "SageMaker Tracking Server Start Failed"
- "SageMaker Tracking Server Stopping"
- "SageMaker Tracking Server Stopped"
- "SageMaker Tracking Server Stop Failed"
- "SageMaker Tracking Server Maintenance In Progress"
- "SageMaker Tracking Server Maintenance Complete"
- "SageMaker Tracking Server Maintenance Failed"
- "SageMaker MLFlow Tracking Server Creating Run"
- "SageMaker MLFlow Tracking Server Creating RegisteredModel"
- "SageMaker MLFlow Tracking Server Creating ModelVersion"
- "SageMaker MLFlow Tracking Server Transitioning ModelVersion Stage"
- "SageMaker MLFlow Tracking Server Setting Registered Model Alias"

For more information about EventBridge, see the *Amazon EventBridge User Guide*.

Topics

- MLflow Tracking Servers
- Launch the MLflow UI using a presigned URL
- Integrate MLflow with your environment
- MLflow tutorials using example Jupyter notebooks
- Troubleshoot common setup issues
- Clean up MLflow resources
- Amazon SageMaker Experiments in Studio Classic

MLflow Tracking Servers

An MLflow Tracking Server is a stand-alone HTTP server that serves multiple REST API endpoints for tracking runs and experiments. A tracking server is required to begin tracking your machine learning (ML) experiments with SageMaker AI and MLflow. You can create a tracking server through the Studio UI, or through the AWS CLI for more granular security customization.

You must have the correct IAM permissions configured to create an MLflow Tracking Server.

Topics

- Set up IAM permissions for MLflow
- Create a tracking server using Studio
- Create a tracking server using the AWS CLI

Set up IAM permissions for MLflow

You must configure the necessary IAM service roles to get started with MLflow in Amazon SageMaker AI.

If you create a new Amazon SageMaker AI domain to access your experiments in Studio, you can configure the necessary IAM permissions during domain setup. For more information, see Set up MLflow IAM permissions when creating a new domain.

To set up permissions using the IAM console, see Create necessary IAM service roles in the IAM console.

You must configure authorization controls for `sagemaker-mlflow` actions. You can optionally define more granular authorization controls to govern action-specific MLflow permissions. For more information, see Create action-specific authorization controls.

Set up MLflow IAM permissions when creating a new domain

When setting up a new Amazon SageMaker AI domain for your organization, you can configure IAM permissions for your domain service role through the **Users and ML Activities** settings.

To configure IAM permissions for using MLflow with SageMaker AI when setting up a new domain

1. Set up a new domain using the SageMaker AI console. On the **Set up SageMaker AI domain** page, choose **Set up for organizations**. For more information, see Custom setup using the console.
2. When setting up **Users and ML Activities**, choose from the following ML activities for MLflow: **Use MLflow**, **Manage MLflow Tracking Servers**, and **Access required to AWS Services for MLflow**. For more information about these activities, see the explanations that follow this procedure.
3. Complete the setup and creation of your new domain.

The following MLflow ML activities are available in Amazon SageMaker Role Manager:

- **Use MLflow**: This ML activity grants the domain service role permission to call MLflow REST APIs in order to manage experiments, runs, and models in MLflow.
- **Manage MLflow Tracking Servers**: This ML activity grants the domain service role permission to create, update, start, stop, and delete tracking servers.
- **Access required to AWS Services for MLflow**: This ML activity provides the domain service role permissions needed to access Amazon S3 and the SageMaker AI Model Registry. This allows you to use the domain service role as the tracking server service role.

For more information about ML activities in Role Manager, see ML activity reference.

Create necessary IAM service roles in the IAM console

If you did not create or update your domain service role, you must instead create the following service roles in the IAM console in order to create and use an MLflow Tracking Server:

- A tracking server IAM service role that the tracking server can use to access SageMaker AI resources
- A SageMaker AI IAM service role that SageMaker AI can use to create and manage MLflow resources

IAM policies for the tracking server IAM service role

The tracking server IAM service role is used by the tracking server to access the resources it needs such as Amazon S3 and the SageMaker Model Registry.

When creating the tracking server IAM service role, use the following IAM trust policy:

JSON

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Principal": {
                 "Service": [
                      "sagemaker.amazonaws.com"
                 ]
             },
             "Action": "sts:AssumeRole"
         }
     ]
 }
```

In the IAM console, add the following permissions policy to your tracking server service role:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "s3:Get*",
                "s3:Put*",
                "s3:List*",
                "sagemaker:AddTags",
                "sagemaker:CreateModelPackageGroup",
                "sagemaker:CreateModelPackage",
                "sagemaker:UpdateModelPackage",
                "sagemaker:DescribeModelPackageGroup"
            ],
            "Resource": "*"
        }
    ]
}
```

IAM policy for the SageMaker AI IAM service role

The SageMaker AI service role is used by the client accessing the MLflow Tracking Server and needs permissions to call MLflow REST APIs. The SageMaker AI service role also needs SageMaker API permissions to create, view update, start, stop, and delete tracking servers.

You can create a new role or update an existing role. The SageMaker AI service role needs the following policy:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker-mlflow:*",
                "sagemaker:CreateMlflowTrackingServer",
                "sagemaker:ListMlflowTrackingServers",
                "sagemaker:UpdateMlflowTrackingServer",
                "sagemaker:DeleteMlflowTrackingServer",
                "sagemaker:StartMlflowTrackingServer",
                "sagemaker:StopMlflowTrackingServer",
                "sagemaker:CreatePresignedMlflowTrackingServerUrl"
            ],
            "Resource": "*"
```

```
        }
    ]
}
```

Create action-specific authorization controls

You must set up authorization controls for `sagemaker-mlflow`, and can optionally configure action-specific authorization controls to govern more granular MLflow permissions that your users have on an MLflow Tracking Server.

> **Note**
>
> The following steps assume that you have an ARN for an MLflow Tracking Server already available. To learn how to create a tracking server, see Create a tracking server using Studio or Create a tracking server using the AWS CLI.

The following command creates a file called `mlflow-policy.json` that provides your tracking server with IAM permissions for all available SageMaker AI MLflow actions. You can optionally limit the permissions a user has by choosing the specific actions you want that user to perform. For a list of available actions, see IAM actions supported for MLflow.

```
# Replace "Resource":"*" with "Resource":"TrackingServerArn"
# Replace "sagemaker-mlflow:*" with specific actions

printf '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker-mlflow:*",
            "Resource": "*"
        }
    ]
}' > mlflow-policy.json
```

Use the `mlflow-policy.json` file to create an IAM policy using the AWS CLI.

```
aws iam create-policy \
  --policy-name MLflowPolicy \
```

```
  --policy-document file://mlflow-policy.json
```

Retrieve your account ID and attach the policy to your IAM role.

```
# Get your account ID
aws sts get-caller-identity

# Attach the IAM policy using your exported role and account ID
aws iam attach-role-policy \
  --role-name $role_name \
  --policy-arn arn:aws:iam::123456789012:policy/MLflowPolicy
```

IAM actions supported for MLflow

The following SageMaker AI MLflow actions are supported for authorization access control:

- sagemaker-mlflow:AccessUI
- sagemaker-mlflow:CreateExperiment
- sagemaker-mlflow:SearchExperiments
- sagemaker-mlflow:GetExperiment
- sagemaker-mlflow:GetExperimentByName
- sagemaker-mlflow:DeleteExperiment
- sagemaker-mlflow:RestoreExperiment
- sagemaker-mlflow:UpdateExperiment
- sagemaker-mlflow:CreateRun
- sagemaker-mlflow:DeleteRun
- sagemaker-mlflow:RestoreRun
- sagemaker-mlflow:GetRun
- sagemaker-mlflow:LogMetric
- sagemaker-mlflow:LogBatch
- sagemaker-mlflow:LogModel
- sagemaker-mlflow:LogInputs
- sagemaker-mlflow:SetExperimentTag
- sagemaker-mlflow:SetTag

- sagemaker-mlflow:DeleteTag
- sagemaker-mlflow:LogParam
- sagemaker-mlflow:GetMetricHistory
- sagemaker-mlflow:SearchRuns
- sagemaker-mlflow:ListArtifacts
- sagemaker-mlflow:UpdateRun
- sagemaker-mlflow:CreateRegisteredModel
- sagemaker-mlflow:GetRegisteredModel
- sagemaker-mlflow:RenameRegisteredModel
- sagemaker-mlflow:UpdateRegisteredModel
- sagemaker-mlflow:DeleteRegisteredModel
- sagemaker-mlflow:GetLatestModelVersions
- sagemaker-mlflow:CreateModelVersion
- sagemaker-mlflow:GetModelVersion
- sagemaker-mlflow:UpdateModelVersion
- sagemaker-mlflow:DeleteModelVersion
- sagemaker-mlflow:SearchModelVersions
- sagemaker-mlflow:GetDownloadURIForModelVersionArtifacts
- sagemaker-mlflow:TransitionModelVersionStage
- sagemaker-mlflow:SearchRegisteredModels
- sagemaker-mlflow:SetRegisteredModelTag
- sagemaker-mlflow:DeleteRegisteredModelTag
- sagemaker-mlflow:DeleteModelVersionTag
- sagemaker-mlflow:DeleteRegisteredModelAlias
- sagemaker-mlflow:SetRegisteredModelAlias
- sagemaker-mlflow:GetModelVersionByAlias
- sagemaker-mlflow:FinalizeLoggedModel
- sagemaker-mlflow:GetLoggedModel
- sagemaker-mlflow:DeleteLoggedModel

- sagemaker-mlflow:SearchLoggedModels
- sagemaker-mlflow:SetLoggedModelTags
- sagemaker-mlflow:DeleteLoggedModelTag
- sagemaker-mlflow:ListLoggedModelArtifacts
- sagemaker-mlflow:LogLoggedModelParams
- sagemaker-mlflow:LogOutputs

Create a tracking server using Studio

You can create a tracking server from the SageMaker Studio MLflow UI. If you created your SageMaker Studio domain following the **Set up for organizations** workflow, the service role for your SageMaker Studio domain has sufficient permissions to serve as the SageMaker AI IAM service roles and the tracking server IAM service role.

Create a tracking server from the SageMaker Studio MLflow UI with the following steps:

1. Navigate to Studio from the SageMaker AI console. Be sure that you are using the new Studio experience and have updated from Studio Classic. For more information, see Migration from Amazon SageMaker Studio Classic.
2. Choose **MLflow** in the **Applications** pane of the Studio UI.
3. **(Optional)** If have not already created a Tracking Server or if you need to create a new one, you can choose **Create**. Then provide a unique tracking server name and S3 URI for artifact storage and create a tracking server. You can optionally choose **Configure** for more granular tracking server customization.
4. Choose **Create** in the **MLflow Tracking Servers** pane. The Studio domain IAM service role is used for the tracking server IAM service role.
5. Provide a unique name for your tracking server and an Amazon S3 URI for your tracking server artifact store. Your tracking server and the Amazon S3 bucket must be in the **same AWS Region**.

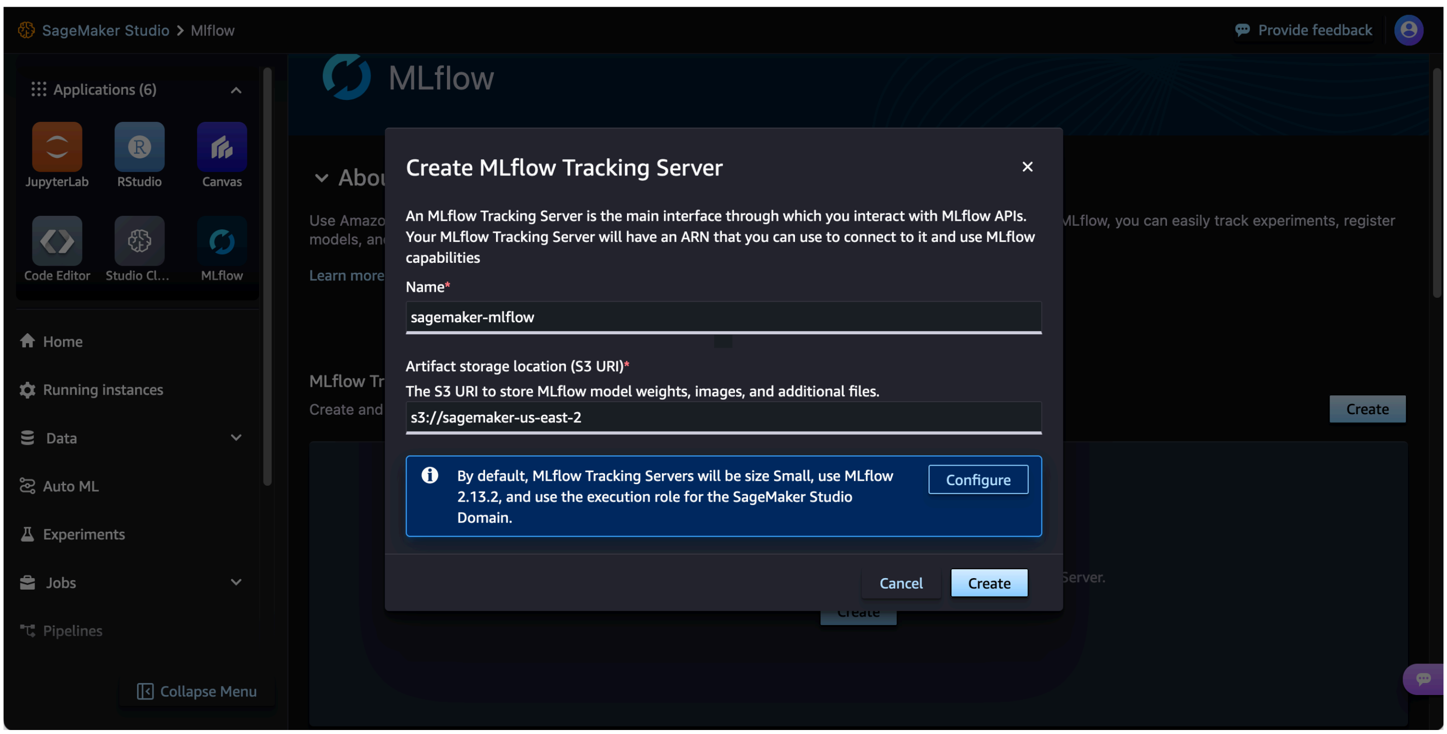
   Important

   When you provide the Amazon S3 URI for your artifact store, ensure the Amazon S3 bucket is in the same AWS Region as your tracking server. **Cross-region artifact storage is not supported**.

6. **(Optional)** Choose **Configure** to change default settings such as tracking server size, tags, and the IAM service role.
7. Choose **Create**.

> **Note**
>
> It may take up to 25 minutes to complete tracking server creation. If the tracking server takes over 25 minutes to create, check that you have the necessary IAM permissions. For more information on IAM permissions, see [Set up IAM permissions for MLflow](). When you successfully create a tracking server, it automatically starts.

8. After creating your tracking server, you can launch the MLflow UI. For more information, see [Launch the MLflow UI using a presigned URL]().



Create a tracking server using the AWS CLI

You can create a tracking server using the AWS CLI for more granular security customization.

Prerequisites

To create a tracking server using the AWS CLI, you must have the following:

- **Access to a terminal.** This can include local IDEs, an Amazon EC2 instance, or AWS CloudShell.
- **Access to a development environment.** This can include local IDEs or a Jupyter notebook environment within Studio or Studio Classic.
- **A configured AWS CLI installation**. For more information, see Configure the AWS CLI.
- **An IAM role with appropriate permissions**. The following steps require your environment to have `iam:CreateRole`, `iam:CreatePolicy`, `iam:AttachRolePolicy`, and `iam:ListPolicies` permissions. These permissions are needed on the role that is being used to run the steps in this user guide. The instructions in this guide create an IAM role that is used as the execution role of the MLflow Tracking Server so that it can access data in your Amazon S3 buckets. Additionally, a policy is created to give the IAM role of the user that is interacting with the Tracking Server via the MLflow SDK permission to call MLflow APIs. For more information, see Modifying a role permissions policy (console) .

  If using a SageMaker Studio Notebook, update the service role for your Studio user profile with these IAM permissions. To update the service role, navigate to the SageMaker AI console and select the domain you are using. Then, under the domain, select the user profile you are using. You will see the service role listed there. Navigate to the IAM console, search for the service role under **Roles**, and update your role with a policy that allows the `iam:CreateRole`, `iam:CreatePolicy`, `iam:AttachRolePolicy`, and `iam:ListPolicies` actions.

Set up AWS CLI model

Follow these command line steps within a terminal to set up the AWS CLI for Amazon SageMaker AI with MLflow.

1. Install an updated version of the AWS CLI. For more information, see Install or update to the latest version of the AWS CLI in the *AWS CLI User Guide*.
2. Verify that the AWS CLI is installed using the following command:

   ```
   aws sagemaker help
   ```

   Press q to exit the prompt.

   For troubleshooting help, see Troubleshoot common setup issues.

Set up MLflow infrastructure

The following section shows you how to set up an MLflow Tracking Server along with the Amazon S3 bucket and IAM role needed for the tracking server.

Create an S3 bucket

Within your terminal, use the following commands to create a general purpose Amazon S3 bucket:

> **Important**
>
> When you provide the Amazon S3 URI for your artifact store, ensure the Amazon S3 bucket is in the same AWS Region as your tracking server. **Cross-region artifact storage is not supported**.

```
bucket_name=bucket-name
region=valid-region

aws s3api create-bucket \
  --bucket $bucket_name \
  --region $region \
  --create-bucket-configuration LocationConstraint=$region
```

The output should look similar to the following:

```
{
    "Location": "/bucket-name"
}
```

Set up IAM trust policies

Use the following steps to create an IAM trust policy. For more information about roles and trust policies, see [Roles terms and concepts](#) in the *AWS Identity and Access Management User Guide*.

1. Within your terminal, use the following command to create a file called `mlflow-trust-policy.json`.

   ```
   cat <<EOF > /tmp/mlflow-trust-policy.json
   {
        "Version": "2012-10-17",
   ```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                     "sagemaker.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
EOF
```

2. Within your terminal, use the following command to create a file called `custom-policy.json`.

```
cat <<EOF > /tmp/custom-policy.json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:Get*",
                "s3:Put*",
                "sagemaker:AddTags",
                "sagemaker:CreateModelPackageGroup",
                "sagemaker:CreateModelPackage",
                "sagemaker:DescribeModelPackageGroup",
                "sagemaker:UpdateModelPackage",
                "s3:List*"
            ],
            "Resource": "*"
        }
    ]
}
EOF
```

3. Use the trust policy file to create a role. Then, attach IAM role policies that allow MLflow to access Amazon S3 and SageMaker Model Registry within your account. MLflow must have access to Amazon S3 for your tracking server's artifact store and SageMaker Model Registry for automatic model registration.

> **Note**
>
> If you are updating an existing role, use the following command instead: `aws iam update-assume-role-policy --role-name $role_name --policy-document file:///tmp/mlflow-trust-policy.json`.

```
role_name=role-name

aws iam  create-role \
  --role-name $role_name \
  --assume-role-policy-document file:///tmp/mlflow-trust-policy.json

aws iam put-role-policy \
  --role-name $role_name \
  --policy-name custom-policy \
  --policy-document file:///tmp/custom-policy.json

role_arn=$(aws iam get-role --role-name  $role_name --query 'Role.Arn' --output
 text)
```

Create MLflow tracking server

Within your terminal, use the `create-mlflow-tracking-server` API to create a tracking server in the AWS Region of your choice. This step can take up to 25 minutes.

You can optionally specify the size of your tracking server with the parameter `--tracking-server-config`. Choose between `"Small"`, `"Medium"`, and `"Large"`. The default MLflow Tracking Server configuration size is `"Small"`. You can choose a size depending on the projected use of the tracking server such as the volume of data logged, number of users, and frequency of use. For more information, see [MLflow Tracking Server sizes](#).

The following command creates a new tracking server with automatic model registration enabled. To deactivate automatic model registration, specify `--no-automatic-model-registration`.

After creating your tracking server, you can launch the MLflow UI. For more information, see [Launch the MLflow UI using a presigned URL](#).

Note

It may take up to 25 minutes to complete tracking server creation. If the tracking server takes over 25 minutes to create, check that you have the necessary IAM permissions. For more information on IAM permissions, see Set up IAM permissions for MLflow. When you successfully create a tracking server, it automatically starts.

When you create a tracking server, we recommend specifying the latest version. For information about the available versions, see Tracking server versions.

By default, the tracking server that's created is the latest version. However, we recommend always specifying the latest version explicitly because the underlying MLflow APIs can change.

```
ts_name=tracking-server-name
region=valid-region
version=valid-version

aws sagemaker create-mlflow-tracking-server \
 --tracking-server-name $ts_name \
 --artifact-store-uri s3://$bucket_name \
 --role-arn $role_arn \
 --automatic-model-registration \
 --region $region \
 --mlflow-version $version
```

The output should be similar to the following:

```
{
    "TrackingServerArn": "arn:aws:sagemaker:region:123456789012:mlflow-tracking-
server/tracking-server-name"
}
```

Important

Take note of the tracking server ARN for later use. You will also need the `$bucket_name` for clean up steps.

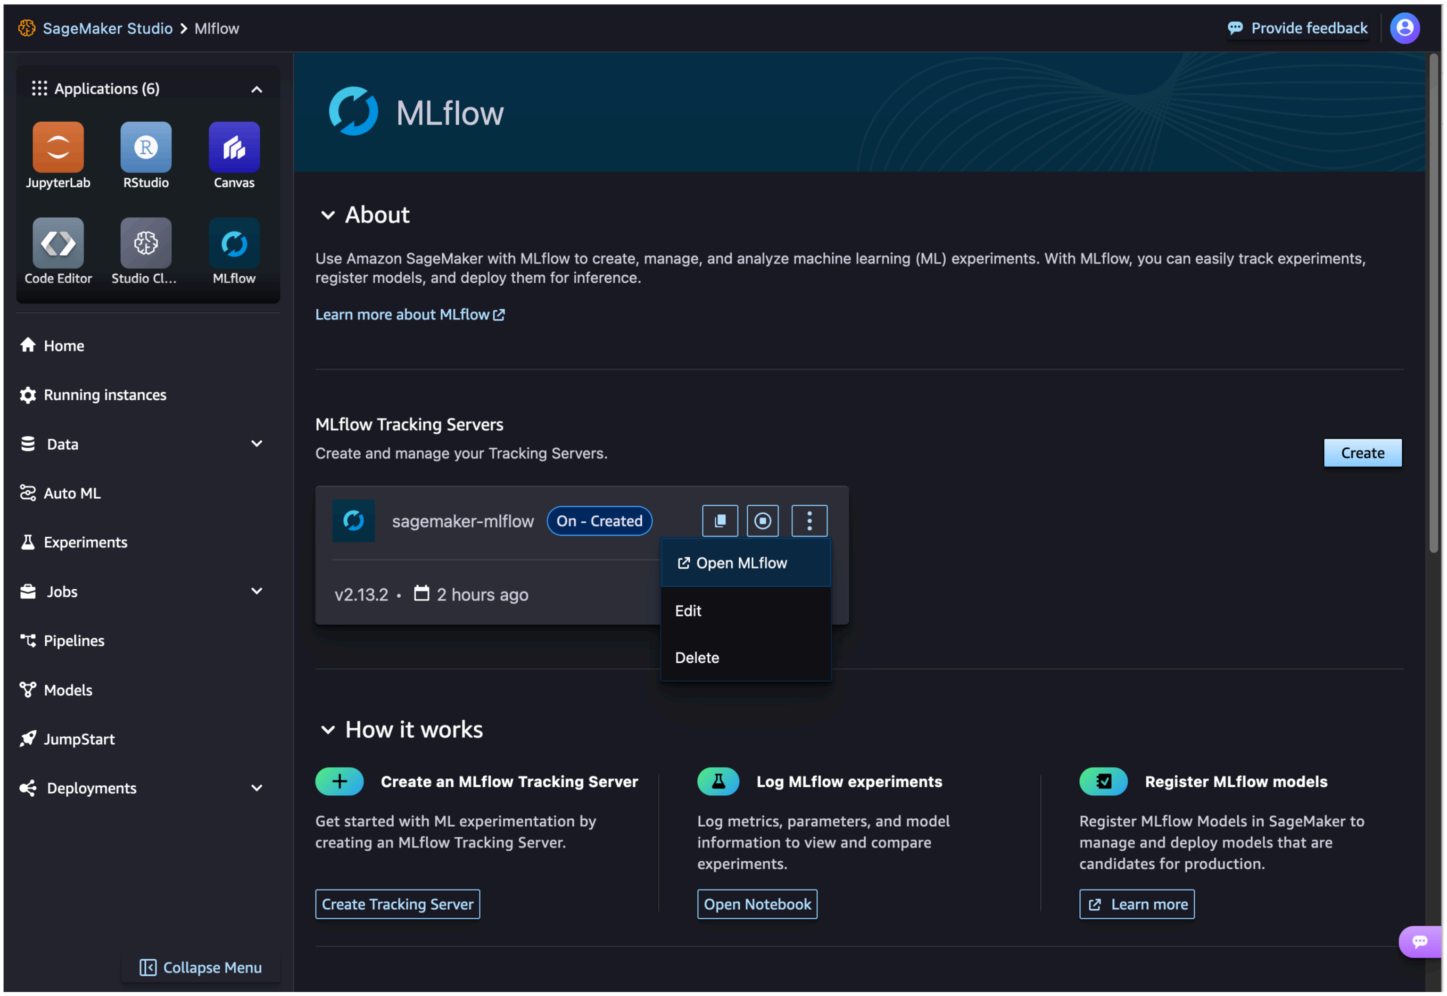
Launch the MLflow UI using a presigned URL

You can access the MLflow UI to view your experiments using a presigned URL. You can launch the MLflow UI either through Studio or using the AWS CLI in a terminal of your choice.

Launch the MLflow UI using Studio

After creating your tracking server, you can launch the MLflow UI directly from Studio.

1. Navigate to Studio from the SageMaker AI console. Be sure that you are using the new Studio experience and have updated from Studio Classic. For more information, see Migration from Amazon SageMaker Studio Classic.
2. Choose **MLflow** in the **Applications** pane of the Studio UI.
3. **(Optional)** If have not already created a tracking server or if you need to create a new one, you can choose **Create**. Then provide a unique tracking server name and S3 URI for artifact storage and create a tracking server. You can optionally choose **Configure** for more granular tracking server customization.
4. Find the tracking server of your choice in the **MLflow Tracking Servers** pane. If the tracking server is **Off**, start the tracking server.
5. Choose the vertical menu icon in the right corner of the tracking server pane. Then, choose **Open MLflow**. This launches a presigned URL in a new tab in your current browser.



Launch the MLflow UI using the AWS CLI

You can access the MLflow UI to view your experiments using a presigned URL.

Within your terminal, use the `create-presigned-mlflow-tracking-server-url` API to generate a presigned URL.

```
aws sagemaker create-presigned-mlflow-tracking-server-url \
  --tracking-server-name $ts_name \
  --session-expiration-duration-in-seconds 1800 \
  --expires-in-seconds 300 \
  --region $region
```

The output should look similar to the following:

```
{
```

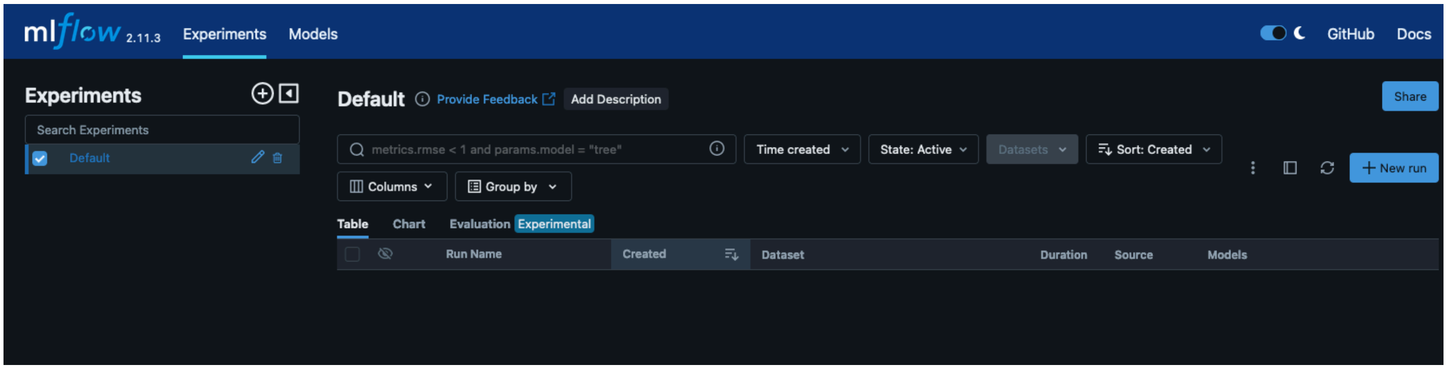
```
    "AuthorizedUrl": "https://unique-key.us-west-2.experiments.sagemaker.aws.a2z.com/
auth?authToken=example_token"
}
```

Copy the entire presigned URL into the browser of your choice. You can use a new tab or a new private window. Press q to exit the prompt.

The `--session-expiration-duration-in-seconds` parameter determines the length of time that your MLflow UI session remains valid. The session duration time is the amount of time that the MLflow UI can be loaded in the browser before a new presigned URL must be created. The minimum session duration is 30 minutes (1800 seconds) and the maximum session duration is 12 hours (43200 seconds). The default session duration is 12 hours if no other duration is specified.

The `--expires-in-seconds parameter` determines the length of time that your presigned URL remains valid. The minimum URL expiration length is 5 seconds and the maximum URL expiration length is 5 minutes (300 seconds). The default URL expiration length is 300 seconds. The presigned URL can be used only once.

The window should look similar to the following.



Integrate MLflow with your environment

The following page describes how to get started with the MLflow SDK and the AWS MLflow plugin within your development environment. This can include local IDEs or a Jupyter Notebook environment within Studio or Studio Classic.

Amazon SageMaker AI uses an MLflow plugin to customize the behavior of the MLflow Python client and integrate AWS tooling. The AWS MLflow plugin authenticates API calls made with MLflow using AWS Signature Version 4. The AWS MLflow plugin allows you to connect to your MLflow tracking server using the tracking server ARN. For more information about plugins, see AWS MLflow plugin and MLflow plugins.

> **Important**
>
> Your user IAM permissions within your development environment must have access to any relevant MLflow API actions to successfully run provided examples. For more information, see Set up IAM permissions for MLflow.

For more information about using the MLflow SDK, see Python API in the MLflow documentation.

Install MLflow and the AWS MLflow plugin

Within your development environment, install both MLflow and the AWS MLflow plugin.

```
pip install sagemaker-mlflow
```

To ensure compatibility between your MLflow client and tracking server, use the corresponding MLflow version based on your tracking server version:

- For tracking server 2.13.x, use `mlflow==2.13.2`
- For tracking server 2.16.x, use `mlflow==2.16.2`
- For tracking server 3.0.x, use `mlflow==3.0.0`

To see which versions of MLflow are available to use with SageMaker AI, see Tracking server versions.

Connect to your MLflow Tracking Server

Use `mlflow.set_tracking_uri` to connect to a your tracking server from your development environment using its ARN:

```
import mlflow

arn = "YOUR-TRACKING-SERVER-ARN"

mlflow.set_tracking_uri(arn)
```

Log metrics, parameters, and MLflow models during training

After connecting to your MLflow Tracking Server, you can use the MLflow SDK to log metrics, parameters, and MLflow models.

Log training metrics

Use `mlflow.log_metric` within an MLflow training run to track metrics. For more information about logging metrics using MLflow, see mlflow.log_metric.

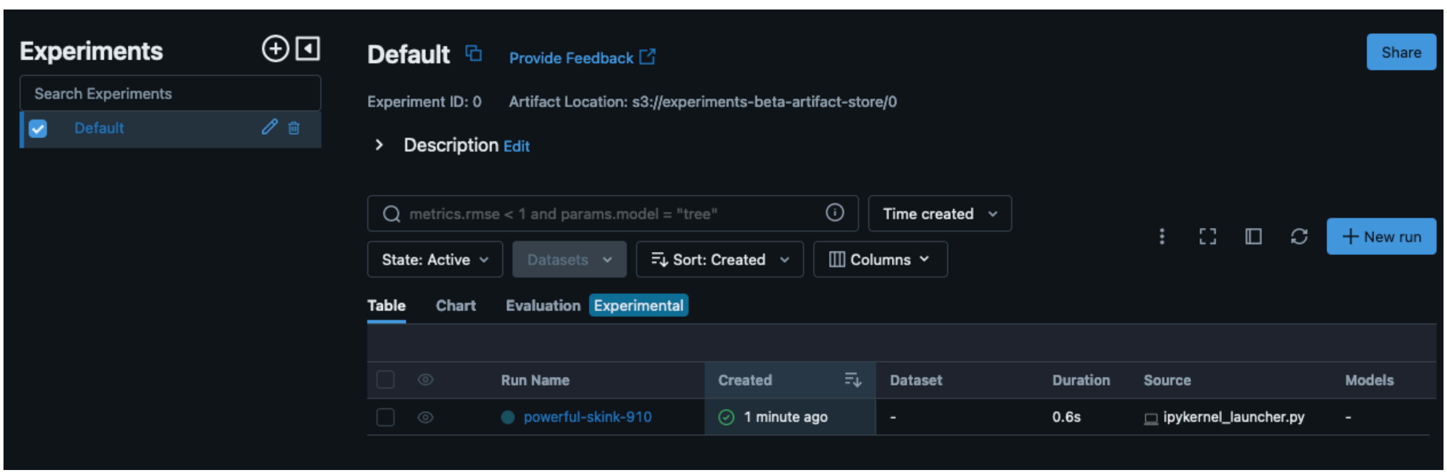
```
with mlflow.start_run():
    mlflow.log_metric("foo", 1)

print(mlflow.search_runs())
```

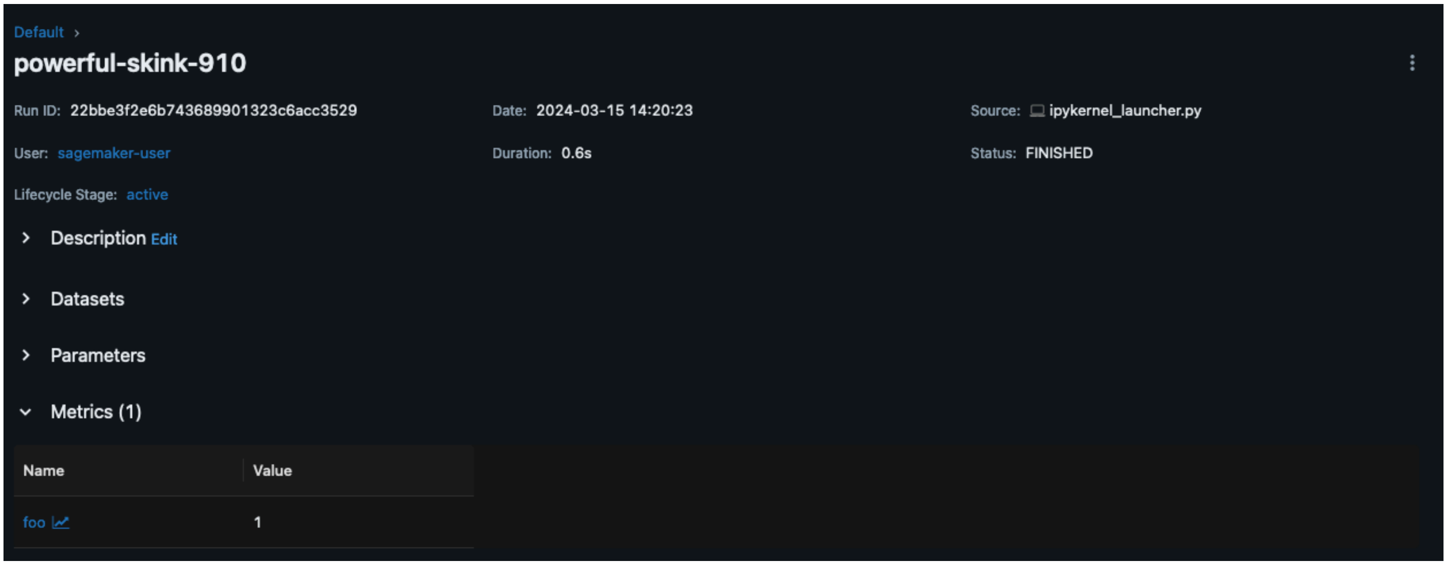
This script should create an experiment run and print out an output similar to the following:

```
run_id experiment_id status artifact_uri ... tags.mlflow.source.name tags.mlflow.user
 tags.mlflow.source.type tags.mlflow.runName
0 607eb5c558c148dea176d8929bd44869 0 FINISHED s3://
dddd/0/607eb5c558c148dea176d8929bd44869/a... ... file.py user-id LOCAL experiment-code-
name
```

Within the MLflow UI, this example should look similar to the following:



Choose **Run Name** to see more run details.



Log parameters and models

Note

The following example requires your environment to have `s3:PutObject` permissions. This permission should be associated with the IAM Role that the MLflow SDK user assumes when they log into or federate into their AWS account. For more information, see [User and role policy examples](#).

The following example takes you through a basic model training workflow using SKLearn and shows you how to track that model in an MLflow experiment run. This example logs parameters, metrics, and model artifacts.

```
import mlflow

from mlflow.models import infer_signature

import pandas as pd
from sklearn import datasets
from sklearn.model_selection import train_test_split
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score

# This is the ARN of the MLflow Tracking Server you created
mlflow.set_tracking_uri(your-tracking-server-arn)
mlflow.set_experiment("some-experiment")
```

```
# Load the Iris dataset
X, y = datasets.load_iris(return_X_y=True)

# Split the data into training and test sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2,
 random_state=42)

# Define the model hyperparameters
params = {"solver": "lbfgs", "max_iter": 1000, "multi_class": "auto", "random_state":
 8888}

# Train the model
lr = LogisticRegression(**params)
lr.fit(X_train, y_train)

# Predict on the test set
y_pred = lr.predict(X_test)

# Calculate accuracy as a target loss metric
accuracy = accuracy_score(y_test, y_pred)

# Start an MLflow run and log parameters, metrics, and model artifacts
with mlflow.start_run():
    # Log the hyperparameters
    mlflow.log_params(params)

    # Log the loss metric
    mlflow.log_metric("accuracy", accuracy)

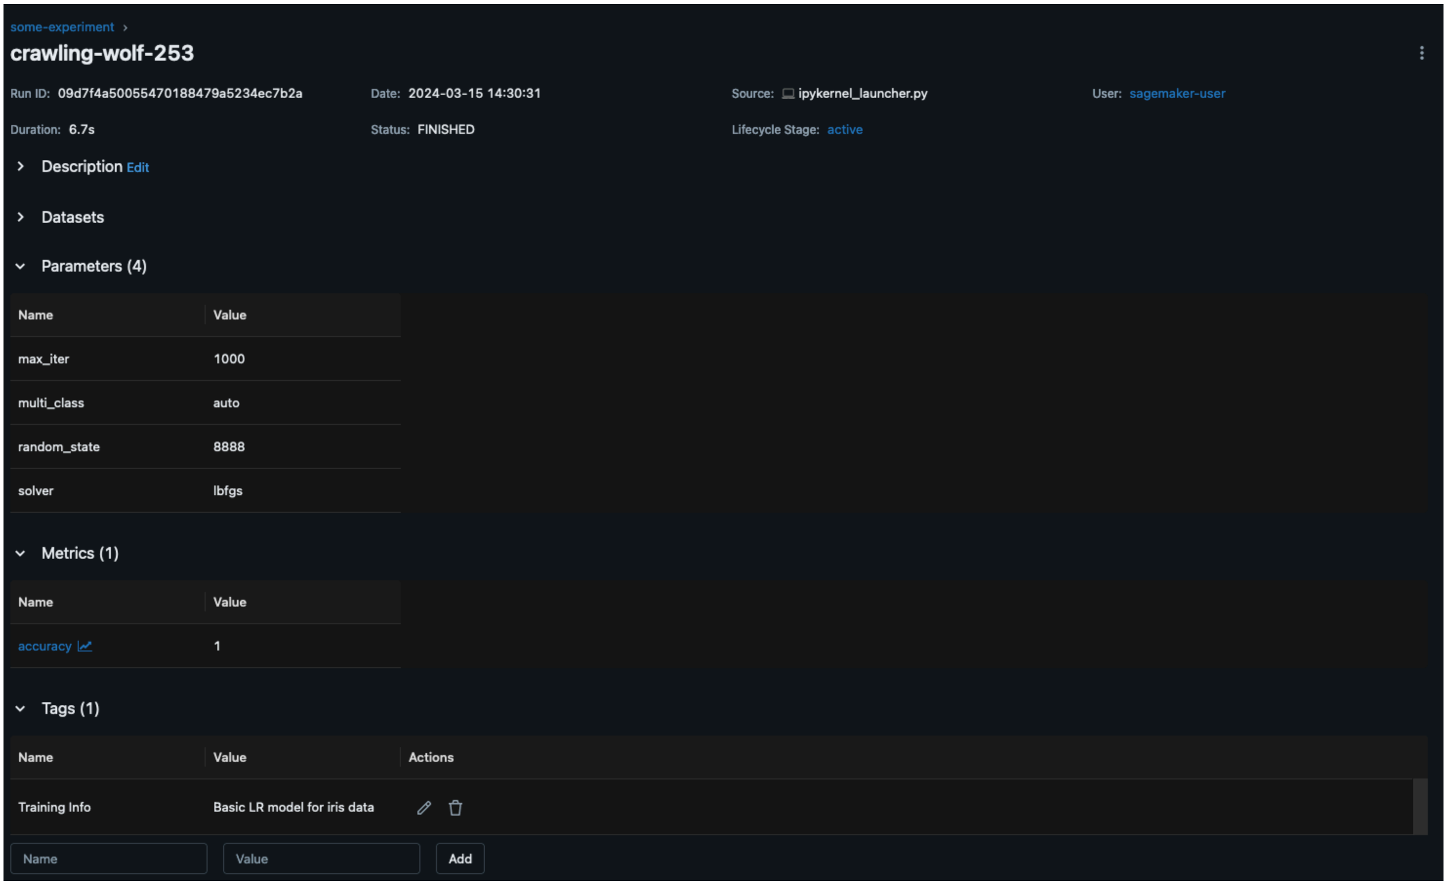
    # Set a tag that we can use to remind ourselves what this run was for
    mlflow.set_tag("Training Info", "Basic LR model for iris data")

    # Infer the model signature
    signature = infer_signature(X_train, lr.predict(X_train))

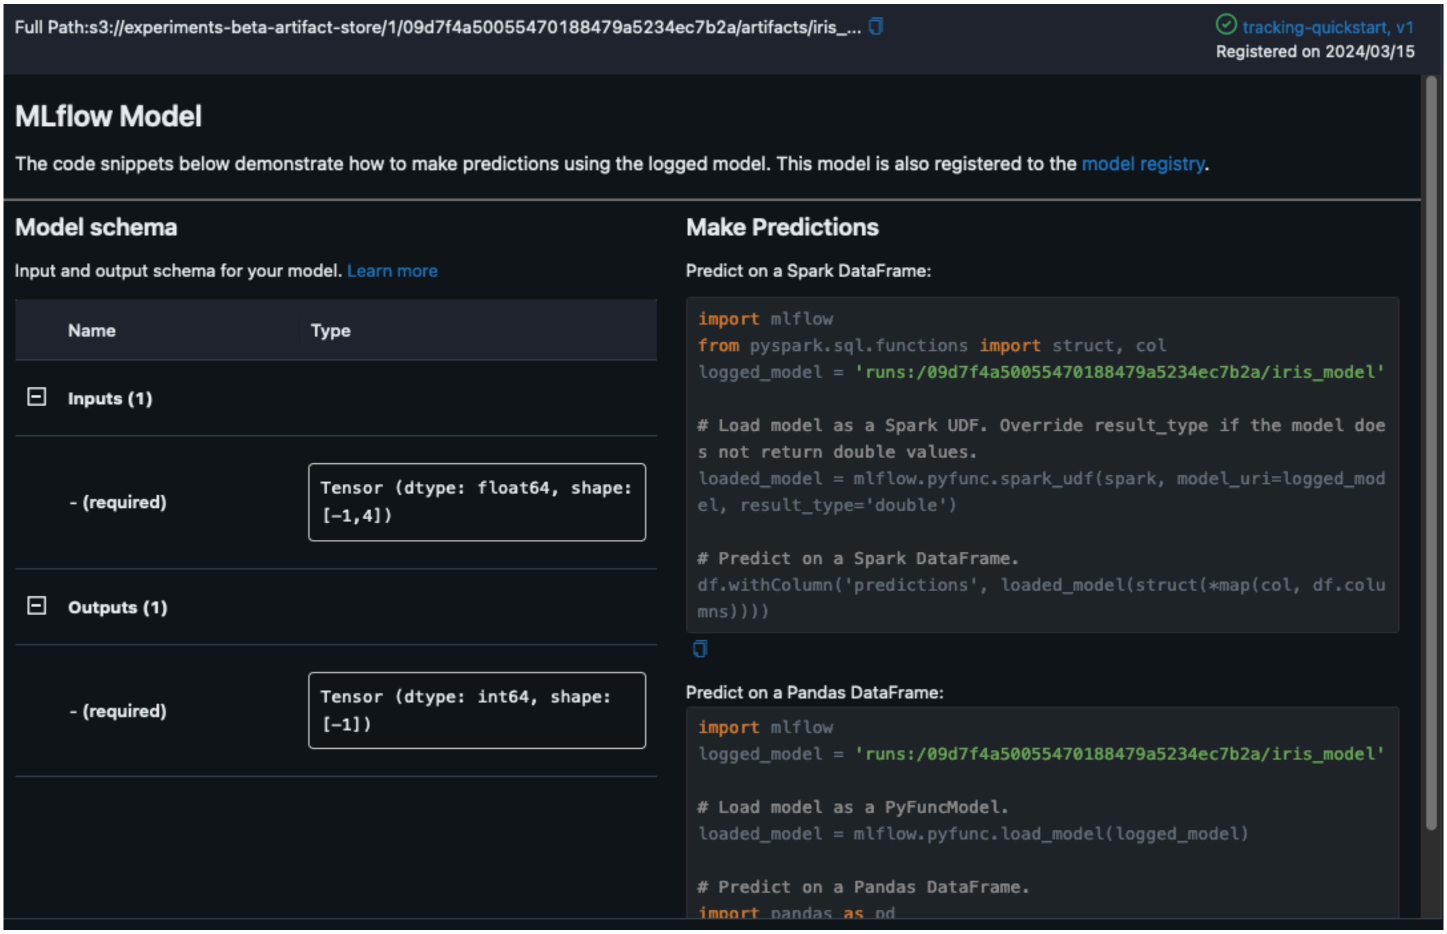
    # Log the model
    model_info = mlflow.sklearn.log_model(
        sk_model=lr,
        name="iris_model", # Changed from artifact_path to name for MLflow 3.0
        signature=signature,
        input_example=X_train,
        registered_model_name="tracking-quickstart",
```

```
    )
```

Within the MLflow UI, choose the experiment name in the left navigation pane to explore all associated runs. Choose the **Run Name** to see more information about each run. For this example, your experiment run page for this run should look similar to the following.



This example logs the logistic regression model. Within the MLflow UI, you should also see the logged model artifacts.



Automatically register SageMaker AI models with SageMaker Model Registry

You can log MLflow models and automatically register them with SageMaker Model Registry using either the Python SDK or directly through the MLflow UI.

> **Note**
>
> Do not use spaces in a model name. While MLflow supports model names with spaces, SageMaker AI Model Package does not. The auto-registration process fails if you use spaces in your model name.

Register models using the SageMaker Python SDK

Use `create_registered_model` within your MLflow client to automatically create a model package group in SageMaker AI that corresponds to an existing MLflow model of your choice.

```
import mlflow
```

```
from mlflow import MlflowClient

mlflow.set_tracking_uri(arn)

client = MlflowClient()

mlflow_model_name = 'AutoRegisteredModel'
client.create_registered_model(mlflow_model_name, tags={"key1": "value1"})
```

Use `mlflow.register_model()` to automatically register a model with the SageMaker Model Registry during model training. When registering the MLflow model, a corresponding model package group and model package version are created in SageMaker AI.

```
import mlflow.sklearn
from mlflow.models import infer_signature
from sklearn.datasets import make_regression
from sklearn.ensemble import RandomForestRegressor

mlflow.set_tracking_uri(arn)
params = {"n_estimators": 3, "random_state": 42}
X, y = make_regression(n_features=4, n_informative=2, random_state=0, shuffle=False)

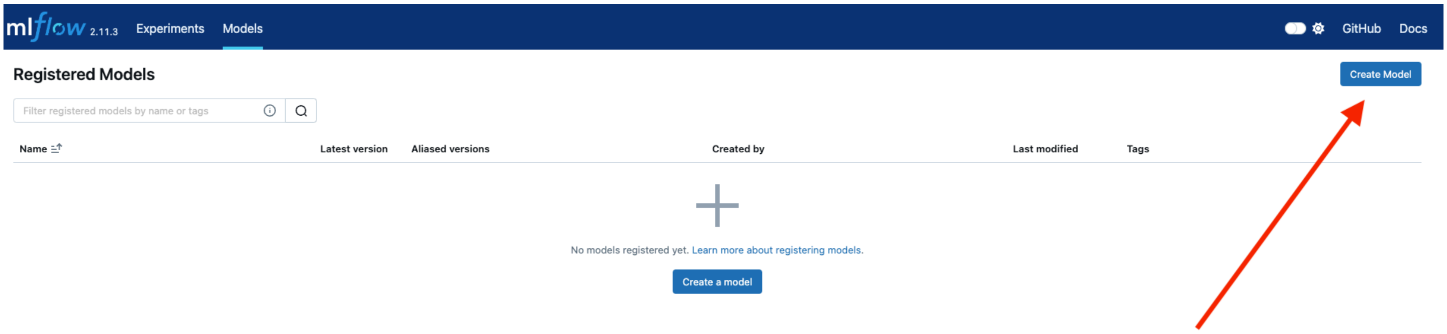
# Log MLflow entities
with mlflow.start_run() as run:
    rfr = RandomForestRegressor(**params).fit(X, y)
    signature = infer_signature(X, rfr.predict(X))
    mlflow.log_params(params)
    mlflow.sklearn.log_model(rfr, artifact_path="sklearn-model", signature=signature)

model_uri = f"runs:/{run.info.run_id}/sklearn-model"
mv = mlflow.register_model(model_uri, "RandomForestRegressionModel")

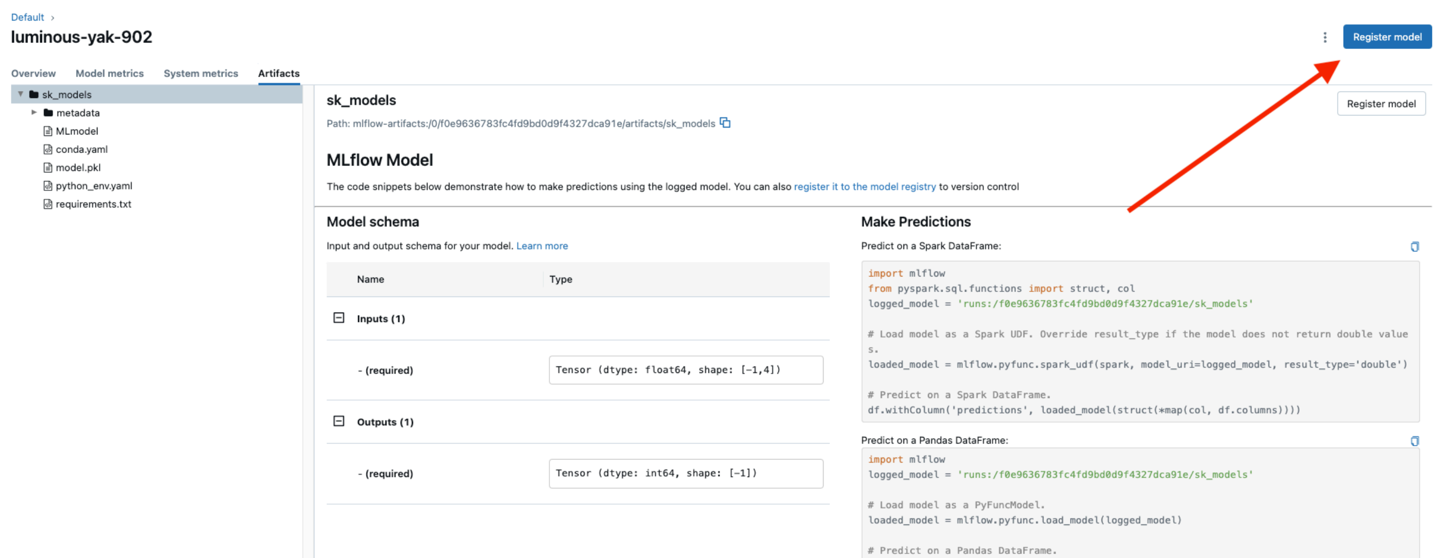
print(f"Name: {mv.name}")
print(f"Version: {mv.version}")
```

Register models using the MLflow UI

You can alternatively register a model with the SageMaker Model Registry directly in the MLflow UI. Within the **Models** menu in the MLflow UI, choose **Create Model**. Any models newly created in this way are added to the SageMaker Model Registry.

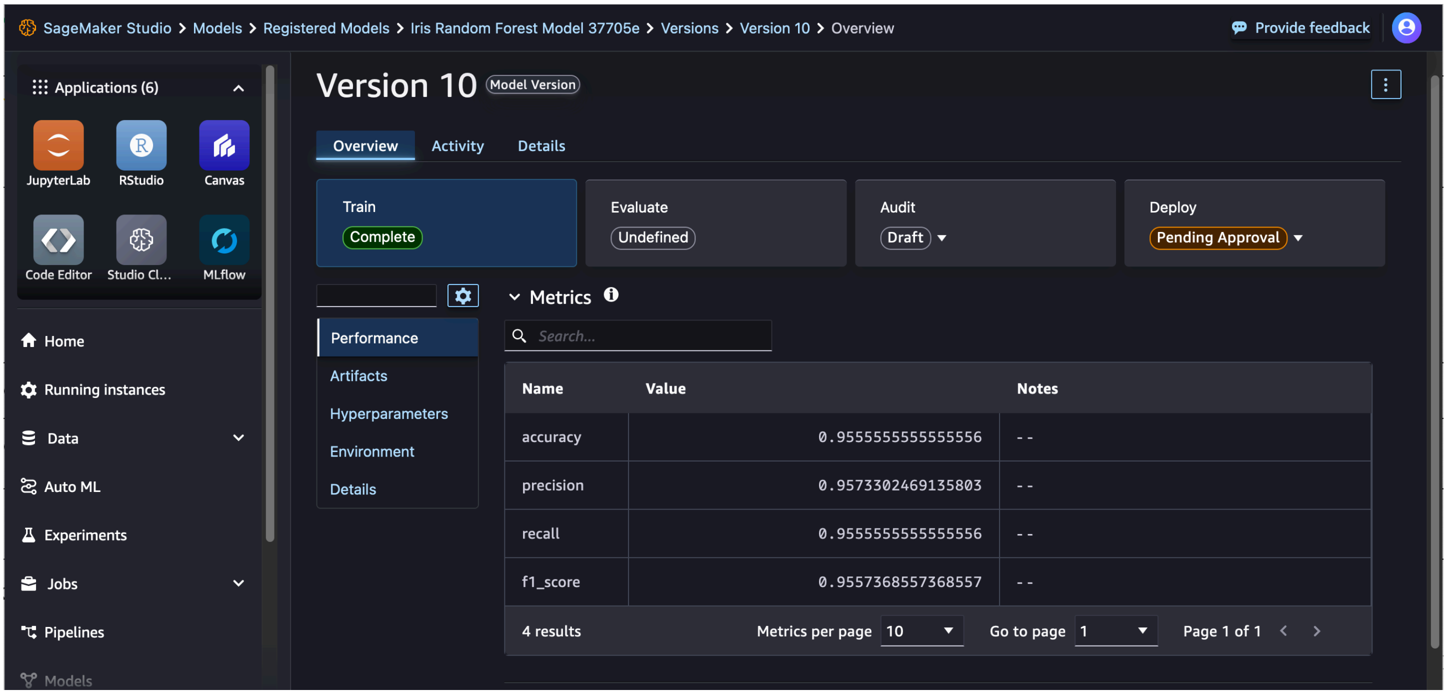


After logging a model during experiment tracking, navigate to the run page in the MLflow UI. Choose the **Artifacts** pane and choose **Register model** in the upper right corner to register the model version in both MLflow and SageMaker Model Registry.



View registered models in Studio

Within the SageMaker Studio landing page, choose **Models** on the left navigation pane to view your registered models. For more information on getting started with Studio, see [Launch Amazon SageMaker Studio](#).



Deploy MLflow models with `ModelBuilder`

You can deploy MLflow models to a SageMaker AI endpoint using Amazon SageMaker AI Model Builder. For more information about Amazon SageMaker AI Model Builder, see [Create a model in Amazon SageMaker AI with ModelBuilder](#).

`ModelBuilder` is a Python class that takes a framework model or a user-specified inference specification and converts it to a deployable model. For more details about the `ModelBuilder` class, see [ModelBuilder](#).

To deploy your MLflow model using `ModelBuilder`, provide a path to your MLflow artifacts in the `model_metadata["MLFLOW_MODEL_PATH"]` attribute. Read on for more information about valid model path input formats:

> **Note**
>
> If you provide your model artifact path in the form of an MLflow run ID or MLflow model registry path, then you must also specify your tracking server ARN through the `model_metadata["MLFLOW_TRACKING_ARN"]` attribute.

- Model paths that require an ARN in the `model_metadata`
- Model paths that do not require an ARN in the `model_metadata`

Model paths that require an ARN in the `model_metadata`

The following model paths do require that you specify an ARN in the `model_metadata` for deployment:

- MLflow run ID: *runs:/aloy-run-id/run-relative/path/to/model*
- MLflow model registry path: *models:/model-name/model-version*

Model paths that do not require an ARN in the `model_metadata`

The following model paths do not require that you specify an ARN in the `model_metadata` for deployment:

- Local model path: */Users/me/path/to/local/model*
- Amazon S3 model path: *s3://amzn-s3-demo-bucket/path/to/model*
- Model package ARN: *arn:aws:sagemaker:region:account-id:mlflow-tracking-server/tracking-server-name*

For more information on how MLflow model deployment works with Amazon SageMaker AI, see Deploy MLflow Model to Amazon SageMaker AI in the MLflow documentation.

If using an Amazon S3 path, you can find the path of your registered model with the following commands:

```
registered_model = client.get_registered_model(name='AutoRegisteredModel')
source_path = registered_model.latest_versions[0].source
```

The following sample is an overview of how to deploy your MLflow model using `ModelBuilder` and an MLflow model registry path. Because this sample provides the model artifact path in the form of an MLflow model registry path, the call to `ModelBuilder` must also specify a tracking server ARN through the `model_metadata["MLFLOW_TRACKING_ARN"]` attribute.

Important

You must use version 2.224.0 or later of the SageMaker Python SDK to use `ModelBuilder`.

Note

Use the following code example for reference. For end-to-end examples that show you how to deploy registered MLflow models, see MLflow tutorials using example Jupyter notebooks.

```
from sagemaker.serve import ModelBuilder
from sagemaker.serve.mode.function_pointers import Mode
from sagemaker.serve import SchemaBuilder

my_schema = SchemaBuilder(
    sample_input=sample_input,
    sample_output=sample_output
)

model_builder = ModelBuilder(
    mode=Mode.SAGEMAKER_ENDPOINT,
    schema_builder=my_schema,
    role_arn="Your-service-role-ARN",
    model_metadata={
        # both model path and tracking server ARN are required if you use an mlflow run
 ID or mlflow model registry path as input
        "MLFLOW_MODEL_PATH": "models:/sklearn-model/1"
        "MLFLOW_TRACKING_ARN": "arn:aws:sagemaker:region:account-id:mlflow-tracking-
server/tracking-server-name"
    }
)
model = model_builder.build()
predictor = model.deploy( initial_instance_count=1, instance_type="ml.c6i.xlarge" )
```

To maintain lineage tracking for MLflow models deployed using `ModelBuilder`, you must have the following IAM permissions:

- `sagemaker:CreateArtifact`
- `sagemaker:ListArtifacts`
- `sagemaker:AddAssociation`
- `sagemaker:DescribeMLflowTrackingServer`

> **Important**
>
> Lineage tracking is optional. Deployment succeeds without the permissions related to lineage tracking. If you do not have the permissions configured, you will see a lineage tracking permissions error when calling `model.deploy()`. However, the endpoint deployment still succeeds and you can directly interact with your model endpoint. If the permissions above are configured, lineage tracking information is automatically created and stored.

For more information and end-to-end examples, see MLflow tutorials using example Jupyter notebooks.

MLflow tutorials using example Jupyter notebooks

The following tutorials demonstrate how to integrate MLflow experiments into your training workflows. To clean up resources created by a notebook tutorial, see Clean up MLflow resources.

You can run SageMaker AI example notebooks using JupyterLab in Studio. For more information on JupyterLab, see JupyterLab user guide.

Explore the following example notebooks:

- SageMaker Training with MLflow — Train and register a Scikit-Learn model using SageMaker AI in script mode. Learn how to integrate MLflow experiments into your training script. For more information on model training, see Train a Model with Amazon SageMaker AI.
- SageMaker AI HPO with MLflow — Learn how to track your ML experiment in MLflow with Amazon SageMaker AI automatic model tuning (AMT) and the SageMaker AI Python SDK. Each training iteration is logged as a run within the same experiment. For more information about hyperparameter optimization (HPO), see Perform Automatic Model Tuning with Amazon SageMaker AI.
- SageMaker Pipelines with MLflow — Use Amazon SageMaker Pipelines and MLflow to train, evaluate and register a model. This notebook uses the `@step` decorator to build a SageMaker AI Pipeline. For more information on pipelines and the `@step` decorator, see Create a pipeline with `@step`-decorated functions.
- Deploy an MLflow Model to SageMaker AI — Train a decision tree model using SciKit-Learn. Then, use Amazon SageMaker AI `ModelBuilder` to deploy the model to a SageMaker

AI endpoint and run inference using the deployed model. For more information about `ModelBuilder`, see [Deploy MLflow models with `ModelBuilder`].

Troubleshoot common setup issues

Explore common troubleshooting issues.

Could not find executable named 'groff'

When using the AWS CLI, you might encounter the following error: `Could not find executable named 'groff'`.

If using a Mac, you can resolve this issue with the following command:

```
brew install groff
```

On a Linux machine, use the following commands:

```
sudo apt-get update -y
sudo apt-get install groff -y
```

Command not found: jq

When creating your AuthZ permission policy JSON file, you might encounter the following error: `jq: command not found`.

If using a Mac, you can resolve this issue with the following command:

```
brew install jq
```

On a Linux machine, use the following commands:

```
sudo apt-get update -y
sudo apt-get install jq -y
```

AWS MLflow plugin installation speeds

Installing the AWS MLflow plugin can take several minutes when using a Mac Python environment.

UnsupportedModelRegistryStoreURIException

If you see the `UnsupportedModelRegistryStoreURIException`, do the following:

1. Restart your Jupyter notebook Kernel.
2. Reinstall the AWS MLflow plugin:

```
!pip install --force-reinstall sagemaker-mlflow
```

Clean up MLflow resources

We recommend deleting any resources when you no longer need them. You can delete tracking servers through Amazon SageMaker Studio or using the AWS CLI. You can delete additional resources such as Amazon S3 buckets, IAM roles, and IAM policies using the AWS CLI or directly in the AWS console.

> **Important**
>
> Don't delete the IAM role that you've used to create until you've deleted the tracking server itself. Otherwise, you'll lose access to the tracking server.

Stop tracking servers

We recommend stopping your tracking server when it is no longer in use. You can stop a tracking server in Studio or using the AWS CLI.

Stop a tracking server using Studio

To stop a tracking server in Studio:

1. Navigate to Studio.
2. Choose **MLflow** in the **Applications** pane of the Studio UI.
3. Find the tracking server of your choice in the **MLflow Tracking Servers** pane. Choose the **Stop** icon in the right corner of the tracking server pane.

> **Note**
>
> If your tracking server is **Off**, you see the **Start** icon. If the tracking server is **On**, you see the **Stop** icon.

Stop a tracking server using the AWS CLI

To stop the tracking server using the AWS CLI, use the following command:

```
aws sagemaker stop-mlflow-tracking-server \
  --tracking-server-name $ts_name \
  --region $region
```

To start the tracking server using the AWS CLI, use the following command:

> **Note**
>
> It may take up to 25 minutes to start your tracking server.

```
aws sagemaker start-mlflow-tracking-server \
  --tracking-server-name $ts_name \
  --region $region
```

Delete tracking servers

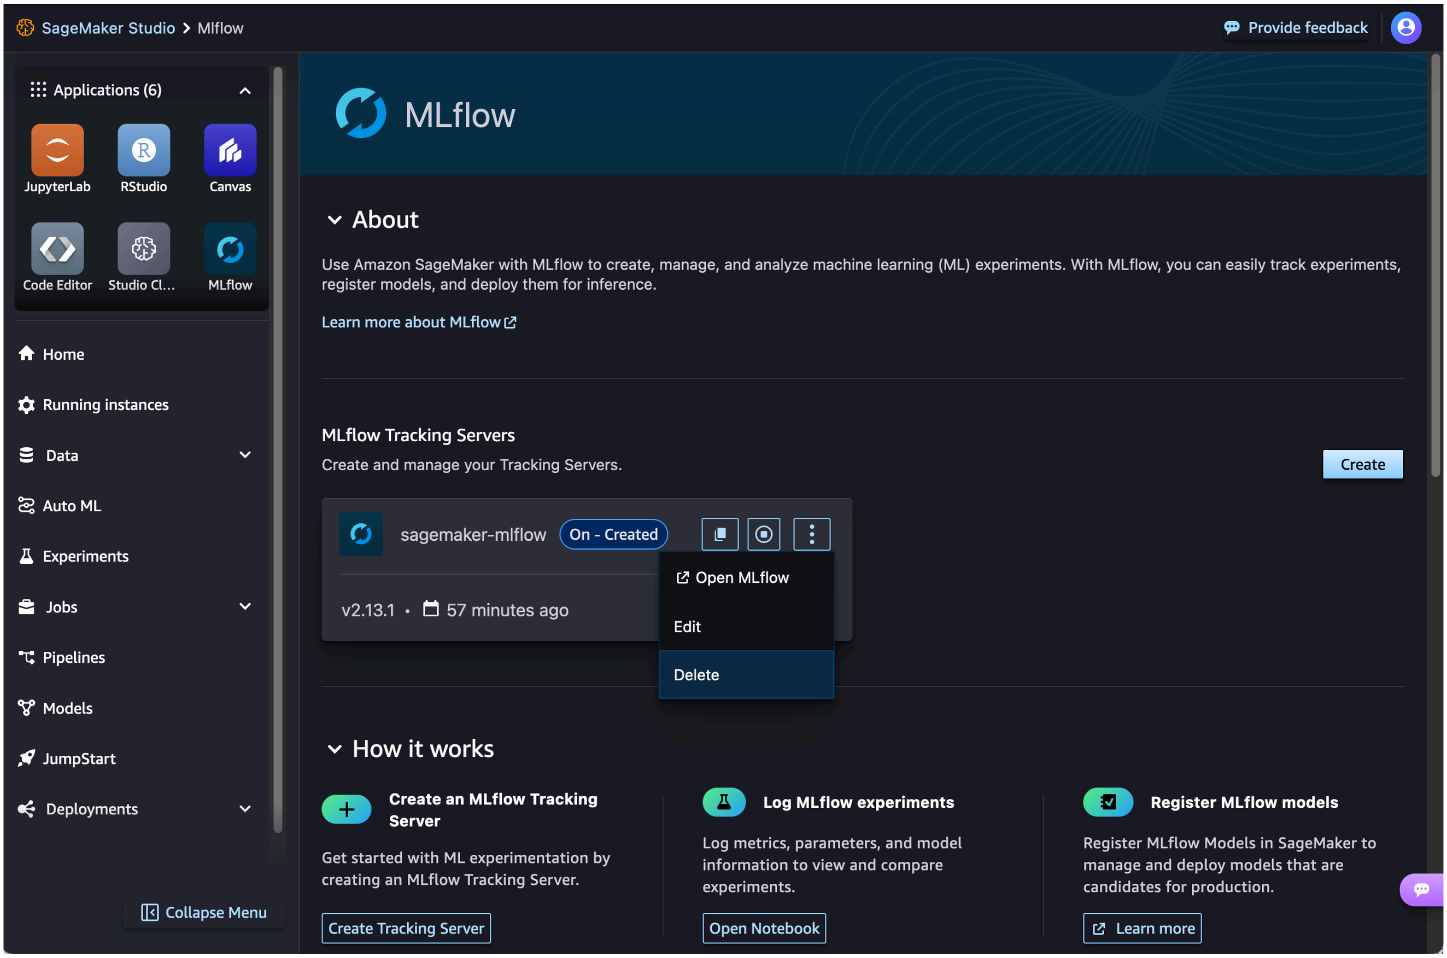
You can fully delete a tracking server in Studio or using the AWS CLI.

Delete a tracking server using Studio

To delete a tracking server in Studio:

1. Navigate to Studio.
2. Choose **MLflow** in the **Applications** pane of the Studio UI.
3. Find the tracking server of your choice in the **MLflow Tracking Servers** pane. Choose the vertical menu icon in the right corner of the tracking server pane. Then, choose **Delete**.

4. Choose **Delete** to confirm deletion.



Delete a tracking server using the AWS CLI

Use the `DeleteMLflowTrackingServer` API to delete any tracking servers that you created. This may take some time.

```
aws sagemaker delete-mlflow-tracking-server \
  --tracking-server-name $ts_name \
  --region $region
```

To view the status of your tracking server, use the `DescribeMLflowTrackingServer` API and check the `TrackingServerStatus`.

```
aws sagemaker describe-mlflow-tracking-server \
  --tracking-server-name $ts_name \
```

```
--region $region
```

Delete Amazon S3 buckets

Delete any Amazon S3 bucket used as an artifact store for your tracking server using the following commands:

```
aws s3 rm s3://$bucket_name --recursive
aws s3 rb s3://$bucket_name
```

You can alternatively delete an Amazon S3 bucket associated with your tracking server directly in the AWS console. For more information, see Deleting a bucket in the *Amazon S3 User Guide*.

Delete registered models

You can delete any model groups and model versions created with MLflow directly in Studio. For more information, see Delete a Model Group and Delete a Model Version.

Delete experiments or runs

You can use the MLflow SDK to delete experiments or runs.

- mlflow.delete_experiment
- mlflow.delete_run

Amazon SageMaker Experiments in Studio Classic

> **Important**
>
> Experiment tracking using the SageMaker Experiments Python SDK is only available in Studio Classic. We recommend using the new Studio experience and creating experiments using the latest SageMaker AI integrations with MLflow. There is no MLflow UI integration with Studio Classic. If you want to use MLflow with Studio, you must launch the MLflow UI using the AWS CLI. For more information, see Launch the MLflow UI using the AWS CLI.

Amazon SageMaker Experiments Classic is a capability of Amazon SageMaker AI that lets you create, manage, analyze, and compare your machine learning experiments in Studio Classic. Use

SageMaker Experiments to view, manage, analyze, and compare both custom experiments that you programmatically create and experiments automatically created from SageMaker AI jobs.

Experiments Classic automatically tracks the inputs, parameters, configurations, and results of your iterations as *runs*. You can assign, group, and organize these runs into *experiments*. SageMaker Experiments is integrated with Amazon SageMaker Studio Classic, providing a visual interface to browse your active and past experiments, compare runs on key performance metrics, and identify the best performing models. SageMaker Experiments tracks all of the steps and artifacts that went into creating a model, and you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

Migrate from Experiments Classic to Amazon SageMaker AI with MLflow

Past experiments created using Experiments Classic are still available to view in Studio Classic. If you want to maintain and use past experiment code with MLflow, you must update your training code to use the MLflow SDK and run the training experiments again. For more information on getting started with the MLflow SDK and the AWS MLflow plugin, see Integrate MLflow with your environment.

Example notebooks for Experiments Classic

The following example notebooks demonstrate how to track runs for various model training experiments. You can view the resulting experiments in Studio Classic after running the notebooks. For a tutorial that showcases additional features of Studio Classic, see Amazon SageMaker Studio Classic Tour.

Track experiments in a notebook environment

To learn more about tracking experiments in a notebook environment, see the following example notebooks:

- Track an experiment while training a Keras model locally
- Track an experiment while training a Pytorch model locally or in your notebook

Track bias and explainability for your experiments with SageMaker Clarify

For a step-by-step guide on tracking bias and explainability for your experiments, see the following example notebook:

- Fairness and Explainability with SageMaker Clarify

Track experiments for SageMaker training jobs using script mode

For more information about tracking experiments for SageMaker training jobs, see the following example notebooks:

- Run a SageMaker AI Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification
- Track an experiment while training a Pytorch model with a SageMaker Training Job
- Train a TensorFlow model with a SageMaker training job and track it using SageMaker Experiments

View experiments and runs

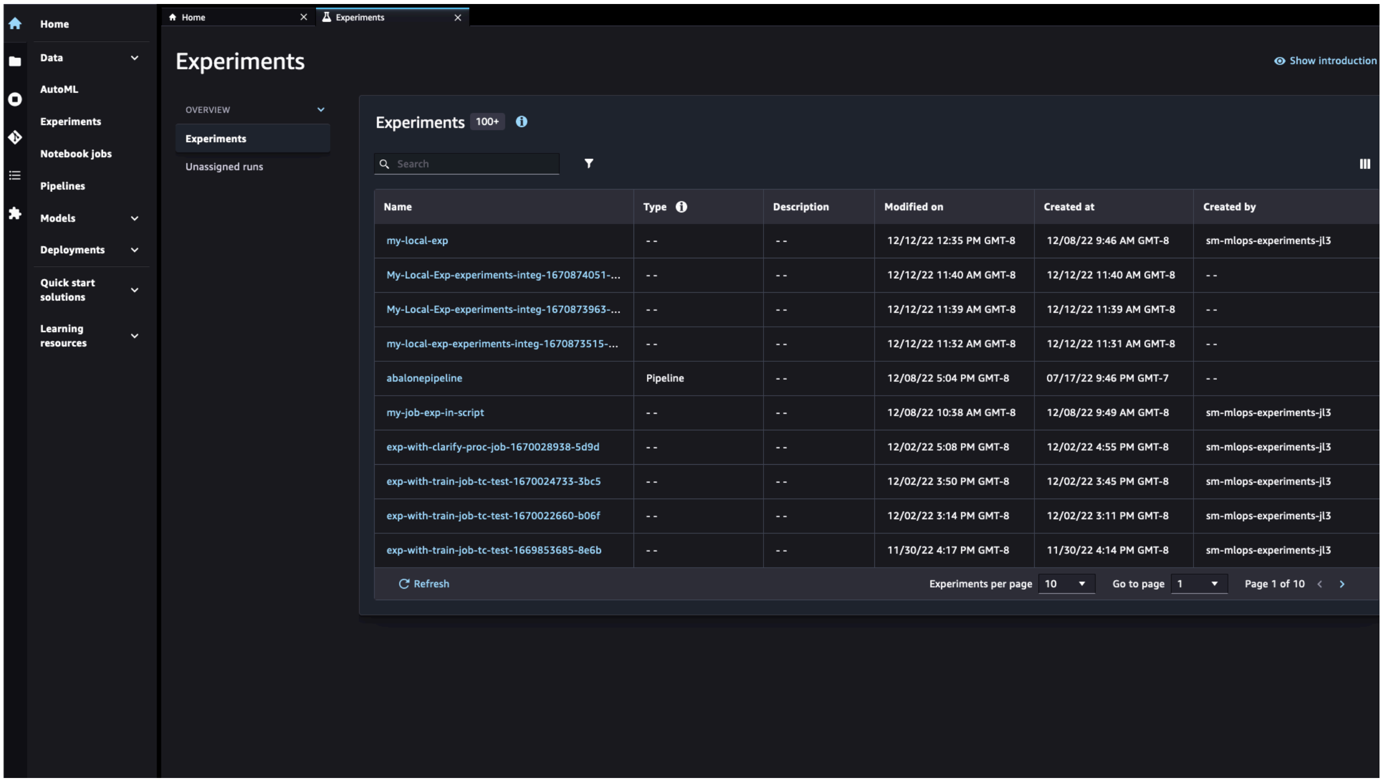
Amazon SageMaker Studio Classic provides an experiments browser that you can use to view lists of experiments and runs. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison. You can filter the list of experiments by entity name, type, and tags.

To view experiments and runs

1. To view the experiment in Studio Classic, in the left sidebar, choose **Experiments**.

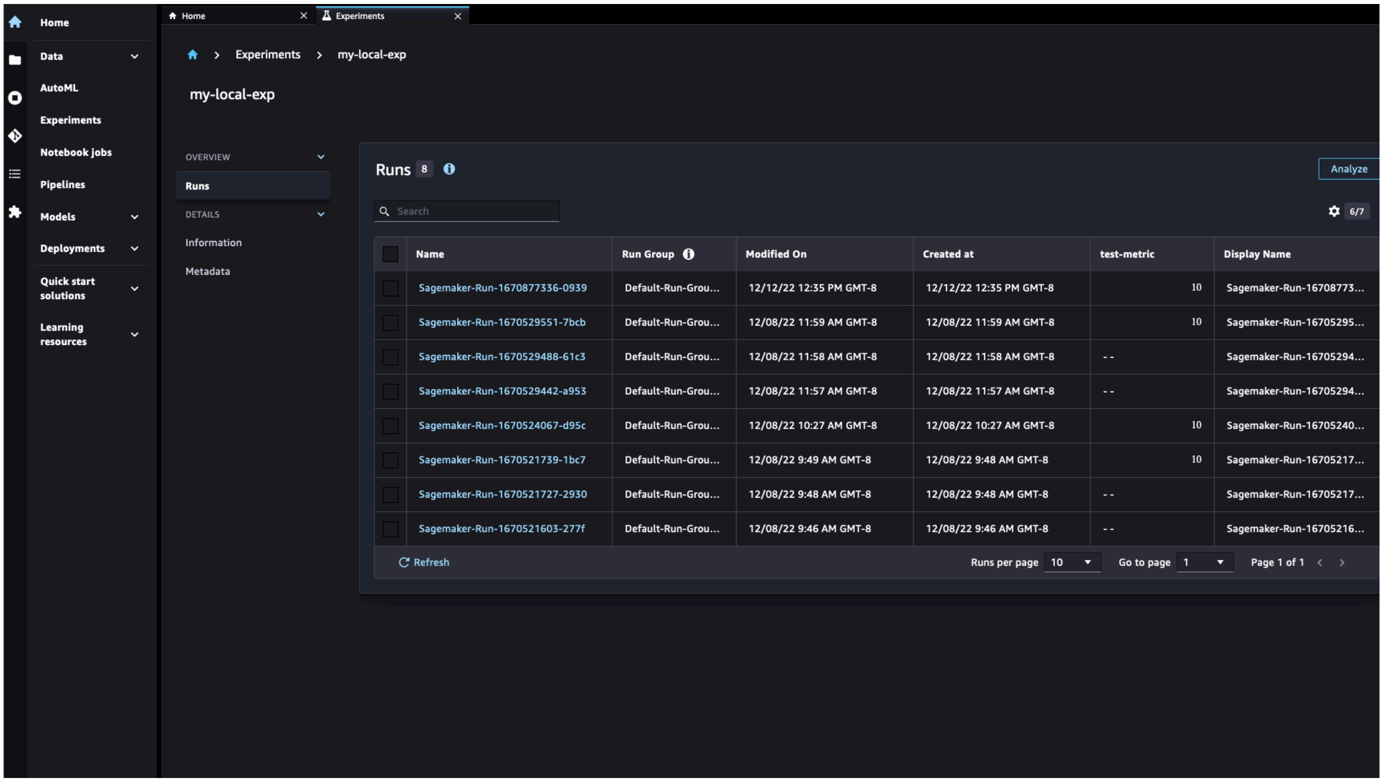
   Select the name of the experiment to view all associated runs. You can search experiments by typing directly into the **Search** bar or filtering for experiment type. You can also choose which columns to display in your experiment or run list.

   It might take a moment for the list to refresh and display a new experiment or experiment run. You can click **Refresh** to update the page. Your experiment list should look similar to the following:



2. In the experiments list, double-click an experiment to display a list of the runs in the experiment.

> **Note**
>
> Experiment runs that are automatically created by SageMaker AI jobs and containers are visible in the Experiments Studio Classic UI by default. To hide runs created by SageMaker AI jobs for a given experiment, choose the settings icon () and toggle **Show jobs**.



3. Double-click a run to display information about a specific run.

   In the **Overview** pane, choose any of the following headings to see available information about each run:

   - **Metrics** – Metrics that are logged during a run.
   - **Charts** – Build your own charts to compare runs.
   - **Output artifacts** – Any resulting artifacts of the experiment run and the artifact locations in Amazon S3.
   - **Bias reports** – Pre-training or post-training bias reports generated using Clarify.
   - **Explainability**– Explainability reports generated using Clarify.
   - **Debugs** – A list of debugger rules and any issues found.

Automatic model tuning with SageMaker AI

Amazon SageMaker AI automatic model tuning (AMT) finds the best version of a model by running many training jobs on your dataset. Amazon SageMaker AI automatic model tuning (AMT) is also known as hyperparameter tuning. To do this, AMT uses the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that creates a model that performs the best, as measured by a metric that you choose.

For example, running a *binary classification* problem on a marketing dataset. Your goal is to maximize the *area under the curve (AUC)* metric of the algorithm by training an XGBoost algorithm with Amazon SageMaker AI model. You want to find which values for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters that will train the best model. Specify a range of values for these hyperparameters. Then, SageMaker AI hyperparameter tuning searches within the ranges to find a combination that creates a training job that creates a model with the highest AUC. To conserve resources or meet a specific model quality expectation, set up completion criteria to stop tuning after the criteria have been met.

You can use SageMaker AI AMT with built-in algorithms, custom algorithms, or SageMaker AI pre-built containers for machine learning frameworks.

SageMaker AI AMT can use an Amazon EC2 Spot instance to optimize costs when running training jobs. For more information, see Managed Spot Training in Amazon SageMaker AI.

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm that you need to train
- A clear understanding of how you measure success

Prepare your dataset and algorithm so that they work in SageMaker AI and successfully run a training job at least once. For information about setting up and running a training job, see Guide to getting set up with Amazon SageMaker AI.

Understand the hyperparameter tuning strategies available in Amazon SageMaker AI

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate your productivity by trying many variations of a model. It looks for the best model automatically by focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you must choose the right ranges to explore. This page provides a brief explanation of the different hyperparameter tuning strategies that you can use with Amazon SageMaker AI.

Use the API reference guide to understand how to interact with hyperparameter tuning. You can use the tuning strategies described on this page with the HyperParameterTuningJobConfig and HyperbandStrategyConfig APIs.

> **Note**
>
> Because the algorithm itself is stochastic, the hyperparameter tuning model may fail to converge on the best answer. This can occur even if the best possible combination of values is within the ranges that you choose.

Grid search

When using grid search, hyperparameter tuning chooses combinations of values from the range of categorical values that you specify when you create the job. Only categorical parameters are supported when using the grid search strategy. You do not need to specify the `MaxNumberOfTrainingJobs`. The number of training jobs created by the tuning job is automatically calculated to be the total number of distinct categorical combinations possible. If specified, the value of `MaxNumberOfTrainingJobs` should equal the total number of distinct categorical combinations possible.

Random search

When using random search, hyperparameter tuning chooses a random combination of hyperparameter values in the ranges that you specify for each training job it launches. The choice of hyperparameter values doesn't depend on the results of previous training jobs. As a result, you can run the maximum number of concurrent training jobs without changing the performance of the tuning.

For an example notebook that uses random search, see the Random search and hyperparameter scaling with SageMaker XGBoost and Automatic Model Tuning notebook.

Bayesian optimization

Bayesian optimization treats hyperparameter tuning like a *regression* problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results. It then runs training jobs to test these values. After testing a set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses an Amazon SageMaker AI implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to use the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not yet well understood. The explore/exploit trade-off is common in many machine learning problems.

Hyperband

Hyperband is a multi-fidelity based tuning strategy that dynamically reallocates resources. Hyperband uses both intermediate and final results of training jobs to re-allocate epochs to well-utilized hyperparameter configurations and automatically stops those that underperform. It also seamlessly scales to using many parallel training jobs. These features can significantly speed up hyperparameter tuning over random search and Bayesian optimization strategies.

Hyperband should only be used to tune iterative algorithms that publish results at different resource levels. For example, Hyperband can be used to tune a neural network for image classification which publishes accuracy metrics after every epoch.

Hyperband with early stopping

Training jobs can be stopped early when they are unlikely to improve the objective metric of the hyperparameter tuning job. This can help reduce compute time and avoid overfitting your model. Hyperband uses an advanced internal mechanism to apply early stopping. The parameter `TrainingJobEarlyStoppingType` in the `HyperParameterTuningJobConfig` API must be set to `OFF` when using the Hyperband internal early stopping feature.

> **Note**
>
> Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions. As such, it should be considered part of the scientific development process.

Define metrics and environment variables

A tuning job optimizes hyperparameters for training jobs that it launches by using a metric to evaluate performance. This guide shows how to define metrics so that you can use a custom algorithm for training, or use a built-in algorithm from Amazon SageMaker AI. This guide also shows how to specify environment variables during an Automatic model tuning (AMT) job.

Define metrics

Amazon SageMaker AI hyperparameter tuning parses your machine learning algorithm's `stdout` and `stderr` streams to find metrics, such as loss or validation-accuracy. The metrics show how well the model is performing on the dataset.

The following sections describe how to use two types of algorithms for training: built-in and custom.

Use a built-in algorithm for training

If you use one of the [SageMaker AI built-in algorithms](), metrics are already defined for you. In addition, built-in algorithms automatically send metrics to hyperparameter tuning for optimization. These metrics are also written to Amazon CloudWatch logs. For more information, see [Log Amazon SageMaker AI Events with Amazon CloudWatch]().

For the objective metric for the tuning job, choose one of the metrics that the built-in algorithm emits. For a list of available metrics, see the model tuning section for the appropriate algorithm in Use Amazon SageMaker AI Built-in Algorithms or Pre-trained Models.

You can choose up to 40 metrics to monitor in your tuning job. Select one of those metrics to be the objective metric. The hyperparameter tuning job returns the training job that performed the best against the objective metric.

> **Note**
>
> Hyperparameter tuning automatically sends an additional hyperparameter `_tuning_objective_metric` to pass your objective metric to the tuning job for use during training.

Use a custom algorithm for training

This section shows how to define your own metrics to use your own custom algorithm for training. When doing so, make sure that your algorithm writes at least one metric to `stderr` or `stdout`. Hyperparameter tuning parses these streams to find algorithm metrics that show how well the model is performing on the dataset.

You can define custom metrics by specifying a name and regular expression for each metric that your tuning job monitors. Then, pass these metric definitions to the `CreateHyperParameterTuningJob` API in the `TrainingJobDefinition` parameter in the `MetricDefinitions` field of `AlgorithmSpecification`.

The following shows sample output from a log written to `stderr` or `stdout` by a training algorithm.

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
 disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744;  Iteration 0 took
 0.704s;  Elapsed=0s
```

The following code example shows how to use regular expressions in Python (regex). This is used to search the sample log output and capture the numeric values of four different metrics.

```
[
    {
```

```
        "Name": "ganloss",
        "Regex": "GAN_loss=(.*?);",
    },
    {
        "Name": "disc-combined",
        "Regex": "disc-combined=(.*?);",
    },
    {
        "Name": "discloss",
        "Regex": "disc_train_loss=(.*?);",
    },
    {
        "Name": "loss",
        "Regex": "Loss = (.*?);",
    },
]
```

In regular expressions, parenthesis `()` are used to group parts of the regular expression together.

- For the `loss` metric that is defined in the code example, the expression `(.*?);` captures any character between the exact text `"Loss="` and the first semicolon (`;`) character.
- The character `.` instructs the regular expression to match any character.
- The character `*` means to match zero or more characters.
- The character `?` means capture only until the first instance of the `;` character.

The loss metric defined in the code sample will capture `Loss = 16.020744` from the sample output.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the SageMaker API, specify the value of the `name` key in the `HyperParameterTuningJobObjective` field of the `HyperParameterTuningJobConfig` parameter that you send to the [`CreateHyperParameterTuningJob`](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_CreateHyperParameterTuningJob.html) operation.

Specify environment variables

SageMaker AI AMT optimizes hyperparameters within a tuning job to find the best parameters for model performance. You can use environment variables to configure your tuning job to change its behavior. You can also use environment variables that you used during training inside your tuning job.

If you want to use an environment variable from your tuning job or specify a new environment variable, input a string value for `Environment` within the SageMaker AI HyperParameterTrainingJobDefinition API. Pass this training job definition to the CreateHyperParameterTuningJob API.

For example, the environment variable `SM_LOG_LEVEL` can be set to the following values to tailor the output from a Python container.

```
NOTSET=0
DEBUG=10
INFO=20
WARN=30
ERROR=40
CRITICAL=50
```

As an example, to set the log level to `10` to debug your container logs, set the environment variable inside the HyperParameterTrainingJobDefinition, as follows.

```
{
   "HyperParameterTuningJobConfig": {
   ...,
   }
   "TrainingJobDefinition": {
      ...,
      "Environment" : [
          {
            "SM_LOG_LEVEL": 10
          }
      ],
      ...,
   },
   ...,
}
```

Define Hyperparameter Ranges

This guide shows how to use SageMaker APIs to define hyperparameter ranges. It also provides a list of hyperparameter scaling types that you can use.

Choosing hyperparameters and ranges significantly affects the performance of your tuning job. Hyperparameter tuning finds the best hyperparameter values for your model by searching over a range of values that you specify for each tunable hyperparameter. You can also specify up to 100 static hyperparameters that do not change over the course of the tuning job. You can use up to 100 hyperparameters in total (static + tunable). For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning. You can also use autotune to find optimal tuning job settings. For more information, see the following **Autotune** section.

Note

SageMaker AI Automatic Model Tuning (AMT) may add additional hyperparameters(s) that contribute to the limit of 100 total hyperparameters. Currently, to pass your objective metric to the tuning job for use during training, SageMaker AI adds `_tuning_objective_metric` automatically.

Static hyperparameters

Use static hyperparameters for the following cases: For example, you can use AMT to tune your model using `param1` (a tunable parameter) and `param2` (a static parameter). If you do, then use a search space for `param1` that lies between two values, and pass `param2` as a static hyperparameter, as follows.

```
param1: ["range_min","range_max"]
param2: "static_value"
```

Static hyperparameters have the following structure:

```
"StaticHyperParameters": {
    "objective" : "reg:squarederror",
    "dropout_rate": "0.3"
}
```

You can use the Amazon SageMaker API to specify key value pairs in the StaticHyperParameters field of the `HyperParameterTrainingJobDefinition` parameter that you pass to the CreateHyperParameterTuningJob operation.

Dynamic hyperparameters

You can use the SageMaker API to define hyperparameter ranges. Specify the names of hyperparameters and ranges of values in the `ParameterRanges` field of the `HyperParameterTuningJobConfig` parameter that you pass to the [`CreateHyperParameterTuningJob`](#) operation.

The `ParameterRanges` field has three subfields: categorical, integer, and continuous. You can define up to 30 total (categorical + integer + continuous) tunable hyperparameters to search over.

> **Note**
>
> Each categorical hyperparameter can have at most 30 different values.

Dynamic hyperparameters have the following structure:

```
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue" : "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
            "MinValue": "1",
            "ScalingType": "Auto"
        }
    ]
}
```

If you create a tuning job with a `Grid` strategy, you can only specify categorical values. You don't need to provide the `MaxNumberofTrainingJobs`. This value is inferred from the total number of configurations that can be produced from your categorical parameters. If specified, the value of `MaxNumberOfTrainingJobs` should be equal to the total number of distinct categorical combinations possible.

Autotune

To save time and resources searching for hyperparameter ranges, resources or objective metrics, autotune can automatically guess optimal values for some hyperparameter fields. Use autotune to find optimal values for the following fields:

- **ParameterRanges** – The names and ranges of hyperparameters that a tuning job can optimize.
- **ResourceLimits** – The maximum resources to be used in a tuning job. These resources can include the maximum number of training jobs, maximum runtime of a tuning job, and the maximum number of training jobs that can be run at the same time.
- **TrainingJobEarlyStoppingType** – A flag that stops a training job if a job is not significantly improving against an objective metric. Defaults to enabled. For more information, see Stop Training Jobs Early.
- **RetryStrategy** – The number of times to retry a training job. Non-zero values for `RetryStrategy` can increase the likelihood that your job will complete successfully.
- **Strategy** – Specifies how hyperparameter tuning chooses the combinations of hyperparameter values to use for the training job that it launches.
- **ConvergenceDetected** – A flag to indicate that Automatic Model Tuning (AMT) has detected model convergence.

To use autotune, do the following:

1. Specify the hyperparameter and an example value in the `AutoParameters` field of the ParameterRanges API.
2. Enable autotune.

AMT will determine if your hyperparameters and example values are eligible for autotune. Hyperparameters that can be used in autotune are automatically assigned to the appropriate parameter range type. Then, AMT uses `ValueHint` to select an optimal range for you. You can use the `DescribeHyperParameterTrainingJob` API to view these ranges.

The following example shows you how to configure a tuning job that uses autotune. In the configuration example, the hyperparameter `max_depth` has `ValueHint` containing an example value of `4`.

```
config = {
    'Autotune': {'Mode': 'Enabled'},
    'HyperParameterTuningJobName':'my-autotune-job',
    'HyperParameterTuningJobConfig': {
        'HyperParameterTuningJobObjective': {'Type': 'Minimize', 'MetricName': 
 'validation:rmse'},
        'ResourceLimits': {'MaxNumberOfTrainingJobs': 5, 'MaxParallelTrainingJobs': 1},
        'ParameterRanges': {
            'AutoParameters': [
                {'Name': 'max_depth', 'ValueHint': '4'}
            ]
        }
    },
    'TrainingJobDefinition': {
    .... }
```

Continuing the previous example, a tuning job is created after the previous configuration is included in a call to the `CreateHyperParameterTuningJob` API. Then, autotune converts the max_depth hyperparameter in AutoParameters to the hyperparameter `IntegerParameterRanges`. The following response from a `DescribeHyperParameterTrainingJob` API shows that the optimal `IntegerParameterRanges` for `max_depth` are between `2` and `8`.

```
{
    'HyperParameterTuningJobName':'my_job',
    'HyperParameterTuningJobConfig': {
        'ParameterRanges': {
            'IntegerParameterRanges': [
                {'Name': 'max_depth', 'MinValue': '2', 'MaxValue': '8'},
            ],
        }
    },
    'TrainingJobDefinition': {
        ...
    },
    'Autotune': {'Mode': 'Enabled'}
```

```
}
```

Hyperparameter scaling types

For integer and continuous hyperparameter ranges, you can choose the scale that you want hyperparameter tuning to use. For example, to search the range of values, you can specify a value for the `ScalingType` field of the hyperparameter range. You can choose from the following hyperparameter scaling types:

Auto

SageMaker AI hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude). Uniformly searching values from the range provides a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have values greater than 0.

Choose logarithmic scaling when you're searching a range that spans several orders of magnitude.

For example, if you're tuning a [Tune a linear learner model](#) model, and you specify a range of values between .0001 and 1.0 for the `learning_rate` hyperparameter, consider the following: Searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would. This is because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0. As a result, that leaves only 10 percent of your training budget for the values between .0001 and .1.

`ReverseLogarithmic`

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. Reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

For an example notebook that uses hyperparameter scaling, see these Amazon SageMaker AI hyperparameter examples on GitHub.

Track and set completion criteria for your tuning job

You can use completion criteria to instruct Automatic model tuning (AMT) to stop your tuning job if certain conditions are met. With these conditions, you can set a minimum model performance or maximum number of training jobs that don't improve when evaluated against the objective metric. You can also track the progress of your tuning job and decide to let it continue or to stop it manually. This guide shows you how to set completion criteria, check the progress of and stop your tuning job manually.

Set completion criteria for your tuning job

During hyperparameter optimization, a tuning job will launch several training jobs inside a loop. The tuning job will do the following.

- Check your training jobs for completion and update statistics accordingly
- Decide what combination of hyperparameters to evaluate next.

AMT will continuously check the training jobs that were launched from your tuning job to update statistics. These statistics include tuning job runtime and best training job. Then, AMT determines whether it should stop the job according to your completion criteria. You can also check these statistics and stop your job manually. For more information about stopping a job manually, see the Stopping your tuning job manually section.

As an example, if your tuning job meets your objective, you can stop tuning early to conserve resources or ensure model quality. AMT checks your job performance against your completion criteria and stops the tuning job if any have been met.

You can specify the following kinds of completion criteria:

- `MaxNumberOfTrainingJobs` – The maximum number of training jobs to be run before tuning is stopped.

- `MaxNumberOfTrainingJobsNotImproving` – The maximum number of training jobs that do not improve performance against the objective metric from the current best training job. As an example, if the best training job returned an objective metric that had an accuracy of `90%`, and `MaxNumberOfTrainingJobsNotImproving` is set to `10`. In this example, tuning will stop after `10` training jobs fail to return an accuracy higher than `90%`.
- `MaxRuntimeInSeconds` – The upper limit of wall clock time in seconds of how long a tuning job can run.
- `TargetObjectiveMetricValue` – The value of the objective metric against which the tuning job is evaluated. Once this value is met, AMT stops the tuning job.
- `CompleteOnConvergence` – A flag to stop tuning after an internal algorithm determines that the tuning job is unlikely to improve more than 1% over the objective metric from the best training job.

Selecting completion criteria

You can choose one or multiple completion criteria to stop your hyperparameter tuning job after a condition has been meet. The following instructions show you how to select completion criteria and how to decide which is the most appropriate for your use case.

- Use `MaxNumberOfTrainingJobs` in the ResourceLimits API to set an upper limit for the number of training jobs that can be run before your tuning job is stopped. Start with a large number and adjust it based on model performance against your tuning job objective. Most users input values of around `50` or more training jobs to find an optimal hyperparameter configuration. Users looking for higher levels of model performance will use `200` or more training jobs.
- Use `MaxNumberOfTrainingJobsNotImproving` in the BestObjectiveNotImproving API field to stop training if model performance fails to improve after a specified number of jobs. Model performance is evaluated against an objective function. After the `MaxNumberOfTrainingJobsNotImproving` is met, AMT will stop the tuning job. Tuning jobs tend to make the most progress in the beginning of the job. Improving model performance against an objective function will require a larger number of training jobs towards the end of tuning. Select a value for `MaxNumberOfTrainingJobsNotImproving` by checking the performance of similar training jobs against your objective metric.
- Use `MaxRuntimeInSeconds` in the ResourceLimits API to set an upper limit for the amount of wall clock time that the tuning job may take. Use this field to meet a deadline by which the tuning job must complete or to limit compute resources.

To get an estimated total compute time in seconds for a tuning job, use the following formula:

Estimated max compute time in seconds= `MaxRuntimeInSeconds` * `MaxParallelTrainingJobs` * `MaxInstancesPerTrainingJob`

> **Note**
>
> The actual duration of a tuning job may deviate slightly from the value specified in this field.

- Use `TargetObjectiveMetricValue` in the [TuningJobCompletionCriteria](#) API to stop your tuning job. You stop the tuning job after any training job that is launched by the tuning job reaches this objective metric value. Use this field if your use case depends on reaching a specific performance level, rather than spending compute resources to find the best possible model.
- Use `CompleteOnConvergence` in the [TuningJobCompletionCriteria](#) API to stop a tuning job after AMT has detected that the tuning job has converged, and is unlikely to make further significant progress. Use this field when it is not clear what values for any of the other completion criteria should be used. AMT determines convergence based on an algorithm developed and tested on a wide range of diverse benchmarks. A tuning job is defined to have converged when none of the training jobs return significant improvement (1% or less). Improvement is measured against the objective metric returned by the highest performing job, so far.

Combining different completion criteria

You can also combine any of the different completion criteria in the same tuning job. AMT will stop the tuning job when any one of the completion criteria is met. For example, if you want to tune your model until it meets an objective metric, but don't want to keep tuning if your job has converged, use the following guidance.

- Specify `TargetObjectiveMetricValue` in the [TuningJobCompletionCriteria](#) API to set a target objective metrics value to reach.
- Set [CompleteOnConvergence](#) to `Enabled` to stop a tuning job if AMT has determined that model performance is unlikely to improve.

Track tuning job progress

You can use the `DescribeHyperParameterTuningJob` API to track the progress of your tuning job at any time while it is running. You don't have to specify completion criteria to obtain tracking information for your tuning job. Use the following fields to obtain statistics about your tuning job.

- BestTrainingJob – An object that describes the best training job obtained so far, evaluated against your objective metric. Use this field to check your current model performance and the value of the objective metric of this best training job.
- ObjectiveStatusCounters – An object that specifies the total number of training jobs completed in a tuning job. To estimate average duration of a tuning job, use `ObjectiveStatusCounters` and the total runtime of a tuning job. You can use the average duration to estimate how much longer your tuning job will run.
- `ConsumedResources` – The total resources, such as `RunTimeInSeconds`, consumed by your tuning job. Compare `ConsumedResources`, found in the DescribeHyperParameterTuningJob API, against `BestTrainingJob` in the same API. You can also compare `ConsumedResources` against the response from the ListTrainingJobsForHyperParameterTuningJob API to assess if your tuning job is making satisfactory progress given the resources being consumed.
- TuningJobCompletionDetails – Tuning job completion information that includes the following:
  - The timestamp of when convergence is detected if the job has converged.
  - The number of training jobs that have not improved model performance. Model performance is evaluated against the objective metric from the best training job.

  Use the tuning job completion criteria to assess how likely your tuning job is to improve your model performance. Model performance is evaluated against the best objective metric if it ran to completion.

Stopping your tuning job manually

You can determine if you should let the tuning job run until it completes or if you should stop the tuning job manually. To determine this, use the information returned by the parameters in the `DescribeHyperParameterTuningJob` API, as shown in the previous **Tracking tuning job progress** section. As an example, if your model performance does not improve after several training jobs complete, you may choose to stop the tuning job. Model performance is evaluated against the best objective metric.

To stop the tuning job manually, use the [StopHyperParameterTuningJob](#) API and provide the name of the tuning job to be stopped.

Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker AI that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- The **job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
- The **training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.
- The **tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

Get Started

You can create a new hyperparameter tuning job, clone a job, add, or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker AI API.

- **In the console**: To create a new job, open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/, choose **Hyperparameter tuning jobs** from the **Training**, menu, and then choose **Create hyperparameter tuning job**. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) topic.

> **Note**
>
> When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call `CreateHyperParameterTuningJob` to tune multiple algorithms, you must provide a list of training definitions using `TrainingJobDefinitions` instead of specifying a single TrainingJobDefinition. You must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources that you want to use for the tuning job. Choose only one of these definition types depending on the number of algorithms that are being tuned.

Topics

Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

This guide shows you how to create a new hyperparameter optimization (HPO) tuning job for one or more algorithms. To create an HPO job, define the settings for the tuning job, and create training job definitions for each algorithm being tuned. Next, configure the resources for and create the tuning job. The following sections provide details about how to complete each step. We provide an example of how to tune multiple algorithms using the SageMaker AI SDK for Python client at the end of this guide.

Components of a tuning job

An HPO tuning job contains the following three components:

- Tuning job settings
- Training job definitions
- Tuning job configuration

The way that these components are included in your HPO tuning job depends on whether your tuning job contains one or multiple training algorithms. The following guide describes each of the components and gives an example of both types of tuning jobs.

Tuning job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when you're tuning a single algorithm. After you define the job settings, you can create individual training definitions for each algorithm or variation that you want to tune.

Warm start

If you cloned this job, you can use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature, and it's only available when tuning a single algorithm. With the warm start option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

> **Note**
>
> Warm start is compatible only with tuning jobs that were created after October 1, 2018. For more information, see [Run a warm start job](#).

Early stopping

To reduce compute time and avoid overfitting your model, you can stop training jobs early. Early stopping is helpful when the training job is unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it’s disabled by default. For more information about how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see [Stop Training Jobs Early](#).

Tuning strategy

Tuning strategy can be either random, Bayesian, or Hyperband. These selections specify how automatic tuning algorithms search specified hyperparameter ranges that are selected in a later step. Random search chooses random combinations of values from the specified ranges and can be run sequentially or in parallel. Bayesian optimization chooses values based on what is likely to get the best result according to the known history of previous selections. Hyperband uses a multi-fidelity strategy that dynamically allocates resources toward well-utilized jobs and automatically stops those that underperform. The new configuration that starts after stopping other configurations is chosen randomly.

Hyperband can only be used with iterative algorithms, or algorithms that run steps in iterations, such as XGBoost or Random Cut Forest. Hyperband can't be used with non-iterative algorithms, such as decision trees or k-Nearest Neighbors. For more information about search strategies, see How Hyperparameter Tuning Works.

> **Note**
>
> Hyperband uses an advanced internal mechanism to apply early stopping. Therefore, when you use the Hyperband internal early stopping feature, the parameter `TrainingJobEarlyStoppingType` in the `HyperParameterTuningJobConfig` API must be set to `OFF`.

Tags

To help you manage tuning jobs, you can enter tags as key-value pairs to assign metadata to tuning jobs. Values in the key-value pair are not required. You can use the key without values. To see the keys associated with a job, choose the **Tags** tab on the details page for tuning job. For more information about using tags for tuning jobs, see Manage Hyperparameter Tuning and Training Jobs.

Training job definitions

To create a training job definition, you must configure the algorithm and parameters, define the data input and output, and configure resources. Provide at least one `TrainingJobDefinition` for each HPO tuning job. Each training definition specifies the configuration for an algorithm.

To create several definitions for your training job, you can clone a job definition. Cloning a job can save time because it copies all of the job settings, including data channels and Amazon S3 storage locations for output artifacts. You can edit a cloned job to change what you need for your use case.

Topics

- Configure algorithm and parameters
- Define data input and output
- Configure training job resources
- Add or clone a training job

Configure algorithm and parameters

The following list describes what you need to configure the set of hyperparameter values for each training job.

- A name for your tuning job
- Permission to access services
- Parameters for any algorithm options
- An objective metric
- The range of hyperparameter values, when required

Name

Provide a unique name for the training definition.

Permissions

Amazon SageMaker AI requires permissions to call other services on your behalf. Choose an AWS Identity and Access Management (IAM) role, or let AWS create a role with the `AmazonSageMakerFullAccess` IAM policy attached.

Optional security settings

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a virtual private cloud (VPC).

> **Note**
>
> Inter-container encryption is only available when you create a job definition from the API.

Algorithm options

You can choose built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the Amazon Elastic Container Registry (Amazon ECR) image information pre-populated.
- If you choose your own container, you must specify the (Amazon ECR) image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a CSV file from Amazon S3, you should select the file.

Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you must define your metrics. You can define up to 20 metrics for your tuning job to monitor. You must choose one metric as the objective metric. For more information about how to define a metric for a tuning job, see Define metrics.

Objective metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page. The detail page provides a summary of the best training job that is found using this objective metric.

Hyperparameter configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm that's being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter’s type to **static**. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define data input and output

Each training job definition for a tuning job must configure the channels for data inputs, data output locations, and optionally, any checkpoint storage locations for each training job.

Input data configuration

Input data is defined by channels. Each channel its own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the algorithm that you choose supports multiple input channels, you can specify those, too. For example, when you use the XGBoost churn prediction notebook, you can add two channels: train and validation.

Checkpoint configuration

Checkpoints are periodically generated during training. For the checkpoints to be saved, you must choose an Amazon S3 location. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Checkpoints in Amazon SageMaker AI.

Output data configuration

Define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure training job resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker AI to use spare capacity to run jobs. For more information, see Managed Spot Training in Amazon SageMaker AI.

Stopping condition

The stopping condition specifies the maximum duration that's allowed for each training job.

Add or clone a training job

After you create a training job definition for a tuning job, you will return to the **Training Job Definition(s)** panel. This panel is where you can create additional training job definitions to train additional algorithms. You can select the **Add training job definition** and work through the steps to define a training job again.

Alternatively, to replicate an existing training job definition and edit it for the new algorithm, choose **Clone** from the **Action** menu. The clone option can save time because it copies all of the job’s settings, including the data channels and Amazon S3 storage locations. For more information about cloning, see Manage Hyperparameter Tuning and Training Jobs.

Tuning job configuration

Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most). You can also specify the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes that you have requested across all of your training definitions. The total number of jobs can’t exceed the number of jobs that your definitions are expected to run.

Review the job settings, the training job definitions, and the resource limits. Then select **Create hyperparameter tuning job**.

HPO tuning job example

To run a hyperparameter optimization (HPO) training job, first create a training job definition for each algorithm that's being tuned. Next, define the tuning job settings and configure the resources for the tuning job. Finally, run the tuning job.

If your HPO tuning job contains a single training algorithm, the SageMaker AI tuning function will call the `HyperparameterTuner` API directly and pass in your parameters. If your HPO tuning job contains multiple training algorithms, your tuning function will call the `create` function of the `HyperparameterTuner` API. The `create` function tells the API to expect a dictionary containing one or more estimators.

In the following section, code examples show how to tune a job containing either a single training algorithm or multiple algorithms using the SageMaker AI Python SDK.

Create training job definitions

When you create a tuning job that includes multiple training algorithms, your tuning job configuration will include the estimators and metrics and other parameters for your training jobs. Therefore, you need to create the training job definition first, and then configure your tuning job.

The following code example shows how to retrieve two SageMaker AI containers containing the built-in algorithms XGBoost and Linear Learner. If your tuning job contains only one training algorithm, omit one of the containers and one of the estimators.

```
import sagemaker
from sagemaker import image_uris

from sagemaker.estimator import Estimator

sess = sagemaker.Session()
region = sess.boto_region_name
role = sagemaker.get_execution_role()

bucket = sess.default_bucket()
prefix = "sagemaker/multi-algo-hpo"

# Define the training containers and intialize the estimators
xgb_container = image_uris.retrieve("xgboost", region, "latest")
ll_container = image_uris.retrieve("linear-learner", region, "latest")

xgb_estimator = Estimator(
    xgb_container,
    role=role,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    output_path='s3://{}/{}/xgb_output".format(bucket, prefix)',
    sagemaker_session=sess,
)

ll_estimator = Estimator(
    ll_container,
    role,
    instance_count=1,
    instance_type="ml.c4.xlarge",
    output_path="s3://{}/{}/ll_output".format(bucket, prefix),
    sagemaker_session=sess,
)

# Set static hyperparameters
ll_estimator.set_hyperparameters(predictor_type="binary_classifier")
xgb_estimator.set_hyperparameters(
    eval_metric="auc",
    objective="binary:logistic",
```

```
    num_round=100,
    rate_drop=0.3,
    tweedie_variance_power=1.4,
)
```

Next, define your input data by specifying the training, validation, and testing datasets, as shown in the following code example. This example shows how to tune multiple training algorithms.

```
training_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/train".format(bucket, prefix), content_type="csv"
)
validation_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/validate".format(bucket, prefix), content_type="csv"
)
test_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/test".format(bucket, prefix), content_type="csv"
)

train_inputs = {
    "estimator-1": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
    "estimator-2": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
}
```

If your tuning algorithm contains only one training algorithm, your `train_inputs` should contain only one estimator.

You must upload the inputs for the training, validation, and training datasets to your Amazon S3 bucket before you use those in an HPO tuning job.

Define resources and settings for your tuning job

This section shows how to initialize a tuner, define resources, and specify job settings for your tuning job. If your tuning job contains multiple training algorithms, these settings are applied to all of the algorithms that are contained inside your tuning job. This section provides two code examples to define a tuner. The code examples show you how to optimize a single training algorithm followed by an example of how to tune multiple training algorithms.

Tune a single training algorithm

The following code example shows how to initialize a tuner and set hyperparameter ranges for one SageMaker AI built-in algorithm, XGBoost.

```
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

hyperparameter_ranges = {
    "max_depth": IntegerParameter(1, 10),
    "eta": ContinuousParameter(0.1, 0.3),
}

objective_metric_name = "validation:accuracy"

tuner = HyperparameterTuner(
    xgb_estimator,
    objective_metric_name,
    hyperparameter_ranges,
    objective_type="Maximize",
    max_jobs=5,
    max_parallel_jobs=2,
)
```

Tune multiple training algorithms

Each training job requires different configurations, and these are specified using a dictionary. The following code example shows how to initialize a tuner with configurations for two SageMaker AI built-in algorithms, XGBoost and Linear Learner. The code example also shows how to set a tuning strategy and other job settings, such as the compute resources for the tuning job. The following code example uses `metric_definitions_dict`, which is optional.

```
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

# Initialize your tuner
tuner = HyperparameterTuner.create(
    estimator_dict={
        "estimator-1": xgb_estimator,
```

```
        "estimator-2": ll_estimator,
    },
    objective_metric_name_dict={
        "estimator-1": "validation:auc",
        "estimator-2": "test:binary_classification_accuracy",
    },
    hyperparameter_ranges_dict={
        "estimator-1": {"eta": ContinuousParameter(0.1, 0.3)},
        "estimator-2": {"learning_rate": ContinuousParameter(0.1, 0.3)},
    },
    metric_definitions_dict={
        "estimator-1": [
            {"Name": "validation:auc", "Regex": "Overall test accuracy: (.*?);"}
        ],
        "estimator-2": [
            {
                "Name": "test:binary_classification_accuracy",
                "Regex": "Overall test accuracy: (.*?);",
            }
        ],
    },
    strategy="Bayesian",
    max_jobs=10,
    max_parallel_jobs=3,
)
```

Run your HPO tuning job

Now you can run your tuning job by passing your training inputs to the `fit` function of the `HyperparameterTuner` class. The following code example shows how to pass the `train_inputs` parameter, that is defined in a previous code example, to your tuner.

```
tuner.fit(inputs=train_inputs, include_cls_metadata ={}, estimator_kwargs ={})
```

Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker AI provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/. Select **Hyperparameter tuning job** from the **Training** menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting **Create hyperparameter tuning job**.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting **Create Model** or you can clone the training job by selecting **Clone**.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in Add or clone a training job step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the Components of a tuning job section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes, such as cost allocation or access control. To add tags using the SageMaker SDK, use AddTags API. For more information about using tagging for AWS resources, see Tagging AWS resources.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost algorithm with Amazon SageMaker AI to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level SDK for Python (Boto3) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker AI high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker AI notebook instance

Topics

Create a Notebook Instance

Important

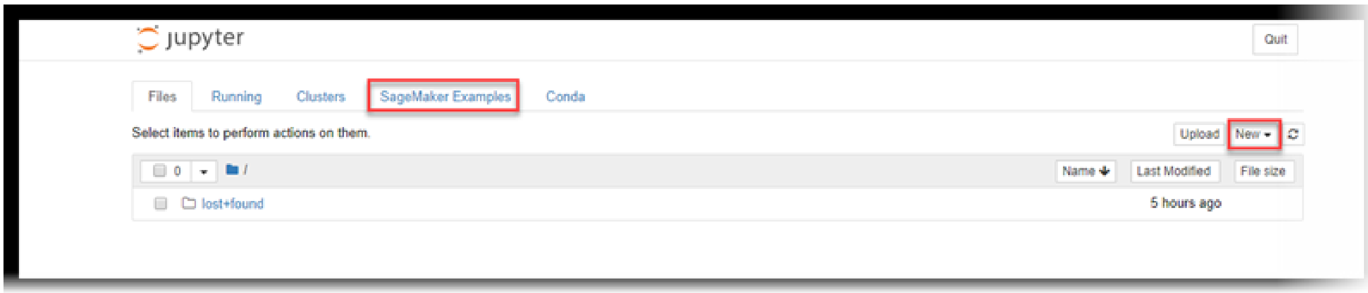
Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.

AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing **Open** next to its name. The Jupyter notebook server page appears:



3. To create a notebook, choose **Files**, **New**, and **conda_python3**. .
4. Name the notebook.

Next Step

Get the Amazon SageMaker AI Boto 3 Client

Get the Amazon SageMaker AI Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```
import sagemaker
import boto3

import numpy as np                                # For performing matrix operations
 and numerical processing
import pandas as pd                               # For manipulating tabular data
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines `region` and `smclient` objects that you will use to call the built-in XGBoost algorithm and set the SageMaker AI hyperparameter tuning job.

Next Step

Get the SageMaker AI Execution Role

Get the SageMaker AI Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance.

To find the ARN of the IAM execution role attached to a notebook instance:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. On the left navigation pane, choose **Notebook** then **Notebook instances**.
3. From the list of notebooks, select the notebook that you want to view.
4. The ARN is in the **Permissions and encryption** section.

Alternatively, Amazon SageMaker Python SDK users can retrieve the ARN of the execution role attached to their user profile or a notebook instance by running the following code:

```
from sagemaker import get_execution_role

role = get_execution_role()
print(role)
```

For more information about using `get_execution_role` in the Amazon SageMaker Python SDK, see Session. For more information about roles, see How to use SageMaker AI execution roles.

Next Step

Use an Amazon S3 bucket for input and output

Use an Amazon S3 bucket for input and output

Set up a S3 bucket to upload training datasets and save training output data for your hyperparameter tuning job.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker AI session. `prefix` is the path within the bucket where SageMaker AI stores the data for the current training job.

```
sess = sagemaker.Session()
bucket = sess.default_bucket() # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

To use a specific S3 bucket (Optional)

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain **`sagemaker`**, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```
bucket = "sagemaker-your-preferred-s3-bucket"

sess = sagemaker.Session(
    default_bucket = bucket
)
```

> **Note**
>
> The name of the bucket doesn't need to contain **`sagemaker`** if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

Next Step

[Download, Prepare, and Upload Training Data](#)

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.

For more information about the dataset and the data transformation that the example performs, see the *hpo_xgboost_direct_marketing_sagemaker_APIs* notebook in the **Hyperparameter Tuning** section of the **SageMaker AI Examples** tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```
!wget -N https://archive.ics.uci.edu/ml/machine-learning-databases/00222/bank-
additional.zip
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)     # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)         # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)
            # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired',
 'unemployed']), 1, 0)   # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)
            # Convert categorical variables to sets of indicators
model_data
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx',
 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)

train_data, validation_data, test_data = np.split(model_data.sample(frac=1,
 random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])

pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('test.csv', index=False, header=False)
```

```
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/
train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/
validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job

Configure and Launch a Hyperparameter Tuning Job

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
>
> AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

A hyperparameter is a high-level parameter that influences the learning process during model training. To get the best model predictions, you can optimize a hyperparameter configuration or set hyperparameter values. The process of finding an optimal configuration is called hyperparameter tuning. To configure and launch a hyperparameter tuning job, complete the steps in these guides.

Topics

- Settings for the hyperparameter tuning job
- Configure the training jobs
- Name and launch the hyperparameter tuning job
- Monitor the Progress of a Hyperparameter Tuning Job

- View the Status of the Training Jobs
- View the Best Training Job

Settings for the hyperparameter tuning job

To specify settings for the hyperparameter tuning job, define a JSON object when you create the tuning job. Pass this JSON object as the value of the `HyperParameterTuningJobConfig` parameter to the `CreateHyperParameterTuningJob` API.

In this JSON object, specify the following:

In this JSON object, you specify:

- `HyperParameterTuningJobObjective` – The objective metric used to evaluate the performance of the training job launched by the hyperparameter tuning job.
- `ParameterRanges` – The range of values that a tunable hyperparameter can use during optimization. For more information, see Define Hyperparameter Ranges
- `RandomSeed` – A value used to initialize a pseudo-random number generator. Setting a random seed will allow the hyperparameter tuning search strategies to produce more consistent configurations for the same tuning job (optional).
- `ResourceLimits` – The maximum number of training and parallel training jobs that the hyperparameter tuning job can use.

> **Note**
>
> If you use your own algorithm for hyperparameter tuning, rather than a SageMaker AI built-in algorithm, you must define metrics for your algorithm. For more information, see Define metrics.

The following code example shows how to configure a hyperparameter tuning job using the built-in XGBoost algorithm. The code example shows how to define ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters. For more information about these and other hyperparameters see XGBoost Parameters.

In this code example, the objective metric for the hyperparameter tuning job finds the hyperparameter configuration that maximizes `validation:auc`. SageMaker AI built-in algorithms automatically write the objective metric to CloudWatch Logs. The following code example also shows how to set a RandomSeed.

```
tuning_job_config = {
    "ParameterRanges": {
      "CategoricalParameterRanges": [],
      "ContinuousParameterRanges": [
        {
          "MaxValue": "1",
          "MinValue": "0",
          "Name": "eta"
        },
        {
          "MaxValue": "2",
          "MinValue": "0",
          "Name": "alpha"
        },
        {
          "MaxValue": "10",
          "MinValue": "1",
          "Name": "min_child_weight"
        }
      ],
      "IntegerParameterRanges": [
        {
          "MaxValue": "10",
          "MinValue": "1",
          "Name": "max_depth"
        }
      ]
    },
    "ResourceLimits": {
      "MaxNumberOfTrainingJobs": 20,
      "MaxParallelTrainingJobs": 3
    },
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {
      "MetricName": "validation:auc",
      "Type": "Maximize"
    },
    "RandomSeed" : 123
  }
```

Configure the training jobs

The hyperparameter tuning job will launch training jobs to find an optimal configuration of hyperparameters. These training jobs should be configured using the SageMaker AI `CreateHyperParameterTuningJob` API.

To configure the training jobs, define a JSON object and pass it as the value of the `TrainingJobDefinition` parameter inside `CreateHyperParameterTuningJob`.

In this JSON object, you can specify the following:

- `AlgorithmSpecification` – The registry path of the Docker image containing the training algorithm and related metadata. To specify an algorithm, you can use your own custom built algorithm inside a Docker container or a SageMaker AI built-in algorithm (required).
- `InputDataConfig` – The input configuration, including the `ChannelName`, `ContentType`, and data source for your training and test data (required).
- `InputDataConfig` – The input configuration, including the `ChannelName`, `ContentType`, and data source for your training and test data (required).
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- `RoleArn` – The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that SageMaker AI uses to perform tasks. Tasks include reading input data, downloading a Docker image, writing model artifacts to an S3 bucket, writing logs to Amazon CloudWatch Logs, and writing metrics to Amazon CloudWatch (required).
- `StoppingCondition` – The maximum runtime in seconds that a training job can run before being stopped. This value should be greater than the time needed to train your model (required).
- `MetricDefinitions` – The name and regular expression that defines any metrics that the training jobs emit. Define metrics only when you use a custom training algorithm. The example in the following code uses a built-in algorithm, which already has metrics defined. For information about defining metrics (optional), see Define metrics.
- `TrainingImage` – The Dockercontainer image that specifies the training algorithm (optional).
- `StaticHyperParameters` – The name and values of hyperparameters that are not tuned in the tuning job (optional).

The following code example sets static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the [XGBoost algorithm with Amazon SageMaker AI](#) built-in algorithm.

SageMaker Python SDK v1

```
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}/{}/train'.format(bucket, prefix)
s3_input_validation ='s3://{}/{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
      "TrainingImage": training_image,
      "TrainingInputMode": "File"
    },
    "InputDataConfig": [
      {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_train
          }
        }
      },
      {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
          }
        }
      }
    ],
```

```
    "OutputDataConfig": {
      "S3OutputPath": "s3://{}/{}/output".format(bucket,prefix)
    },
    "ResourceConfig": {
      "InstanceCount": 2,
      "InstanceType": "ml.c4.2xlarge",
      "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
      "eval_metric": "auc",
      "num_round": "100",
      "objective": "binary:logistic",
      "rate_drop": "0.3",
      "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
      "MaxRuntimeInSeconds": 43200
    }
}
```

SageMaker Python SDK v2

```
training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')

s3_input_train = 's3://{}/{}/train'.format(bucket, prefix)
s3_input_validation ='s3://{}/{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
      "TrainingImage": training_image,
      "TrainingInputMode": "File"
    },
    "InputDataConfig": [
      {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_train
```

```
          }
        }
      },
      {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
          }
        }
      }
    ],
    "OutputDataConfig": {
      "S3OutputPath": "s3://{}/{}/output".format(bucket,prefix)
    },
    "ResourceConfig": {
      "InstanceCount": 2,
      "InstanceType": "ml.c4.2xlarge",
      "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
      "eval_metric": "auc",
      "num_round": "100",
      "objective": "binary:logistic",
      "rate_drop": "0.3",
      "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
      "MaxRuntimeInSeconds": 43200
    }
}
```

Name and launch the hyperparameter tuning job

After you configure the hyperparameter tuning job, you can launch it by calling the `CreateHyperParameterTuningJob` API. The following code example uses `tuning_job_config` and `training_job_definition`. These were defined in the previous two code examples to create a hyperparameter tuning job.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
 tuning_job_name,
                                           HyperParameterTuningJobConfig =
 tuning_job_config,
                                           TrainingJobDefinition =
 training_job_definition)
```

Monitor the Progress of a Hyperparameter Tuning Job

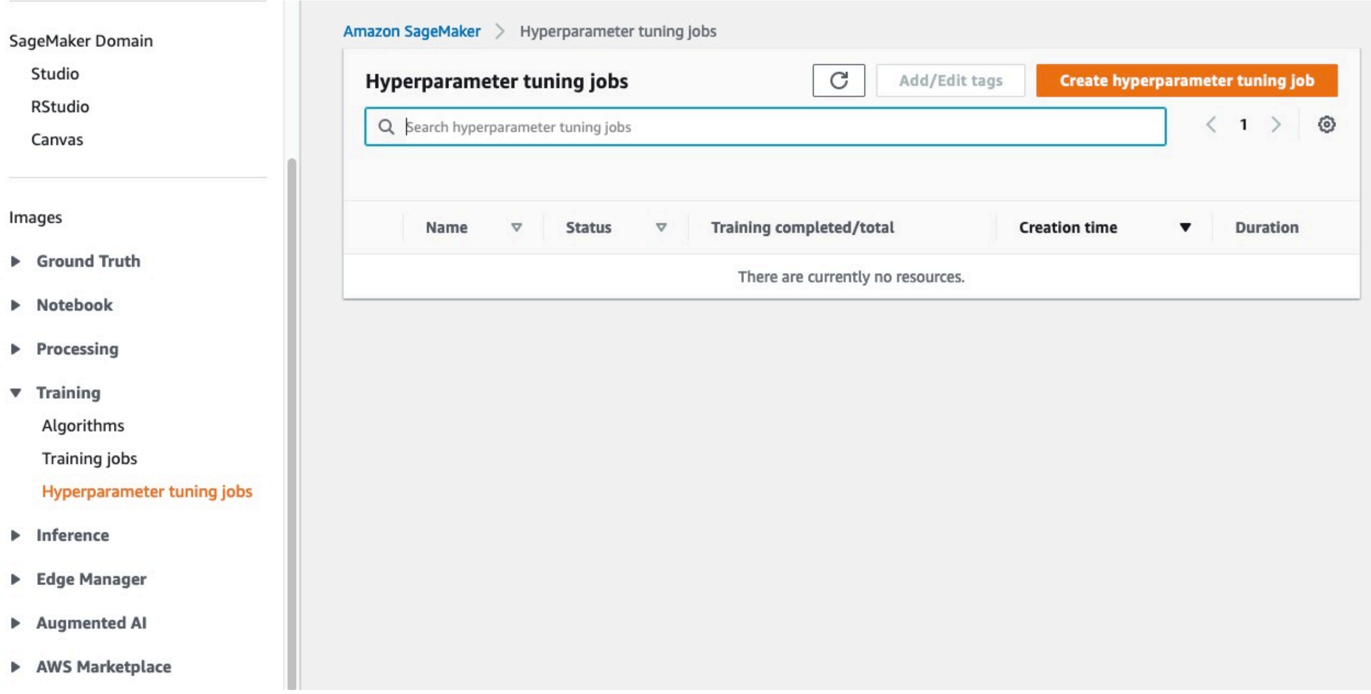
To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker AI console.

Topics

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Hyperparameter tuning jobs**.



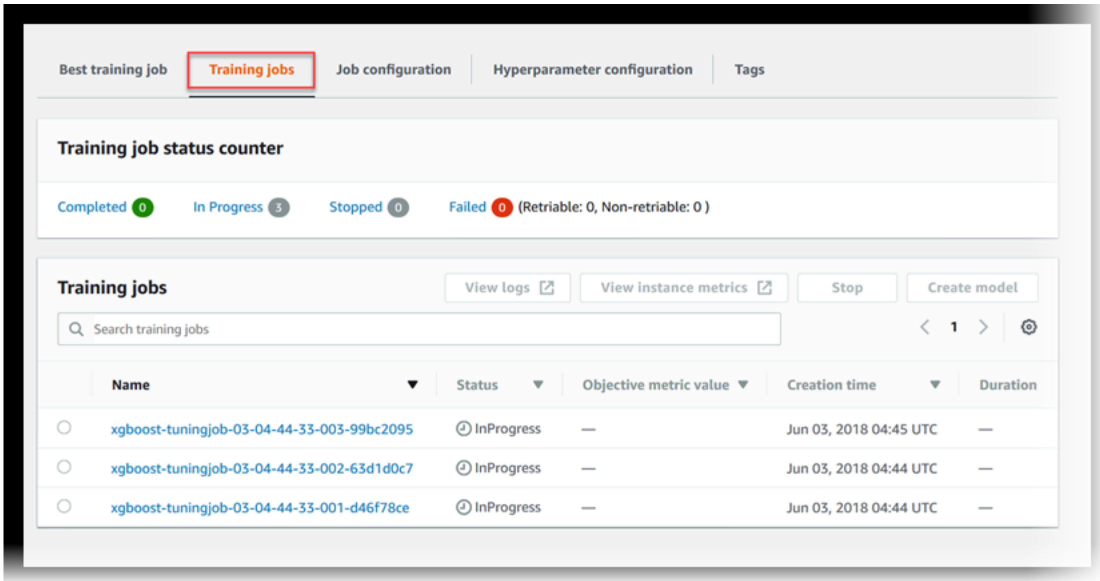
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

   - `Completed`—The hyperparameter tuning job successfully completed.
   - `InProgress`—The hyperparameter tuning job is in progress. One or more training jobs are still running.
   - `Failed`—The hyperparameter tuning job failed.
   - `Stopped`—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
   - `Stopping`—The hyperparameter tuning job is in the process of stopping.

View the Status of the Training Jobs

To view the status of the training jobs that the hyperparameter tuning job launched

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.



3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

   A training job can be:

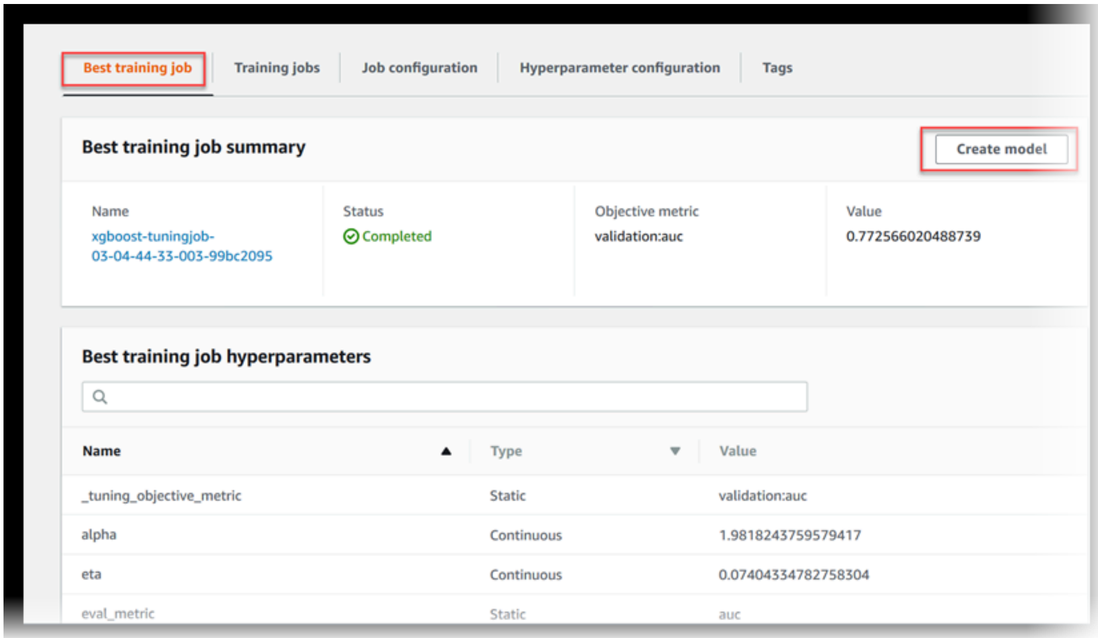
   - `Completed`—The training job successfully completed.
   - `InProgress`—The training job is in progress.
   - `Stopped`—The training job was manually stopped before it completed.
   - `Failed (Retryable)`—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
   - `Failed (Non-retryable)`—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.

> **Note**
>
> Hyperparameter tuning jobs can be stopped and the underlying resources deleted, but the jobs themselves cannot be deleted.

View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.



To deploy the best training job as a model that you can host at a SageMaker AI endpoint, choose **Create model**.

Next Step

[Clean up](#)

Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

> **Note**
>
> If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.

2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.
4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with `/aws/sagemaker/`.

Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the Amazon SageMaker Python SDK, set the `early_stopping_type` parameter of the HyperParameterTuner object to `Auto`.
- In the Amazon SageMaker AI console, in the **Create hyperparameter tuning job** workflow, under **Early stopping**, choose **Auto**.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the `hpo_image_classification_early_stopping.ipynb` notebook in the **Hyperparameter Tuning** section of the **SageMaker AI Examples** in a notebook instance.

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker AI evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.

- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker AI stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker AI algorithms support early stopping:

- LightGBM
- CatBoost
- AutoGluon-Tabular
- TabTransformer
- Linear Learner Algorithm—Supported only if you use `objective_loss` as the objective metric.
- XGBoost algorithm with Amazon SageMaker AI
- Image Classification - MXNet
- Object Detection - MXNet
- Sequence-to-Sequence Algorithm
- IP Insights

> **Note**
>
> This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow

Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see the tf.keras.callbacks.ProgbarLogger API.

MXNet

Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see the mxnet.callback APIs.

Chainer

Extend chainer by using the `extensions.Evaluator` class. For information, see the chainer.training.extensions.Evaluator API.

PyTorch and Spark

There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see Understand the hyperparameter tuning strategies available in Amazon SageMaker AI. Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

Note

Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons to consider warm start include the following:

- To gradually increase the number of training jobs over several tuning jobs based on results after each iteration.
- To tune a model using new data that you received.
- To change hyperparameter ranges that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.

Topics

Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

`IDENTICAL_DATA_AND_ALGORITHM`

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run an warm start tuning job of type `IDENTICAL_DATA_AND_ALGORITHM`, there is an additional field in the response to `DescribeHyperParameterTuningJob` named `OverallBestTrainingJob`. The value of this field is the TrainingJobSummary for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

`TRANSFER_LEARNING`

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (`Completed`, `Stopped`, or `Failed`) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.
- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. For example, if the parent job has a tunable categorical hyperparameter with the possible values `red` and `blue`, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of `red` in the parent job, and you change the static value to `blue` in the new tuning job, it also counts as 2 changes.
- Warm start tuning is not recursive. For example, if you create `MyTuningJob3` as a warm start tuning job with `MyTuningJob2` as a parent job, and `MyTuningJob2` is itself an warm start

tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.

- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.
- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker AI Python SDK to create a warm start tuning job.

Topics

- Create a Warm Start Tuning Job (Low-level SageMaker AI API for Python (Boto 3))
- Create a Warm Start Tuning Job (SageMaker AI Python SDK)

Create a Warm Start Tuning Job (Low-level SageMaker AI API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker AI API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:

```
warm_start_config = {
          "ParentHyperParameterTuningJobs" : [
          {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
```

```
        ],
        "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```

Create the warm start tuning job:

```
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
 'MyWarmStartTuningJob',
   HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning
 configuration
   TrainingJobDefinition = training_job_definition, # See notebook for job definition
   WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker AI Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a HyperparameterTuner object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification - MXNet algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges.

```
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                         'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```
from sagemaker.tuner import WarmStartConfig,WarmStartTypes

parent_tuning_job_name = "MyParentTuningJob"
```

```
warm_start_config =
 WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
 parents={parent_tuning_job_name})
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```
imageclassification.set_hyperparameters(num_layers=18,
                                        image_shape='3,224,224',
                                        num_classes=257,
                                        num_training_samples=15420,
                                        mini_batch_size=128,
                                        epochs=30,
                                        optimizer='sgd',
                                        top_k='2',
                                        precision_dtype='float32',
                                        augmentation_type='crop')
```

Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```
tuner_warm_start = HyperparameterTuner(imageclassification,
                            'validation:accuracy',
                            hyperparameter_ranges,
                            objective_type='Maximize',
                            max_jobs=10,
                            max_parallel_jobs=2,
                            base_tuning_job_name='warmstart',
                            warm_start_config=warm_start_config)
```

Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```
tuner_warm_start.fit(
        {'train': s3_input_train, 'validation': s3_input_validation},
        include_cls_metadata=False)
```

Resource Limits for Automatic Model Tuning

SageMaker AI sets the following default limits for resources used by automatic model tuning:

Resource	Regions	Default limits	Can be increased to
Number of parallel (concurrent) hyperparameter tuning jobs	All	100	N/A
Number of hyperpara meters that can be searched *	All	30	N/A
Number of metrics defined per hyperparameter tuning job	All	20	N/A
Number of parallel training jobs per hyperparameter tuning job	All	10	100
[Bayesian optimizat ion] Number of training jobs per hyperparameter tuning job	All	750	N/A
[Random search] Number of training jobs per hyperpara meter tuning job	All	750	10000
[Hyperband] Number of training jobs per hyperparameter tuning job	All	750	N/A

Resource	Regions	Default limits	Can be increased to
[Grid] Number of training jobs per hyperparameter tuning job, either specified explicitly or inferred from the search space	All	750	N/A
Maximum run time for a hyperparameter tuning job	All	30 days	N/A

* Each categorical hyperparameter can have at most 30 different values.

Resource limit example

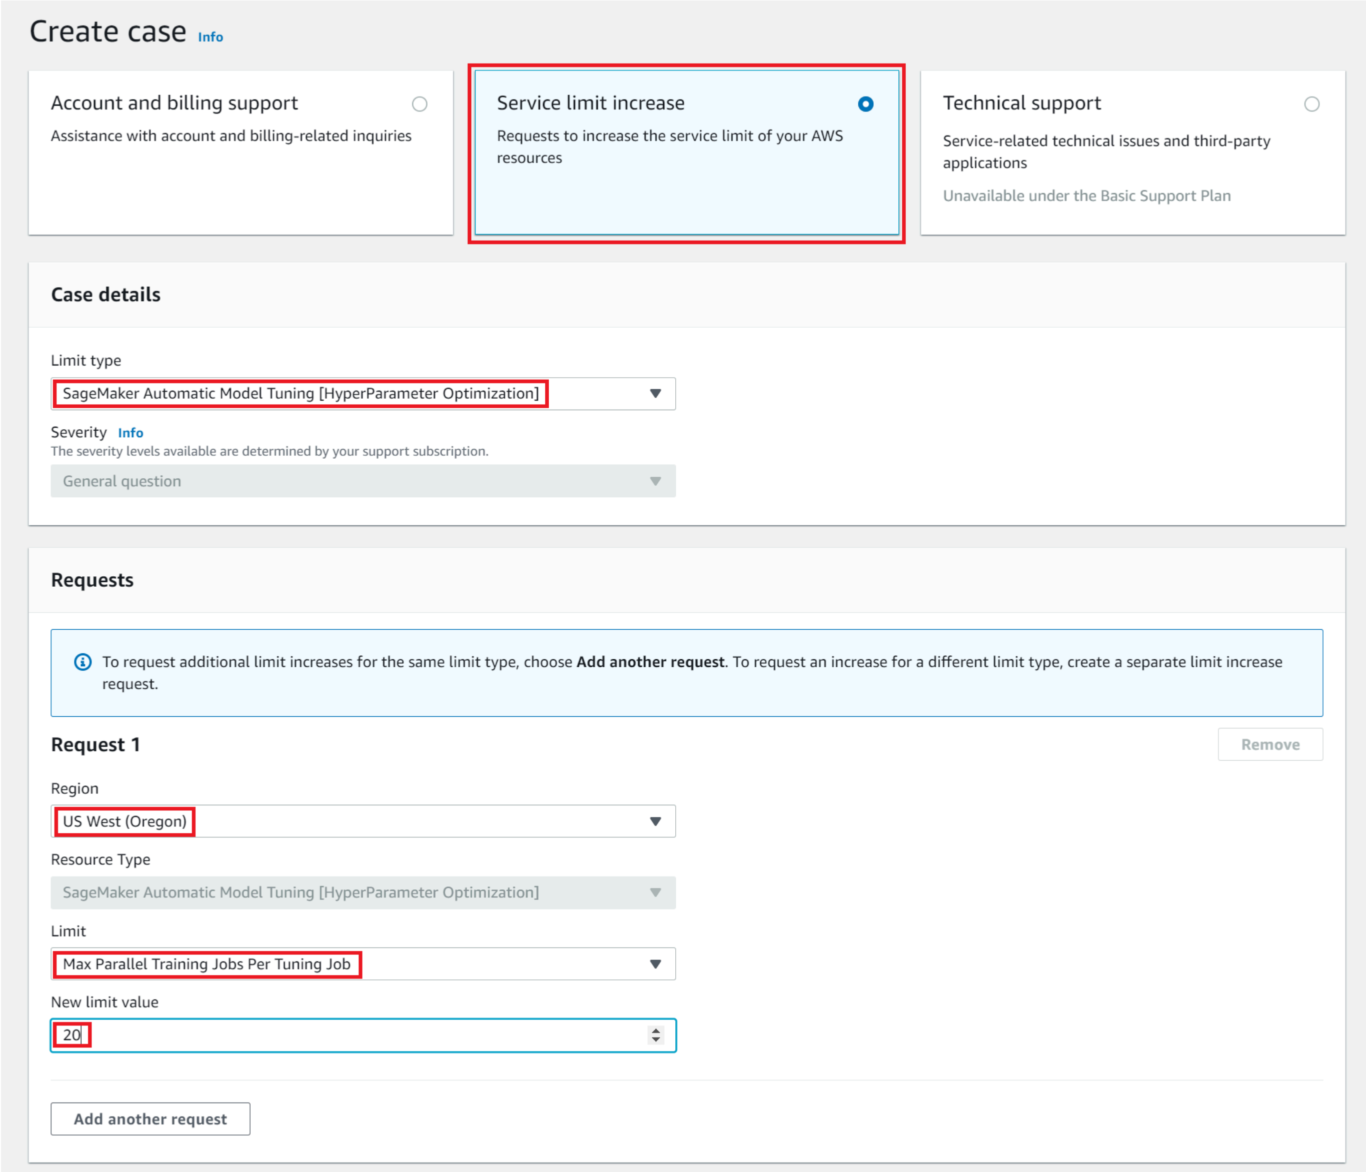
When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker AI training jobs, see SageMaker AI Limits. Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one **ml.m4.xlarge** instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 750.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker AI training **ml.m4.xlarge** instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

- SageMaker AI training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose **Create case**.
2. On the **Create case** page, choose **Service limit increase**.
3. On the **Case details** panel, select **SageMaker AI Automatic Model Tuning [Hyperparameter Optimization]** for the **Limit type**
4. On the **Requests** panel for **Request 1**, select the **Region**, the resource **Limit** to increase and the **New Limit value** you are requesting. Select **Add another request** if you have additional requests for quota increases.



5. In the **Case description** panel, provide a description of your use case .
6. In the **Contact options** panel, select your preferred **Contact methods** (**Web**, **Chat** or **Phone**) and then choose **Submit**.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization (HPO) is not a fully-automated process. To improve optimization, follow these best practices for hyperparameter tuning.

Topics

- [Choosing a tuning strategy]

Choosing a tuning strategy

For large jobs, using the Hyperband tuning strategy can reduce computation time. Hyperband has an early stopping mechanism to stop under-performing jobs. Hyperband can also reallocate resources towards well-utilized hyperparameter configurations and run parallel jobs. For smaller training jobs using less runtime, use either random search or Bayesian optimization.

Use Bayesian optimization to make increasingly informed decisions about improving hyperparameter configurations in the next run. Bayesian optimization uses information gathered from prior runs to improve subsequent runs. Because of its sequential nature, Bayesian optimization cannot massively scale.

Use random search to run a large number of parallel jobs. In random search, subsequent jobs do not depend on the results from prior jobs and can be run independently. Compared to other strategies, random search is able to run the largest number of parallel jobs.

Use grid search to reproduce results of a tuning job, or if simplicity and transparency of the optimization algorithm are important. You can also use grid search to explore the entire hyperparameter search space evenly. Grid search methodically searches through every hyperparameter combination to find optimal hyperparameter values. Unlike grid search, Bayesian optimization, random search and Hyperband all draw hyperparameters randomly from the search space. Because grid search analyzes every combination of hyperparameters, optimal hyperparameter values will be identical between tuning jobs that use the same hyperparameters.

Choosing the number of hyperparameters

During optimization, the computational complexity of a hyperparameter tuning job depends on the following:

- The number of hyperparameters
- The range of values that Amazon SageMaker AI has to search

Although you can simultaneously specify up to 30 hyperparameters, limiting your search to a smaller number can reduce computation time. Reducing computation time allows SageMaker AI to converge more quickly to an optimal hyperparameter configuration.

Choosing hyperparameter ranges

The range of values that you choose to search can adversely affect hyperparameter optimization. For example, a range that covers every possible hyperparameter value can lead to large compute times and a model that doesn't generalize well to unseen data. If you know that using a subset of the largest possible range is appropriate for your use case, consider limiting the range to that subset.

Using the correct scales for hyperparameters

During hyperparameter tuning, SageMaker AI attempts to infer if your hyperparameters are log-scaled or linear-scaled. Initially, SageMaker AI assumes linear scaling for hyperparameters. If hyperparameters are log-scaled, choosing the correct scale will make your search more efficient. You can also select `Auto` for `ScalingType` in the [CreateHyperParameterTuningJob](#) API if you want SageMaker AI to detect the scale for you.

Choosing the best number of parallel training jobs

You can use the results of previous trials to improve the performance of subsequent trials. Choose the largest number of parallel jobs that would provide a meaningful incremental result that is also within your region and account compute constraints. Use the `MaxParallelTrainingJobs` field to limit the number of training jobs that a hyperparameter tuning job can launch in parallel. For more information, see [Running multiple HPO jobs in parallel on Amazon SageMaker AI](#).

Running training jobs on multiple instances

When a training job runs on multiple machines in distributed mode, each machine emits an objective metric. HPO can only use one of these emitted objective metrics to evaluate model performance, In distributed mode, HPO uses the objective metric that was reported by the last running job across all instances.

Using a random seed to reproduce hyperparameter configurations

You can specify an integer as a random seed for hyperparameter tuning and use that seed during hyperparameter generation. Later, you can use the same seed to reproduce hyperparameter configurations that are consistent with your previous results. For random search and Hyperband strategies, using the same random seed can provide up to 100% reproducibility of the previous hyperparameter configuration for the same tuning job. For Bayesian strategy, using the same random seed will improve reproducibility for the same tuning job.

Data refining during training with Amazon SageMaker smart sifting

SageMaker smart sifting is a capability of SageMaker Training that helps improve the efficiency of your training datasets and reduce total training time and cost.

Modern deep learning models such as large language models (LLMs) or vision transformer models often require massive datasets to achieve acceptable accuracy. For example, LLMs often require trillions of tokens or petabytes of data to converge. The growing size of training datasets, along with the size of state-of-the-art models, can increase the compute time and cost of model training.

Invariably, samples in a dataset do not contribute equally to the learning process during model training. A significant proportion of computational resources provisioned during training might be spent on processing easy samples that do not contribute substantially to the overall accuracy of a model. Ideally, training datasets would only include samples that are actually improving the model convergence. Filtering out less helpful data can reduce training time and compute cost. However, identifying less helpful data can be challenging and risky. It is practically difficult to identify which samples are less informative before training, and model accuracy can be impacted if the wrong samples or too many samples are excluded.

Smart sifting of data with Amazon SageMaker AI can help reduce training time and cost by improving data efficiency. The SageMaker smart sifting algorithm evaluates the loss value of each data during the data loading stage of a training job and excludes samples which are less informative to the model. By using refined data for training, the total time and cost of training your model is reduced by eliminating unnecessary forward and backward passes on non-improving data. Therefore, there is minimal or no impact on the accuracy of the model.

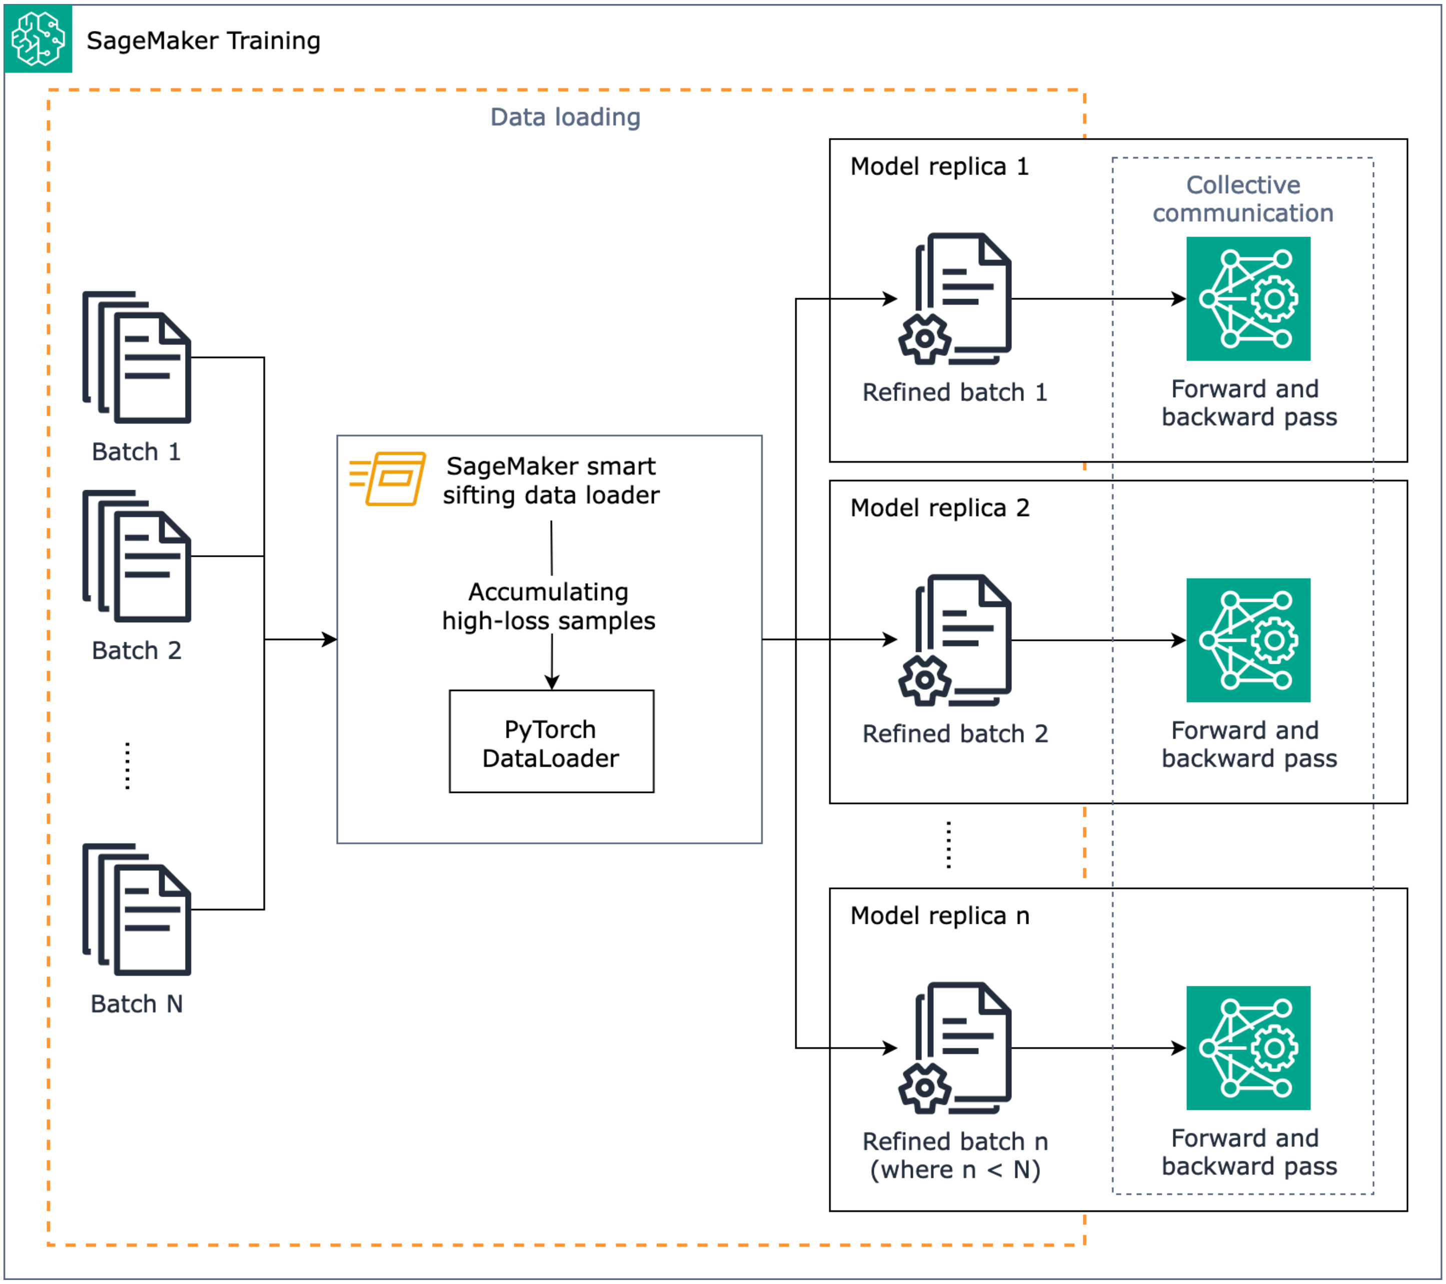
SageMaker smart sifting is available through SageMaker Training Deep Learning Containers (DLCs) and supports PyTorch workloads via the PyTorch `DataLoader`. Just a few lines of code change are needed to implement SageMaker smart sifting and you do not need to change your existing training or data processing workflows.

Topics

How SageMaker smart sifting works

The goal of SageMaker smart sifting is to sift through your training data during the training process and only feed more informative samples to the model. During typical training with PyTorch, data is iteratively sent in batches to the training loop and to accelerator devices (such as GPUs or Trainium chips) by the PyTorch `DataLoader`. SageMaker smart sifting is implemented at this data loading stage and is thus independent of any upstream data pre-processing in your training pipeline. SageMaker smart sifting uses your model and its user-specified loss function to do an evaluative forward pass of each data sample as it is loaded. Samples that return *low-loss* values have less of an impact on the model's learning and are thus excluded from training, because it is already *easy* for the model to make the right prediction about them with high confidence. Meanwhile, those relatively high-loss samples are what the model still needs to learn, so these are kept for training. A key input you can set for SageMaker smart sifting is the proportion of data to exclude. For example, by setting the proportion to 25%, samples distributed in the lowest quartile of the distribution of loss (taken from a user-specified number of previous samples) are excluded from training. High-loss samples are accumulated in a refined data batch. The refined data batch is sent to the training loop (forward and backward pass), and the model learns and trains on the refined data batch.

The following diagram shows an overview of how the SageMaker smart sifting algorithm is designed.



In short, SageMaker smart sifting operates during training as data is loaded. The SageMaker smart sifting algorithm runs loss calculation over the batches, and sifts non-improving data out before the forward and backward pass of each iteration. The refined data batch is then used for the forward and backward pass.

> **Note**
>
> Smart sifting of data on SageMaker AI uses additional forward passes to analyze and filter your training data. In turn, there are fewer backward passes as less impactful data

is excluded from your training job. Because of this, models which have long or expensive backward passes see the greatest efficiency gains when using smart sifting. Meanwhile, if your model's forward pass takes longer than its backward pass, overhead could increase total training time. To measure the time spent by each pass, you can run a pilot training job and collect logs that record the time on the processes. Also consider using SageMaker Profiler that provides profiling tools and UI application. To learn more, see Amazon SageMaker Profiler.

SageMaker smart sifting works for PyTorch-based training jobs with classic distributed data parallelism, which makes model replicas on each GPU worker and performs `AllReduce`. It works with PyTorch DDP and the SageMaker AI distributed data parallel library.

Supported frameworks and AWS Regions

Before using SageMaker smart sifting data loader, check if your framework of choice is supported, that the instance types are available in your AWS account, and that your AWS account is in one of the supported AWS Regions.

Note

SageMaker smart sifting supports PyTorch model training with traditional data parallelism and distributed data parallelism, which makes model replicas in all GPU workers and uses the `AllReduce` operation. It doesn’t work with model parallelism techniques, including sharded data parallelism. Because SageMaker smart sifting works for data parallelism jobs, make sure that the model you train fits in each GPU memory.

Supported Frameworks

SageMaker smart sifting supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

Topics

- PyTorch

PyTorch

Framework	Framework version	Deep Learning Container URI	
PyTorch	2.1.0	*763104351884* .dkr.ecr.*region*.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-ubuntu20.04-sagemaker	

For more information about the pre-built containers, see SageMaker AI Framework Containers in the *AWS Deep Learning Containers GitHub repository*.

AWS Regions

The containers packaged with the SageMaker smart sifting library are available in the AWS Regions where AWS Deep Learning Containers are in service.

Instance types

You can use SageMaker smart sifting for any PyTorch training jobs on any instance types. We recommend that you use P4d, P4de, or P5 instances.

SageMaker smart sifting within your training script

The SageMaker smart sifting library is packaged in the SageMaker AI framework DLCs as a complementary library. It provides a filtering logic against training samples that have relatively lower impact on model training, and your model can reach the desired model accuracy with fewer training samples when compared to the model training with full data samples.

To learn how to implement the smart sifting tool into your training script, choose one of the following based on the framework you use.

Topics

- [Apply SageMaker smart sifting to your Hugging Face Transformers script]

Apply SageMaker smart sifting to your PyTorch script

These instructions demonstrate how to enable SageMaker smart sifting with your training script.

1. Configure the SageMaker smart sifting interface.

   The SageMaker smart sifting library implements a relative-threshold loss-based sampling technique that helps filter out samples with lower impact on reducing the loss value. The SageMaker smart sifting algorithm calculates the loss value of every input data sample using a forward pass, and calculates its relative percentile against the loss values of preceding data.

   The following two parameters are what you need to specify to the `RelativeProbabilisticSiftConfig` class for creating a sifting configuration object.

   - Specify the proportion of data that should be used for training to the `beta_value` parameter.
   - Specify the number of samples used in the comparison with the `loss_history_length` parameter.

   The following code example demonstrates setting up an object of the `RelativeProbabilisticSiftConfig` class.

```
from smart_sifting.sift_config.sift_configs import (
    RelativeProbabilisticSiftConfig
    LossConfig
    SiftingBaseConfig
)

sift_config=RelativeProbabilisticSiftConfig(
    beta_value=0.5,
    loss_history_length=500,
    loss_based_sift_config=LossConfig(
         sift_config=SiftingBaseConfig(sift_delay=0)
    )
)
```

For more information about the `loss_based_sift_config` parameter and related classes, see the section called "SageMaker smart sifting configuration modules" in the SageMaker smart sifting Python SDK reference section.

The `sift_config` object in the preceding code example is used in step 4 for setting up the `SiftingDataloader` class.

2. (Optional) Configure a SageMaker smart sifting batch transform class.

   Different training use cases require different training data formats. Given the variety of data formats, the SageMaker smart sifting algorithm needs to identify how to perform sifting on a particular batch. To address this, SageMaker smart sifting provides a batch transform module that helps convert batches into standardized formats that it can efficiently sift.

   a. SageMaker smart sifting handles batch transform of training data in the following formats: Python lists, dictionaries, tuples, and tensors. For these data formats, SageMaker smart sifting automatically handles the batch data format conversion, and you can skip the rest of this step. If you skip this step, in step 4 for configuring `SiftingDataloader`, leave the `batch_transforms` parameter of `SiftingDataloader` to its default value, which is `None`.

   b. If your dataset is not in these format, you should proceed to the rest of this step to create a custom batch transform using `SiftingBatchTransform`.

      In cases in which your dataset isn't in one of the supported formats by SageMaker smart sifting, you might run into errors. Such data format errors can be resolved by adding the `batch_format_index` or `batch_transforms` parameter to the `SiftingDataloader` class, which you set up in step 4. The following shows example errors due to an incompatible data format and resolutions for them.

Error Message	Resolution
Batches of type *`{type(batch)}`* are not supported by default.	This error indicates the batch format is not supported by default. You should implement a custom batch transform class, and use this by specifying it to the `batch_transforms` parameter of the `SiftingDataloader` class.

Error Message	Resolution
Unable to index the batch of type *{type(batch)}*	This error indicates the batch object cannot be indexed normally. User must implement a custom batch transform and pass this using the `batch_transforms` parameter.
Batch size *{batch_size}* does not match dimension 0 or dimension 1 sizes	This error occurs when the provided batch size does not match the 0th or 1st dimensions of the batch. User must implement a custom batch transform and pass this using the `batch_transforms` parameter.
Both dimension 0 and dimension 1 match batch size	This error indicates that since multiple dimensions match the provided batch size, more information is required to sift the batch. The user can provide the `batch_format_index` parameter to indicate if the batch is indexable by sample or feature. Users may also implement a custom batch transform, but this is more work than required.

To resolve the aforementioned issues, you need to create a custom batch transform class using the `SiftingBatchTransform` module. A batch transform class should consist of a pair of transform and reverse-transform functions. The function pair converts your data format to a format that SageMaker smart sifting algorithm can process. After you create a batch transform class, the class returns a `SiftingBatch` object that you'll pass to the `SiftingDataloader` class in step 4.

The following are examples of custom batch transform classes of the `SiftingBatchTransform` module.

- An example of a custom list batch transform implementation with SageMaker smart sifting for cases where the dataloader chunk has inputs, masks, and labels.

```
from typing import Any

import torch

from smart_sifting.data_model.data_model_interface import
 SiftingBatchTransform
from smart_sifting.data_model.list_batch import ListBatch

class ListBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
        inputs = batch[0].tolist()
        labels = batch[-1].tolist()  # assume the last one is the list of
 labels
        return ListBatch(inputs, labels)

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs),
 torch.tensor(list_batch.labels)]
        return a_batch
```

- An example of a custom list batch transform implementation with SageMaker smart sifting for cases where no labels are needed for reverse transformation.

```
class ListBatchTransformNoLabels(SiftingBatchTransform):
    def transform(self, batch: Any):
        return ListBatch(batch[0].tolist())

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs)]
        return a_batch
```

- An example of a custom tensor batch implementation with SageMaker smart sifting for cases where the data loader chunk has inputs, masks, and labels.

```
from typing import Any

from smart_sifting.data_model.data_model_interface import
 SiftingBatchTransform
from smart_sifting.data_model.tensor_batch import TensorBatch

class TensorBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
```

```
        a_tensor_batch = TensorBatch(
            batch[0], batch[-1]
        )  # assume the last one is the list of labels
        return a_tensor_batch

    def reverse_transform(self, tensor_batch: TensorBatch):
        a_batch = [tensor_batch.inputs, tensor_batch.labels]
        return a_batch
```

After you create a `SiftingBatchTransform`-implemted batch transform class, you use this class in step 4 for setting up the `SiftingDataloader` class. The rest of this guide assumes that a `ListBatchTransform` class is created. In step 4, this class is passed to the `batch_transforms`.

3. Create a class for implementing the SageMaker smart sifting `Loss` interface. This tutorial assumes that the class is named `SiftingImplementedLoss`. While setting up this class, we recommend that you use the same loss function in the model training loop. Go through the following substeps for creating a SageMaker smart sifting `Loss` implemented class.

   a. SageMaker smart sifting calculates a loss value for each training data sample, as opposed to calculating a single loss value for a batch. To ensure that SageMaker smart sifting uses the same loss calculation logic, create a smart-sifting-implemented loss function using the SageMaker smart sifting `Loss` module that uses your loss function and calculates loss per training sample.

      Tip

      SageMaker smart sifting algorithm runs on every data sample, not on the entire batch, so you should add an initialization function to set the PyTorch loss function without any reduction strategy.

      ```
      class SiftingImplementedLoss(Loss):
          def __init__(self):
              self.loss = torch.nn.CrossEntropyLoss(reduction='none')
      ```

      This is also shown in the following code example.

   b. Define a loss function that accepts the `original_batch` (or `transformed_batch` if you have set up a batch transform in step 2) and the PyTorch model. Using the specified loss function with no reduction, SageMaker smart sifting runs a forward pass for each data sample to evaluate its loss value.

The following code is an example of a smart-sifting-implemented `Loss` interface named `SiftingImplementedLoss`.

```
from typing import Any

import torch
import torch.nn as nn
from torch import Tensor

from smart_sifting.data_model.data_model_interface import SiftingBatch
from smart_sifting.loss.abstract_sift_loss_module import Loss

model=... # a PyTorch model based on torch.nn.Module

class SiftingImplementedLoss(Loss):
    # You should add the following initializaztion function
    # to calculate loss per sample, not per batch.
    def __init__(self):
        self.loss_no_reduction = torch.nn.CrossEntropyLoss(reduction='none')

    def loss(
        self,
        model: torch.nn.Module,
        transformed_batch: SiftingBatch,
        original_batch: Any = None,
    ) -> torch.Tensor:
        device = next(model.parameters()).device
        batch = [t.to(device) for t in original_batch] # use this if you use
 original batch and skipped step 2
        # batch = [t.to(device) for t in transformed_batch] # use this if you
 transformed batches in step 2

        # compute loss
        outputs = model(batch)
        return self.loss_no_reduction(outputs.logits, batch[2])
```

Before the training loop hits the actual forward pass, this sifting loss calculation is done during the data loading phase of fetching a batch in each iteration. The individual loss value is then compared to previous loss values, and its relative percentile is estimated per the object of `RelativeProbabilisticSiftConfig` you have set up in step 1.

4. Wrap the PyTroch data loader by the SageMaker AI `SiftingDataloader` class.

   Finally, use all the SageMaker smart sifting implemented classes you configured in the previous steps to the SageMaker AI `SiftingDataloder` configuration class. This class is a wrapper for PyTorch [`DataLoader`](). By wrapping PyTorch `DataLoader`, SageMaker smart sifting is registered to run as part of data loading in each iteration of a PyTorch training job. The following code example demonstrates implementing SageMaker AI data sifting to a PyTorch `DataLoader`.

```
from smart_sifting.dataloader.sift_dataloader import SiftingDataloader
from torch.utils.data import DataLoader

train_dataloader = DataLoader(...) # PyTorch data loader

# Wrap the PyTorch data loader by SiftingDataloder
train_dataloader = SiftingDataloader(
    sift_config=sift_config, # config object of RelativeProbabilisticSiftConfig
    orig_dataloader=train_dataloader,
    batch_transforms=ListBatchTransform(), # Optional, this is the custom class
 from step 2
    loss_impl=SiftingImplementedLoss(), # PyTorch loss function wrapped by the
 Sifting Loss interface
    model=model,
    log_batch_data=False
)
```

Apply SageMaker smart sifting to your Hugging Face Transformers script

There are two ways to implement the SageMaker smart sifting into the Transformers `Trainer` class.

> **Note**
>
> If you use one of the DLCs for PyTorch with the SageMaker smart sifting package installed, note that you need to install the `transformers` library. You can install additional packages by [extending the DLCs]() or passing `requirements.txt` to the training job

launcher class for PyTorch (sagemaker.pytorch.PyTorch) in the SageMaker AI Python SDK.

Simple setup

The simplest way to implement SageMaker smart sifting into the Transformers `Trainer` class is to use the `enable_sifting` function. This function accepts an existing `Trainer` object, and wraps the existing `DataLoader` object with `SiftingDataloader`. You can continue using the same training object. See the following example usage.

```
from smart_sifting.integrations.trainer import enable_sifting
from smart_sifting.loss.abstract_sift_loss_module import Loss
from smart_sifting.sift_config.sift_configs import (
    RelativeProbabilisticSiftConfig
    LossConfig
    SiftingBaseConfig
)

class SiftingImplementedLoss(Loss):
   def loss(self, model, transformed_batch, original_batch):
        loss_fct = MSELoss(reduction="none") # make sure to set reduction to "none"
        logits = model.bert(**original_batch)
        return loss_fct(logits, original_batch.get("labels"))

sift_config = RelativeProbabilisticSiftConfig(
    beta_value=0.5,
    loss_history_length=500,
    loss_based_sift_config=LossConfig(
         sift_config=SiftingBaseConfig(sift_delay=0)
    )
)

trainer = Trainer(...)
enable_sifting(trainer, sift_config, loss=SiftingImplementedLoss()) # updates the
 trainer with Sifting Loss and config
trainer.train()
```

The `SiftingDataloader` class is an iterable data loader. The exact size of the resulting dataset is not known beforehand due to the random sampling during sifting. As a result, the Hugging Face `Trainer` expects the `max_steps` training argument. Note that this argument overrides the epoch configuration parameter `num_train_epochs`. If your original data loader was also iterable, or your training uses `max_steps` and a single epoch, then the `SiftingDataloader` performs the same as the existing dataloader. If the original dataloader was not iterable or `max_steps` was not provided, the Hugging Face Trainer might throw an error message similar to the following.

```
args.max_steps must be set to a positive value if dataloader does not have a length,
was -1
```

To address this, the `enable_sifting` function provides an optional `set_epochs` parameter. This enables training with epochs, using the number of epochs provided by [num_train_epochs argument](#) of the `Trainer` class, and sets `max_steps` to the maximum system integer, allowing training to progress until the specified epochs have completed.

Custom setup

For a custom integration of the SageMaker smart sifting dataloader, you can utilize a custom Hugging Face `Trainer` class. Within any subclass of `Trainer`, the `get_train_dataloader()` function can be overridden to return an object of the `SiftingDataloader` class instead. For cases with existing custom trainers, this approach might be less intrusive but requires code changes than the simple setup option. The following is an example implementation of SageMaker smart sifting into a custom Hugging Face `Trainer` class.

```
from smart_sifting.sift_config.sift_configs import (
    RelativeProbabilisticSiftConfig
    LossConfig
    SiftingBaseConfig
)
from smart_sifting.dataloader.sift_dataloader import SiftingDataloader
from smart_sifting.loss.abstract_sift_loss_module import Loss
from smart_sifting.data_model.data_model_interface import SiftingBatch,
 SiftingBatchTransform
from smart_sifting.data_model.list_batch import ListBatch

class SiftingListBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
        inputs = batch[0].tolist()
        labels = batch[-1].tolist()  # assume the last one is the list of labels
        return ListBatch(inputs, labels)

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs), torch.tensor(list_batch.labels)]
```

```
        return a_batch

class SiftingImplementedLoss():
    # You should add the following initializaztion function
    # to calculate loss per sample, not per batch.
    def __init__(self):
        self.celoss = torch.nn.CrossEntropyLoss(reduction='none')

    def loss(
        self,
        model: torch.nn.Module,
        transformed_batch: SiftingBatch,
        original_batch: Any = None,
    ) -> torch.Tensor:
        device = next(model.parameters()).device
        batch = [t.to(device) for t in original_batch]

        # compute loss
        outputs = model(batch)
        return self.celoss(outputs.logits, batch[2])

class SiftingImplementedTrainer(Trainer):
    def get_train_dataloader(self):
        dl = super().get_train_dataloader()

        sift_config = RelativeProbabilisticSiftConfig(
            beta_value=0.5,
            loss_history_length=500,
            loss_based_sift_config=LossConfig(
                sift_config=SiftingBaseConfig(sift_delay=0)
            )
        )

        return SiftingDataloader(
                sift_config=sift_config,
                orig_dataloader=dl,
                batch_transforms=SiftingListBatchTransform(),
                loss_impl=SiftingImplementedLoss(),
                model=self.model
        )
```

Using the wrapped `Trainer` class, create an object of it as follows.

```
trainer = SiftingImplementedTrainer(
    model=model,
    args=training_args,
    train_dataset=small_train_dataset,
    eval_dataset=small_eval_dataset
)

trainer.train()
```

Troubleshooting

If you run into an error, use the following list to try to troubleshoot the issue. If you need further support, reach out to the SageMaker AI team at `<sm-smart-sifting-feedback@amazon.com>`.

Exceptions from the SageMaker smart sifting library

Use the following reference of exceptions raised by the SageMaker smart sifting library to troubleshoot errors and identify causes.

Exception Name	Description
SiftConfigValidationException	Thrown from the SageMaker smart sifting library in case of any missing Config key or unsupported value type for Sift Key
UnsupportedDataFormatException	Thrown from the SageMaker smart sifting library in case of any unsupported DataFormat for Sifting logic
LossImplementationNotProvidedException	Thrown in case of missing or not implement ing Loss interface

Security in SageMaker smart sifting

Because the SageMaker smart sifting library runs processes of removing less valuable training samples, it requires full access to training datasets as they are produced by the data loader. This access is not different than the access already provided to PyTorch in normal training scenario.

SageMaker smart sifting has built-in logging with security implications. By default, SageMaker smart sifting logs are only application-level logs containing metrics, latencies, and user errors or warnings. Users can, however, choose to enable verbose logs, which log full batch data to show which samples were removed from a given batch. These logs are emitted using Python loggers and are not uploaded or stored anywhere by the library. In the case of automatic log uploading to CloudWatch or similar services, please note that using verbose logs may result in sensitive training data being uploaded off of the training instance.

Beyond the aforementioned logging, SageMaker smart sifting does not have any network functionality nor does it interact with the local file system. User data is stored as in-memory objects for the entirety of the time it is used by the library.

SageMaker smart sifting Python SDK reference

This page provides a reference of Python modules you need for applying SageMaker smart sifting to your training script.

SageMaker smart sifting configuration modules

class `smart_sifting.sift_config.sift_configs.RelativeProbabilisticSiftConfig()`

The SageMaker smart sifting configuration class.

Parameters

- `beta_value` (float) – A beta (constant) value. It is used to calculate the probability of selecting a sample for training based on the percentile of the loss in the loss values history. Lowering the beta value results in a lower percentage of data sifted, and raising it results in a higher percentage of data sifted. There's no minimum or maximum value for the beta value, other than it must be a positive value. The following reference table gives information for sifting rates with respect to `beta_value`.

`beta_value`	Proportion of data kept (%)	Proportion of data sifted out (%)
0.1	90.91	9.01
0.25	80	20

beta_value	Proportion of data kept (%)	Proportion of data sifted out (%)
0.5	66.67	33.33
1	50	50
2	33.33	66.67
3	25	75
10	9.09	90.92
100	0.99	99.01

- `loss_history_length` (int) – The number of previous training losses to store for the relative threshold loss based sampling.
- `loss_based_sift_config` (dict or a `LossConfig` object) – Specify a `LossConfig` object that returns the SageMaker smart sifting Loss interface configuration.

class `smart_sifting.sift_config.sift_configs.LossConfig()`

The configuration class for the `loss_based_sift_config` parameter of the `RelativeProbabilisticSiftConfig` class.

Parameters

- `sift_config` (dict or a `SiftingBaseConfig` object) – Specify a `SiftingBaseConfig` object that returns a sifting base configuration dictionary.

class `smart_sifting.sift_config.sift_configs.SiftingBaseConfig()`

The configuration class for the `sift_config` parameter of `LossConfig`.

Parameters

- `sift_delay` (int) – The number of training steps to wait for before starting sifting. We recommend that you start sifting after all the layers in the model have enough view of the training data. The default value is `1000`.

- `repeat_delay_per_epoch` (bool) – Specify whether to delay sifting every epoch. The default value is `False`.

SageMaker smart sifting data batch transform modules

class `smart_sifting.data_model.data_model_interface.SiftingBatchTransform`

A SageMaker smart sifting Python module for defining how to perform batch transform. Using this, you can set up a batch transform class that converts the data format of your training data to `SiftingBatch` format. SageMaker smart sifting can sift and accumulate data in this format into a sifted batch.

class `smart_sifting.data_model.data_model_interface.SiftingBatch`

An interface to define a batch data type that can be sifted and accumulated.

class `smart_sifting.data_model.list_batch.ListBatch`

A module for keeping track of a list batch for sifting.

class `smart_sifting.data_model.tensor_batch.TensorBatch`

A module for keeping track of a tensor batch for sifting.

SageMaker smart sifting loss implementation module

class `smart_sifting.loss.abstract_sift_loss_module.Loss`

A wrapper module for registering the SageMaker smart sifting interface to the loss function of a PyTorch-based model.

SageMaker smart sifting data loader wrapper module

class `smart_sifting.dataloader.sift_dataloader.SiftingDataloader`

A wrapper module for registering the SageMaker smart sifting interface to the data loader of a PyTorch-based model.

The Main Sifting Dataloader iterator sifts out training samples from a dataloader based on a sift configuration.

Parameters

- `sift_config` (dict or a `RelativeProbabilisticSiftConfig` object) – A `RelativeProbabilisticSiftConfig` object.
- `orig_dataloader` (a PyTorch DataLoader object) – Specify the PyTorch Dataloader object to be wrapped.
- `batch_transforms` (a `SiftingBatchTransform` object) – (Optional) If your data format is not supported by the SageMaker smart sifting library's default transform, you must create a batch transform class using the `SiftingBatchTransform` module. This parameter is used to pass the batch transform class. This class is used for `SiftingDataloader` to convert the data into a format that the SageMaker smart sifting algorithm can accept.
- `model` (a PyTorch model object) – The original PyTorch model
- `loss_impl` (a sifting loss function of `smart_sifting.loss.abstract_sift_loss_module.Loss`) – A sifting loss function that is configured with the `Loss` module and wraps the PyTorch loss function.
- `log_batch_data` (bool) – Specify whether to log batch data. If set to `True`, SageMaker smart sifting logs the details of the batches that are kept or sifted. We recommend that you turn it on only for a pilot training job. When logging is on, the samples are loaded to GPU and transferred to CPU, which introduces overhead. The default value is `False`.

SageMaker smart sifting release notes

See the following release notes to track the latest updates for the SageMaker smart sifting capability.

SageMaker smart sifting release notes: November 29, 2023

New Features

- Launched the Amazon SageMaker smart sifting library at AWS re:Invent 2023.

Migration to AWS Deep Learning Containers

- The SageMaker smart sifting library passed integration testing and is available in AWS Deep Learning Containers. To find a complete list of the pre-built containers with the SageMaker smart sifting library, see the section called "Supported frameworks and AWS Regions".

Debugging and improving model performance

The essence of training machine learning models, deep learning neural networks, transformer models is in achieving stable model convergence, and as such, state-of-the-art models have millions, billions, or trillions of model parameters. The number of operations to update the gigantic number of model parameters during each iteration can easily become astronomical. To identify model convergence issues, it is important to be able to access the model parameters, activations, and gradients computed during optimization processes.

Amazon SageMaker AI provides two debugging tools to help identify such convergence issues and gain visibility into your models.

Amazon SageMaker AI with TensorBoard

To offer a greater compatiblity with the open-source community tools within the SageMaker AI Training platform, SageMaker AI hosts TensorBoard as an application in SageMaker AI domain. You can bring your training jobs to SageMaker AI and keep using the TensorBoard summary writer to collect the model output tensors. Because TensorBoard is implemented into SageMaker AI domain, it also gives you more options to manage user profiles under the SageMaker AI domain in your AWS account, and provides fine control over the user profiles by granting access to specific actions and resources. To learn more, see the section called “TensorBoard in SageMaker AI”.

Amazon SageMaker Debugger

Amazon SageMaker Debugger is a capability of SageMaker AI that provides tools to register hooks to callbacks to extract model output tensors and save them in Amazon Simple Storage Service. It provides built-in rules for detecting model convergence issues, such as overfitting, saturated activation functions, vanishing gradients, and more. You can also set up the built-in rules with Amazon CloudWatch Events and AWS Lambda for taking automated actions against detected issues, and set up Amazon Simple Notification Service to receive email or text notifications. To learn more, see the section called “SageMaker Debugger”.

Topics

TensorBoard in Amazon SageMaker AI

Amazon SageMaker AI with TensorBoard is a capability of Amazon SageMaker AI that brings the TensorBoard visualization tools to SageMaker AI and integrated with SageMaker Training and domain. It provides options to administer your AWS account and users belonging to the account through SageMaker AI domain, to give the domain users access to the TensorBoard data with appropriate permissions to Amazon S3, and help the domain users perform model debugging tasks using the TensorBoard visualization plugins. SageMaker AI with TensorBoard is extended with the SageMaker AI Data Manager plugin, with which domain users can access a number of training jobs in one place within the TensorBoard application.

> **Note**
>
> This feature is for debugging the training of deep learning models using PyTorch or TensorFlow.

For data scientists

Training large models can have scientific problems that require data scientists to debug and resolve them in order to improve model convergence and stabilize gradient descent processes.

When you encounter model training issues, such as loss not converging, or vanishing or exploding weights and gradients, you need to access tensor data to dive deep and analyze the model parameters, scalars, and any custom metrics. Using SageMaker AI with TensorBoard, you can visualize model output tensors extracted from training jobs. As you experiment with different models, multiple training runs, and model hyperparameters, you can select multiple training jobs in TensorBoard and compare them in one place.

For administrators

Through the TensorBoard landing page in the SageMaker AI console or SageMaker AI domain, you can manage TensorBoard application users if you are an administrator of an AWS account or SageMaker AI domain. Each domain user can access their own TensorBoard application given the granted permissions. As a SageMaker AI domain administrator and domain user, you can create and delete the TensorBoard application given the permission level you have.

> **Note**
>
> You cannot share the TensorBoard application for collaboration purposes because SageMaker AI domain does not allow application sharing among users. Users can share the output tensors saved in an S3 bucket, if they have access to the bucket.

Supported frameworks and AWS Regions

The TensorBoard application in SageMaker AI is available for the following machine learning frameworks and AWS Regions.

Frameworks

- PyTorch
- TensorFlow
- Hugging Face Transformers

AWS Regions

- US East (N. Virginia) (`us-east-1`)
- US East (Ohio) (`us-east-2`)
- US West (Oregon) (`us-west-2`)
- Europe (Frankfurt) (`eu-central-1`)
- Europe (Ireland) (`eu-west-1`)

> **Note**
>
> Amazon SageMaker AI with TensorBoard runs on an `ml.r5.large` instance and incurs charges after the SageMaker AI free tier or the free trial period of the feature. For more information, see Amazon SageMaker AI Pricing.

Topics

- Prepare a training job to collect TensorBoard output data
- Accessing the TensorBoard application on SageMaker AI

- [Load and visualize output tensors using the TensorBoard application]
- [Delete unused TensorBoard applications]

Prepare a training job to collect TensorBoard output data

A typical training job for machine learning in SageMaker AI consists of two main steps: preparing a training script and configuring a SageMaker AI estimator object of the SageMaker AI Python SDK. In this section, you'll learn about the required changes to collect TensorBoard-compatible data from SageMaker training jobs.

Prerequisites

The following list shows the prerequisites to start using SageMaker AI with TensorBoard.

- A SageMaker AI domain that's set up with Amazon VPC in your AWS account.

  For instructions on setting up a domain, see Onboard to Amazon SageMaker AI domain using quick setup. You also need to add domain user profiles for individual users to access the TensorBoard on SageMaker AI. For more information, see Add user profiles.
- The following list is the minimum set of permissions for using TensorBoard on SageMaker AI.
  - `sagemaker:CreateApp`
  - `sagemaker:DeleteApp`
  - `sagemaker:DescribeTrainingJob`
  - `sagemaker:Search`
  - `s3:GetObject`
  - `s3:ListBucket`

Step 1: Modify your training script with open-source TensorBoard helper tools

Make sure you determine which output tensors and scalars to collect, and modify code lines in your training script using any of the following tools: TensorBoardX, TensorFlow Summary Writer, PyTorch Summary Writer, or SageMaker Debugger.

Also make sure that you specify the TensorBoard data output path as the log directory (`log_dir`) for callback in the training container.

For more information about callbacks per framework, see the following resources.

- For PyTorch, use torch.utils.tensorboard.SummaryWriter. See also the Using TensorBoard in PyTorch and Log scalars sections in the *PyTorch tutorials*. Alternatively, you can use TensorBoardX Summary Writer.

```
LOG_DIR="/opt/ml/output/tensorboard"
tensorboard_callback=torch.utils.tensorboard.writer.SummaryWriter(log_dir=LOG_DIR)
```

- For TensorFlow, use the native callback for TensorBoard, tf.keras.callbacks.TensorBoard.

```
LOG_DIR="/opt/ml/output/tensorboard"
tensorboard_callback=tf.keras.callbacks.TensorBoard(
    log_dir=LOG_DIR, histogram_freq=1)
```

- For Transformers with PyTorch, you can use transformers.integrations.TensorBoardCallback.

  For Transformers with TensorFlow, use the `tf.keras.tensorboard.callback`, and pass that to the keras callback in transformers.

  > **Tip**
  >
  > You can also use a different container local output path. However, in Step 2: Create a SageMaker training estimator object with the TensorBoard output configuration, you must map the paths correctly for SageMaker AI to successfully search the local path and save the TensorBoard data to the S3 output bucket.

- For guidance on modifying training scripts using the SageMaker Debugger Python library, see the section called "Adapting your training script to register a hook".

Step 2: Create a SageMaker training estimator object with the TensorBoard output configuration

Use the `sagemaker.debugger.TensorBoardOutputConfig` while configuring a SageMaker AI framework estimator. This configuration API maps the S3 bucket you specify for saving TensorBoard data with the local path in the training container (`/opt/ml/output/tensorboard`). Pass the object of the module to the `tensorboard_output_config` parameter of the estimator class. The following code snippet shows an example of preparing a TensorFlow estimator with the TensorBoard output configuration parameter.

Note

This example assumes that you use the SageMaker Python SDK. If you use the low-level SageMaker API, you should include the following to the request syntax of the CreateTrainingJob API.

```
"TensorBoardOutputConfig": {
  "LocalPath": "/opt/ml/output/tensorboard",
  "S3OutputPath": "s3_output_bucket"
}
```

```
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import TensorBoardOutputConfig

# Set variables for training job information,
# such as s3_out_bucket and other unique tags.
...

LOG_DIR="/opt/ml/output/tensorboard"

output_path = os.path.join(
    "s3_output_bucket", "sagemaker-output", "date_str", "your-training_job_name"
)

tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path=os.path.join(output_path, 'tensorboard'),
    container_local_output_path=LOG_DIR
)

estimator = TensorFlow(
    entry_point="train.py",
    source_dir="src",
    role=role,
    image_uri=image_uri,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    base_job_name="your-training_job_name",
    tensorboard_output_config=tensorboard_output_config,
    hyperparameters=hyperparameters
)
```

> **Note**
>
> The TensorBoard application does not provide out-of-the-box support for SageMaker AI hyperparameter tuning jobs, as the `CreateHyperParameterTuningJob` API is not integrated with the TensorBoard output configuration for the mapping. To use the TensorBoard application for hyperparameter tuning jobs, you need to write code for uploading metrics to Amazon S3 in your training script. Once the metrics are uploaded to an Amazon S3 bucket, you can then load the bucket into the TensorBoard application on SageMaker AI.

Accessing the TensorBoard application on SageMaker AI

You can access TensorBoard by two methods: programmatically using the `sagemaker.interactive_apps.tensorboard` module that generates an unsigned or a presigned URL, or using the TensorBoard landing page in the SageMaker AI console. After you open TensorBoard, SageMaker AI runs the TensorBoard plugin and automatically finds all training job output data in a TensorBoard-compatible file format.

Topics

- Open TensorBoard using the sagemaker.interactive_apps.tensorboard module
- Open TensorBoard using the get_app_url function as an estimator class method
- Open TensorBoard through the SageMaker AI console

Open TensorBoard using the `sagemaker.interactive_apps.tensorboard` module

The `sagemaker.interactive_apps.tensorboard` module provides a function called `get_app_url` that generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker AI or Amazon EC2. This is to provide a unified experience for both Studio Classic and non-Studio Classic users. For the Studio environment, you can open TensorBoard by running the `get_app_url()` function as it is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio Classic environments, you can open TensorBoard by providing your domain and user profile information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard by running the `get_app_url` function in your Jupyter notebook or terminal.

> **Note**
>
> This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics

- Option 1: For SageMaker AI Studio Classic
- Option 2: For non-Studio Classic environments

Option 1: For SageMaker AI Studio Classic

If you are using SageMaker Studio Classic, you can directly open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` function as follows. As you are already within the Studio Classic environment and signed in as a domain user, `get_app_url()` generates unsigned URL because it is not necessary to authenticate again.

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` function returns in the your environment's default web browser.

```
from sagemaker.interactive_apps import tensorboard

region = "us-west-2"
app = tensorboard.TensorBoardApp(region)

app.get_app_url(
    training_job_name="your-training_job_name" # Optional. Specify the job name to
 track a specific training job
)
```

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.

```
from sagemaker.interactive_apps import tensorboard
```

```
region = "us-west-2"
app = tensorboard.TensorBoardApp(region)
print("Navigate to the following URL:")
print(
    app.get_app_url(
        training_job_name="your-training_job_name", # Optional. Specify the name of the
 job to track.
        open_in_default_web_browser=False           # Set to False to print the URL to
 terminal.
    )
)
```

Note that if you run the preceding two code samples outside the SageMaker AI Studio Classic environment, the function will return a URL to the TensorBoard landing page in the SageMaker AI console, because these do not have sign-in information to your domain and user profile. For creating a presigned URL, see Option 2 in the following section.

Option 2: For non-Studio Classic environments

If you use non-Studio Classic environments, such as SageMaker Notebook instance or Amazon EC2, and want to open TensorBoard directly from the environment you are in, you need to generate a URL presigned with your domain and user profile information. A *presigned* URL is a URL that's signed in to Amazon SageMaker Studio Classic while the URL is being created with your domain and user profile, and therefore granted access to all of the domain applications and files associated with your domain. To open TensorBoard through a presigned URL, use the `get_app_url` function with your domain and user profile name as follows.

Note that this option requires the domain user to have the `sagemaker:CreatePresignedDomainUrl` permission. Without the permission, the domain user will receive an exception error.

> **Important**
>
> Do not share any presigned URLs. The `get_app_url` function creates presigned URLs, which automatically authenticates with your domain and user profile and gives access to any applications and files associated with your domain.

```
print(
```

```
    app.get_app_url(
        training_job_name="your-training_job_name", # Optional. Specify the name of the
 job to track.
        create_presigned_domain_url=True,           # Required to be set to True for
 creating a presigned URL.
        domain_id="your-domain-id",                 # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        user_profile_name="your-user-profile-name", # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        open_in_default_web_browser=False,          # Optional. Set to False to print
 the URL to terminal.
        optional_create_presigned_url_kwargs={}     # Optional. Add any additional args
 for Boto3 create_presigned_domain_url
    )
)
```

Tip

The `get_app_url` function runs the [`SageMaker.Client.create_presigned_domain_url`](#) API in the AWS SDK for Python (Boto3) in the backend. As the Boto3 `create_presigned_domain_url` API creates presigned domain URLs that expire in 300 seconds by default, presigned TensorBoard application URLs also expire in 300 seconds. If you want to extend the expiration time, pass the `ExpiresInSeconds` argument to the `optional_create_presigned_url_kwargs` argument of the `get_app_url` function as follows.

```
optional_create_presigned_url_kwargs={"ExpiresInSeconds": 1500}
```

Note

If any of your input passed to the arguments of `get_app_url` is invalid, the function outputs a URL to the TensorBoard landing page instead of opening the TensorBoard application. The output message would be similar to the following.

```
Navigate to the following URL:
https://us-west-2.console.aws.amazon.com/sagemaker/home?region=us-west-2#/
tensor-board-landing
```

Open TensorBoard using the `get_app_url` function as an `estimator` class method

If you are in the process of running a training job using the `estimator` class of the SageMaker Python SDK and have an active object of the `estimator` class, you can also access the [`get_app_url` function as a class method](#) of the `estimator` class. Open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` method as follows. The `get_app_url` class method pulls the training job name from the estimator and opens the TensorBoard application with the specified job.

> **Note**
>
> This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics

Option 1: For SageMaker Studio Classic

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` method returns in the your environment's default web browser.

```
estimator.get_app_url(
    app_type=SupportedInteractiveAppTypes.TENSORBOARD # Required.
)
```

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.

```
print(
    estimator.get_app_url(
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required.
```

```
        open_in_default_web_browser=False, # Optional. Set to False to print the URL to
 terminal.
    )
)
```

Note that if you run the preceding two code samples outside the SageMaker AI Studio Classic environment, the function will return a URL to the TensorBoard landing page in the SageMaker AI console, because these do not have sign-in information to your domain and user profile. For creating a presigned URL, see Option 2 in the following section.

Option 2: For non-Studio Classic environments

If you use non-Studio Classic environments, such as SageMaker Notebook instance and Amazon EC2, and want to generate a presigned URL to open the TensorBoard application, use the `get_app_url` method with your domain and user profile information as follows.

Note that this option requires the domain user to have the `sagemaker:CreatePresignedDomainUrl` permission. Without the permission, the domain user will receive an exception error.

> **Important**
>
> Do not share any presigned URLs. The `get_app_url` function creates presigned URLs, which automatically authenticates with your domain and user profile and gives access to any applications and files associated with your domain.

```
print(
    estimator.get_app_url(
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required
        create_presigned_domain_url=True,           # Required to be set to True for
 creating a presigned URL.
        domain_id="your-domain-id",                 # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        user_profile_name="your-user-profile-name", # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        open_in_default_web_browser=False,            # Optional. Set to False to print
 the URL to terminal.
        optional_create_presigned_url_kwargs={}       # Optional. Add any additional
 args for Boto3 create_presigned_domain_url
    )
```

```
)
```

Open TensorBoard through the SageMaker AI console

You can also use the SageMaker AI console UI to open the TensorBoard application. There are two options to open the TensorBoard application through the SageMaker AI console.

Topics

Option 1: Launch TensorBoard from the domain details page

Navigate to the domain details page

The following procedure shows how to navigate to the domain details page.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain in which you want to launch the TensorBoard application.

Launch a user profile application

The following procedure shows how to launch a Studio Classic application that is scoped to a user profile.

1. On the domain details page, choose the **User profiles** tab.
2. Identify the user profile for which you want to launch the Studio Classic application.
3. Choose **Launch** for your selected user profile, then choose **TensorBoard**.

Option 2: Launch TensorBoard from the TensorBoard landing page

The following procedure describes how to launch a TensorBoard application from the TensorBoard landing page.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.

2. On the left navigation pane, choose **TensorBoard**.
3. Under **Get started**, select the domain in which you want to launch the Studio Classic application. If your user profile only belongs to one domain, you do not see the option for selecting a domain.
4. Select the user profile for which you want to launch the Studio Classic application. If there is no user profile in the domain, choose **Create user profile**. For more information, see [Add and Remove User Profiles](#).
5. Choose **Open TensorBoard**.

The following screenshot shows the location of TensorBoard in the left navigation pane of the SageMaker AI console and the SageMaker AI with TensorBoard landing page in the main pane.

Load and visualize output tensors using the TensorBoard application

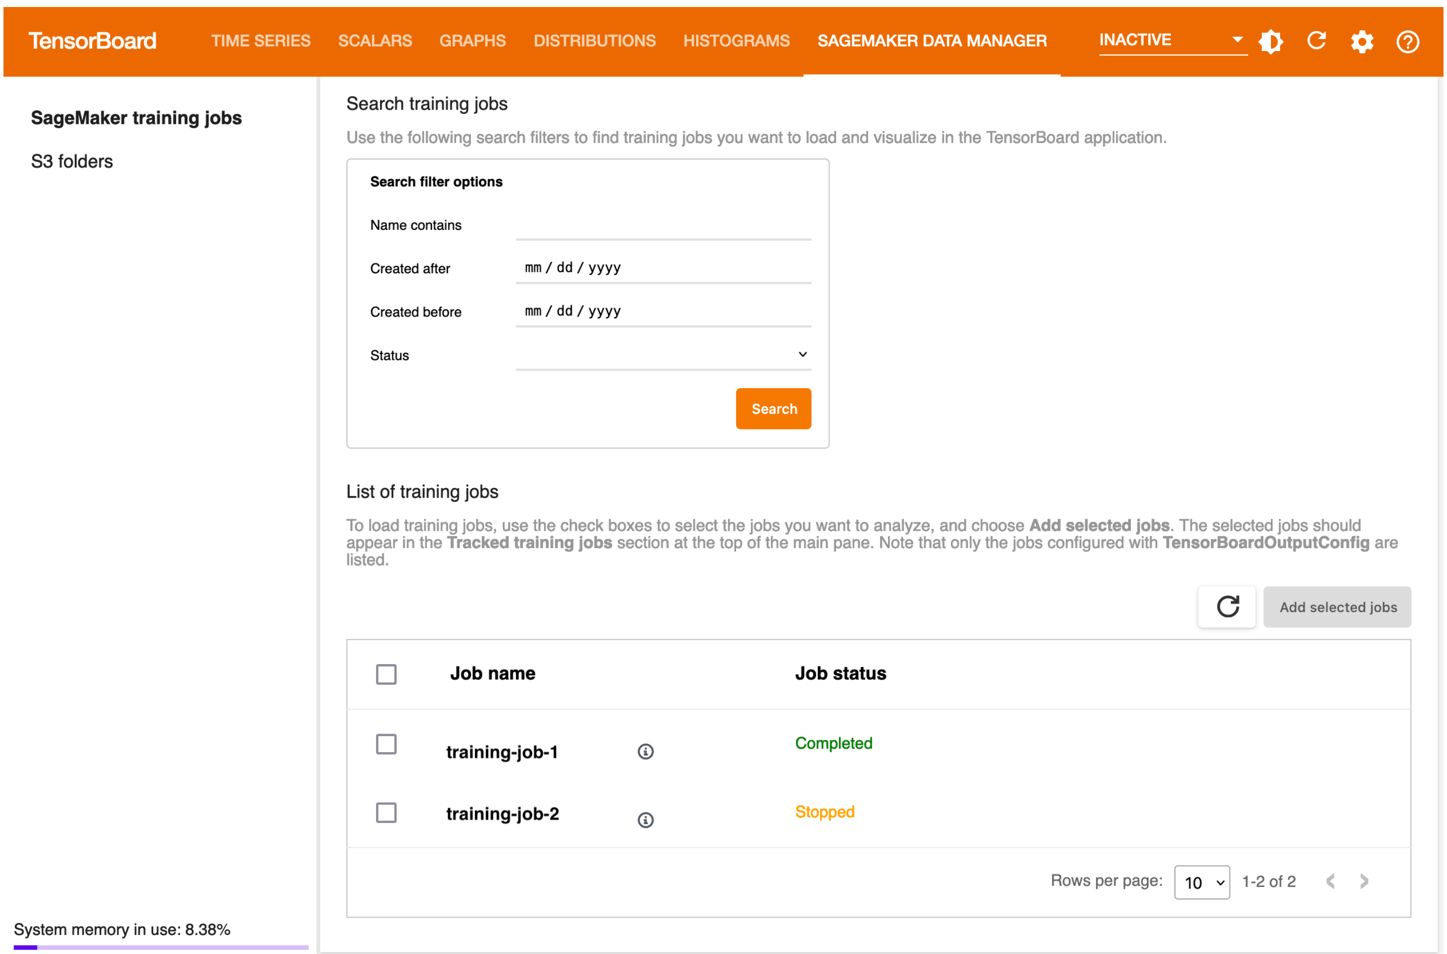
You can conduct an online or offline analysis by loading collected output tensors from S3 buckets paired with training jobs during or after training.

When you open the TensorBoard application, TensorBoard opens with the **SageMaker AI Data Manager** tab. The following screenshot shows the full view of the SageMaker AI Data Manager tab in the TensorBoard application.

> **Note**
>
> The visualization plugins might not appear when you first launch the TensorBoard application. After you select training jobs in the SageMaker AI Data Manager plugin, the

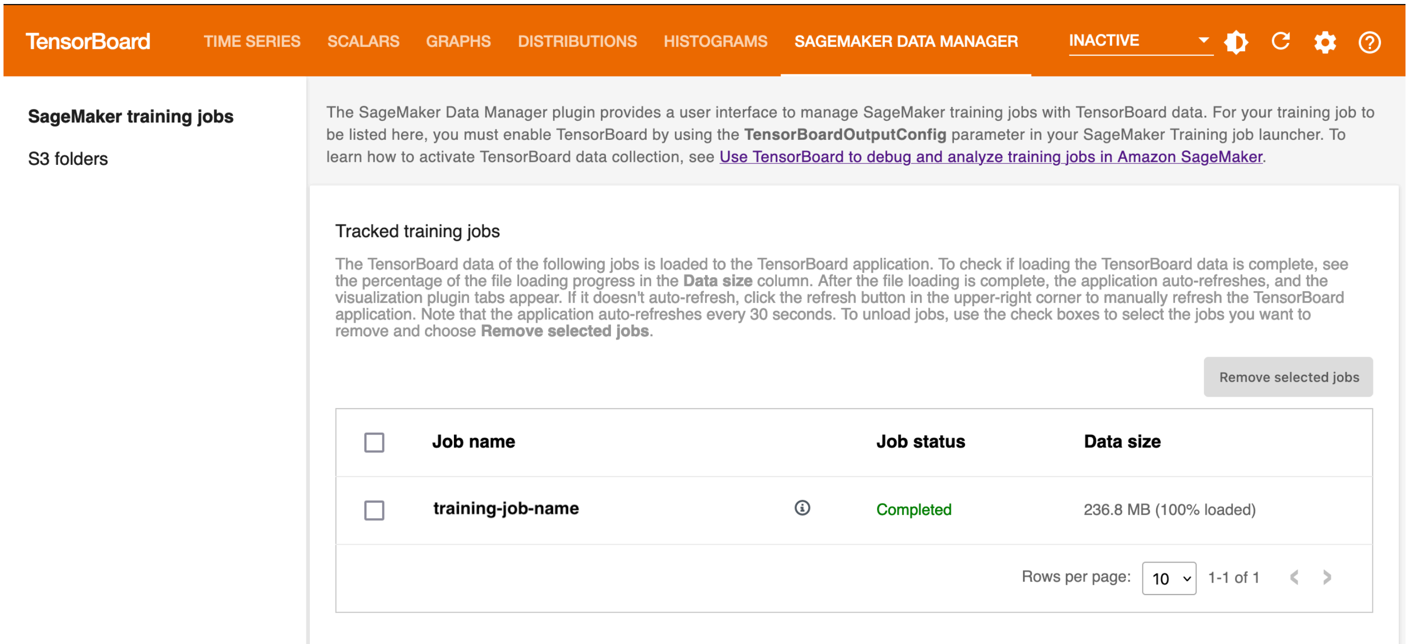
TensorBoard application loads the TensorBoard data and populates the visualization plugins.

> **Note**
>
> The TensorBoard application automatically shuts down after 1 hour of inactivity. If you want to shut the application down when you are done using it, make sure to manually shut down TensorBoard to avoid paying for the instance hosting it. For instructions on deleting the application, see Delete unused TensorBoard applications.



In the **SageMaker AI Data Manager** tab, you can select any training job and load TensorBoard-compatible training output data from Amazon S3.

1. In the **Search training jobs** section, use the filters to narrow down the list of training jobs you want to find, load, and visualize.
2. In the **List of training jobs** section, use the check boxes to choose training jobs from which you want to pull data and visualize for debugging.
3. Choose **Add selected jobs**. The selected jobs should appear in the **Tracked training jobs** section, as shown in the following screenshot.



> **Note**
>
> The **SageMaker AI Data Manager** tab only shows training jobs configured with the `TensorBoardOutputConfig` parameter. Make sure you have configured the SageMaker AI estimator with this parameter. For more information, see [Step 2: Create a SageMaker training estimator object with the TensorBoard output configuration](#).

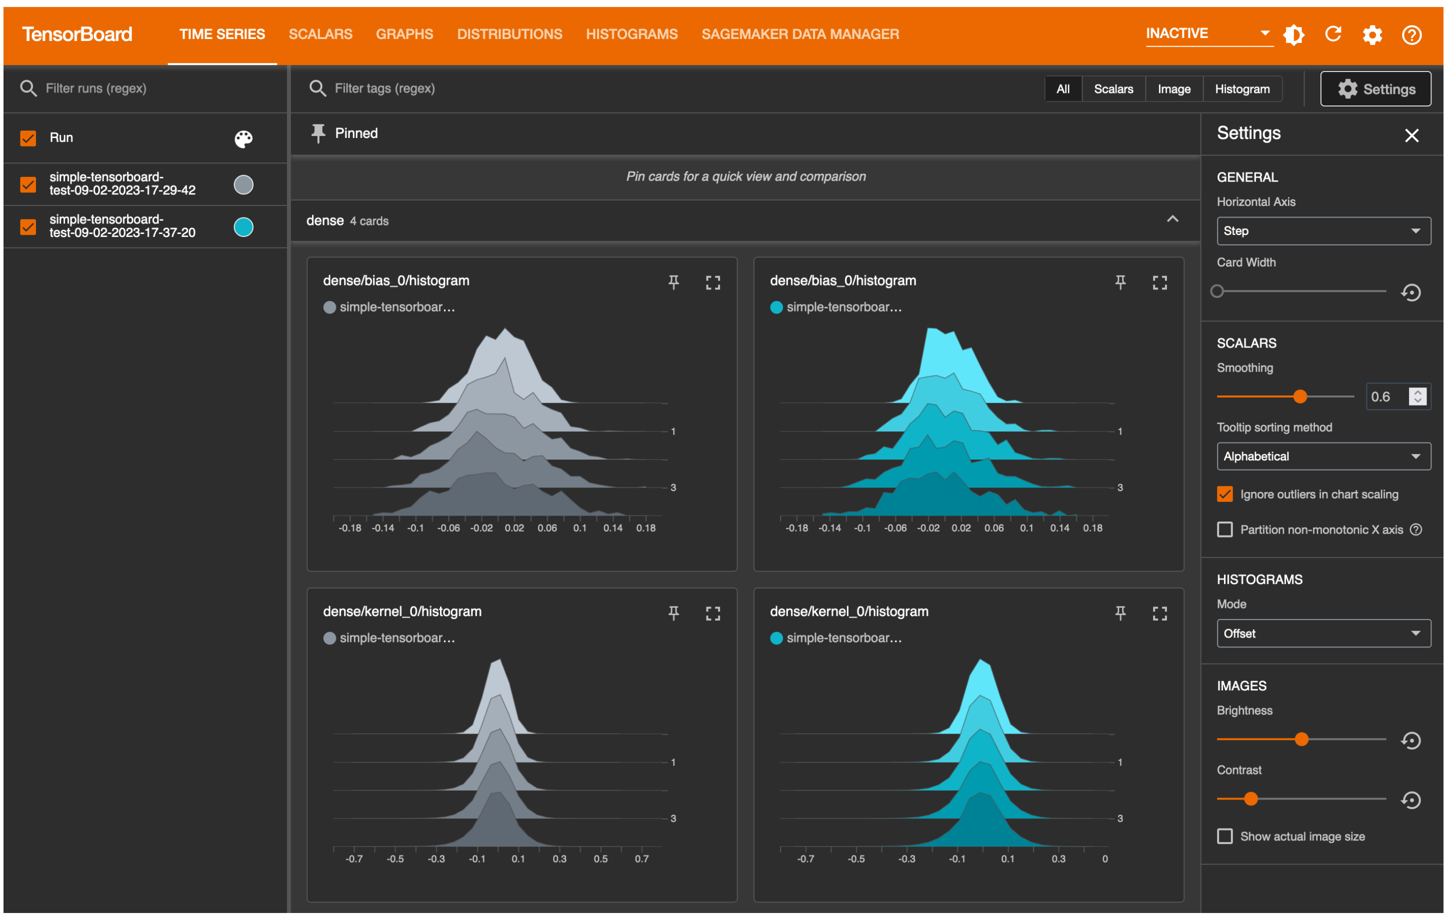
> **Note**
>
> The visualization tabs might not appear if you are using SageMaker AI with TensorBoard for the first time or no data is loaded from a previous use. After adding training jobs and waiting for a few seconds, refresh the viewer by choosing the clockwise circular arrow on the upper-right corner. The visualization tabs should appear after the job data are

successfully loaded. You can also set to auto-refresh using the **Settings** button next to the refresh button in the upper right corner.

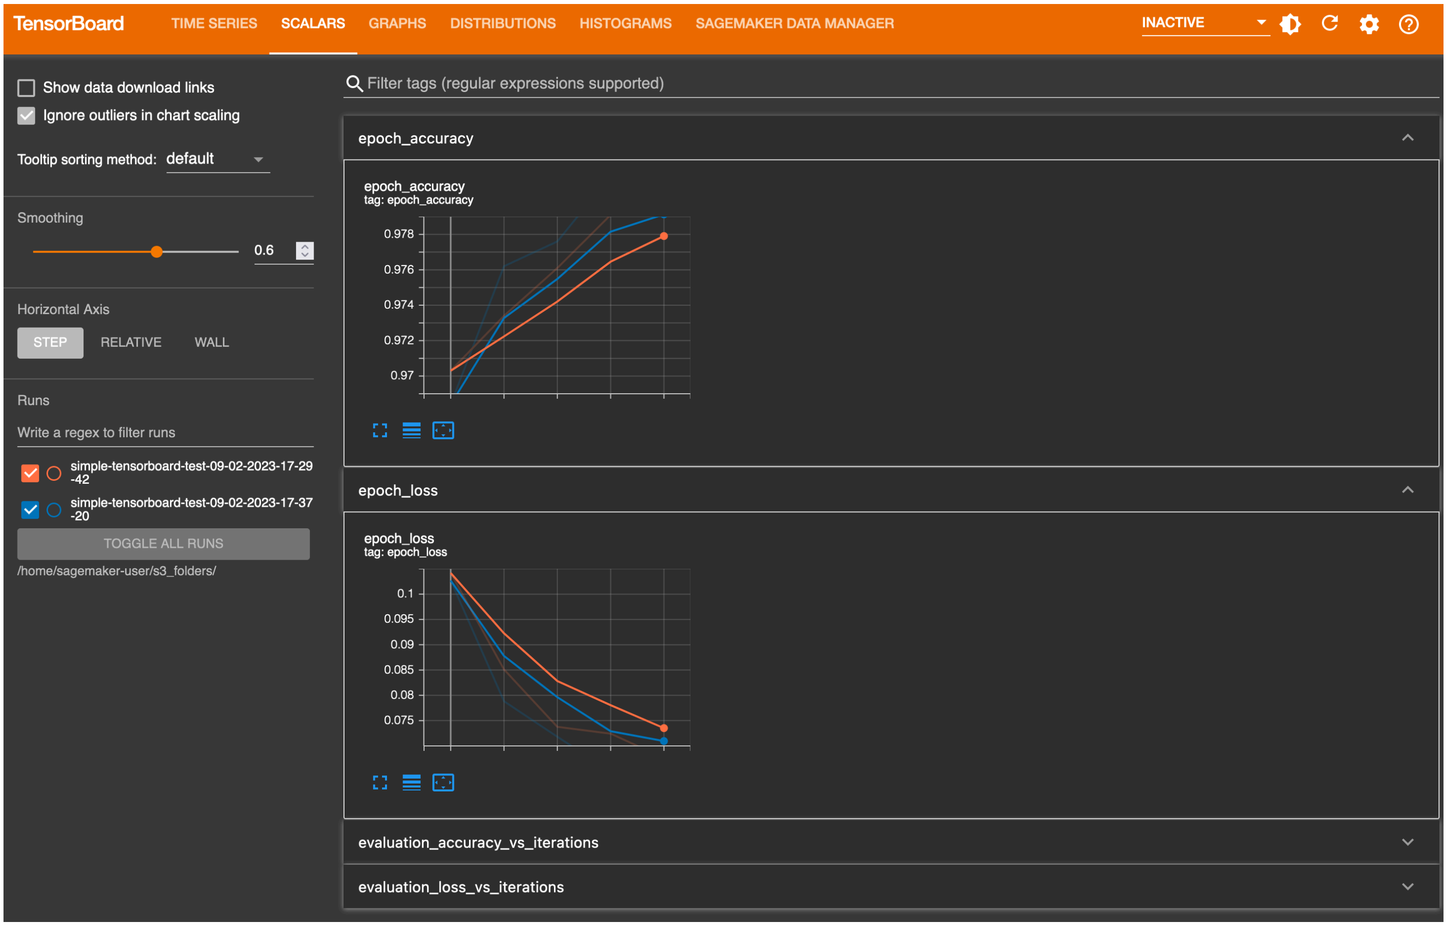
Visualization of the output tensors in TensorBoard

In the graphics tabs, you can find the list of the loaded training jobs in the left pane. You can also use the check boxes of the training jobs to show or hide visualizations. The TensorBoard dynamic plugins are activated dynamically depending on how you have set your training script to include summary writers and pass callbacks for tensor and scalar collection, and therefore the graphics tabs also appear dynamically. The following screenshots show example views of each tab with visualization of two training jobs that collected metrics for time series, scalar, graph, distribution, and histogram plugins.

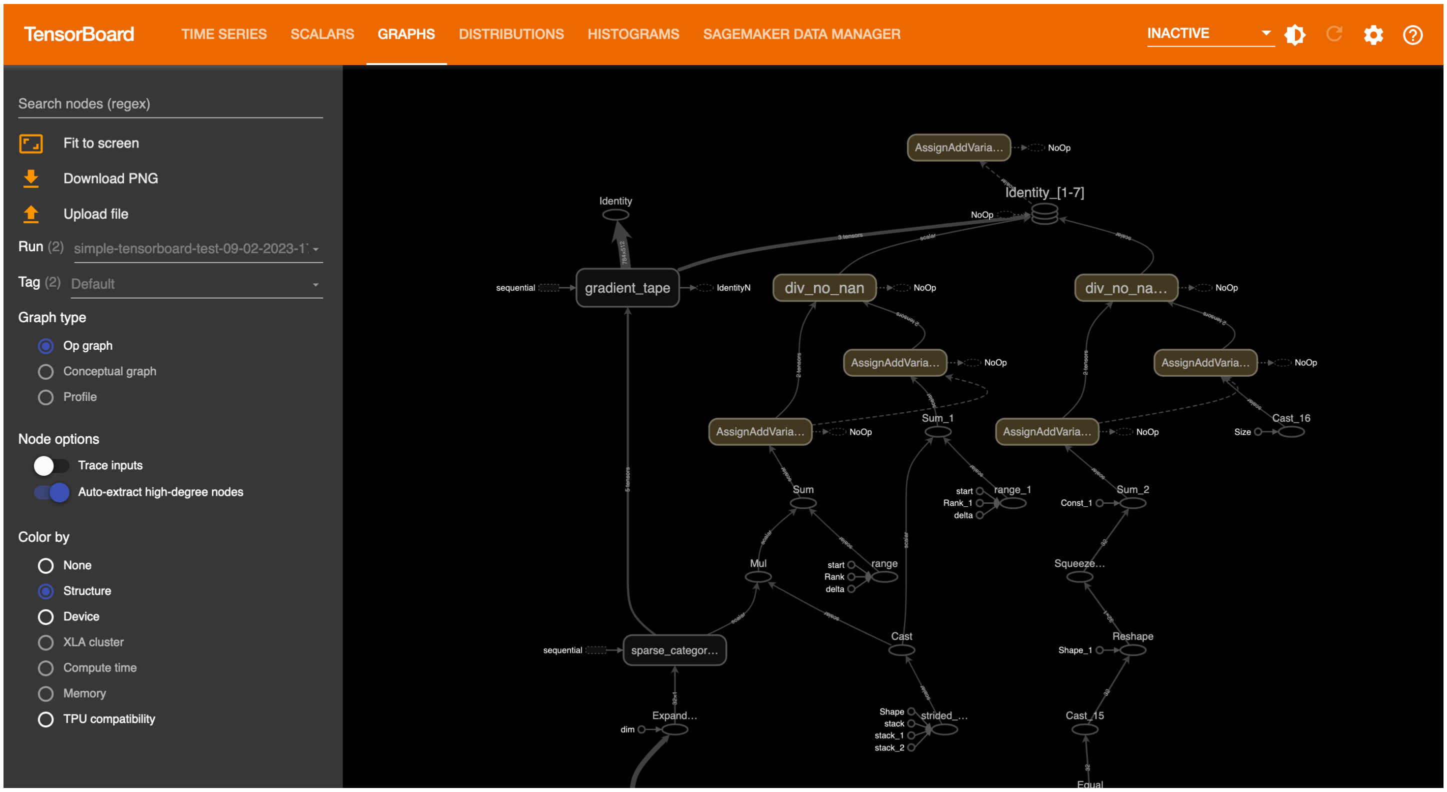
The TIME SERIES tab view



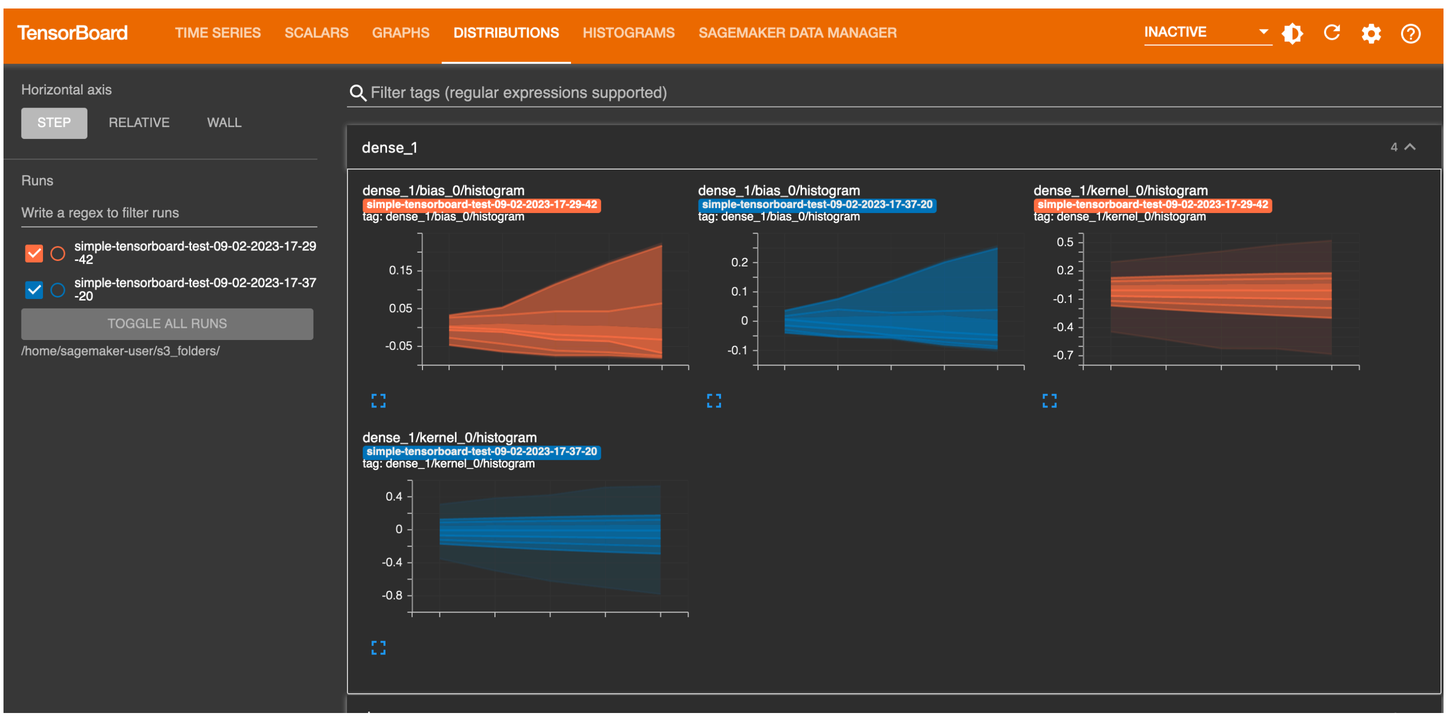
The SCALARS tab view



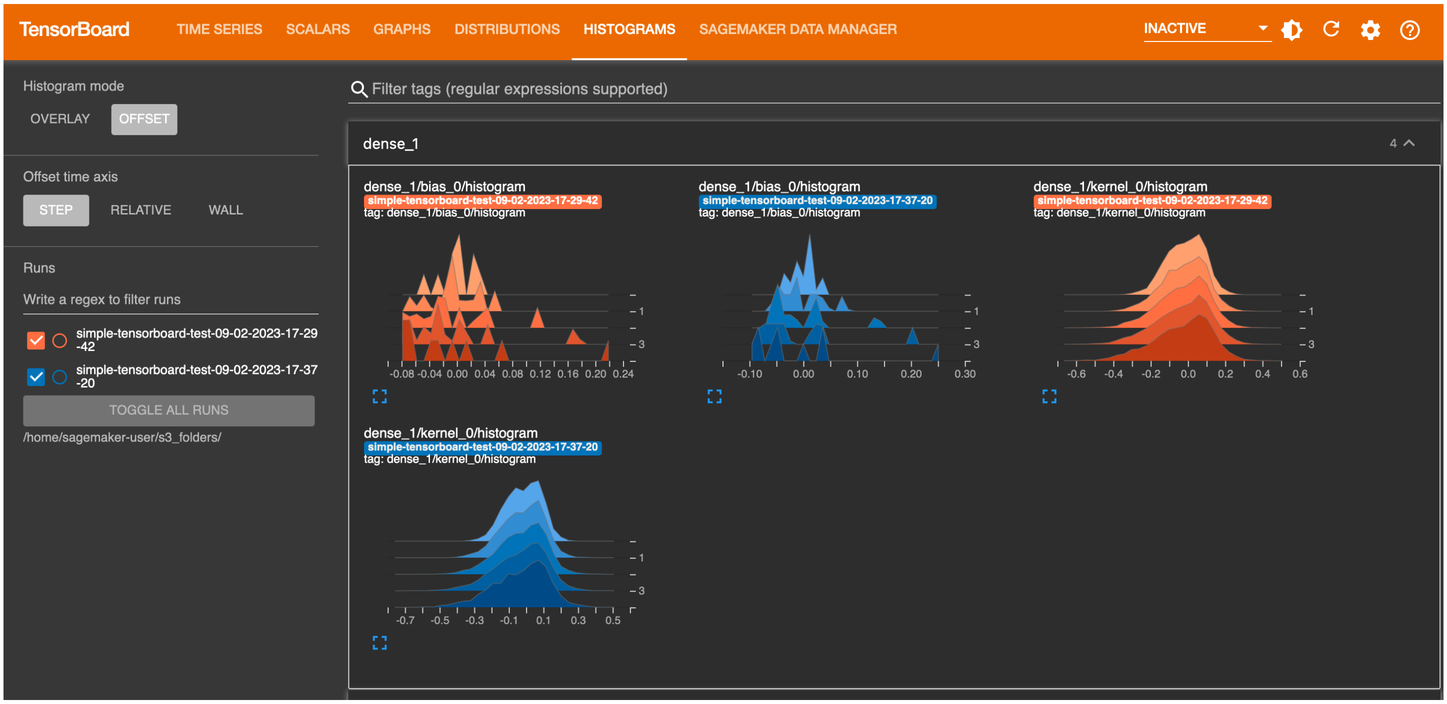
The GRAPHS tab view



The DISTRIBUTIONS tab view



The HISTOGRAMS tab view



Delete unused TensorBoard applications

After you are done with monitoring and experimenting with jobs in TensorBoard, shut the TensorBoard application down.

1. Open the SageMaker AI console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Choose your domain.
5. Choose your user profile.
6. Under **Apps**, choose **Delete App** for the TensorBoard row.
7. Choose **Yes, delete app**.
8. Type **`delete`** in the text box, then choose **Delete**.
9. A blue message should appear at the top of the screen: **default is being deleted**.

Amazon SageMaker Debugger

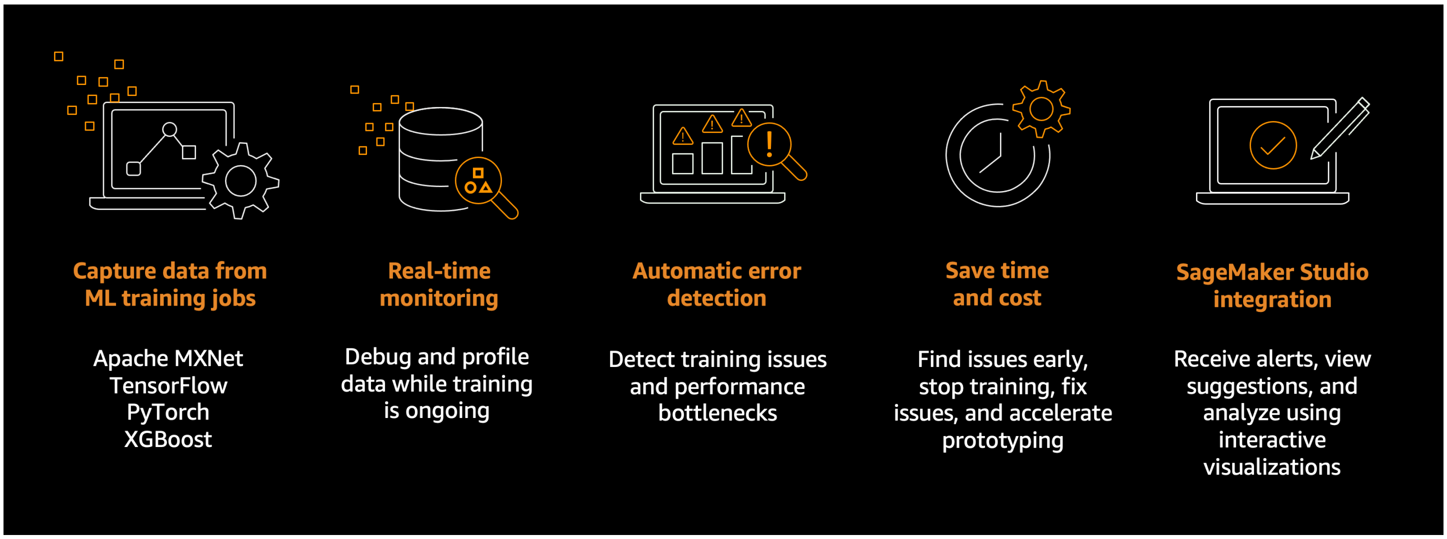
Debug model output tensors from machine learning training jobs in real time and detect non-converging issues using Amazon SageMaker Debugger.

Amazon SageMaker Debugger features

A machine learning (ML) training job can have problems such as overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger provides tools to debug training jobs and resolve such problems to improve the performance of your model. Debugger also offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports the Apache MXNet, PyTorch, TensorFlow, and XGBoost frameworks. For more information about available frameworks and versions supported by SageMaker Debugger, see [Supported frameworks and algorithms](#).



The high-level Debugger workflow is as follows:

1. Modify your training script with the `sagemaker-debugger` Python SDK if needed.
2. Configure a SageMaker training job with SageMaker Debugger.
   - Configure using the SageMaker AI Estimator API (for Python SDK).
   - Configure using the SageMaker AI [`CreateTrainingJob` request (for Boto3 or CLI)](#).
   - Configure [custom training containers](#) with SageMaker Debugger.
3. Start a training job and monitor training issues in real time.
   - [List of Debugger built-in rules](#).
4. Get alerts and take prompt actions against the training issues.

- Receive texts and emails and stop training jobs when training issues are found using Use Debugger built-in actions for rules.
- Set up your own actions using Amazon CloudWatch Events and AWS Lambda.

5. Explore deep analysis of the training issues.
   - For debugging model output tensors, see Visualize Debugger Output Tensors in TensorBoard.
6. Fix the issues, consider the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics

Supported frameworks and algorithms

The following table shows SageMaker AI machine learning frameworks and algorithms supported by Debugger.

SageMaker AI-supported frameworks and algorithms	Debugging output tensors
TensorFlow	AWS TensorFlow deep learning containers 1.15.4 or later
PyTorch	AWS PyTorch deep learning containers 1.5.0 or later

MXNet	AWS MXNet deep learning containers 1.6.0 or later
XGBoost	1.0-1, 1.2-1, 1.3-1
SageMaker AI generic estimator	Custom training containers (available for TensorFlow, PyTorch, MXNet, and XGBoost with manual hook registration)

- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

> **Important**
>
> For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the `tf.keras` modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. For instructions on how to update your training script, see the section called "TensorFlow".

> **Important**
>
> From PyTorch v1.12.0 and later, SageMaker Debugger deprecates the zero code change support for debugging models.
> This is due to breaking changes that cause SageMaker Debugger to interfere with the `torch.jit` functionality. For instructions on how to update your training script, see the section called "PyTorch".

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

AWS Regions

Amazon SageMaker Debugger is available in all regions where Amazon SageMaker AI is in service except the following region.

- Asia Pacific (Jakarta): `ap-southeast-3`

To find if Amazon SageMaker AI is in service in your AWS Region, see AWS Regional Services.

Use Debugger with Custom Training Containers

Bring your training containers to SageMaker AI and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the `sagemaker-debugger` client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with custom training containers.

Debugger Open-Source GitHub Repositories

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker AI CreateTrainingJob and DescribeTrainingJob API operations. The `sagemaker-debugger` client library provides tools to register *hooks* and access the training data through its *trial* feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and `sagemaker-debugger` API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Python SDK - Debugger APIs
- The `sagemaker-debugger` Python SDK documentation for the Amazon SageMaker Debugger open source client library
- The `sagemaker-debugger` PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- [Amazon SageMaker Debugger APIs]
- [Configure Debugger using SageMaker API]

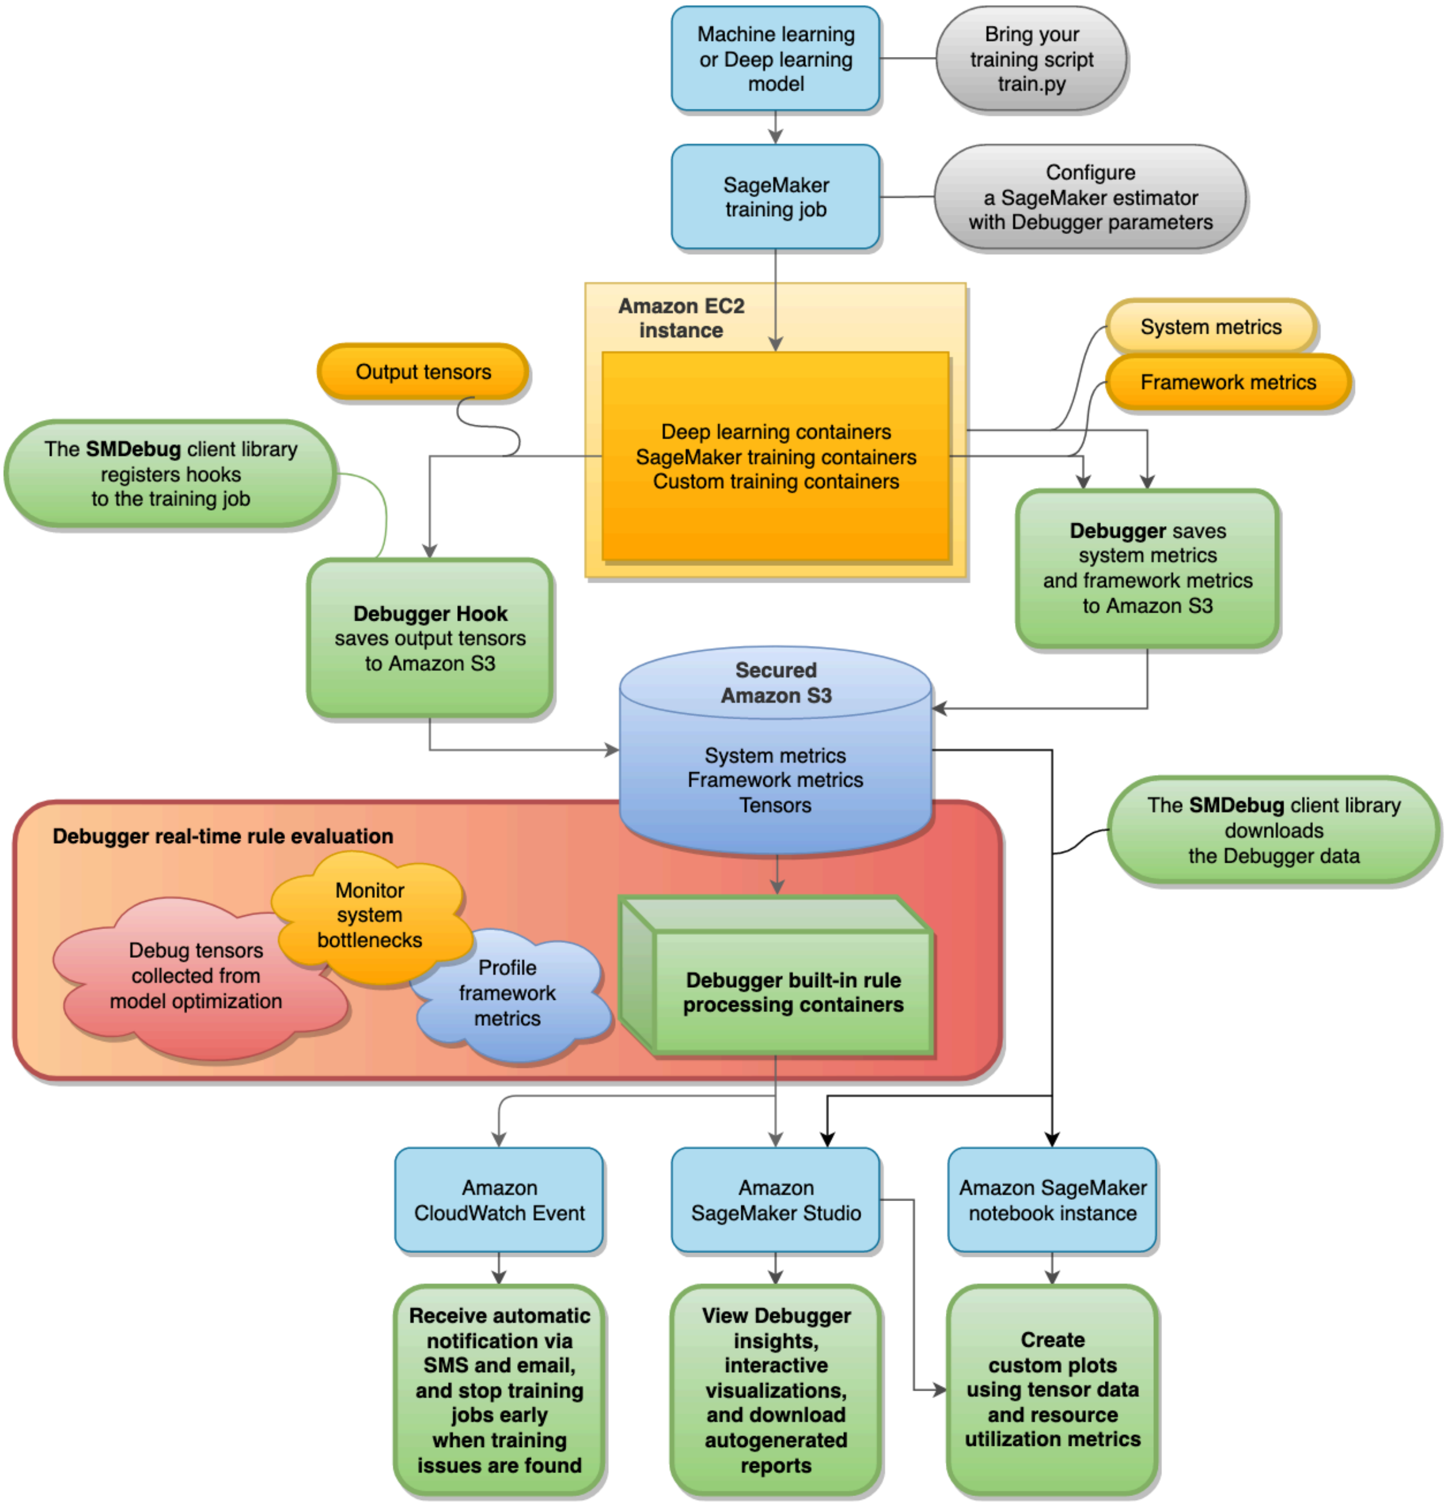
Amazon SageMaker Debugger architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.



Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

> **Note**
>
> By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker AI estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the `ProfilerReport` rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

Debugger tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

Debugging models with Amazon SageMaker Debugger in Studio Classic

Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds

This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker AI in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

Debug Models with Amazon SageMaker Debugger (part 1)

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the `debugger.ipynb` notebook file and the `mnist_keras_tf.py` training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path `keras_script_path` to the `mnist_keras_tf.py` file inside the `debugger.ipynb` notebook. For example, if you cloned the two files in the same directory, set it as `keras_script_path = "mnist_keras_tf.py"`.

Deep dive on Amazon SageMaker Debugger and SageMaker AI model monitor

Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker AI Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

Debug Models with Debugger (part 2)

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

Debugger example notebooks

SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker AI ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the `SMDebug` client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Training and pruning models with Amazon SageMaker Experiments and Debugger

Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds

Train and Prune Models with SageMaker AI Experiments and Debugger

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as *trials* through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.

SageMaker AI Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker AI to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

```
Pruning iteration: 0

----------------------------------------------------------------
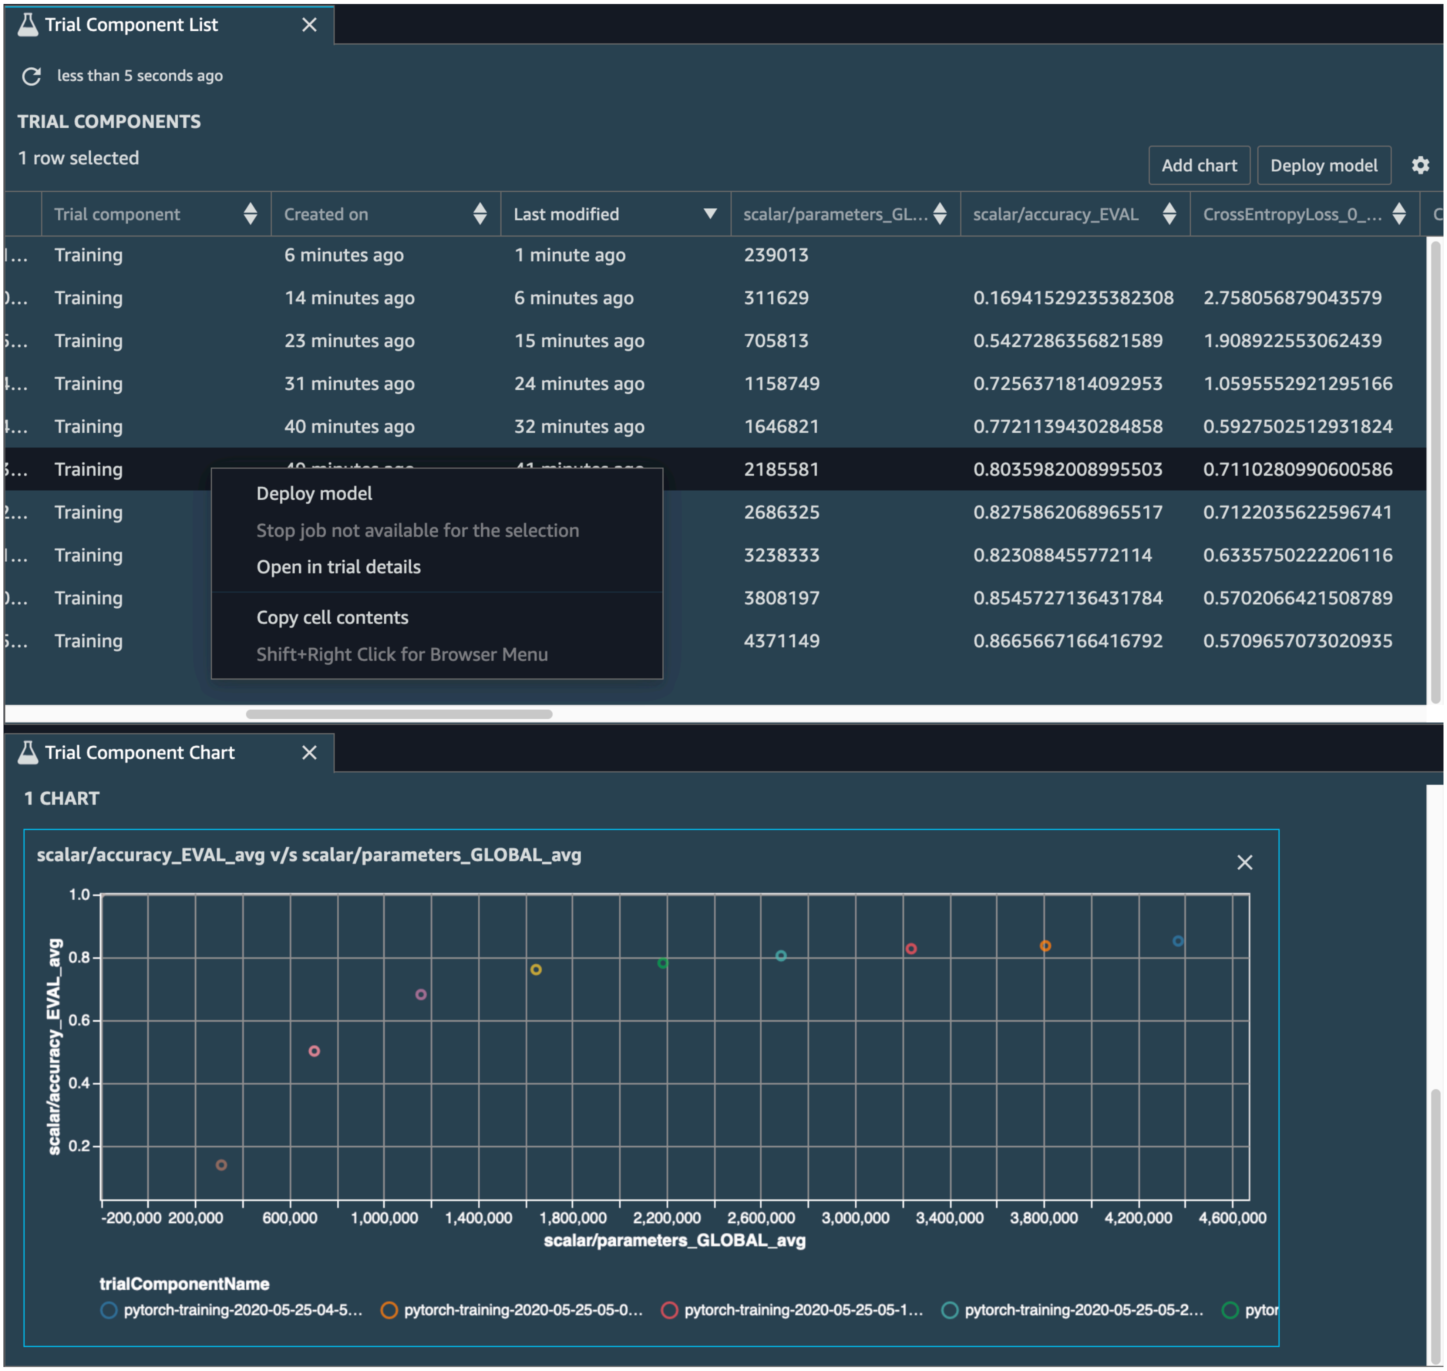
```

You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.



In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

Note

To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
        print('acc:{:.4f}'.format(correct/total))
        hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the
 pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```

Using SageMaker Debugger to monitor a convolutional autoencoder model training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

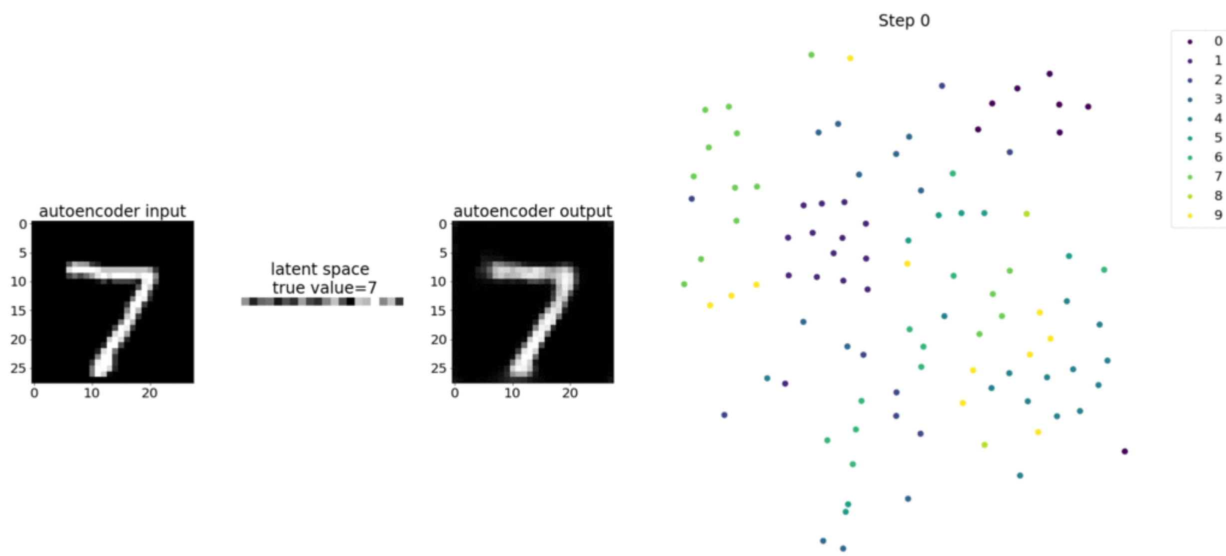
The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two *deconvolutional* layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.



Using SageMaker Debugger to monitor attentions in BERT model training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on *transfer learning* and the *Transformer model* for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high *attention* to appropriate verb tokens or pronoun tokens from a subject token.

The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called *attention*.

This notebook demonstrates how to use the [pre-trained BERT model from the GluonNLP model zoo] on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting *attention scores* and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker AI Debugger, you can retrieve the tensors and plot the *attention-head view* in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.

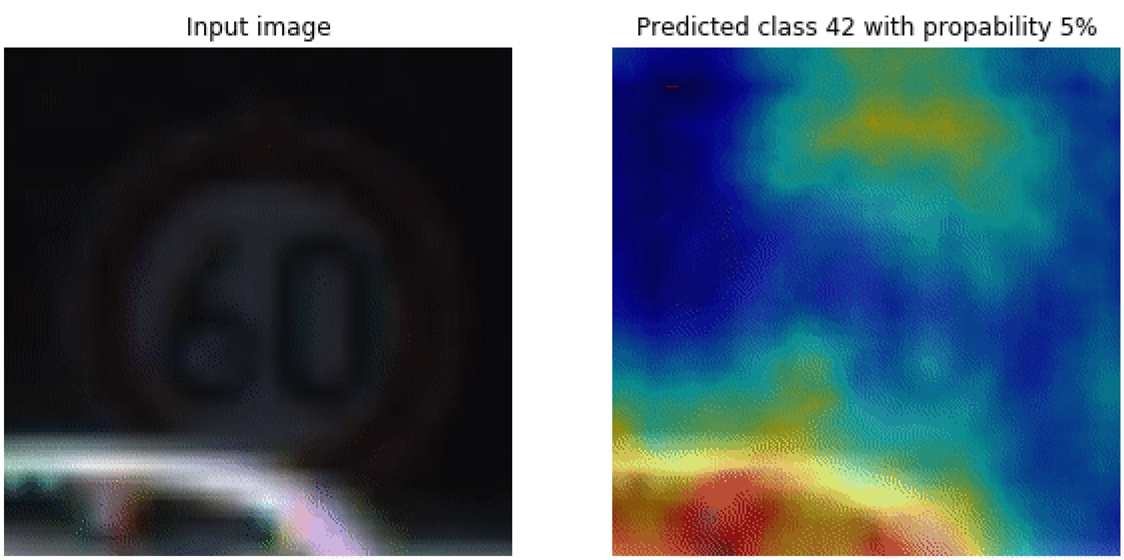
Using SageMaker Debugger to visualize class activation maps in convolutional neural networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a *convolutional neural network (CNN or ConvNet)* is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on [the German Traffic Sign Dataset](), which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.



During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a *saliency map*) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Debugging training jobs using Amazon SageMaker Debugger

To prepare your training script and run training jobs with SageMaker Debugger to debug model training progress, you follow the typical two-step process: modify your training script using the `sagemaker-debugger` Python SDK, and construct a SageMaker AI estimator using the SageMaker Python SDK. Go through the following topics to learn how to use SageMaker Debugger's debugging functionality.

Topics

Adapting your training script to register a hook

Amazon SageMaker Debugger comes with a client library called the `sagemaker-debugger` Python SDK. The `sagemaker-debugger` Python SDK provides tools for adapting your training script before training and analysis tools after training. In this page, you'll learn how to adapt your training script using the client library.

The `sagemaker-debugger` Python SDK provides wrapper functions that help register a hook to extract model tensors, without altering your training script. To get started with collecting model output tensors and debug them to find training issues, make the following modifications in your training script.

> **Tip**
>
> While you're following this page, use the `sagemaker-debugger` open source SDK documentation for API references.

Topics

Adapt your PyTorch training script

To start collecting model output tensors and debug training issues, make the following modifications to your PyTorch training script.

> **Note**
>
> SageMaker Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.

For PyTorch 1.12.0

If you bring a PyTorch training script, you can run the training job and extract model output tensors with a few additional code lines in your training script. You need to use the hook APIs in the `sagemaker-debugger` client library. Walk through the following instructions that break down the steps with code examples.

1. Create a hook.

   (Recommended) For training jobs within SageMaker AI

   ```
   import smdebug.pytorch as smd
   hook=smd.get_hook(create_if_not_exists=True)
   ```

   When you launch a training job in the section called "Launch training jobs with Debugger using the SageMaker Python SDK" with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker AI adds a JSON configuration file to your training instance that is picked up by the `get_hook` function. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns None.

   (Optional) For training jobs outside SageMaker AI

   If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode because the Rules require

SageMaker AI ML training instances and S3 to store outputs from the remote instances in real time. The `smd.get_hook` API returns `None` in this case.

If you want to create a manual hook to save tensors in local mode, use the following code snippet with the logic to check if the `smd.get_hook` API returns `None` and create a manual hook using the `smd.Hook` class. Note that you can specify any output directory in your local machine.

```
import smdebug.pytorch as smd
hook=smd.get_hook(create_if_not_exists=True)

if hook is None:
    hook=smd.Hook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

2. Wrap your model with the hook's class methods.

   The `hook.register_module()` method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called "Launch training jobs with Debugger using the SageMaker Python SDK". The collectable tensors through this hook method are weights, biases, activations, gradients, inputs, and outputs.

```
hook.register_module(model)
```

> **Tip**
>
> If you collect the entire output tensors from a large deep learning model, the total size of those collections can exponentially grow and might cause bottlenecks. If you want to save specific tensors, you can also use the `hook.save_tensor()` method. This method helps you pick the variable for the specific tensor and save to a custom collection named as you want. For more information, see step 7 of this instruction.

3. Warp the loss function with the hook's class methods.

The `hook.register_loss` method is to wrap the loss function. It extracts loss values every `save_interval` that you'll set during configuration in [the section called "Launch training jobs with Debugger using the SageMaker Python SDK"](), and saves them to the `"losses"` collection.

```
hook.register_loss(loss_function)
```

4. Add `hook.set_mode(ModeKeys.TRAIN)` in the train block. This indicates the tensor collection is extracted during the training phase.

```
def train():
    ...
    hook.set_mode(ModeKeys.TRAIN)
```

5. Add `hook.set_mode(ModeKeys.EVAL)` in the validation block. This indicates the tensor collection is extracted during the validation phase.

```
def validation():
    ...
    hook.set_mode(ModeKeys.EVAL)
```

6. Use [`hook.save_scalar()`]() to save custom scalars. You can save scalar values that aren't in your model. For example, if you want to record the accuracy values computed during evaluation, add the following line of code below the line where you calculate accuracy.

```
hook.save_scalar("accuracy", accuracy)
```

Note that you need to provide a string as the first argument to name the custom scalar collection. This is the name that'll be used for visualizing the scalar values in TensorBoard, and can be any string you want.

7. Use [`hook.save_tensor()`]() to save custom tensors. Similarly to [`hook.save_scalar()`](), you can save additional tensors, defining your own tensor collection. For example, you can extract input image data that are passed into the model and save as a custom tensor by adding the following code line, where `"images"` is an example name of the custom tensor, `image_inputs` is an example variable for the input image data.

```
hook.save_tensor("images", image_inputs)
```

Note that you must provide a string to the first argument to name the custom tensor. `hook.save_tensor()` has the third argument `collections_to_write` to specify the tensor collection to save the custom tensor. The default is `collections_to_write="default"`. If you don't explicitely specify the third argument, the custom tensor is saved to the `"default"` tensor collection.

After you have completed adapting your training script, proceed to the section called "Launch training jobs with Debugger using the SageMaker Python SDK".

Adapt your TensorFlow training script

To start collecting model output tensors and debug training issues, make the following modifications to your TensorFlow training script.

Create a hook for training jobs within SageMaker AI

```
import smdebug.tensorflow as smd

hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)
```

This creates a hook when you start a SageMaker training job. When you launch a training job in the section called "Launch training jobs with Debugger using the SageMaker Python SDK" with any of the `DebuggerHookConfig`, `TensorBoardConfig`, or `Rules` in your estimator, SageMaker AI adds a JSON configuration file to your training instance that is picked up by the `smd.get_hook` method. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns `None`.

(Optional) Create a hook for training jobs outside SageMaker AI

If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode. The `smd.get_hook` method also returns `None` in this case.

If you want to create a manual hook, use the following code snippet with the logic to check if the hook returns `None` and create a manual hook using the `smd.Hook` class.

```
import smdebug.tensorflow as smd
```

```
hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)

if hook is None:
    hook=smd.KerasHook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

After adding the hook creation code, proceed to the following topic for TensorFlow Keras.

> **Note**
>
> SageMaker Debugger currently supports TensorFlow Keras only.

Register the hook in your TensorFlow Keras training script

The following precedure walks you through how to use the hook and its methods to collect output scalars and tensors from your model and optimizer.

1. Wrap your Keras model and optimizer with the hook's class methods.

   The `hook.register_model()` method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called "Launch training jobs with Debugger using the SageMaker Python SDK". The collectable tensors through this hook method are weights, biases, and activations.

   ```
   model=tf.keras.Model(...)
   hook.register_model(model)
   ```

2. Wrap the optimizer by the `hook.wrap_optimizer()` method.

   ```
   optimizer=tf.keras.optimizers.Adam(...)
   optimizer=hook.wrap_optimizer(optimizer)
   ```

3. Compile the model in eager mode in TensorFlow.

   To collect tensors from the model, such as the input and output tensors of each layer, you must run the training in eager mode. Otherwise, SageMaker AI Debugger will not be able to collect the tensors. However, other tensors, such as model weights, biases, and the loss, can be collected without explicitly running in eager mode.

```
model.compile(
    loss="categorical_crossentropy",
    optimizer=optimizer,
    metrics=["accuracy"],
    # Required for collecting tensors of each layer
    run_eagerly=True
)
```

4. Register the hook to the `tf.keras.Model.fit()` method.

   To collect the tensors from the hooks that you registered, add `callbacks=[hook]` to the Keras `model.fit()` class method. This will pass the `sagemaker-debugger` hook as a Keras callback.

```
model.fit(
    X_train, Y_train,
    batch_size=batch_size,
    epochs=epoch,
    validation_data=(X_valid, Y_valid),
    shuffle=True,
    callbacks=[hook]
)
```

5. TensorFlow 2.x provides only symbolic gradient variables that do not provide access to their values. To collect gradients, wrap `tf.GradientTape` by the `hook.wrap_tape()` method, which requires you to write your own training step as follows.

```
def training_step(model, dataset):
    with hook.wrap_tape(tf.GradientTape()) as tape:
        pred=model(data)
        loss_value=loss_fn(labels, pred)
    grads=tape.gradient(loss_value, model.trainable_variables)
    optimizer.apply_gradients(zip(grads, model.trainable_variables))
```

   By wrapping the tape, the `sagemaker-debugger` hook can identify output tensors such as gradients, parameters, and losses. Wrapping the tape ensures that the `hook.wrap_tape()` method around functions of the tape object, such as `push_tape()`, `pop_tape()`, `gradient()`, will set up the writers of SageMaker Debugger and save tensors that are provided as input to `gradient()` (trainable variables and loss) and output of `gradient()` (gradients).

> **Note**
>
> To collect with a custom training loop, make sure that you use eager mode. Otherwise, SageMaker Debugger is not able to collect any tensors.

For a full list of actions that the `sagemaker-debugger` hook APIs offer to construct hooks and save tensors, see Hook Methods in the *`sagemaker-debugger` Python SDK documentation*.

After you have completed adapting your training script, proceed to the section called "Launch training jobs with Debugger using the SageMaker Python SDK".

Launch training jobs with Debugger using the SageMaker Python SDK

To configure a SageMaker AI estimator with SageMaker Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters. To fully utilize the debugging functionality, there are three parameters you need to configure: `debugger_hook_config`, `tensorboard_output_config`, and `rules`.

> **Important**
>
> Before constructing and running the estimator fit method to launch a training job, make sure that you adapt your training script following the instructions at the section called "Adapting your training script to register a hook".

Constructing a SageMaker AI Estimator with Debugger-specific parameters

The code examples in this section show how to construct a SageMaker AI estimator with the Debugger-specific parameters.

> **Note**
>
> The following code examples are templates for constructing the SageMaker AI framework estimators and not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

PyTorch

```
# An example of constructing a SageMaker AI PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

session=boto3.session.Session()
region=session.region_name

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.12.0",
    py_version="py37",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

TensorFlow

```
# An example of constructing a SageMaker AI TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

session=boto3.session.Session()
```

```
region=session.region_name

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```
# An example of constructing a SageMaker AI MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
```

```
    framework_version="1.7.0",
    py_version="py37",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

XGBoost

```
# An example of constructing a SageMaker AI XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

Generic estimator

```
# An example of constructing a SageMaker AI generic estimator using the XGBoost
 algorithm base image
import boto3
```

```
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

Configure the following parameters to activate SageMaker Debugger:

- `debugger_hook_config` (an object of [DebuggerHookConfig]) – Required to activate the hook in the adapted training script during [the section called “Adapting your training script to register a hook”], configure the SageMaker training launcher (estimator) to collect output tensors from your training job, and save the tensors into your secured S3 bucket or local machine. To learn how to configure the `debugger_hook_config` parameter, see [Configuring SageMaker Debugger to save tensors].
- `rules` (a list of [Rule] objects) – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in real time. The built-in rules are logics that automatically debug the training progress of your model and find training issues by analyzing the output tensors saved in your secured S3 bucket. To learn how to configure the `rules` parameter, see How to

configure Debugger built-in rules. To find a complete list of built-in rules for debugging output tensors, see the section called "Debugger rule". If you want to create your own logic to detect any training issues, see the section called "Creating custom rules".

> **Note**
>
> The built-in rules are available only through SageMaker training instances. You cannot use them in local mode.

- `tensorboard_output_config` (an object of `TensorBoardOutputConfig`) – Configure SageMaker Debugger to collect output tensors in the TensorBoard-compatible format and save to your S3 output path specified in the `TensorBoardOutputConfig` object. To learn more, see the section called "Visualize Debugger Output Tensors in TensorBoard".

> **Note**
>
> The `tensorboard_output_config` must be configured with the `debugger_hook_config` parameter, which also requires you to adapt your training script by adding the `sagemaker-debugger` hook.

> **Note**
>
> SageMaker Debugger securely saves output tensors in subfolders of your S3 bucket. For example, the format of the default S3 bucket URI in your account is `s3://amzn-s3-demo-bucket-sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are two subfolders created by SageMaker Debugger: `debug-output`, and `rule-output`. If you add the `tensorboard_output_config` parameter, you'll also find `tensorboard-output` folder.

See the following topics to find more examples of how to configure the Debugger-specific parameters in detail.

Topics

- Configuring SageMaker Debugger to save tensors
- How to configure Debugger built-in rules

- Turn off Debugger
- Useful SageMaker AI estimator class methods for Debugger

Configuring SageMaker Debugger to save tensors

Tensors are data collections of updated parameters from the backward and forward pass of each training iteration. SageMaker Debugger collects the output tensors to analyze the state of a training job. SageMaker Debugger's `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into *collections* and saving them to a target S3 bucket. The following topics show how to use the `CollectionConfig` and `DebuggerHookConfig` API operations, followed by examples of how to use Debugger hook to save, access, and visualize output tensors.

While constructing a SageMaker AI estimator, activate SageMaker Debugger by specifying the `debugger_hook_config` parameter. The following topics include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them.

> **Note**
>
> After properly configured and activated, SageMaker Debugger saves the output tensors in a default S3 bucket, unless otherwise specified. The format of the default S3 bucket URI is `s3://amzn-s3-demo-bucket-sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

Topics

- Configure tensor collections using the CollectionConfig API
- Configure the DebuggerHookConfig API to save tensors
- Example notebooks and code samples to configure Debugger hook

Configure tensor collections using the `CollectionConfig` API

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default `"save_interval"` value.

For a full list of available Debugger built-in collections, see [Debugger Built-in Collections](#).

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see [CollectionConfig](#) in the [Amazon SageMaker Python SDK](#). For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
```

```
            "eval.save_interval": "10"
        }
    )
]
```

Tip

This tensor collection configuration object can be used for both DebuggerHookConfig and Rule API operations.

Configure the DebuggerHookConfig API to save tensors

Use the DebuggerHookConfig API to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```
from sagemaker.debugger import DebuggerHookConfig

debugger_hook_config=DebuggerHookConfig(
    collection_configs=collection_configs
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://amzn-s3-demo-bucket-sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```
from sagemaker.debugger import DebuggerHookConfig

debugger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-uri"
    collection_configs=collection_configs
)
```

For more information, see DebuggerHookConfig in the Amazon SageMaker Python SDK.

Example notebooks and code samples to configure Debugger hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

Topics

- Tensor visualization example notebooks
- Save tensors using Debugger built-in collections
- Save tensors by modifying Debugger built-in collections
- Save tensors using Debugger custom collections

Tensor visualization example notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

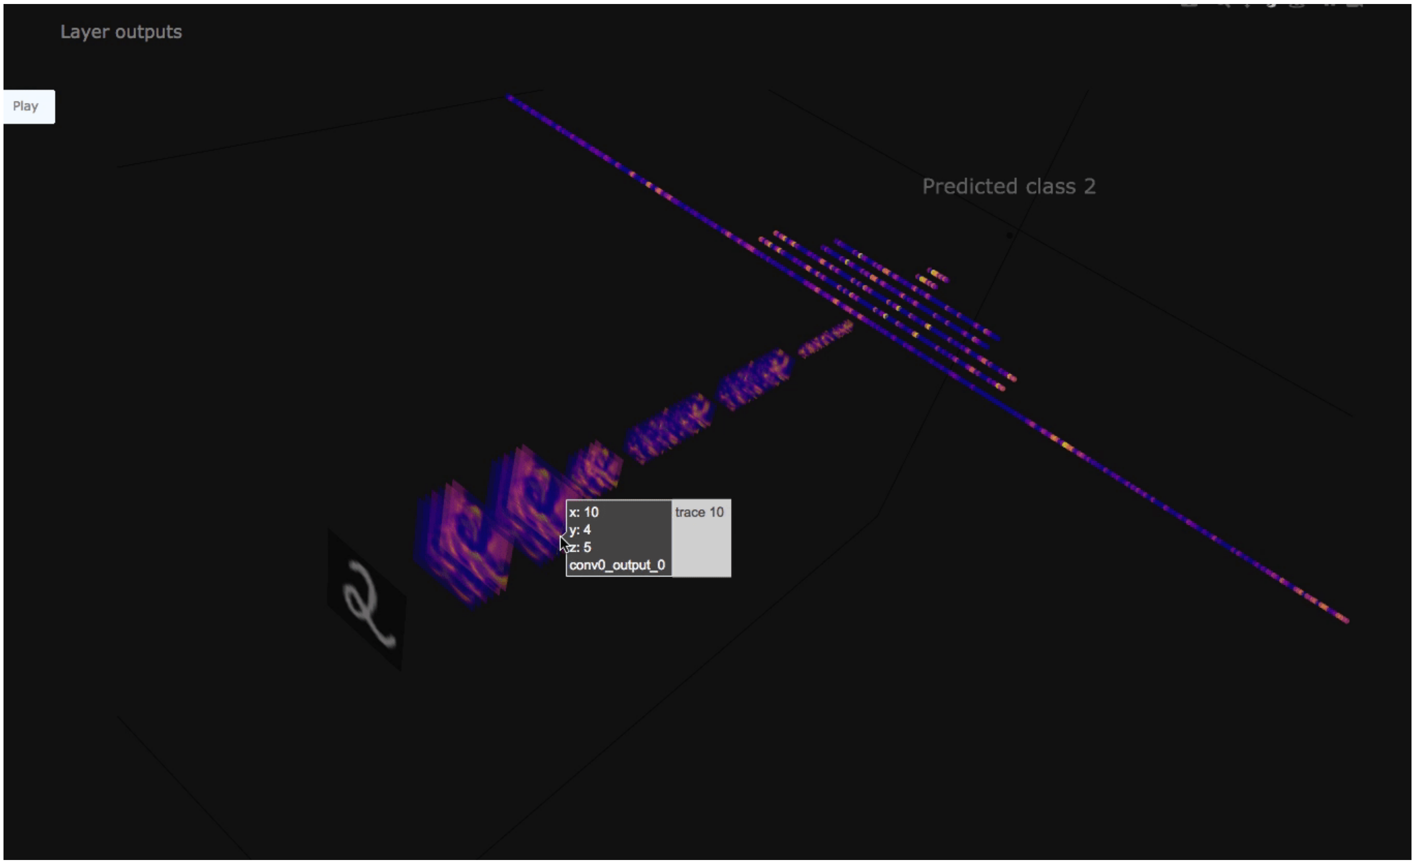
- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.

  This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- Visualizing and Debugging Tensors from MXNet Model Training

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.



In this notebook, the `TensorPlot` class imported from `tensor_plot.py` is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The `tensor_plot.py` script provided with the notebook retrieves tensors using Debugger and visualizes the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- Real-time Tensor Analysis in a SageMaker Notebook with MXNet

This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

Save tensors using Debugger built-in collections

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker AI TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

> **Note**
>
> In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:
>
> ```
> "s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
> ```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
        CollectionConfig(name="weights"),
        CollectionConfig(name="gradients"),
        CollectionConfig(name="losses"),
        CollectionConfig(name="biases")
    ]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
```

```
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                    format(BUCKET_NAME=BUCKET_NAME,
                           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save tensors by modifying Debugger built-in collections

You can modify the Debugger built-in collections using the `CollectionConfig` API operation. The following example shows how to tweak the built-in `losses` collection and construct a SageMaker AI TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
                name="losses",
                parameters={"save_interval": "50"})]

# configure Debugger hook
# set a target S3 bucket as you want
```

```
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                    format(BUCKET_NAME=BUCKET_NAME, 
                           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    
    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig API.

Save tensors using Debugger custom collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
        CollectionConfig(
```

```
            name="custom_activations_collection",
            parameters={
                "include_regex": "relu|tanh", # Required
                "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
            })
    ]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                    format(BUCKET_NAME=BUCKET_NAME,
                           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of `CollectionConfig` parameters, see [Debugger CollectionConfig](#).

How to configure Debugger built-in rules

In the following topics, you'll learn how to use the SageMaker Debugger built-in rules. Amazon SageMaker Debugger's built-in rules analyze tensors emitted during the training of a model. SageMaker AI Debugger offers the `Rule` API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger built-in rules.

Topics

- Use Debugger built-in rules with the default parameter settings
- Use Debugger built-in rules with custom parameter values
- Example notebooks and code samples to configure Debugger rules

Use Debugger built-in rules with the default parameter settings

To specify Debugger built-in rules in an estimator, you need to configure a list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n()),
    ... # You can also append more profiler rules in the
 ProfilerRule.sagemaker(rule_configs.*()) format.
]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger built-in rules.

To find the SageMaker Debugger API reference, see `sagemaker.debugger.rule_configs` and `sagemaker.debugger.Rule`.

For example, to inspect the overall training performance and progress of your model, construct a SageMaker AI estimator with the following built-in rule configuration.

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.loss_not_decreasing()),
```

```
    Rule.sagemaker(rule_configs.overfit()),
    Rule.sagemaker(rule_configs.overtraining()),
    Rule.sagemaker(rule_configs.stalled_training_rule())
]
```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The `loss_not_decreasing`, `overfit`, `overtraining`, and `stalled_training_rule` monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see [Action on Amazon SageMaker Debugger rules](#).

Use Debugger built-in rules with custom parameter values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` classmethods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. The instruction of how to use the `CollectionConfig` class is provided at [Configure tensor collections using the `CollectionConfig` API](#).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in [List of Debugger built-in rules](#).
- The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires `name` and `parameters` arguments.
  - To find available tensor collections for `name`, see [Debugger Built-in Tensor Collections](#).
  - For a full list of adjustable `parameters`, see [Debugger CollectionConfig API](#).

For more information about the Debugger rule class, methods, and parameters, see [SageMaker AI Debugger Rule class](#) in the [Amazon SageMaker Python SDK](#).

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
                "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger built-in rules.

Example notebooks and code samples to configure Debugger rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics

- Debugger built-in rules example notebooks
- Debugger built-in rules example code
- Use Debugger built-in rules with parameter modifications

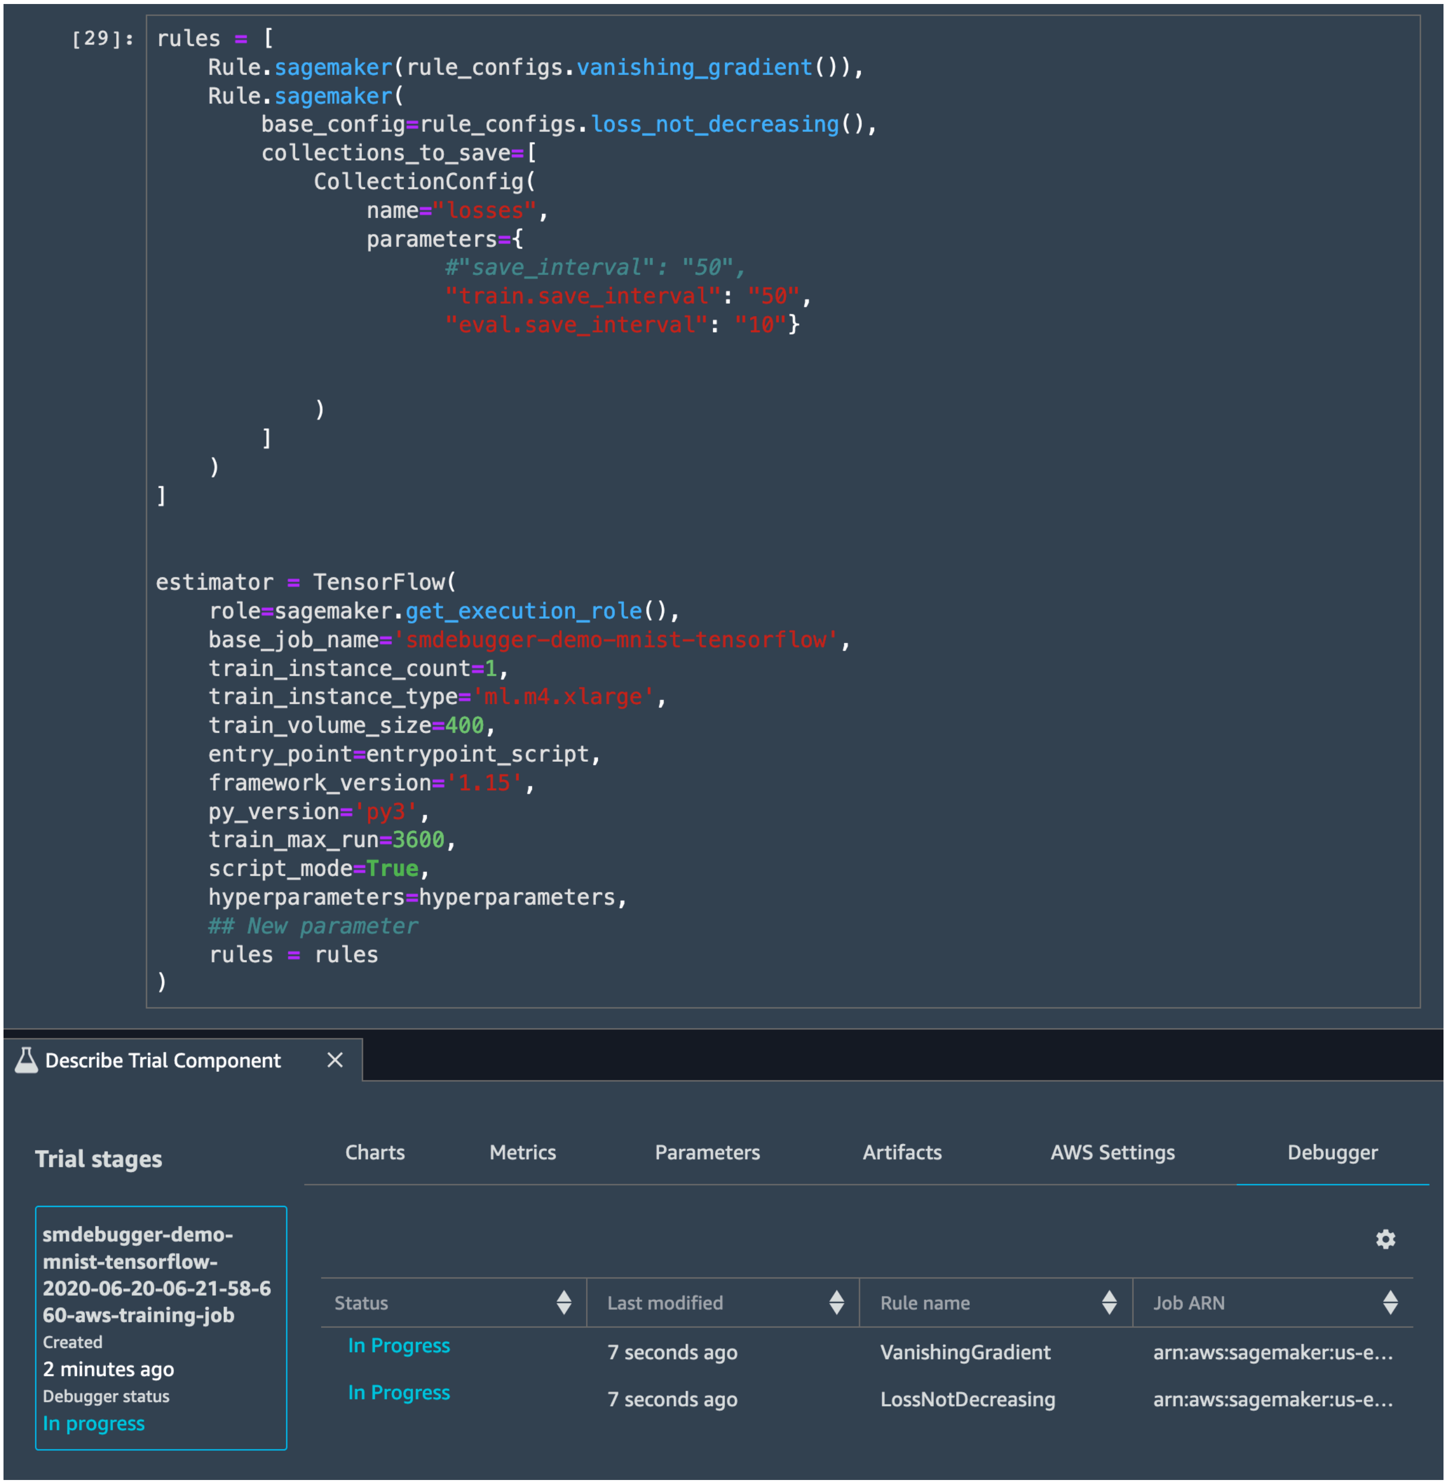
Debugger built-in rules example notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker AI:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet

- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the **Studio Experiment List** tab. For example, as shown in the following screenshot, you can find and open a **Describe Trial Component** window of your current training job. On the Debugger tab, you can check if the Debugger rules, `vanishing_gradient()` and `loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.



There are two ways of using the Debugger built-in rules in the SageMaker AI environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

Debugger built-in rules example code

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger built-in rules.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules=[
            Rule.sagemaker(rule_configs.vanishing_gradient())
            Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker AI estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific arguments below
    rules=built_in_rules
)
sagemaker_estimator.fit()
```

> **Note**
>
> The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger built-in rules with parameter modifications section.

Use Debugger built-in rules with parameter modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the `stalled_training_rule` collects the `losses` tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the `stalled_training_rule` stops the training job.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

built_in_rules_modified=[
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                'threshold': '120',
                'training_job_name_prefix': base_job_name_prefix,
                'stop_training_on_fire' : 'True'
        }
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                      "train.save_interval": "50"
                      "eval.save_interval": "10"
                }
            )
        ]
    )
]

# construct a SageMaker AI estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
```

```
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific arguments below
    rules=built_in_rules_modified
)
sagemaker_estimator.fit()
```

For an advanced configuration of the Debugger built-in rules using the `CreateTrainingJob` API, see Configure Debugger using SageMaker API.

Turn off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To stop both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  > **Warning**
  >
  > If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To stop debugging, set the `debugger_hook_config` parameter to `False`.

  > **Warning**
  >
  > If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```
estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
```

```
)
```

For more information about the Debugger-specific parameters, see SageMaker AI Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the estimator.disable_profiling and estimator.update_profiler classmethods in the Amazon SageMaker Python SDK documentation.

Useful SageMaker AI estimator class methods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.

- To check the base S3 bucket URI of a SageMaker training job:

  ```
  estimator.output_path
  ```

- To check the base job name of a SageMaker training job:

  ```
  estimator.latest_training_job.job_name
  ```

- To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:

  ```
  estimator.latest_training_job.describe()
  ```

- To check a full list of the Debugger rules while a SageMaker training job is running:

```
estimator.latest_training_job.rule_job_summary()
```

- To check the S3 bucket URI where the model parameter data (output tensors) are saved:

```
estimator.latest_job_debugger_artifacts_path()
```

- To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

```
estimator.latest_job_profiler_artifacts_path()
```

- To check the Debugger rule configuration for debugging output tensors:

```
estimator.debugger_rule_configs
```

- To check the list of the Debugger rules for debugging while a SageMaker training job is running:

```
estimator.debugger_rules
```

- To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

```
estimator.profiler_rule_configs
```

- To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

```
estimator.profiler_rules
```

For more information about the SageMaker AI estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

SageMaker Debugger interactive report for XGBoost

Receive training reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. For SageMaker AI XGBoost training jobs, use the Debugger CreateXgboostReport rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the CreateXgboostReport rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

Note

You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

Important

In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics

Construct a SageMaker AI XGBoost estimator with the Debugger XGBoost Report rule

The CreateXgboostReport rule collects the following output tensors from your training job:

- `hyperparameters` – Saves at the first step.
- `metrics` – Saves loss and accuracy every 5 steps.
- `feature_importance` – Saves every 5 steps.
- `predictions` – Saves every 5 steps.
- `labels` – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

When you construct a SageMaker AI estimator for an XGBoost training job, specify the rule as shown in the following example code.

Using the SageMaker AI generic estimator

```
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Add the Debugger XGBoost report rule
    rules=rules
)

estimator.fit(wait=False)
```

Download the Debugger XGBoost training report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Download using the SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

```
estimator.output_path
```

2. Check the current job name.

```
estimator.latest_training_job.job_name
```

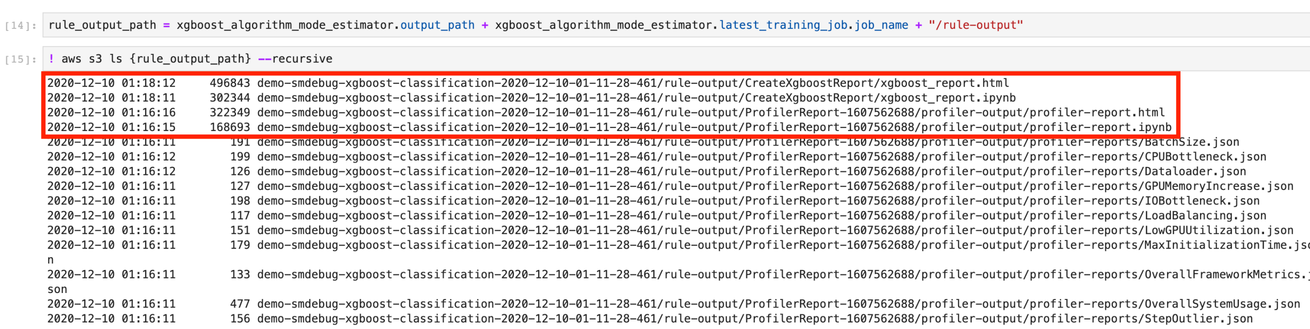
3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/<training-job-name>/rule-output`. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path + "/" +
 estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see [SageMaker Debugger interactive report](#).



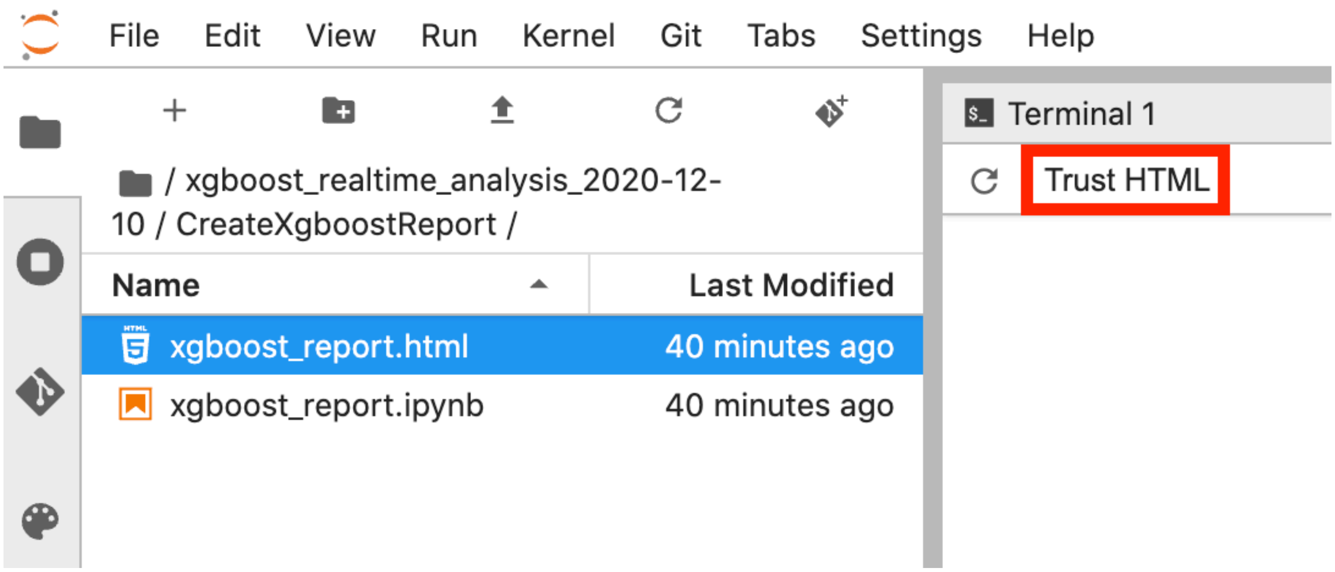
The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

> **Tip**
>
> If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

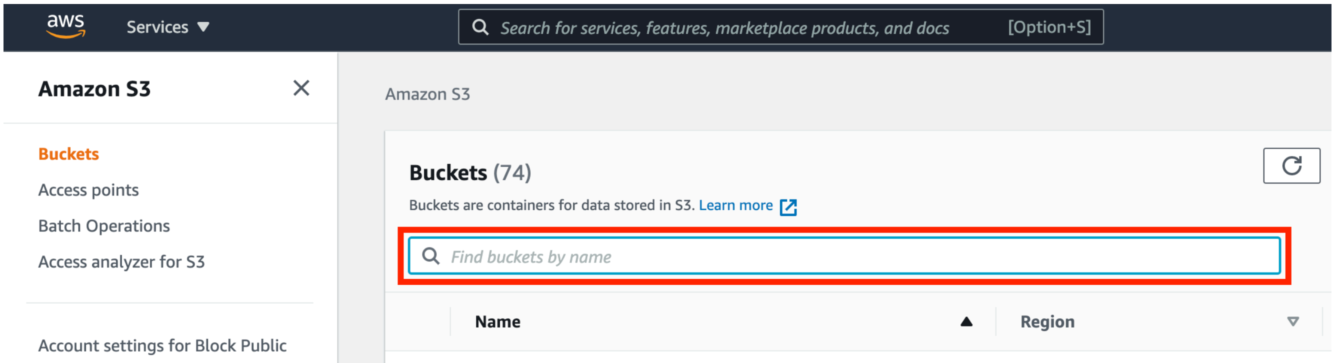
6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.



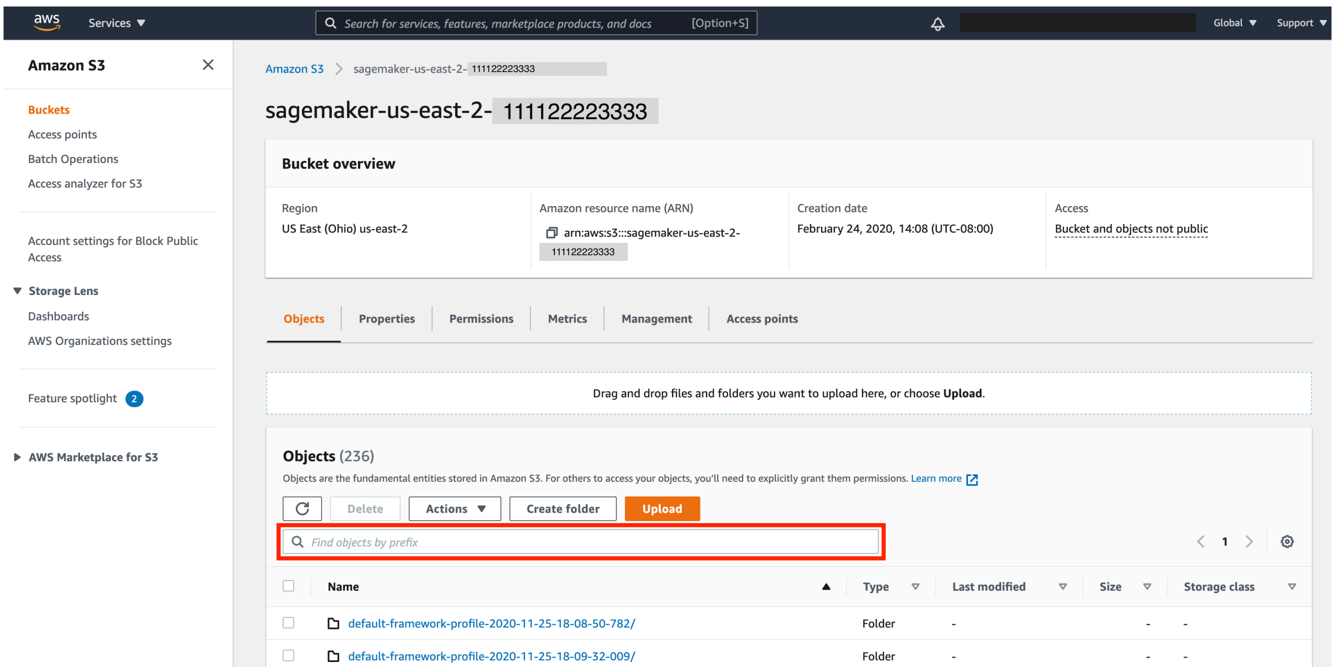
7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

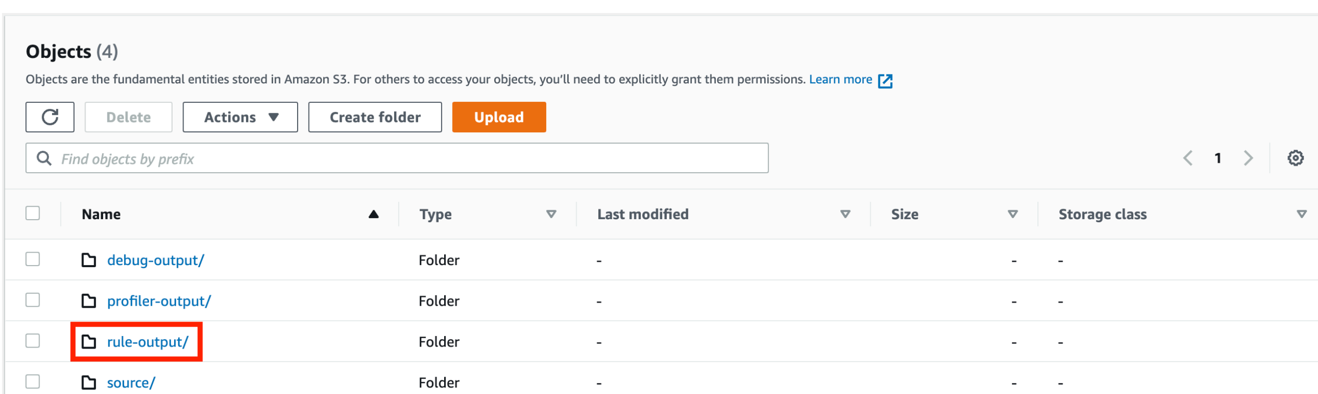
1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.



3. In the base S3 bucket, look up the training job name by entering your job name prefix in **Find objects by prefix** and then choosing the training job name.



4. In the training job's S3 bucket, choose **rule-output/** subfolder. There must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**.



5. In the **rule-output/** folder, choose the **CreateXgboostReport/** folder. The folder contains **xbgoost_report.html** (the autogenerated report in html) and **xbgoost_report.ipynb** (a Jupyter notebook with scripts that are used for generating the report).
6. Choose the **xbgoost_report.html** file, choose **Download actions**, and then choose **Download**.

Debugger XGBoost training report walkthrough

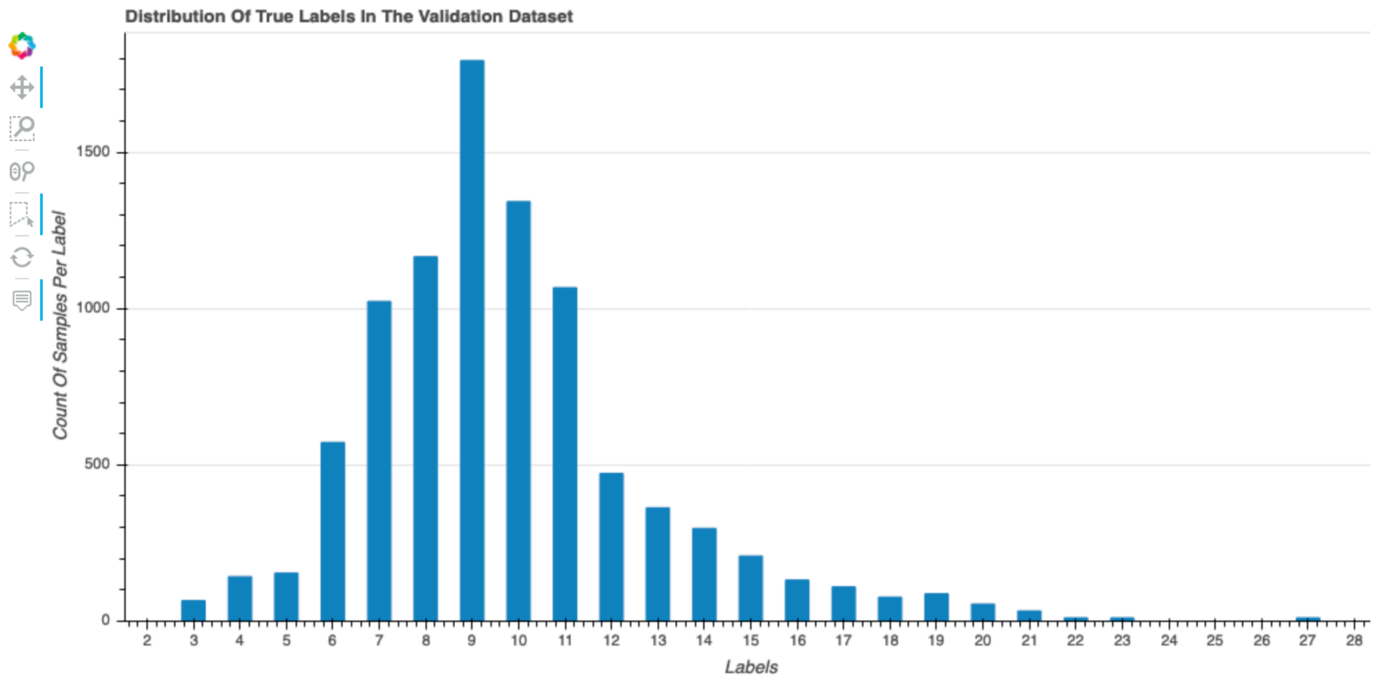
This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics

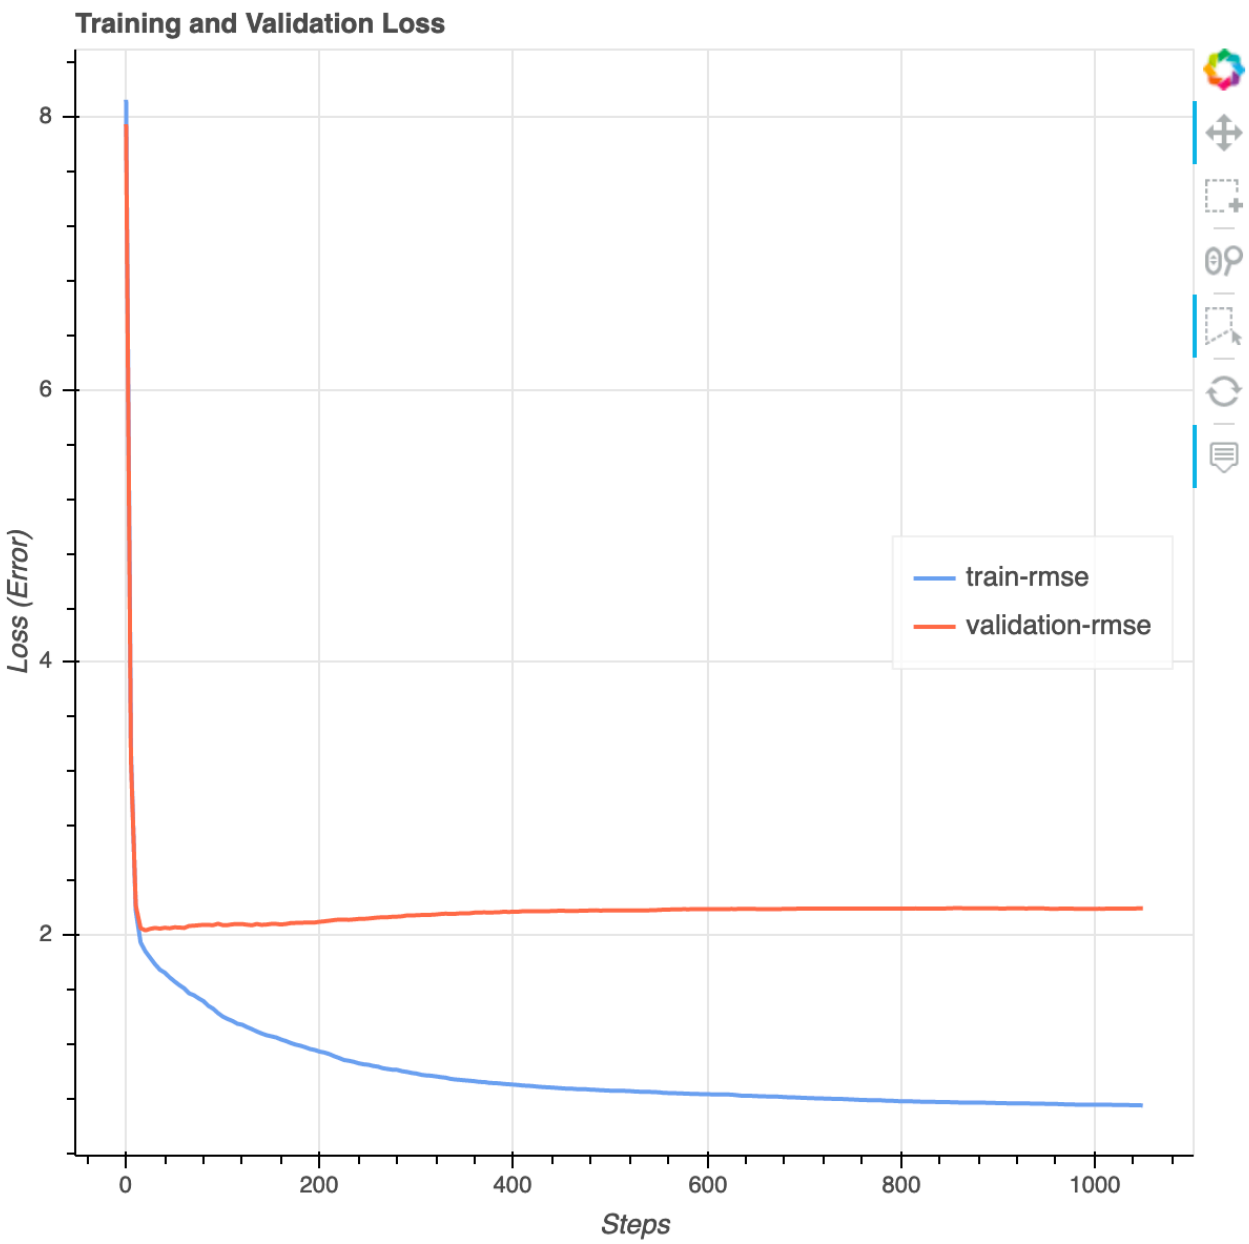
Distribution of true labels of the dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.



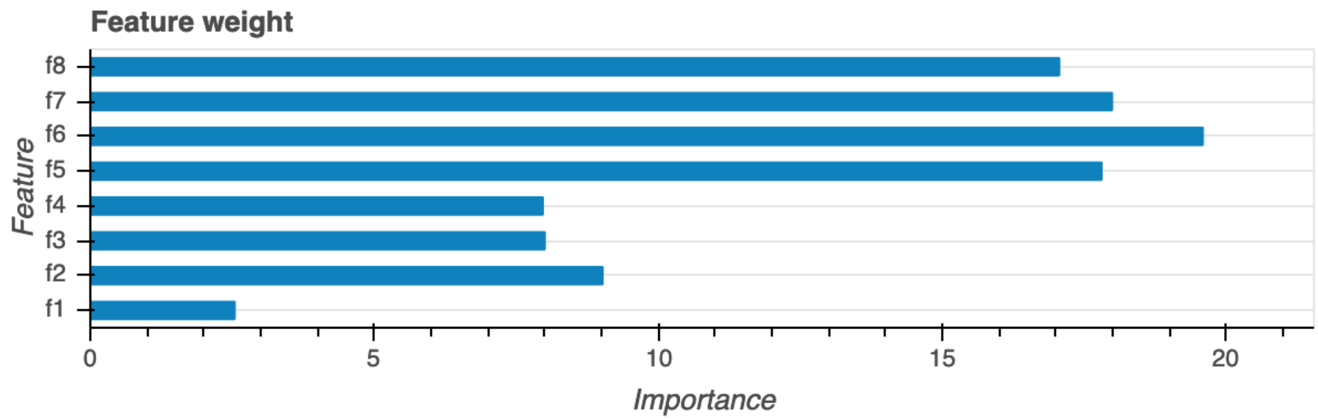
Loss versus step graph

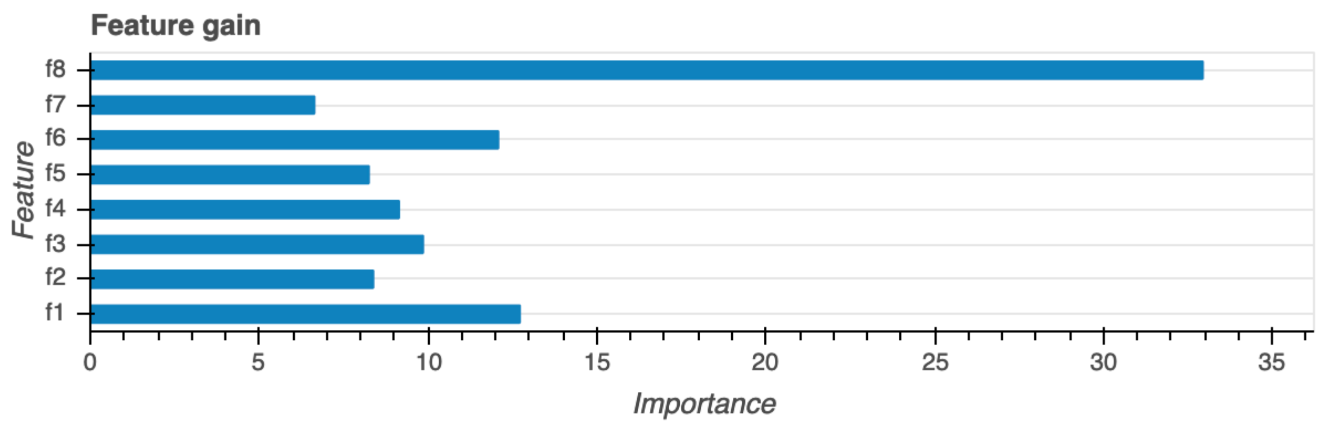
This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.

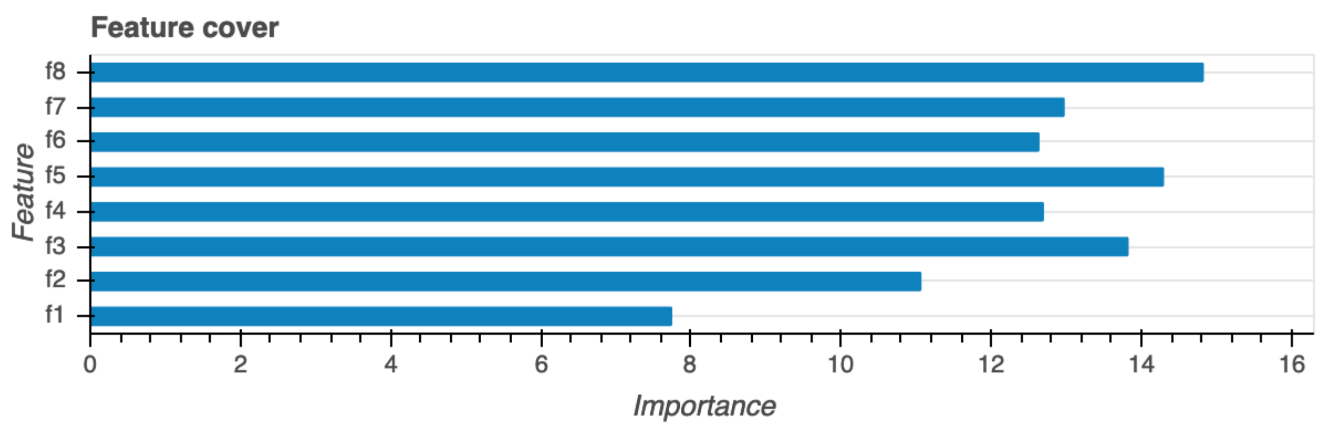


Feature importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.

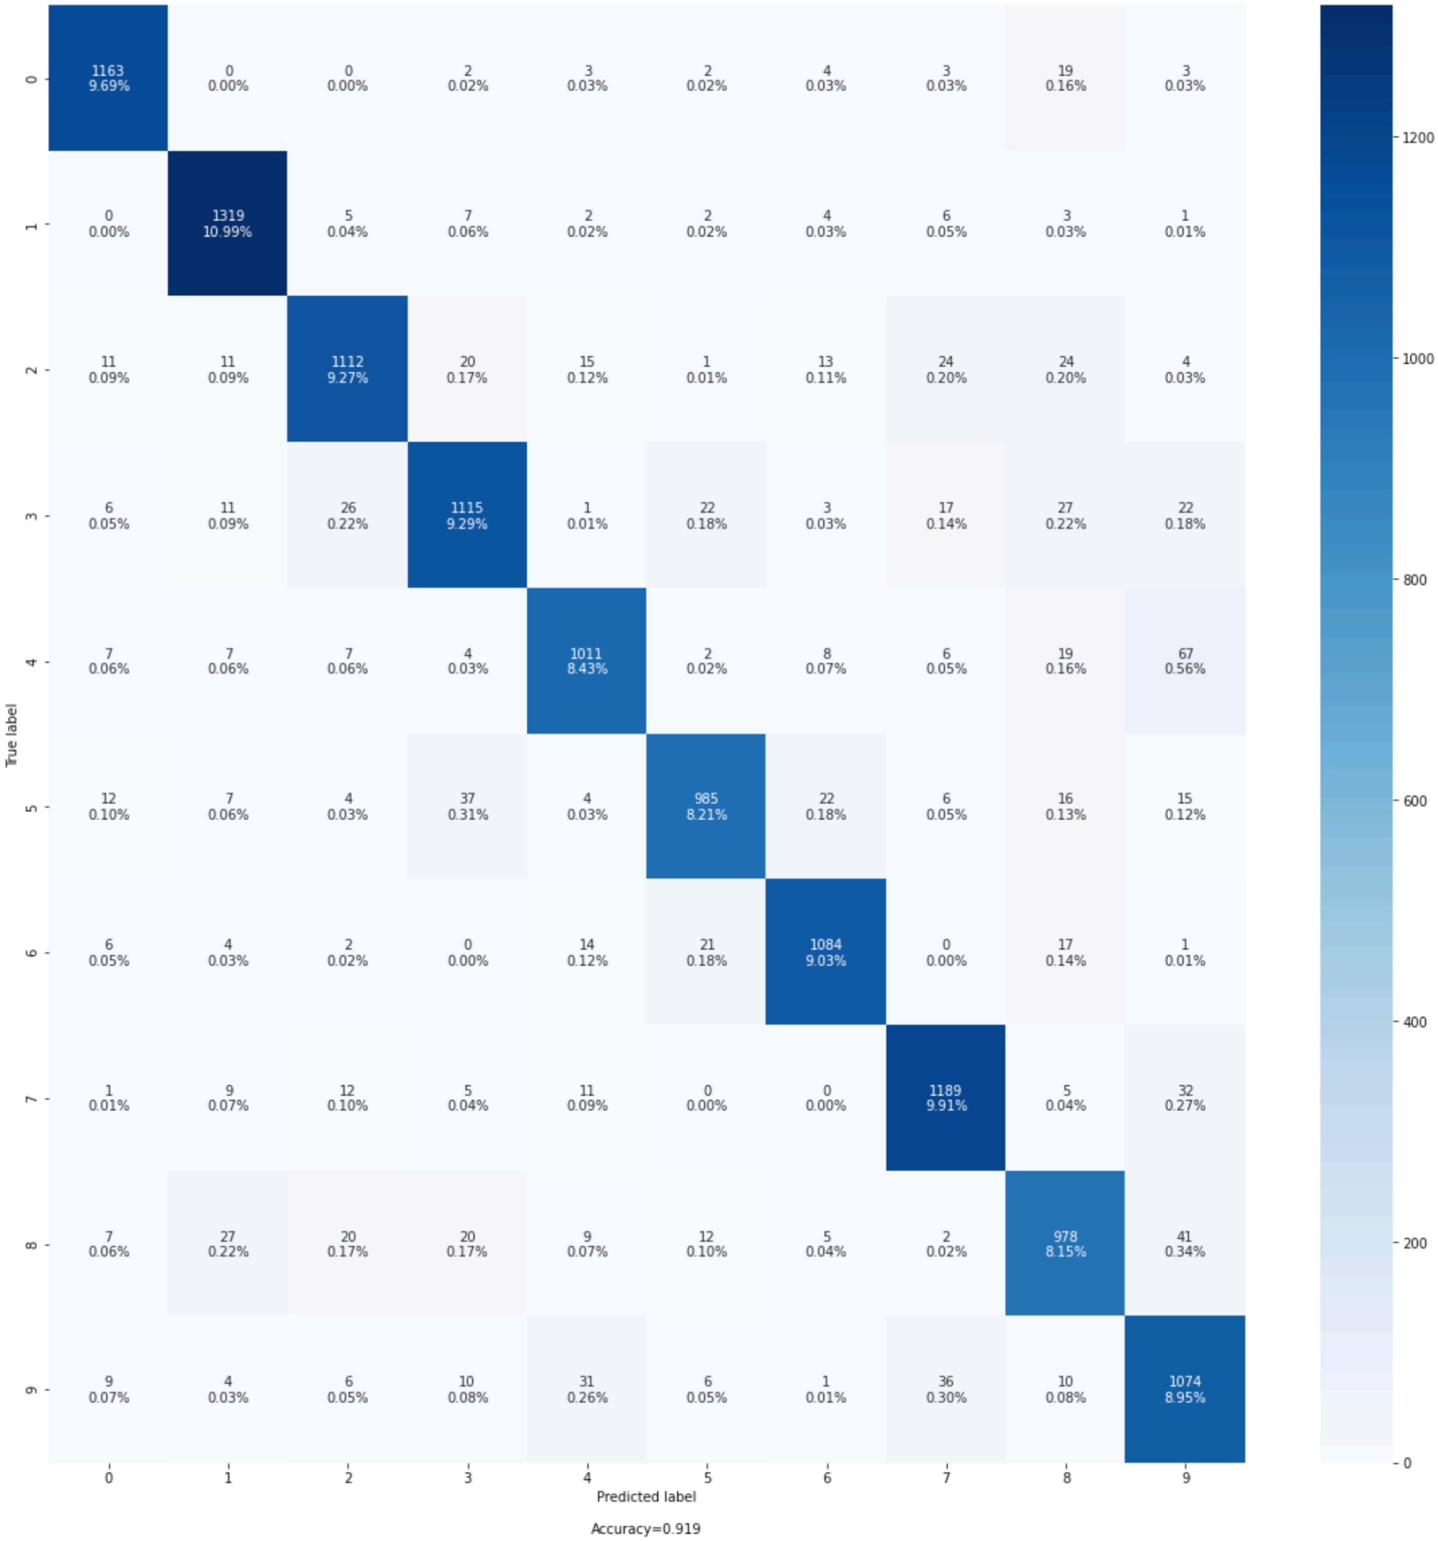






Confusion matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it's also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.



Evaluation of the confusion matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.

Overall Accuracy

```
    Overall Accuracy: 0.919
```

Micro Performance Metrics

```
    Performance metrics calculated globally by counting the total true positives, false negatives, and false positive
s.

    Micro Precision: 0.919
    Micro Recall: 0.919
    Micro F1-score: 0.919
```

Macro Performance Metrics

```
    Performance metrics calculated for each label, and find their unweighted mean.
    This does not take the class imbalance problem into account.

    Macro Precision: 0.919
    Macro Recall: 0.918
    Macro F1-score: 0.918
```

Weighted Performance Metrics

```
    Performance metrics calculated for each label and their average weighted by support
    (the number of true instances for each label).
    This extends the macro option to take the class imbalance into account.
    It might result in an F-score that is not between precision and recall.

    Weighted Precision: 0.92
    Weighted Recall: 0.919
    Weighted F1-score: 0.919
```

Classification Report

```
        The summary of the precision, recall, and F1-score for each class.

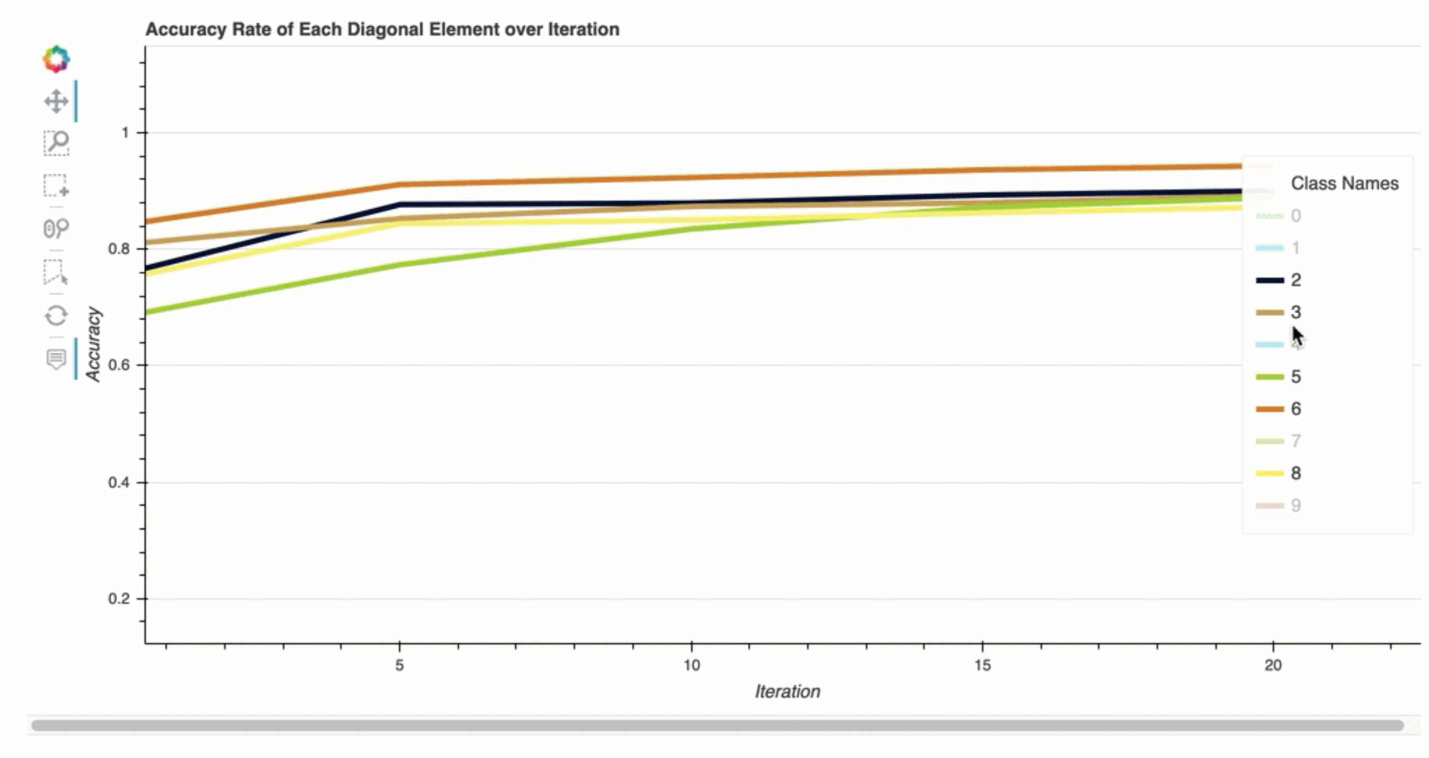
              precision    recall  f1-score   support

         0.0       0.95      0.97      0.96      1199
         1.0       0.94      0.98      0.96      1349
         2.0       0.93      0.90      0.92      1235
         3.0       0.91      0.89      0.90      1250
         4.0       0.92      0.89      0.90      1138
         5.0       0.94      0.89      0.91      1108
         6.0       0.95      0.94      0.95      1149
         7.0       0.92      0.94      0.93      1264
         8.0       0.87      0.87      0.87      1121
         9.0       0.85      0.90      0.88      1187

    accuracy                           0.92     12000
   macro avg       0.92      0.92      0.92     12000
weighted avg       0.92      0.92      0.92     12000
```

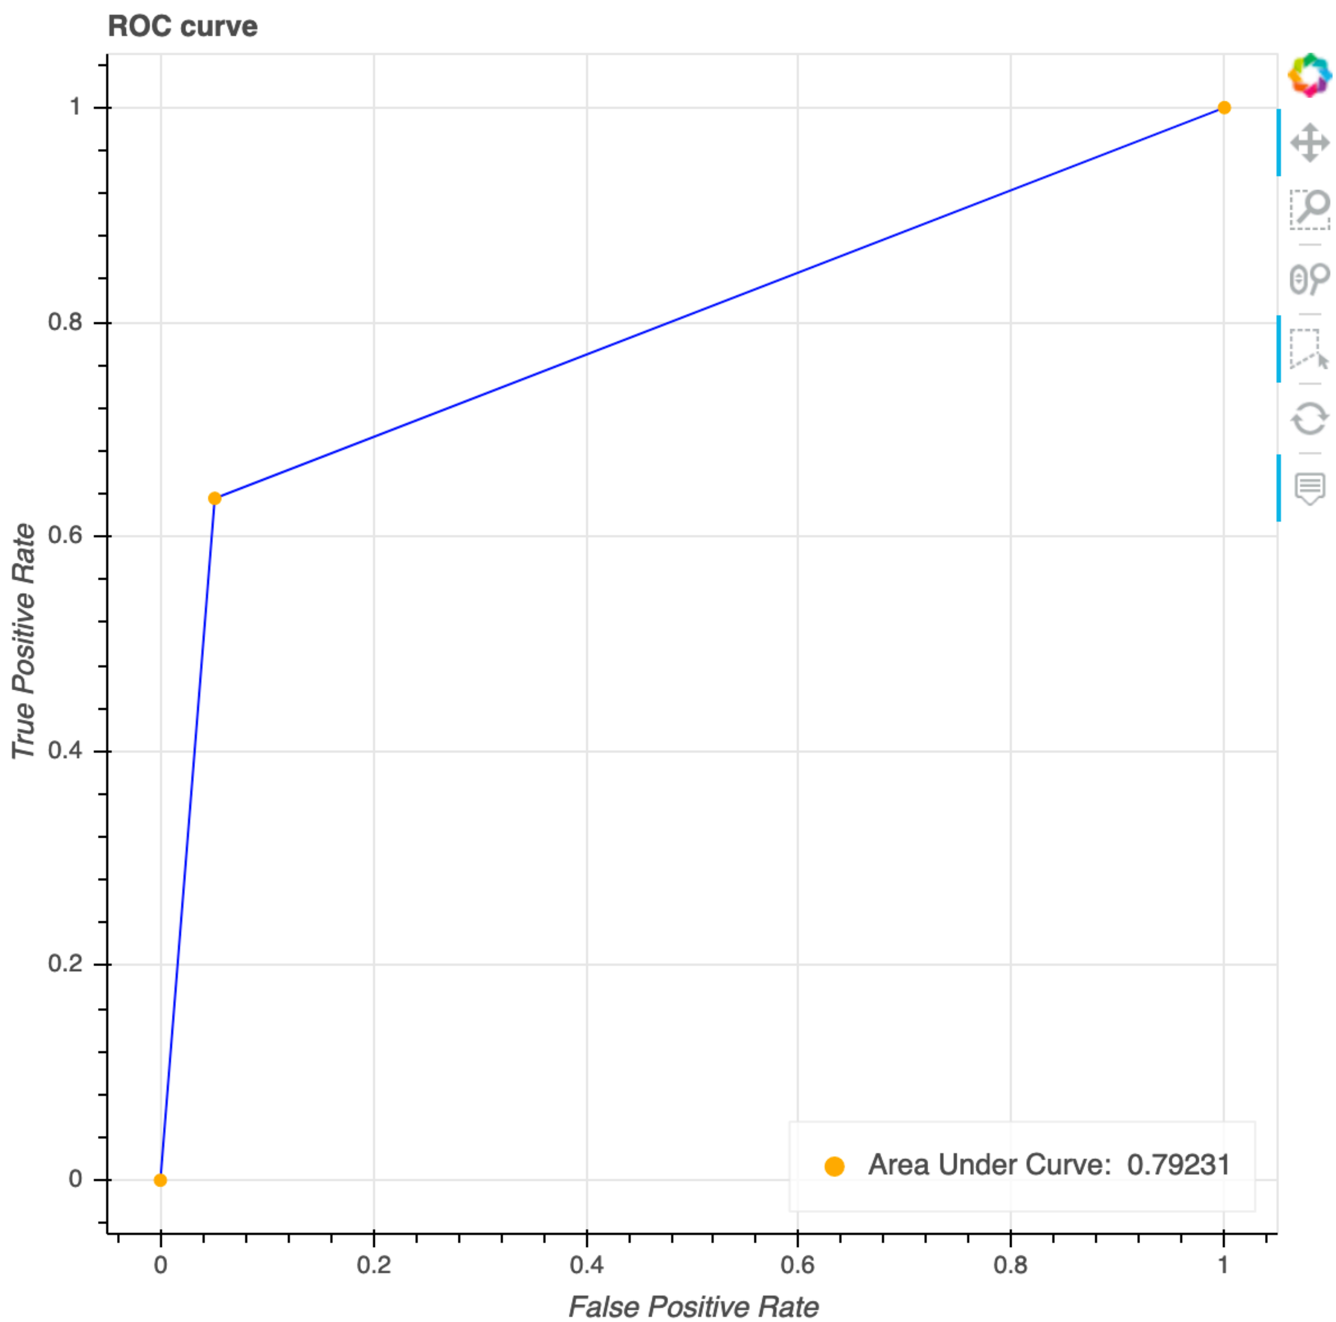
Accuracy rate of each diagonal element over iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.



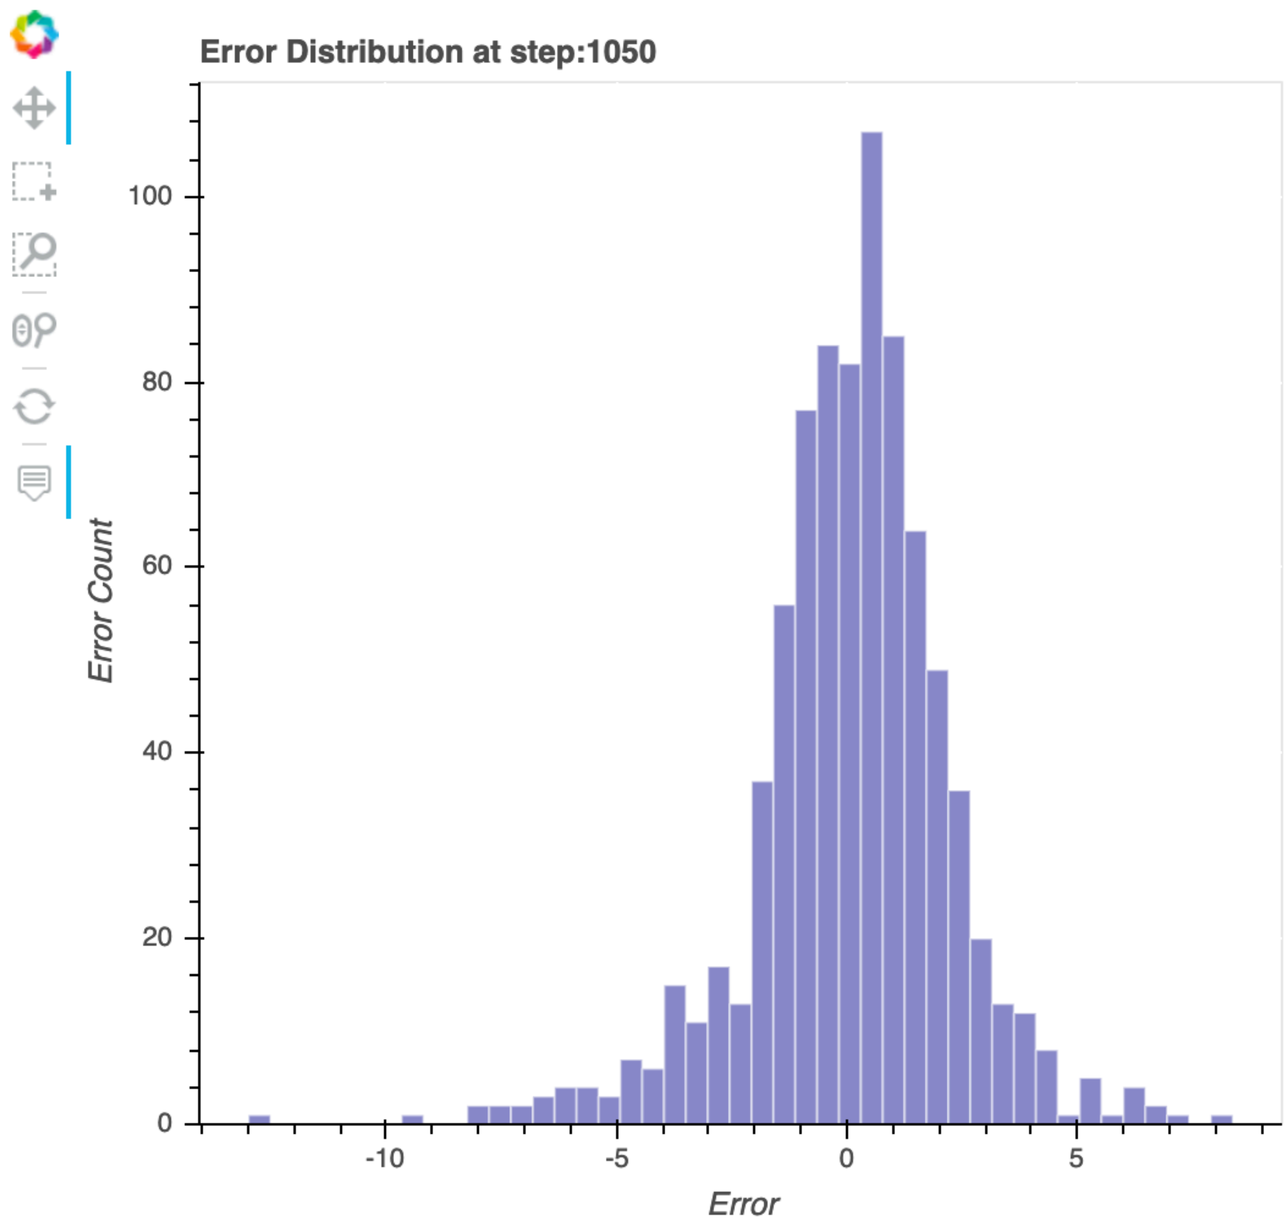
Receiver operating characteristic curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).



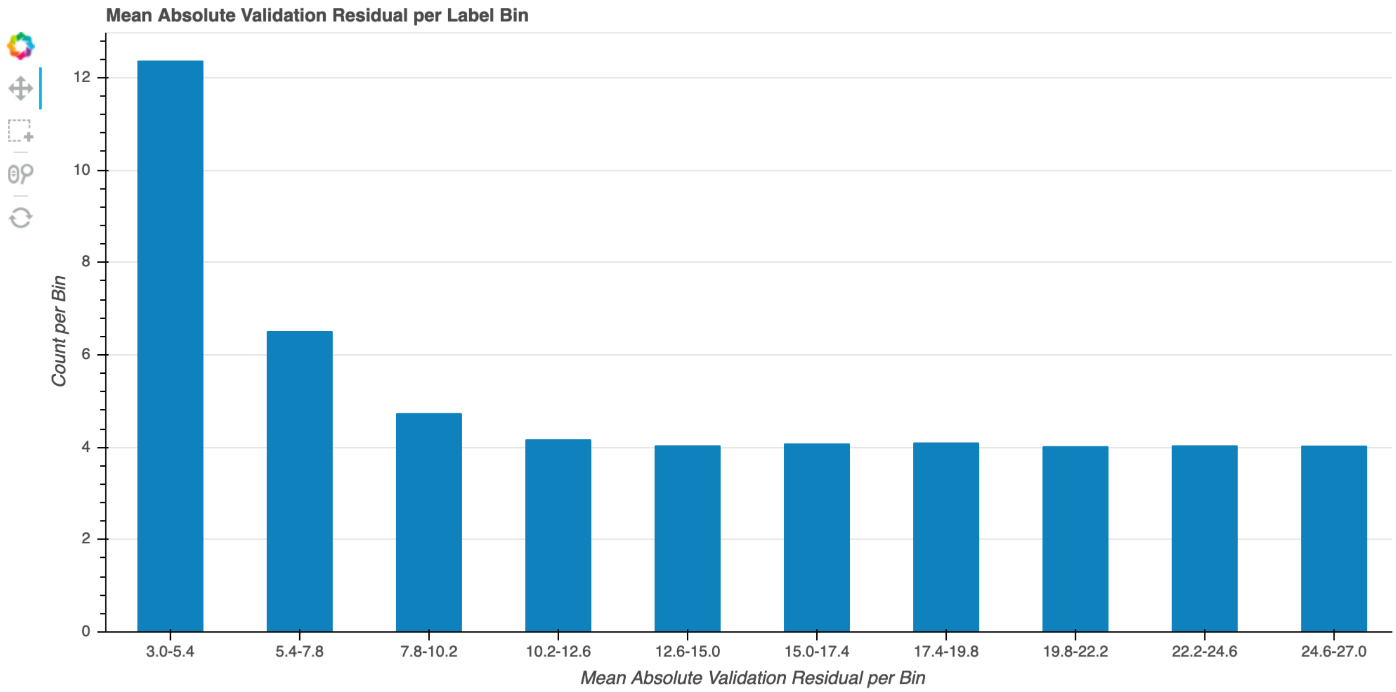
Distribution of residuals at the last saved step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that's centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.



Absolute validation error per label bin over iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.



Action on Amazon SageMaker Debugger rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

Topics

Use Debugger built-in actions for rules

Use Debugger built-in actions to respond to issues found by Debugger rule. The Debugger `rule_configs` class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues. The following topics takes you through the steps to accomplish these tasks.

Topics

- Set up Amazon SNS, create an SMDebugRules topic, and subscribe to the topic
- Set up your IAM role to attach required policies
- Configure Debugger rules with the built-in actions
- Considerations for using the Debugger built-in actions

Set up Amazon SNS, create an `SMDebugRules` topic, and subscribe to the topic

This section walks you through how to set up an Amazon SNS **`SMDebugRules`** topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

> **Note**
>
> For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

To create a SMDebugRules topic

1. Sign in to the AWS Management Console and open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the left navigation pane, choose **Topics**.
3. On the **Topics** page, choose **Create topic**.
4. On the **Create topic** page, in the **Details** section, do the following:

    a. For **Type**, choose **Standard** for topic type.

    b. In **Name**, enter **`SMDebugRules`**.
5. Skip all other optional settings and choose **Create topic**. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

To subscribe to the SMDebugRules topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the left navigation pane, choose **Subscriptions**.
3. On the **Subscriptions** page, choose **Create subscription**.
4. On the **Create subscription** page, in the **Details** section, do the following:

a. For **Topic ARN**, choose the **SMDebugRules** topic ARN. The ARN should be in format of `arn:aws:sns:<region-id>:111122223333:SMDebugRules`.

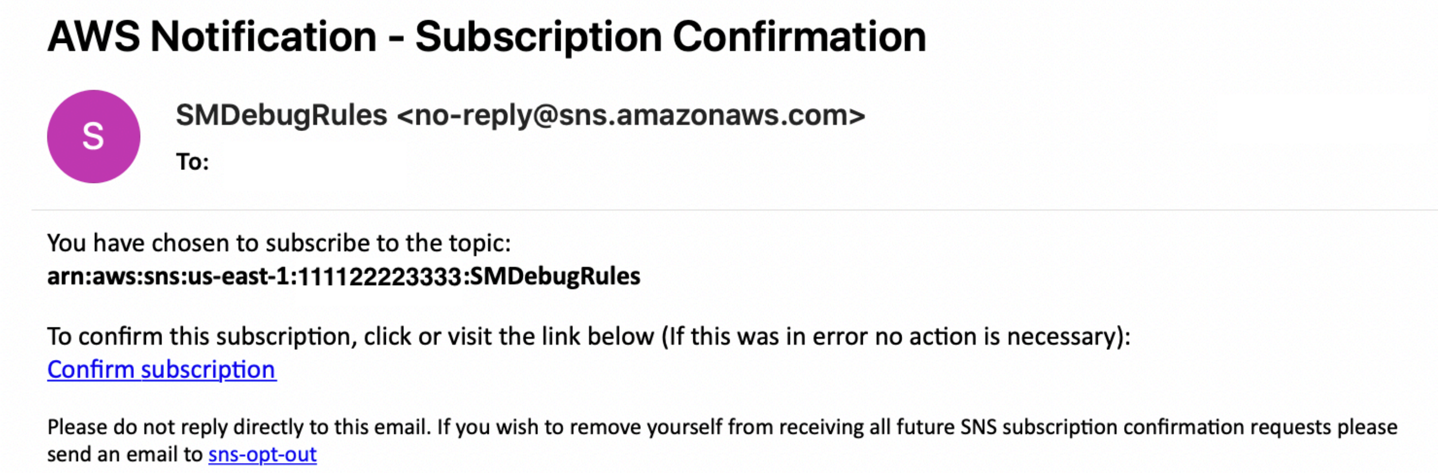
b. For **Protocol**, choose **Email** or **SMS**.

c. For **Endpoint**, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

> **Note**
>
> Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

5. Skip all other optional settings and choose **Create subscription**. If you want to learn more about the optional settings, see [Subscribing to an Amazon SNS topic](#).

After you subscribe to the **SMDebugRules** topic, you receive the following confirmation message in email or by phone:



For more information about Amazon SNS, see [Mobile text messaging (SMS)](#) and [Email notifications](#) in the *Amazon SNS Developer Guide*.

Set up your IAM role to attach required policies

In this step, you add the required policies to your IAM role.

To add the required policies to your IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**, and choose **Create policy**.
3. On the **Create policy** page, do the following to create a new sns-access policy:

   a. Choose the **JSON** tab.

   b. Paste the JSON strings formatted in bold in the following code into the `"Statement"`, replacing the 12-digit AWS account ID with your AWS account ID.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sns:Publish",
                "sns:CreateTopic",
                "sns:Subscribe"
            ],
            "Resource": "arn:aws:sns:*:111122223333:SMDebugRules"
        }
    ]
}
```

   c. At the bottom of the page, choose **Review policy**.

   d. On the **Review policy** page, for **Name**, enter **`sns-access`**.

   e. At the bottom of the page, choose **Create policy**.

4. Go back to the IAM console, and choose **Roles** in the left navigation pane.
5. Look up the IAM role that you use for SageMaker AI model training and choose that IAM role.
6. On the **Permissions** tab of the **Summary** page, choose **Attach policies**.
7. Search for the **sns-access** policy, select the check box next to the policy, and then choose **Attach policy**.

For more examples of setting up IAM policies for Amazon SNS, see [Example cases for Amazon SNS access control](#).

Configure Debugger rules with the built-in actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the `actions` list object. The `rule_configs` is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

> **Note**
>
> Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

To add all of the three built-in actions to a single rule

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```
from sagemaker.debugger import Rule, rule_configs
```

```
# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),         # Required
        rule_parameters={"paramter_key": value },        # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
    rules = rules
)

estimator.fit(wait=False)
```

To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' `name` attribute) as shown in the following example script template. This example shows how to set up [StalledTrainingRule](#) to take two different actions: send an email to `abc@abc.com` when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)
```

```
# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

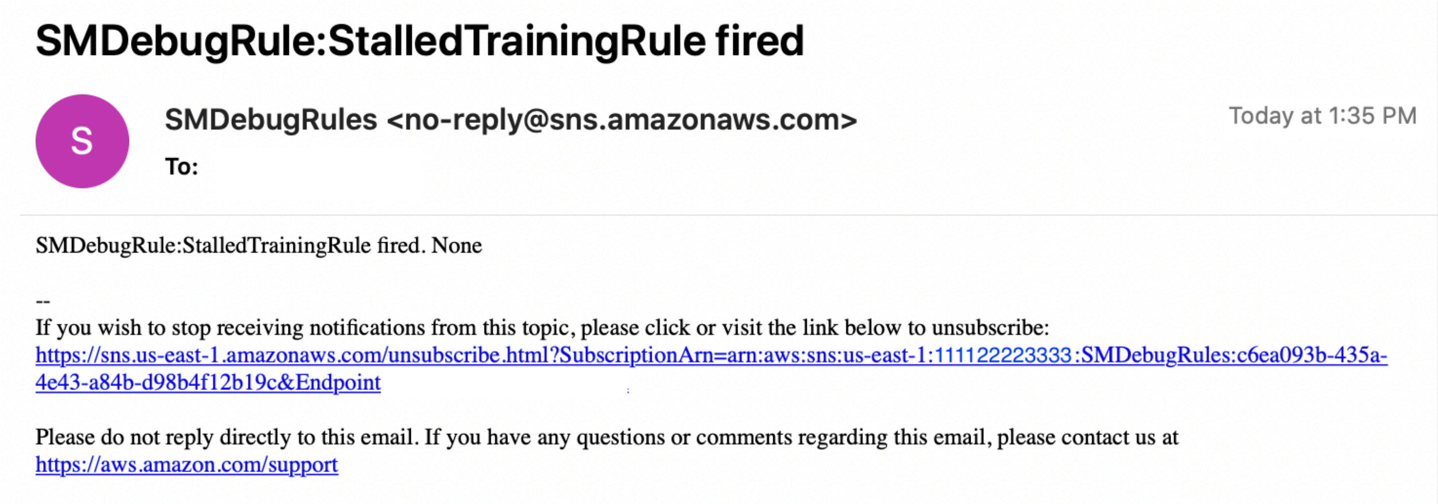
# Configure a rule with the Email built-in action to trigger if a training job stalls
 for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "60",
                "training_job_name_prefix": base_job_name_prefix
        },
        actions=action_email
)
stalled_training_job_rule_text.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job
 stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "120",
                "training_job_name_prefix": base_job_name_prefix
        },
        actions=action_stop_training
)
stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

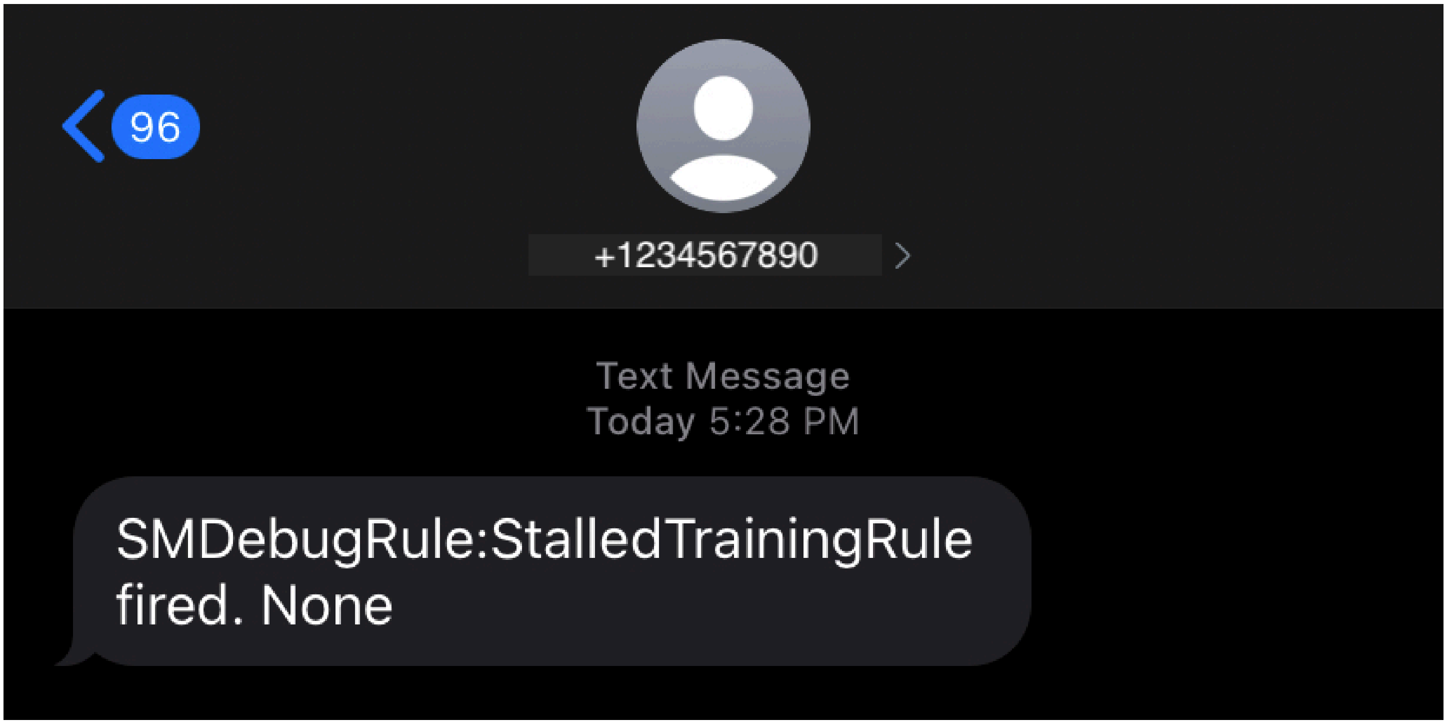
estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.



The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.



Considerations for using the Debugger built-in actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker AI or Amazon VPC.
- The built-in actions cannot be used for Profiler rules.
- The built-in actions cannot be used on training jobs with spot training interruptions.

- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

Actions on rules using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker AI model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

Example notebooks

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using actions on Debugger's built-in rules using Amazon CloudWatch and AWS Lambda.

- Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules

  This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient built-in rule is used while constructing the SageMaker AI TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.
- Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule

  This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule built-in rule invokes issues and stops the training job.

Topics

Access CloudWatch logs for Debugger rules and training jobs

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues. The following procedure shows how to access the related CloudWatch logs. For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker AI.

To access training job logs and Debugger rule job logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane under the **Log** node, choose **Log Groups**.
3. In the log groups list, do the following:
    - Choose **/aws/sagemaker/TrainingJobs** for training job logs.
    - Choose **/aws/sagemaker/ProcessingJobs** for Debugger rule job logs.

Set up Debugger for automated training job termination using CloudWatch and Lambda

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status. The following sections outline the process needed to automate training job termination using using CloudWatch and Lambda.

Topics

Step 1: Create a Lambda function

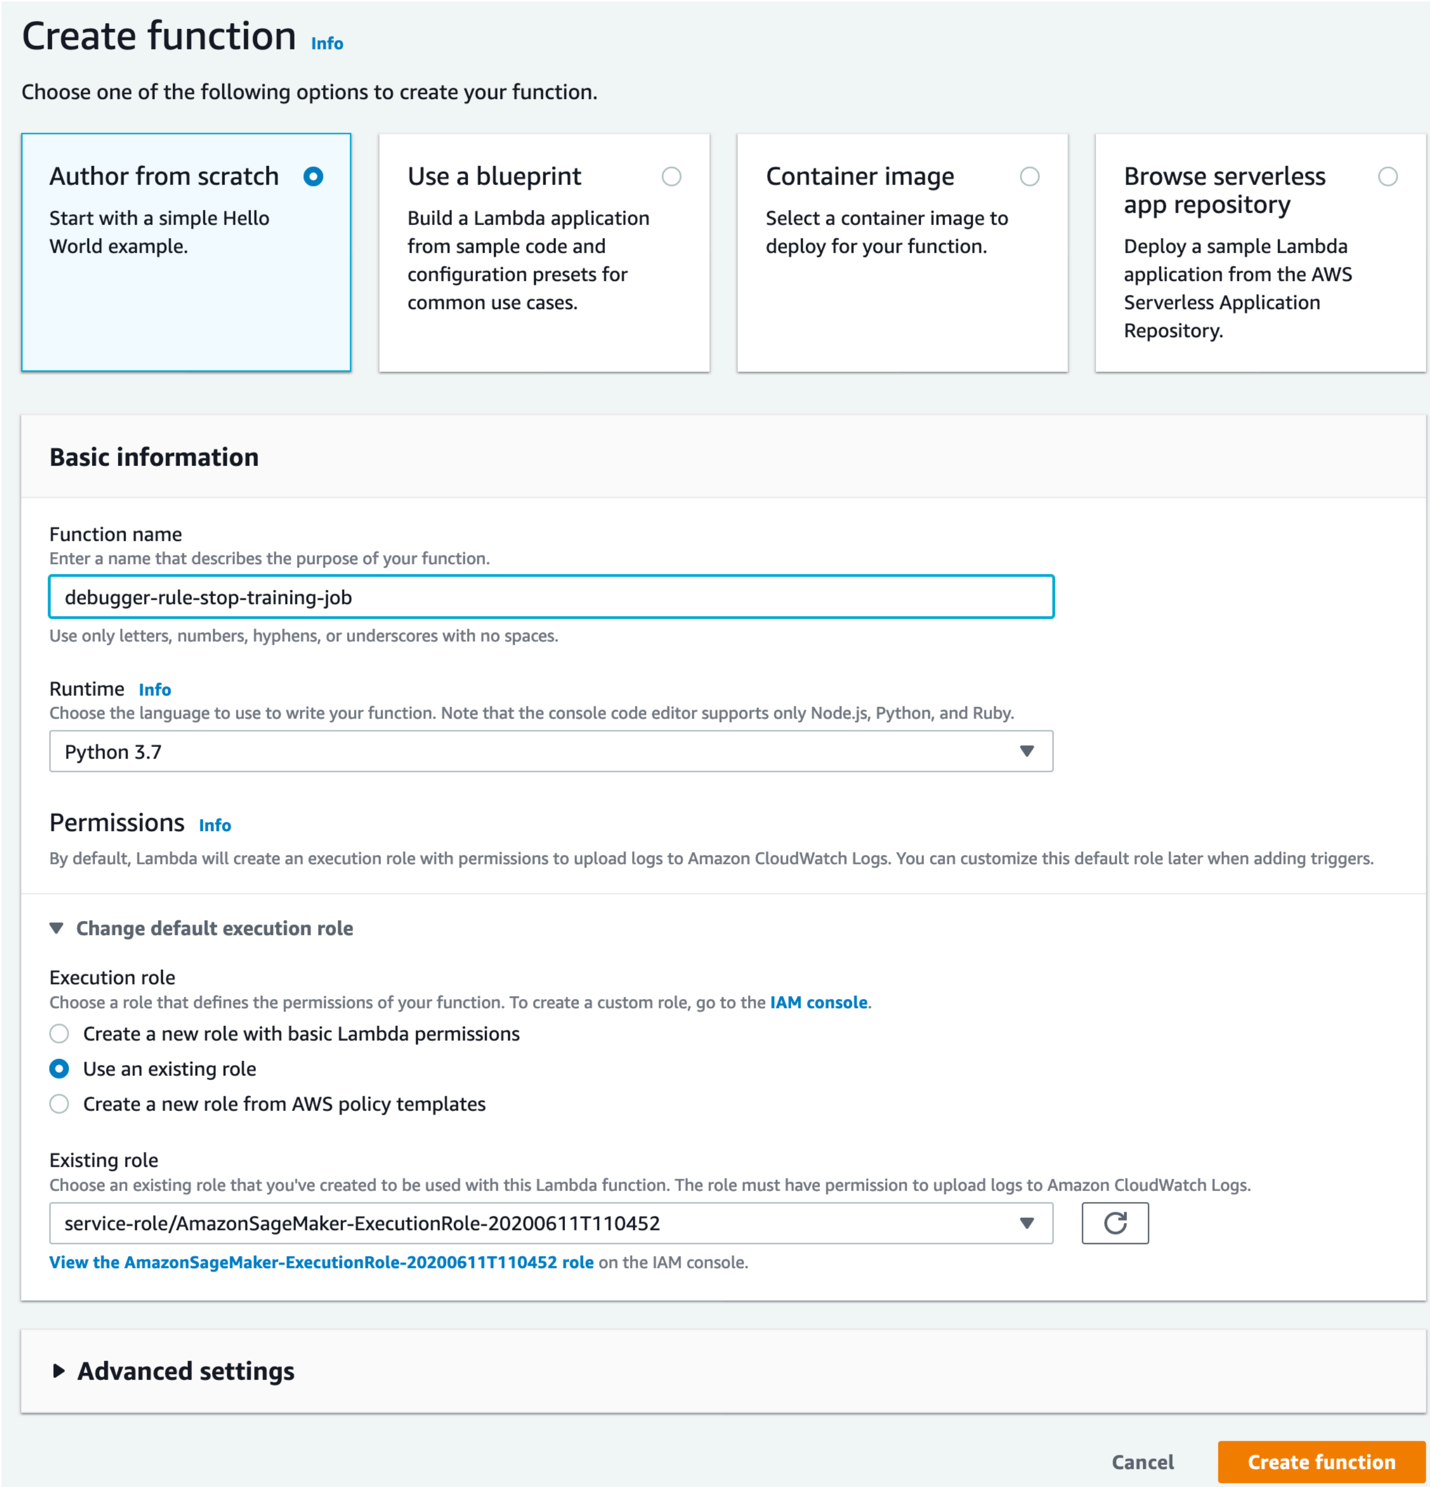
To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions** and then choose **Create function**.
3. On the **Create function** page, choose **Author from scratch** option.
4. In the **Basic information** section, enter a **Function name** (for example, **debugger-rule-stop-training-job**).
5. For **Runtime**, choose **Python 3.7**.
6. For **Permissions**, expand the drop down option, and choose **Change default execution role**.
7. For **Execution role**, choose **Use an existing role** and choose the IAM role that you use for training jobs on SageMaker AI.

> **Note**
>
> Make sure you use the execution role with `AmazonSageMakerFullAccess` and `AWSLambdaBasicExecutionRole` attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:
>
> ```
> import sagemaker
> sagemaker.get_execution_role()
> ```

8. At the bottom of the page, choose **Create function**.

The following figure shows an example of the **Create function** page with the input fields and selections completed.



Create function Info
Choose one of the following options to create your function.
Author from scratch
Start with a simple Hello World example.
Use a blueprint
Build a Lambda application from sample code and configuration presets for common use cases.
Container image
Select a container image to deploy for your function.
Browse serverless app repository
Deploy a sample Lambda application from the AWS Serverless Application Repository.
Basic information
Function name
Enter a name that describes the purpose of your function.
debugger-rule-stop-training-job
Use only letters, numbers, hyphens, or underscores with no spaces.
Runtime Info
Choose the language to use to write your function. Note that the console code editor supports only Node.js, Python, and Ruby.
Python 3.7
Permissions Info
By default, Lambda will create an execution role with permissions to upload logs to Amazon CloudWatch Logs. You can customize this default role later when adding triggers.
Change default execution role
Execution role
Choose a role that defines the permissions of your function. To create a custom role, go to the IAM console.
Create a new role with basic Lambda permissions
Use an existing role
Create a new role from AWS policy templates
Existing role
Choose an existing role that you've created to be used with this Lambda function. The role must have permission to upload logs to Amazon CloudWatch Logs.
service-role/AmazonSageMaker-ExecutionRole-20200611T110452
View the AmazonSageMaker-ExecutionRole-20200611T110452 role on the IAM console.
Advanced settings
Cancel
Create function

Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) `client` for SageMaker AI provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'Evaluating Debugger rules for training job:
 {training_job_name}')
    eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

    if eval_statuses is None or len(eval_statuses) == 0:
        logging.info("Couldn't find any debug rule statuses, skipping...")
        return {
            'statusCode': 200,
            'body': json.dumps('Nothing to do')
        }

    # should only attempt stopping jobs with InProgress status
    training_job_status = event.get("detail").get("TrainingJobStatus", None)
    if training_job_status != 'InProgress':
        logging.debug(f"Current Training job status({training_job_status}) is not
 'InProgress'. Exiting")
        return {
            'statusCode': 200,
            'body': json.dumps('Nothing to do')
        }

    client = boto3.client('sagemaker')

    for status in eval_statuses:
```

```
        logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus='
 + str(status))
        if status.get("RuleEvaluationStatus") == "IssuesFound":
            secondary_status = event.get("detail").get("SecondaryStatus", None)
            logging.info(
                f'About to stop training job, since evaluation of rule
configuration {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' +
                f'\ntraining job "{training_job_name}" status is
"{training_job_status}", secondary status is "{secondary_status}"' +
                f'\nAttempting to stop training job "{training_job_name}"'
            )
            try:
                client.stop_training_job(
                    TrainingJobName=training_job_name
                )
            except Exception as e:
                logging.error(
                    "Encountered error while trying to "
                    "stop training job {}: {}".format(
                        training_job_name, str(e)
                    )
                )
                raise e
    return None
```

For more information about the Lambda code editor interface, see [Creating functions using the AWS Lambda console editor](#).

2. Skip all other settings and choose **Save** at the top of the configuration page.

Step 3: Create a CloudWatch events rule and link to the Lambda function for Debugger

To create a CloudWatch Events rule and link to the Lambda function for Debugger

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Rules** under the **Events** node.
3. Choose **Create rule**.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker AI** for **Service Name**, and choose **SageMaker AI Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```
{
    "source": [
        "aws.sagemaker"
    ],
    "detail-type": [
        "SageMaker Training Job State Change"
    ]
}
```

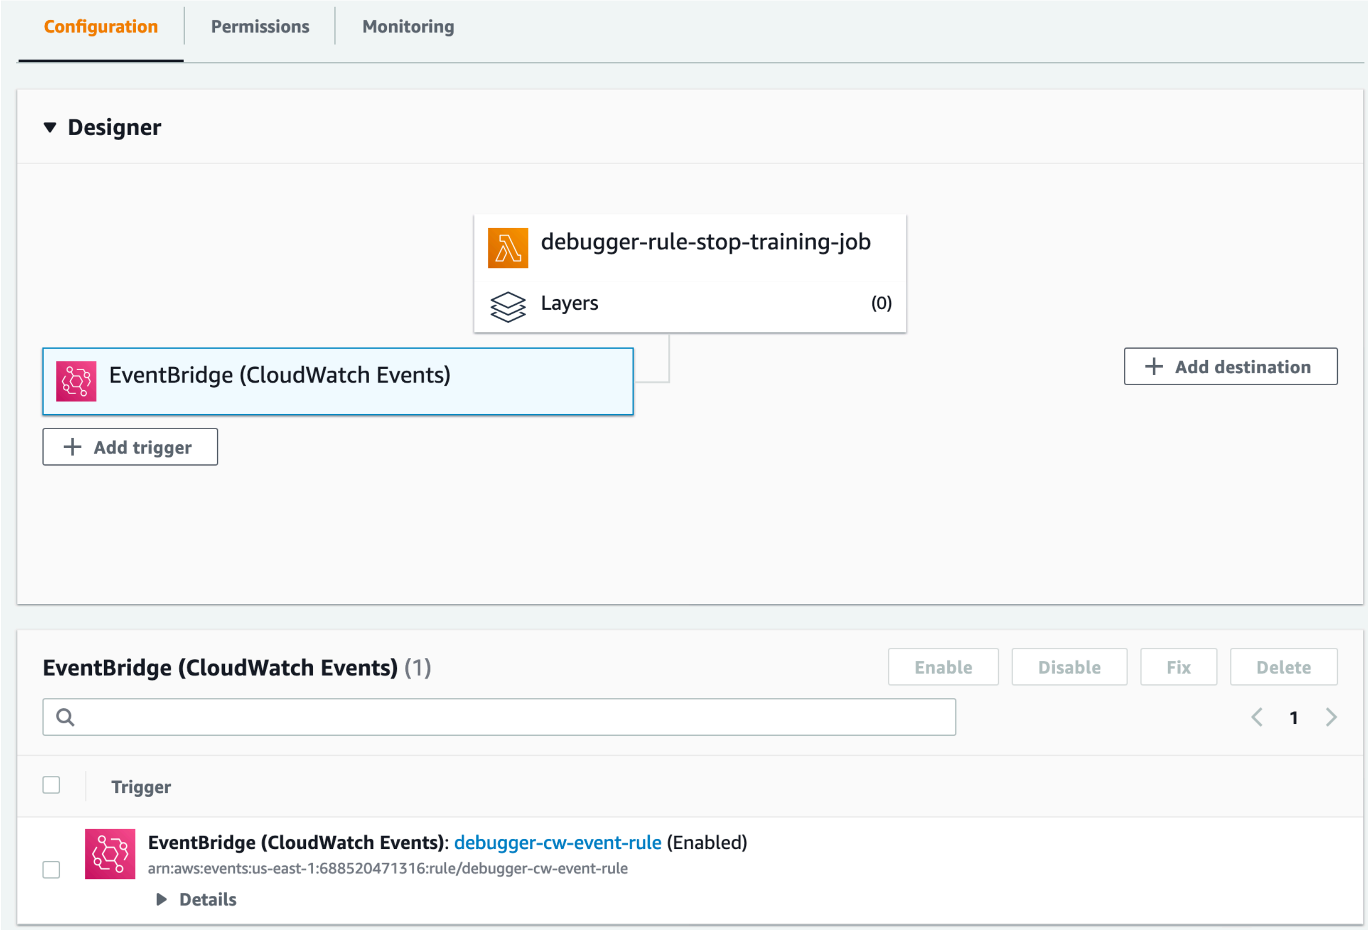
5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:



Disable the CloudWatch Events rule to stop using the automated training job termination

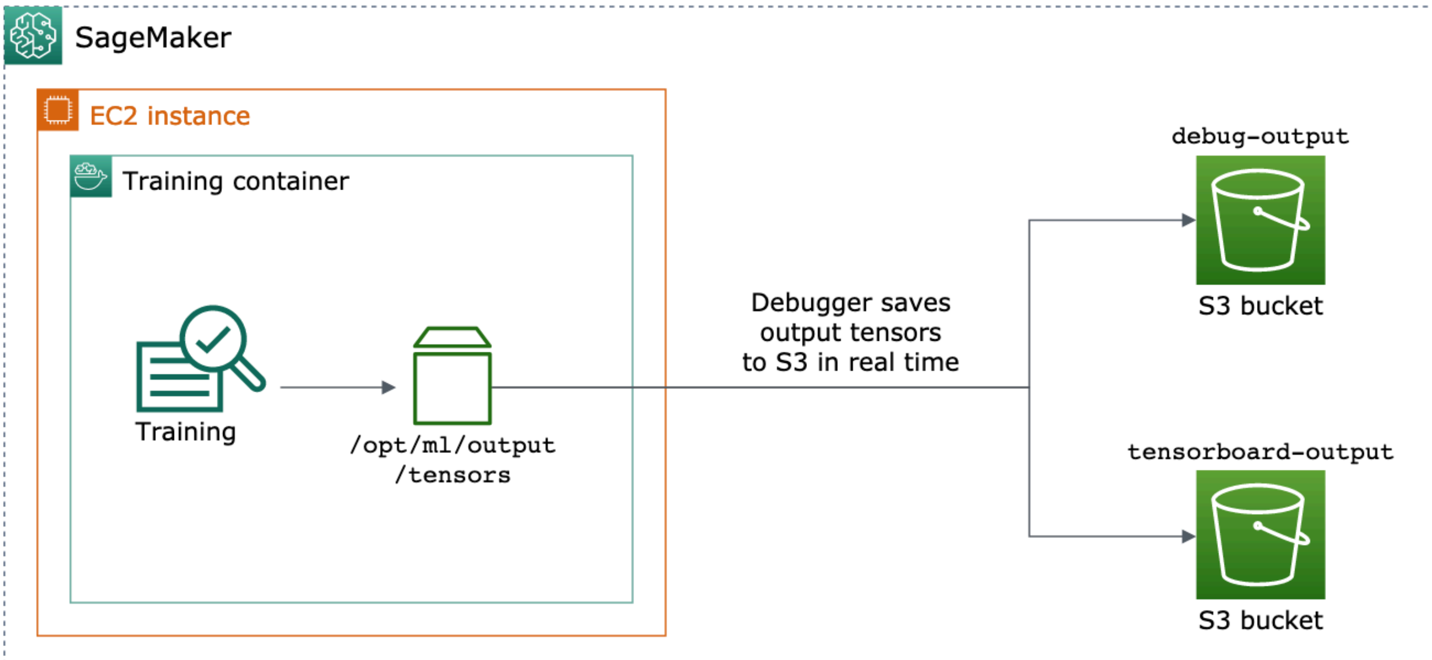
If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda **Designer** panel, choose the **EventBridge (CloudWatch Events)** block linked to the Lambda function. This shows an **EventBridge** panel below the **Designer** panel (for example, see the previous screen shot). Select the check box next to **EventBridge (CloudWatch Events): debugger-cw-event-rule**, and then choose **Disable**. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

Visualize Amazon SageMaker Debugger output tensors in TensorBoard

> **Important**
>
> This page is deprecated in favor of Amazon SageMaker AI with TensoBoard, which provides a comprehensive TensorBoard experience integrated with SageMaker Training and the

access control functionalities of SageMaker AI domain. To learn more, see TensorBoard in Amazon SageMaker AI.

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.



You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an `estimator`.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

To save TensorBoard compatible output tensor files using Debugger

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the default S3 bucket of the current SageMaker AI session or a preferred S3 bucket.

This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

```
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path='s3://{}'.format(bucket)
)
```

For additional information, see the Debugger [`TensorBoardOutputConfig`] API in the [Amazon SageMaker Python SDK].

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the `weights` parameters every 500 steps (the default `save_interval` value for saving tensor collections is 500), and the `bias` parameters every 10 global steps until the global step reaches 500.

```
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(
    hook_parameters={
        "train.save_interval": "100",
        "eval.save_interval": "10"
    },
    collection_configs=[
        CollectionConfig("weights"),
        CollectionConfig(
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        ),
    ]
)
```

For more information about the Debugger configuration APIs, see the Debugger `CollectionConfig` and `DebuggerHookConfig` APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker AI estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker AI estimator. You can replace `estimator` and `Estimator` with other SageMaker AI frameworks' estimator parent classes and estimator classes. Available SageMaker AI framework estimators for this functionality are `TensorFlow`, `PyTorch`, and `MXNet`.

```
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
    debugger_hook_config=hook_config,
    tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```

The `estimator.fit()` method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use `estimator.latest_job_debugger_artifacts_path()`.
- For the TensorBoard S3 output path, use `estimator.latest_job_tensorboard_artifacts_path()`.

4. After the training has completed, check the names of saved output tensors:

```
from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```
tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
print(tensorboard_output_path)
!aws s3 ls {tensorboard_output_path}/
```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

```
!aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.

```
!tar -cf logs.tar logs
```

8. Download and extract the Tensorboard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

```
!tar -xf logs.tar
%load_ext tensorboard
%tensorboard --logdir logs/fit
```

List of Debugger built-in rules

You can use the Debugger built-in rules, provided by Amazon SageMaker Debugger, to analyze metrics and tensors collected while training your models. The following lists the debugger rules, including information and an example on how to configure and deploy each built-in rule.

The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations.

There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

> **Note**
>
> The maximum numbers of built-in rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

> **Important**
>
> To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.
>
> ```
> import sys
> import IPython
> !{sys.executable} -m pip install -U sagemaker smdebug
> IPython.Application.instance().kernel.do_shutdown(True)
> ```

Debugger rule

The following rules are the Debugger built-in rules that are callable using the `Rule.sagemaker` classmethod.

Debugger built-in rules for generating training reports

Scope of Validity	Built-in Rules
Training Report for SageMaker AI XGboost training job	• `create_xgboost_report`

Debugger built-in rules for debugging model training data (output tensors)

Scope of Validity	Built-in Rules
Deep learning frameworks (TensorFlow, MXNet, and PyTorch)	• `dead_relu` • `exploding_tensor` • `poor_weight_initialization` • `saturated_activation` • `vanishing_gradient` • `weight_update_ratio`

Scope of Validity	Built-in Rules
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) and the XGBoost algorithm	• all_zero • class_imbalance • loss_not_decreasing • overfit • overtraining • similar_across_runs • stalled_training_rule • tensor_variance • unchanged_tensor
Deep learning applications	• check_input_images • nlp_sequence_ratio
XGBoost algorithm	• confusion • feature_importance_overweight • tree_depth

To use the built-in rules with default parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
```

```
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
                "key": "value"
        }
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger built-in rules example code.
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see Configure Debugger using SageMaker API.

CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- `hyperparameters` – Saves at the first step
- `metrics` – Saves loss and accuracy every 5 steps
- `feature_importance` – Saves every 5 steps
- `predictions` – Saves every 5 steps
- `labels` – Saves every 5 steps

Parameter Descriptions for the CreateXgboostReport Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String

```
rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]
```

DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns `True`.

Parameter Descriptions for the DeadRelu Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors.

Parameter Name	Description
	The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: `".*relu_output"`
`threshold_inactivity`	Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the `threshold _inactivity` , it is considered to be dead. **Optional** Valid values: Float Default values: `1.0` (in percentage)

Parameter Name	Description
threshold_layer	Returns `True` if the percentage of inactive ReLUs in a layer is greater than `threshold _layer` . Returns `False` if the percentage of inactive ReLUs in a layer is less than `threshold _layer` . **Optional** Valid values: Float Default values: `50.0` (in percentage)

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.dead_relu(),
        rule_parameters={
                "tensor_regex": ".*relu_output|.*ReLU_output",
                "threshold_inactivity": "1.0",
                "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex: ".*relu_output|.*ReLU_output",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see [How to configure Debugger built-in rules](#).

> **Note**
>
> This rule is not available for the XGBoost algorithm.

ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns `True`.

Parameter Descriptions for the ExplodingTensor Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: String Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional**

Parameter Name	Description
	Valid values: String Default value: None
`only_nan`	`True` to monitor the `base_trial` tensors only for `NaN` values and not for infinity. `False` to treat both `NaN` and infinity as exploding values and to monitor for both. **Optional** Default value: `False`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
                "tensor_regex": ".*gradient",
                "only_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Note

This rule is not available for the XGBoost algorithm.

PoorWeightInitialization

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

Parameter Descriptions for the PoorWeightInitialization Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`activation_inputs_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: String Default value: `".*relu_input"`

Parameter Name	Description
`threshold`	If the ratio between minimum and maximum variance of weights per layer exceeds the `threshold` at a step, the rule returns `True`. **Optional** Valid values: Float Default value: `10.0`
`distribution_range`	If the minimum difference between 5th and 95th percentiles of the gradient distribution is less than the `distribution_range` , the rule returns `True`. **Optional** Valid values: Float Default value: `0.001`
`patience`	The number of steps to wait until the loss is considered to be no longer decreasing. **Optional** Valid values: Integer Default value: 5
`steps`	The number of steps this rule analyzes. You typically need to check only the first few iterations. **Optional** Valid values: Float Default value: `10`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.poor_weight_initialization(),
        rule_parameters={
                "activation_inputs_regex": ".*relu_input|.*ReLU_input",
                "threshold": "10.0",
                "distribution_range": "0.001",
                "patience": "5",
                "steps": "10"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex": ".*relu_input|.*ReLU_input",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective `min_threshold` and `max_thresholds` values. If the activity of a node drops below the `threshold_inactivity` percentage, it is considered saturated. If more than a `threshold_layer` percent of the nodes are saturated, the rule returns `True`.

Parameter Descriptions for the SaturatedActivation Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-separated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: String Default value: `".*tanh_input|.*sigmoid_input"`.
`threshold_tanh_min`	The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: `(min_threshold, max_threshold)` . The default

Parameter Name	Description
	values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `-9.4999`
`threshold_tanh_max`	The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `9.4999`
`threshold_sigmoid_min`	The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `-23`

Parameter Name	Description
`threshold_sigmoid_max`	The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `16.99999`
`threshold_inactivity`	The percentage of inactivity below which the activation layer is considered to be saturated. The activation might be active in the beginning of a trial and then slowly become less active during the training process. **Optional** Valid values: Float Default values: `1.0`
`threshold_layer`	Returns `True` if the number of saturated activations in a layer is greater than the `threshold_layer` percentage. Returns `False` if the number of saturated activations in a layer is less than the `threshold_layer` percentage. **Optional** Valid values: Float Default values: `50.0`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.saturated_activation(),
        rule_parameters={
                "tensor_regex": ".*tanh_input|.*sigmoid_input",
                "threshold_tanh_min": "-9.4999",
                "threshold_tanh_max": "9.4999",
                "threshold_sigmoid_min": "-23",
                "threshold_sigmoid_max": "16.99999",
                "threshold_inactivity": "1.0",
                "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_activations_collection",
                parameters={
                    "include_regex": ".*tanh_input|.*sigmoid_input"
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Note

This rule is not available for the XGBoost algorithm.

VanishingGradient

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified `threshold`, the rule returns `True`.

Parameters Descriptions for the VanishingGradient Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	The value at which the gradient is determined to be vanishing. **Optional** Valid values: Float Default value: `0.0000001` .

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
                "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see [How to configure Debugger built-in rules](#).

> **Note**
>
> This rule is not available for the XGBoost algorithm.

WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold value` or if this ratio is smaller than `small_threshold`, the rule returns `True`.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

Parameter Descriptions for the WeightUpdateRatio Rule

Parameter Name,	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`num_steps`	The number of steps across which the rule checks to determine if the tensor has changed. The number of steps across which you want to compare the weight ratios. If you pass no value, the rule runs by default against the current step and the immediately previous saved step. If you override the default by passing a value for this parameter, the comparison is done between weights at step `s` and at a step `>= s - num_steps` .

Parameter Name,	Description
	Optional Valid values: Integer Default value: None
`large_threshold`	The maximum value that the ratio of updates to weight can take before the rule returns `True`. **Optional** Valid values: Float Default value: `10.0`
`small_threshold`	The minimum value that the ratio of updates to weight can take, below which the rule returns `True`. **Optional** Valid values: Float Default value: `0.00000001`
`epsilon`	A small constant used to ensure that Debugger does not divide by zero when computing the ratio updates to weigh. **Optional** Valid values: Float Default value: `0.000000001`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.weight_update_ratio(),
```

```
        rule_parameters={
                "num_steps": "100",
                "large_threshold": "10.0",
                "small_threshold": "0.00000001",
                "epsilon": "0.000000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "train.save_interval": "100"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Note

This rule is not available for the XGBoost algorithm.

AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameters Descriptions for the AllZero Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`threshold`	Specifies the percentage of values in the tensor that needs to be zero for this rule to be invoked. **Optional**

Parameter Name	Description
	Valid values: Float Default value: 100 (in percentage)

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
                "tensor_regex": ".*",
                "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(
                name="all",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the ClassImbalance Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_imbalance`	The acceptable imbalance between the number of samples in the smallest class and in the largest class. Exceeding this threshold value throws an error. **Optional** Valid values: Float Default value: `10`
`threshold_misprediction`	A limit on the fraction of mispredictions allowed for each class. Exceeding this threshold throws an error. The underrepr esented classes are most at risk of crossing this threshold. **Optional** Valid values: Float Default value: `0.7`

Parameter Name	Description
`samples`	The number of labels that have to be processed before an imbalance is evaluated . The rule might not be triggered until it has seen sufficient samples across several steps. The more classes that your dataset contains, the larger this `sample` number should be. **Optional** Valid values: Integer Default value: `500` (assuming a dataset like MNIST with 10 classes)
`argmax`	If `True`, np.argmax is applied to the predictio n tensor. Required when you have a vector of probabilities for each class. It is used to determine which class has the highest probability. **Conditional** Valid values: Boolean Default value: `False`
`labels_regex`	The name of the tensor that contains the labels. **Optional** Valid values: String Default value: `".*labels"`

Parameter Name	Description
`predictions_regex`	The name of the tensor that contains the predictions. **Optional** Valid values: String Default value: `".*predictions"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.class_imbalance(),
        rule_parameters={
                "threshold_imbalance": "10",
                "threshold_misprediction": "0.7",
                "samples": "500",
                "argmax": "False",
                "labels_regex": ".*labels",
                "predictions_regex": ".*predictions"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_output_collection",
                parameters={
                    "include_regex": ".*labels|.*predictions",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the LossNotDecreasing Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-separated string Default value: None
`tensor_regex`	A list of regex patterns that is used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-separated string

Parameter Name	Description
	Default value: None
`use_losses_collection`	If set to `True`, looks for losses in the collection named "losses" when the collection is present. **Optional** Valid values: Boolean Default value: `True`
`num_steps`	The minimum number of steps after which the rule checks if the loss has decreased. Rule evaluation happens every `num_steps` . The rule compares the loss for this step with the loss at a step which is at least `num_steps` behind the current step. For example, suppose that the loss is being saved every three steps, but `num_steps` is set to 10. At step 21, loss for step 21 is compared with loss for step 9. The next step at which loss is checked is step 33, because ten steps after step 21 is step 31, and at step 31 and step 32 loss is not saved. **Optional** Valid values: Integer Default value: `10`

Parameter Name	Description
`diff_percent`	The minimum percentage difference by which the loss should decrease between `num_steps` . **Optional** Valid values: `0.0` < float < `100` Default value: `0.1` (in percentage)
`increase_threshold_percent`	The maximum threshold percent that loss is allowed to increase in case loss has been increasing **Optional** Valid values: `0` < float < `100` Default value: 5 (in percentage)
`mode`	The name of the Debugger mode to query tensor values for rule checking. If this is not passed, the rule checks in order by default for the `mode.EVAL` , then `mode.TRAIN` , and then `mode.GLOBAL` . **Optional** Valid values: String (`EVAL`, `TRAIN`, or `GLOBAL`) Default value: `GLOBAL`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        rule_parameters={
                "tensor_regex": ".*",
                "use_losses_collection": "True",
```

```
                "num_steps": "10",
                "diff_percent": "0.1",
                "increase_threshold_percent": "5",
                "mode": "GLOBAL"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

> **Note**
>
> A standard way to prevent overfitting is to regularize your model.

Parameter Descriptions for the Overfit Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`start_step`	The step from which to start comparing the validation and training loss. **Optional** Valid values: Integer Default value: `0`
`patience`	The number of steps for which the `ratio_threshold` is allowed to exceed the value set before the model is considered to be overfit. **Optional** Valid values: Integer Default value: 1

Parameter Name	Description
`ratio_threshold`	The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a `patience` number of steps, the model is being overfit and the rule returns `True`. **Optional** Valid values: Float Default value: `0.1`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
                "tensor_regex": ".*",
                "start_step": "0",
                "patience": "1",
                "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

> **Note**
>
> Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early. For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

Parameter Descriptions for the Overtraining Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`patience_train`	The number of steps to wait before the training loss is considered to not to be improving anymore. **Optional** Valid values: Integer Default value: 5

Parameter Name	Description
`patience_validation`	The number of steps to wait before the validation loss is considered to not to be improving anymore. **Optional** Valid values: Integer Default value: `10`
`delta`	The minimum threshold by how much the error should improve before it is considered as a new optimum. **Optional** Valid values: Float Default value: `0.01`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overtraining(),
        rule_parameters={
                "patience_train": "5",
                "patience_validation": "10",
                "delta": "0.01"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [How to configure Debugger built-in rules](#).

Parameter Descriptions for the SimilarAcrossRuns Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`other_trials`	A completed training job name whose tensors you want to compare to those tensors gathered from the current `base_trial` . **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors.

Parameter Name	Description
	The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.similar_across_runs(),
        rule_parameters={
                "other_trials": "<specify-another-job-name>",
                "collection_names": "losses",
                "tensor_regex": ".*"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its `threshold` parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

Parameter Descriptions for the StalledTrainingRule Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds. **Optional** Valid values: Integer Default value: `1800`
`stop_training_on_fire`	If set to `True`, watches if the base training job outputs tensors in "`threshold` " seconds. **Optional** Valid values: Boolean Default value: `False`
`training_job_name_prefix`	The prefix of base training job name. If `stop_training_on_fire` is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a `StopTrainingJob` action. Note if there are multiple jobs found with same prefix, the rule skips

Parameter Name	Description
	termination. It is important that the prefix is set unique per each training job. **Optional** Valid values: String

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "1800",
                "stop_training_on_fire": "True",
                "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

TensorVariance

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the TensorVariance Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-separated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-separated string Default value: None

Parameter Name	Description
`max_threshold`	The threshold for the upper bound of tensor variance. **Optional** Valid values: Float Default value: None
`min_threshold`	The threshold for the lower bound of tensor variance. **Optional** Valid values: Float Default value: None

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
                "collection_names": "weights",
                "max_threshold": "10",
                "min_threshold": "0.00001",
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the numpy.allclose method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the UnchangedTensor Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patternsused to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all

Parameter Name	Description
	tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`num_steps`	The number of steps across which the rule checks to determine if the tensor has changed. This checks the last `num_steps` that are available. They don't need to be consecutive. If `num_steps` is 2, at step s it doesn't necessari ly check for s-1 and s. If s-1 isn't available, it checks the last available step along with s. In that case, it checks the last available step with the current step. **Optional** Valid values: Integer Default value: 3
`rtol`	The relative tolerance parameter to be passed to the [`numpy.allclose`](https://numpy.org) method. **Optional** Valid values: Float Default value: `1e-05`

Parameter Name	Description
atol	The absolute tolerance parameter to be passed to the numpy.allclose method. **Optional** Valid values: Float Default value: 1e-08
equal_nan	Whether to compare NaNs as equal. If True, NaNs in input array a are considered equal to NaNs in input array b in the output array. This parameter is passed to the numpy.allclose method. **Optional** Valid values: Boolean Default value: False

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
                "collection_names": "losses",
                "tensor_regex": "",
                "num_steps": "3",
                "rtol": "1e-05",
                "atol": "1e-08",
                "equal_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
```

```
        ]
    )
]
```

CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the CheckInputImages Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_mean`	A threshold that defines by how much mean of the input data can differ from 0. **Optional** Valid values: Float Default value: `0.2`
`threshold_samples`	The number of images that have to be sampled before an error can be thrown. If the value is too low, the estimation of the dataset mean will be inaccurate. **Optional**

Parameter Name	Description
	Valid values: Integer Default value: `500`
`regex`	The name of the input data tensor. **Optional** Valid values: String Default value: `".*hybridsequential0_input_0"` (the name of the input tensor for Apache MXNet models using HybridSequential)
`channel`	The position of the color channel in the input tensor shape array. **Optional** Valid values: Integer Default value: 1 (for example, MXNet expects input data in the form of (batch_size, channel, height, width))

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
                "threshold_mean": "0.2",
                "threshold_samples": "500",
                "regex": ".*hybridsequential0_input_0",
                "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
```

```
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the NLPSequenceRatio Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.

Parameter Name	Description
	Optional Valid values: List of strings or a comma-sep arated string Default value: `".*embedding0_input_0"` (assuming an embedding as the initial layer of the network)
`token_values`	A string of a list of the numerical values of the tokens. For example, "3, 0". **Optional** Valid values: Comma-separated string of numerical values Default value: `0`
`token_thresholds_percent`	A string of a list of thresholds (in percentag es) that correspond to each of the `token_val ues` . For example,"50.0, 50.0". **Optional** Valid values: Comma-separated string of floats Default value: `"50"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.nlp_sequence_ratio(),
        rule_parameters={
                "tensor_regex": ".*embedding0_input_0",
                "token_values": "0",
                "token_thresholds_percent": "50"
        },
        collections_to_save=[
            CollectionConfig(
```

```
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*embedding0_input_0"
                }
            )
        ]
    )
]
```

Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size `category_no*category_no` and populates it with data coming from (`labels`, `predictions`) pairs. For each (`labels`, `predictions`) pair, the count in `confusion[labels][predictions]` is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: `confusion[i][i]/sum_j(confusion[j][j])>=min_diag`
- For elements off the diagonal: `confusion[j][i])/sum_j(confusion[j][i])<=max_off_diag`

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the Confusion Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`category_no`	The number of categories.

Parameter Name	Description
	Optional Valid values: Integer ≥2 Default value: `"None"`
`labels`	The `labels` tensor collection or an 1-d vector of true labels. **Optional** Valid values: String Default value: `"labels"`
`predictions`	The `predictions` tensor collection or an 1-d vector of estimated labels. **Optional** Valid values: String Default value: `"predictions"`
`labels_collection`	The rule inspects the tensors in this collection for `labels`. **Optional** Valid values: String Default value: `"labels"`

Parameter Name	Description
predictions_collection	The rule inspects the tensors in this collection for predictions . **Optional** Valid values: String Default value: "predictions"
min_diag	The minimum threshold for the ratio of data on the diagonal. **Optional** Valid values: 0≤float≤1 Default value: 0.9
max_off_diag	The maximum threshold for the ratio of data off the diagonal. **Optional** Valid values: 0≤float≤1 Default value: 0.1

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
                "category_no": "10",
                "labels": "labels",
                "predictions": "predictions",
                "labels_collection": "labels",
                "predictions_collection": "predictions",
                "min_diag": "0.9",
                "max_off_diag": "0.1"
        },
```

```
        collections_to_save=[
            CollectionConfig(
                name="labels",
                parameters={
                    "save_interval": "500"
                }
            ),
            CollectionConfig(
                name="predictions",
                parameters={
                    "include_regex": "500"
                }
            )
        ]
    )
]
```

> **Note**
>
> This rule infers default values for the optional parameters if their values aren't specified.

FeatureImportanceOverweight

This rule accumulates the weights of the n largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the FeatureImportanceOverweight Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`threshold`	Defines the threshold for the proportion of the cumulative sum of the `n` largest features. The number `n` is defined by the `nfeatures` parameter. **Optional** Valid values: Float Default value: `0.8`
`nfeatures`	The number of largest features. **Optional** Valid values: Integer Default value: 3
`tensor_regex`	Regular expression (regex) of tensor names the rule to analyze. **Optional** Valid values: String Default value: `".*feature_importance/weight"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.feature_importance_overweight(),
        rule_parameters={
                "threshold": "0.8",
                "nfeatures": "3",
                "tensor_regex": ".*feature_importance/weight"
        },
```

```
        collections_to_save=[
            CollectionConfig(
                name="feature_importance",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the `depth` parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see How to configure Debugger built-in rules.

Parameter Descriptions for the TreeDepth Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`depth`	The depth of the tree. The depth of the tree is obtained by computing the base 2 logarithm of the largest node ID. **Optional** Valid values: Float

Parameter Name	Description
	Default value: 4

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tree_depth(),
        rule_parameters={
                "depth": "4"
        },
        collections_to_save=[
            CollectionConfig(
                name="tree",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

Creating custom rules using the Debugger client library

You can create custom rules to monitor your training job using the Debugger rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Prerequisites for creating a custom rule

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger image URIs for custom rule evaluators

Topics

- Use the smdebug client library to create a custom rule as a Python script
- Use the Debugger APIs to run your own custom rules

Use the smdebug client library to create a custom rule as a Python script

The smdebug Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, CustomGradientRule. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker AI estimator when it initiates training job.

```
from smdebug.rules.rule import Rule

class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

Use the Debugger APIs to run your own custom rules

The following code sample shows how to configure a custom rule with the [Amazon SageMaker Python SDK](). This example assumes that the custom rule script you created in the previous step is located at '*path/to/my_custom_rule.py*'.

```
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-
evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
```

```
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- `name` (str): Specify a custom rule name as you want.
- `image_uri` (str): This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker AI rule evaluator images from Amazon SageMaker Debugger image URIs for custom rule evaluators.
- `instance_type` (str): You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- `source` (str): This is the local path or the Amazon S3 URI to your custom rule script.
- `rule_to_invoke` (str): This specifies the particular Rule class implementation in your custom rule script. SageMaker AI supports only one rule to be evaluated at a time in a rule job.
- `collections_to_save` (str): This specifies which tensor collections you will save for the rule to run.
- `rule_parameters` (dictionary): This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker AI estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
                role=sagemaker.get_execution_role(),
                base_job_name='smdebug-custom-rule-demo-tf-keras',
                entry_point='path/to/your_training_script.py'
                train_instance_type='ml.p2.xlarge'
                ...

                # debugger-specific arguments below
                rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet
- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow

Use Debugger with custom training containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker AI. The AWS CLI, SageMaker AI `Estimator` API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs. The following sections will walk you through how to use Debugger with Custom Training Containers.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger hook to your training script.

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

> **Tip**
>
> This custom container with Debugger guide is an extension of the Adapting your own training container guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to build a custom training container

To build a docker container, the basic structure of files should look like the following:

```
### debugger_custom_container_test_notebook.ipynb      # a notebook to run python
 snippet codes
### debugger_custom_container_test_folder              # this is a docker folder
    ###  your-training-script.py                       # your training script with
 Debugger hook
    ###  Dockerfile                                    # a Dockerfile to build your own
 container
```

Register Debugger hook to your training script

To debug your model training, you need to add a Debugger hook to your training script.

> **Note**
>
> This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimater.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):

    ...
    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
              validation_data=(X_valid, Y_valid),
              shuffle=True,
```

```
            # smdebug modification: Pass the Debugger hook in the main() as a Keras
 callback
            callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")

    # hyperparameter settings
    parser.add_argument(...)

    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == "__main__":
    main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

  To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, [TensorFlow Keras ResNet training script in script mode]. The training script imports the `smdebug` library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the `smdebug` hook functionality by adding the `callbacks=[hook]` argument inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

  This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker AI containers, and this example shows details of how to modify a training script.

  The SageMaker AI PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

  This notebook shows detailed steps to change the original PyTorch training script to a modified version to enable Debugger. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and configure a Dockerfile

Open your SageMaker AI JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and `Dockerfile`. The following code example is a `Dockerfile` that includes essential docker build commends. Paste the following code into the `Dockerfile` text file and save it. Upload your training script to the same folder.

```
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf
```

```
# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and push the custom training image to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix,
 ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $byoc_image_uri
!docker push $byoc_image_uri
```

> **Tip**
>
> If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

```
! aws ecr get-login-password --region {region} | docker login --username AWS --
password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
```

Run and debug training jobs using the custom training container

After you build and push your docker container to Amazon ECR, configure a SageMaker AI estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the `smdebug` core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point="./debugger_custom_container_test_folder/your-training-script.py"
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
```

```
estimator.fit()
```

Configure Debugger using SageMaker API

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this section covers how to configure the following low-level API operations.

Topics

JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the DebugHookConfig, DebugRuleConfiguration, ProfilerConfig, and ProfilerRuleConfiguration objects through the SageMaker AI CreateTrainingJob API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request CreateTrainingJob.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

> **Note**
>
> Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules.

```

   },

   "StoppingCondition": {
      "MaxRuntimeInSeconds": 86400
   }
}
```

After saving the JSON file, run the following command in your terminal. (Use `!` at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-
cli.json
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in `VanishingGradient` rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
"DebugHookConfig": {
```

```
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "gradients",
            "CollectionParameters" : {
                "save_interval": "500"
            }
        }
    ]
}
```

This will make the training job save the tensor collection, `gradients`, every `save_interval` of 500 steps. To find available `CollectionName` values, see Debugger Built-in Collections in the *SMDebug client library documentation*. To find available `CollectionParameters` parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the *SageMaker Python SDK documentation*.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in `VanishingGradient` rule on the saved `gradients` collection.

```
"DebugRuleConfigurations": [
    {
        "RuleConfigurationName": "VanishingGradient",
        "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "VanishingGradient",
            "threshold": "20.0"
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the `VanishingGradient` rule on the collection of `gradients` tensor. To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3,
 \"MetricsRegex\": \".*\" }",
        "DetailedProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
 total_time
        "PythonProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3,
 \"ProfilerName\": \"cProfile\", \"cProfileTimer\": \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

Target Time Duration

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10, \"MetricsRegex\": \".*\" }",
        "DetailedProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10 }",
```

```
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
 total_time
        "PythonProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10, \"ProfilerName\": \"cProfile\", \"cProfileTimer\":
 \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport",
        "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "CPUBottleneck_cpu_threshold": "90",
            "IOBottleneck_threshold": "90"
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

Update Debugger profiling configuration using the `UpdateTrainingJob` API

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the `TrainingJobName` parameter.

```
{
    "ProfilerConfig": {
        "DisableProfiler": boolean,
```

```
        "ProfilingIntervalInMilliseconds": number,
        "ProfilingParameters": {
            "string" : "string"
        }
    },
    "ProfilerRuleConfigurations": [
        {
            "RuleConfigurationName": "string",
            "RuleEvaluatorImage": "string",
            "RuleParameters": {
                "string" : "string"
            }
        }
    ],
    "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```

Add Debugger custom rule configuration to the `CreateTrainingJob` API

A custom rule can be configured for a training job using the [DebugHookConfig] and [DebugRuleConfiguration] objects in the [CreateTrainingJob] API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the *smdebug* library using this SageMaker API operation. This example assumes that you've written the custom rule in *custom_rules.py* file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at [Amazon SageMaker Debugger image URIs for custom rule evaluators]. You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ]
},
"DebugRulesConfigurations": [
```

```
    {
        "RuleConfigurationName": "improper_activation_job",
        "RuleEvaluatorImage": "552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rule-evaluator:latest",
        "InstanceType": "ml.c4.xlarge",
        "VolumeSizeInGB": 400,
        "RuleParameters": {
           "source_s3_uri": "s3://bucket/custom_rules.py",
           "rule_to_invoke": "ImproperActivation",
           "collection_names": "relu_activations"
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

SDK for Python (Boto3)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker AI client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

Note

Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules.

```
import sagemaker, boto3
```

```
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker
 session
source = 'source.tar.gz'
project = 'debugger-boto3-test'

tar = tarfile.open(source, 'w:gz')
tar.add ('entry_point/train.py') # Specify the directory and name of your training
 script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-
%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training scrip file location and
 name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        # Specify a training Docker container image URI (Deep Learning Container or
 your own training container) to TrainingImage.

            'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest',
            'RuleParameters': {'rule_to_invoke': 'LossNotDecreasing'}
        }
    ],
    ProfilerConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
        'ProfilingIntervalInMilliseconds': 500,
        'ProfilingParameters': {
            'DataloaderProfilingConfig': '{"StartStep": 5, "NumSteps": 3,
 "MetricsRegex": ".*", }',
            'DetailedProfilingConfig': '{"StartStep": 5, "NumSteps": 3, }',
            'PythonProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "ProfilerName":
 "cprofile", "cProfileTimer": "total_time"}',
            'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for
 profiling outputs
        }
    },
    ProfilerRuleConfigurations=[
        {
            'RuleConfigurationName': 'ProfilerReport',
```

```
            'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest',
            'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}
        }
    ]
)
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in `VanishingGradient` rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'gradients',
            'CollectionParameters' : {
                'train.save_interval': '500',
                'eval.save_interval': '50'
            }
        }
    ]
}
```

This will make the training job save a tensor collection, `gradients`, every `save_interval` of 500 steps. To find available `CollectionName` values, see [Debugger Built-in Collections] in the *SMDebug client library documentation*. To find available `CollectionParameters` parameter keys and values, see the [`sagemaker.debugger.CollectionConfig`] class in the *SageMaker Python SDK documentation*.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in `VanishingGradient` rule on the saved `gradients` collection.

```
DebugRuleConfigurations=[
```

```
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the `VanishingGradient` rule on the collection of `gradients` tensor. To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        }',
        'PythonProfilingConfig': '{
```

```
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time"  # Include only when using cprofile.
 Available options: cpu, off_cpu, total_time
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
 outputs
    }
}
```

Target Time Duration

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', #
 Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10
        }',
        'PythonProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time"  # Include only when using cprofile.
 Available options: cpu, off_cpu, total_time
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
 outputs
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

Update Debugger Profiling Configuration Using the `UpdateTrainingJob` API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker AI client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the `TrainingJobName` parameter.

```
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string' : 'string'
        }
    }
],
```

```
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects using the AWS Boto3 SageMaker AI client's `create_training_job()` function. The following code sample shows how to configure a custom `ImproperActivation` rule written with the *smdebug* library using this SageMaker API operation. This example assumes that you've written the custom rule in *custom_rules.py* file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger image URIs for custom rule evaluators. You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ]
},
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'improper_activation_job',
        'RuleEvaluatorImage': '552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-
debugger-rule-evaluator:latest',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
           'source_s3_uri': 's3://bucket/custom_rules.py',
           'rule_to_invoke': 'ImproperActivation',
           'collection_names': 'relu_activations'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Docker images for Debugger rules. To find the key-value pairs for `RuleParameters`, see List of Debugger built-in rules.

Amazon SageMaker Debugger references

Find more information and references about using Amazon SageMaker Debugger in the following topics.

Topics

- Amazon SageMaker Debugger APIs
- Docker images for Debugger rules
- Amazon SageMaker Debugger exceptions
- Distributed training supported by Amazon SageMaker Debugger

Amazon SageMaker Debugger APIs

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source `sagemaker-debugger` Python SDK that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker AI Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the `SMDebug` Python library to monitor and analyze these tensors using SageMaker AI estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- `CreateTrainingJob` and `UpdateTrainingJob` use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - `CollectionConfiguration`
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `TensorBoardOutputConfig`

  - [ProfilerConfig]
  - [ProfilerRuleConfiguration]
- [DescribeTrainingJob] provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - [DebugHookConfig]
  - [DebugRuleConfiguration]
  - [DebugRuleEvaluationStatus]
  - [ProfilerConfig]
  - [ProfilerRuleConfiguration]
  - [ProfilerRuleEvaluationStatus]

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Data transformation workloads with SageMaker Processing.

Docker images for Debugger rules

Amazon SageMaker AI provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker AI (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker AI high-level Debugger API operations with SageMaker AI Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the `ConfigureTrainingJob`API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the `CreateTrainingJob` API. SageMaker AI uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, the Amazon ECR repository name, and the tag value, see the following topics.

Topics

Amazon SageMaker Debugger image URIs for built-in rule evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

ECR Repository Name: sagemaker-debugger-rules

Tag: latest

Amazon SageMaker Debugger exceptions

Amazon SageMaker Debugger is designed to be aware of that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the smdebug.exceptions module. You can import them as follows:

```
from smdebug.exceptions import *
```

The following exceptions are available:

- `TensorUnavailableForStep` – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.
- `TensorUnavailable` – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
- `StepUnavailable` – The step was not saved and Debugger has no data from the step.
- `StepNotYetAvailable` – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
- `NoMoreData` – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
- `IndexReaderException` – The index reader is not valid.
- `InvalidWorker` – A worker was invoked that was not valid.

- `RuleEvaluationConditionMet` – Evaluation of the rule at the step resulted in the condition being met.
- `InsufficientInformationForRuleInvocation` – Insufficient information was provided to invoke the rule.

Distributed training supported by Amazon SageMaker Debugger

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

  Scope of validity of using Debugger for training jobs with Horovod

Deep Learning Framework	Apache MXNet	TensorFlow 1.x	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes	Yes	Yes
Profiling framework operations	No	No	No	Yes	Yes
Debugging model output tensors	Yes	Yes	Yes	Yes	Yes

- **SageMaker AI distributed data parallel**

  Scope of validity of using Debugger for training jobs with SageMaker AI distributed data parallel

Deep Learning Framework	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes
Profiling framework operations	No*	No**	Yes
Debugging model output tensors	Yes	Yes	Yes

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker AI distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker AI distributed model parallel** – Debugger does not support SageMaker AI distributed model parallel training.
- **Distributed training with SageMaker AI checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker AI checkpoints are enabled. You might see an error that looks like the following:

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing
 Enabled
```

  To use Debugger for training jobs with distributed training options, you need to disable SageMaker AI checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Using SageMaker AI distributed data parallel with Amazon SageMaker Debugger and checkpoints and Saving Checkpoints.
- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- Profiling distributed training framework operations, such as the `AllReduced` operation of SageMaker AI distributed data parallel and Horovod operations, is not available.

Access a training container through AWS Systems Manager for remote debugging

You can securely connect to SageMaker training containers through AWS Systems Manager (SSM). This gives you a shell-level access to debug training jobs that are running within the container. You can also log commands and responses that are streamed to Amazon CloudWatch. If you use your own Amazon Virtual Private Cloud (VPC) to train a model, you can use AWS PrivateLink to set up a VPC endpoint for SSM and connect to containers privately through SSM.

You can connect to SageMaker AI Framework Containers or connect to your own training container set up with the SageMaker Training environment.

Set up IAM permissions

To enable SSM in your SageMaker training container, you need to set up an IAM role for the container. For you or users in your AWS account to access the training containers through SSM, you need to set up IAM users with permissions to use SSM.

IAM role

For a SageMaker training container to start with the SSM agent, provide an IAM role with SSM permissions.

To enable remote debugging for your training job, SageMaker AI needs to start the SSM agent in the training container when the training job starts. To allow the SSM agent to communicate with the SSM service, add the following policy to the IAM role that you use to run your training job.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": "*"
```

```
        }
    ]
 }
```

IAM user

Add the following policy to provide an IAM user with SSM session permissions to connect to an SSM target. In this case, the SSM target is a SageMaker training container.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
            "Resource": "*"
        }
    ]
}
```

You can restrict IAM users to connect only to containers for specific training jobs by adding the `Condition` key, as shown in the following policy sample.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
```

```
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/aws:ssmmessages:target-id": [
                        "sagemaker-training-job:*"
                    ]
                }
            }
        }
    ]
}
```

You can also explicitly use the `sagemaker:EnableRemoteDebug` condition key to restrict remote debugging. The following is an example policy for IAM users to restrict remote debugging.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyRemoteDebugInTrainingJob",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:UpdateTrainingJob"
            ],
            "Resource": "*",
            "Condition": {
                "BoolIfExists": {
                    "sagemaker:EnableRemoteDebug": false
                }
            }
        }
    ]
}
```

For more information, see [Condition keys for Amazon SageMaker AI] in the *AWS Service Authorization Reference*.

How to enable remote debugging for a SageMaker training job

In this section, learn how to enable remote debugging when starting or updating a training job in Amazon SageMaker AI.

SageMaker Python SDK

Using the estimator class in the SageMaker Python SDK, you can turn remote debugging on or off using the `enable_remote_debug` parameter or the `enable_remote_debug()` and `disable_remote_debug()` methods.

To enable remote debugging when you create a training job

To enable remote debugging when you create a new training job, set the `enable_remote_debug` parameter to `True`. The default value is `False`, so if you don't set this parameter at all, or you explicitly set it to `False`, remote debugging functionality is disabled.

```
import sagemaker

session = sagemaker.Session()

estimator = sagemaker.estimator.Estimator(
    ...,
    sagemaker_session=session,
    image_uri="<your_image_uri>", #must be owned by your organization or Amazon
 DLCs
    role=role,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=output_path,
    max_run=1800,
    enable_remote_debug=True
)
```

To enable remote debugging by updating a training job

Using the following estimator class methods, you can enable or disable remote debugging while a training job is running when the `SecondaryStatus` of the job is `Downloading` or `Training`.

```
# Enable RemoteDebug
estimator.enable_remote_debug()

# Disable RemoteDebug
estimator.disable_remote_debug()
```

AWS SDK for Python (Boto3)

To enable remote debugging when you create a training job

To enable remote debugging when you create a new training job, set the value for the `EnableRemoteDebug` key to `True` in the `RemoteDebugConfig` parameter.

```
import boto3

sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    ...,
    TrainingJobName=job_name,
    AlgorithmSpecification={
        // Specify a training Docker container image URI
        // (Deep Learning Container or your own training container) to
 TrainingImage.
        "TrainingImage": "<your_image_uri>",
        "TrainingInputMode": "File"
    },
    RoleArn=iam_role_arn,
    OutputDataConfig=output_path,
    ResourceConfig={
        "InstanceType": "ml.m5.xlarge",
        "InstanceCount": 1,
        "VolumeSizeInGB": 30
    },
    StoppingCondition={
        "MaxRuntimeInSeconds": 86400
    },
    RemoteDebugConfig={
        "EnableRemoteDebug": True
    }
)
```

To enable remote debugging by updating a training job

Using the `update_traing_job` API, you can enable or disable remote debugging while a training job is running when the `SecondaryStatus` of the job is `Downloading` or `Training`.

```
# Update a training job
sm.update_training_job(
    TrainingJobName=job_name,
    RemoteDebugConfig={
        "EnableRemoteDebug": True     # True | False
    }
)
```

AWS Command Line Interface (CLI)

To enable remote debugging when you create a training job

Prepare a `CreateTrainingJob` request file in JSON format, as follows.

```
// train-with-remote-debug.json
{
    "TrainingJobName": job_name,
    "RoleArn": iam_role_arn,
    "AlgorithmSpecification": {
        // Specify a training Docker container image URI (Deep Learning Container or
 your own training container) to TrainingImage.
        "TrainingImage": "<your_image_uri>",
        "TrainingInputMode": "File"
    },
    "OutputDataConfig": {
        "S3OutputPath": output_path
    },
    "ResourceConfig": {
        "InstanceType": "ml.m5.xlarge",
        "InstanceCount": 1,
        "VolumeSizeInGB": 30
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 86400
    },
    "RemoteDebugConfig": {
        "EnableRemoteDebug": True
    }
```

```
}
```

After saving the JSON file, run the following command in the terminal where you submit the training job. The following example command assumes that the JSON file is named `train-with-remote-debug.json`. If you run it from a Jupyter notebook, add an exclamation point (`!`) to the beginning of the line.

```
aws sagemaker create-training-job \
    --cli-input-json file://train-with-remote-debug.json
```

To enable remote debugging by updating a training job

Prepare an `UpdateTrainingJob` request file in JSON format, as follows.

```
// update-training-job-with-remote-debug-config.json
{
    "TrainingJobName": job_name,
    "RemoteDebugConfig": {
        "EnableRemoteDebug": True
    }
}
```

After saving the JSON file, run the following command in the terminal where you submit the training job. The following example command assumes that the JSON file is named `train-with-remote-debug.json`. If you run it from a Jupyter notebook, add an exclamation point (`!`) to the beginning of the line.

```
aws sagemaker update-training-job \
    --cli-input-json file://update-training-job-with-remote-debug-config.json
```

Access your training container

You can access a training container when the `SecondaryStatus` of the corresponding training job is `Training`. The following code examples demonstrate how to check the status of your training job using the `DescribeTrainingJob` API, how to check the training job logs in CloudWatch, and how to log in to the training container.

To check the status of a training job

SageMaker Python SDK

To check the SecondaryStatus of a training job, run the following SageMaker Python SDK code.

```
import sagemaker

session = sagemaker.Session()

# Describe the job status
training_job_info = session.describe_training_job(job_name)
print(training_job_info)
```

AWS SDK for Python (Boto3)

To check the SecondaryStatus of a training job, run the following SDK for Python (Boto3) code.

```
import boto3

session = boto3.session.Session()
region = session.region_name
sm = boto3.Session(region_name=region).client("sagemaker")

# Describe the job status
sm.describe_training_job(TrainingJobName=job_name)
```

AWS Command Line Interface (CLI)

To check the SecondaryStatus of a training job, run the following AWS CLI command for SageMaker AI.

```
aws sagemaker describe-training-job \
    --training-job-name job_name
```

To find the host name of a training container

To connect to the training container through SSM, use this format for the target ID: `sagemaker-training-job:<training-job-name>_algo-<n>`, where `algo-<n>` is the name of the container host. If your job is running on a single instance, the host is always `algo-1`. If you run a distributed training job on multiple instances, SageMaker AI creates an equal number of hosts and log streams. For example, if you use 4 instances, SageMaker AI creates `algo-1`, `algo-2`, `algo-3`, and `algo-4`. You must determine which log stream you want to debug, and its host number. To access log streams that are associated with a training job, do the following.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Training**, then choose **Training jobs**.
3. From the **Training jobs** list, choose the training job that you want to debug. The training job details page opens.
4. In the **Monitor** section, choose **View logs**. The related training job log stream list opens in the CloudWatch console.
5. Log stream names appear in `<training-job-name>/algo-<n>-<time-stamp>` format, with `algo-<n>` representing the host name.

To learn more about how SageMaker AI manages configuration information for multi-instance distributed training, see Distributed Training Configuration.

To access the training container

Use the following command in terminal to start the SSM session (`aws ssm start-session`) and connect to the training container.

```
aws ssm start-session --target sagemaker-training-job:<training-job-name>_algo-<n>
```

For example, if the training job name is `training-job-test-remote-debug` and the host name is `algo-1`, the target ID becomes `sagemaker-training-job:training-job-test-remote-debug_algo-1`. If the output of this command is similar to `Starting session with SessionId:xxxxx`, the connection is successful.

SSM access with AWS PrivateLink

If your training containers run within a Amazon Virtual Private Cloud that is not connected to the public internet, you can use AWS PrivateLink to enable SSM. AWS PrivateLink restricts all network traffic between your endpoint instances, SSM, and Amazon EC2 to the Amazon network. For more information on how to setup SSM access with AWS PrivateLink, see Set up an Amazon VPC endpoint for Session Manager.

Log SSM session commands and results

After following the instructions at Create a Session Manager preferences document (command line), you can create SSM documents that define your preferences for SSM sessions. You can use SSM documents to configure session options, including data encryption, session duration, and logging. For example, you can specify whether to store session log data in an Amazon Simple Storage Service (Amazon S3) bucket or in an Amazon CloudWatch Logs group. You can create documents that define general preferences for all sessions for an AWS account and AWS Region, or documents that define preferences for individual sessions.

Troubleshooting issues by checking error logs from SSM

Amazon SageMaker AI uploads errors from the SSM agent to your CloudWatch Logs in the `/aws/sagemaker/TrainingJobs` log group. SSM agent log streams are named in this format: `<job-name>/algo-<n>-<timestamp>/ssm`. For example, if you create a two-node training job named `training-job-test-remote-debug`, the training job log `training-job-test-remote-debug/algo-<n>-<timestamp>` and multiple SSM agent error logs `training-job-test-remote-debug/algo-<n>-<timestamp>/ssm` are uploaded to your CloudWatch Logs. In this example, you can review the `*/ssm` log streams to troubleshoot SSM issues.

```
training-job-test-remote-debug/algo-1-1680535238
training-job-test-remote-debug/algo-2-1680535238
training-job-test-remote-debug/algo-1-1680535238/ssm
training-job-test-remote-debug/algo-2-1680535238/ssm
```

Considerations

Consider the following when using SageMaker AI remote debugging.

- Remote debugging isn't supported for SageMaker AI algorithm containers or containers from SageMaker AI on AWS Marketplace.
- You can't start an SSM session for containers that have network isolation enabled because the isolation prevents outbound network calls.

Release notes for debugging capabilities of Amazon SageMaker AI

See the following release notes to track the latest updates for debugging capabilities of Amazon SageMaker AI.

December 21, 2023

New features

Released a remote debugging functionality, a new debugging capability of SageMaker AI that gives you a shell-level access to training containers. With this release, you can debug training jobs by logging into the job containers running on SageMaker AI ML instances. To learn more, see the section called "Access a training container through SSM for remote debugging".

September 7, 2023

New features

Added a new utility module `sagemaker.interactive_apps.tensorboard.TensorBoardApp` that provides a function called `get_app_url()`. The `get_app_url()` function generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker AI or Amazon EC2. This is to provide a unified experience for both Studio Classic and non-Studio Classic users. For the Studio Classic environment, you can open TensorBoard by running the `get_app_url()` function as it is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio Classic environments, you can open TensorBoard by providing your domain information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard by running the `get_app_url` function in your Jupyter notebook or terminal. This functionality is available in the SageMaker Python SDK v2.184.0 and later. For more information, see the section called "Accessing the TensorBoard application on SageMaker AI".

April 4, 2023

New features

Released SageMaker AI with TensorBoard, a capability that hosts TensorBoard on SageMaker AI. TensorBoard is available as an application through SageMaker AI domain, and the SageMaker AI Training platform supports TensorBoard output data collection to S3 and loading them automatically to the hosted TensorBoard on SageMaker AI. With this capability, you can run training jobs set up with TensorBoard summary writers in SageMaker AI, save the TensorBoard output files in Amazon S3, open the TensorBoard application directly from the SageMaker AI console, and load the output files using SageMaker AI Data Manager plugin implemented to the hosted TensorBoard interface. You don't need to install TensorBoard manually and host locally on the SageMaker AI IDEs or local machine. To learn more, see the section called "TensorBoard in SageMaker AI".

March 16, 2023

Deprecation notes

SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

With the deprecation, SageMaker Debugger also discontinues support for the following three `ProfilerRules` for framework profiling.

- MaxInitializationTime
- OverallFrameworkMetrics
- StepOutlier

February 21, 2023

Other changes

- The XGBoost report tab has been removed from the SageMaker Debugger's profiler dashboard. You can still access the XGBoost report by downloading it as a Jupyter notebook or a HTML file. For more information, see SageMaker Debugger XGBoost Training Report.
- Starting from this release, the built-in profiler rules are not activated by default. To use the SageMaker Debugger profiler rules to detect certain computational problems, you need to add the rules when you configure a SageMaker training job launcher.

December 1, 2020

Amazon SageMaker Debugger launched deep profiling features at re:Invent 2020.

December 3, 2019

Amazon SageMaker Debugger initially launched at re:Invent 2019.

Profile and optimize computational performance

When training state-of-the-art deep learning models that rapidly grow in size, scaling the training job of such models to a large GPU cluster and identifying computational performance issues from billions and trillions of operations and communications in every iteration of the gradient descent process become a challenge.

SageMaker AI provides profiling tools to visualize and diagnose such complex computation issues arising from running training jobs on AWS cloud computing resources. There are two profiling options that SageMaker AI offers: Amazon SageMaker Profiler and a resource utilzation monitor in Amazon SageMaker Studio Classic. See the following introductions of the two functionalities to gain quick insights and learn which one to use depending on your needs.

Amazon SageMaker Profiler

Amazon SageMaker Profiler is a profiling capability of SageMaker AI with which you can deep dive into compute resources provisioned while training deep learning models, and gain visibility into operation-level details. SageMaker Profiler provides Python modules for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker Python SDK and AWS Deep Learning Containers.

With SageMaker Profiler, you can track all activities on CPUs and GPUs, such as CPU and GPU utilizations, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs.

SageMaker Profiler also offers a user interface (UI) that visualizes the *profile*, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

To learn more about SageMaker Profiler, see the section called “SageMaker Profiler”.

Monitoring AWS compute resources in Amazon SageMaker Studio Classic

SageMaker AI also provides a user interface in Studio Classic for monitoring resource utilization at high level, but with more granularity compared to the default utilization metrics collected from SageMaker AI to CloudWatch.

For any training job you run in SageMaker AI using the SageMaker Python SDK, SageMaker AI starts profiling basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time. It collects these resource utilization metrics every 500 milliseconds.

Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, the monitoring functionality of SageMaker AI provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals, so you can dive deep into the metrics at the level of an operation or a step.

To access the dashboard for monitoring the resource utilization metrics of a training job, see the SageMaker AI Debugger UI in SageMaker Studio Experiments.

Topics

Amazon SageMaker Profiler

> Amazon SageMaker Profiler is currently in preview release and available at no cost in supported AWS Regions. The generally available version of Amazon SageMaker Profiler (if any) may include features and pricing that are different than those offered in preview.

Amazon SageMaker Profiler is a capability of Amazon SageMaker AI that provides a detailed view into the AWS compute resources provisioned during training deep learning models on SageMaker AI. It focuses on profiling the CPU and GPU usage, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs. SageMaker Profiler also offers a user interface (UI) that visualizes the *profile*, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

> **Note**
>
> SageMaker Profiler supports PyTorch and TensorFlow and is available in AWS Deep Learning Containers for SageMaker AI. To learn more, see the section called "Supported framework images, AWS Regions, and instance types".

For data scientists

Training deep learning models on a large compute cluster often has computational optimization problems, such as bottlenecks, kernel launch latencies, memory limit, and low resource utilization.

To identify such computational performance issues, you need to profile deeper into the compute resources to understand which kernels introduce latencies and which operations cause bottlenecks. Data scientists can take the benefit from using the SageMaker Profiler UI for visualizing the detailed profile of training jobs. The UI provides a dashboard furnished with summary charts and a timeline interface to track every event on the compute resources. Data scientists can also add custom annotations to track certain parts of the training job using the SageMaker Profiler Python modules.

For administrators

Through the Profiler landing page in the SageMaker AI console or SageMaker AI domain, you can manage the Profiler application users if you are an administrator of an AWS account or SageMaker AI domain. Each domain user can access their own Profiler application given the granted permissions. As a SageMaker AI domain administrator and domain user, you can create and delete the Profiler application given the permission level you have.

Topics

Supported framework images, AWS Regions, and instance types

This feature supports the following machine learning frameworks and AWS Regions.

> **Note**
>
> To use this feature, make sure that you have installed the SageMaker Python SDK version 2.180.0 or later.

SageMaker AI framework images pre-installed with SageMaker Profiler

SageMaker Profiler is pre-installed in the following AWS Deep Learning Containers for SageMaker AI.

PyTorch images

PyTorch versions	AWS DLC image URI
2.2.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.2.0-gpu-py310-cu121-ubuntu20.04-sagemaker
2.1.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-ubuntu20.04-sagemaker
2.0.1	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu118-ubuntu20.04-sagemaker *763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu121-ubuntu20.04-sagemaker
1.13.1	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:1.13.1-gpu-py39-cu117-ubuntu20.04-sagemaker

TensorFlow images

TensorFlow versions	AWS DLC image URI
2.13.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.13.0-gpu-py310-cu118-ubuntu20.04-sagemaker
2.12.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.12.0-gpu-py310-cu118-ubuntu20.04-sagemaker
2.11.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.11.0-gpu-py39-cu112-ubuntu20.04-sagemaker

Important

Distribution and maintenance of the framework containers in the preceding tables are under the Framework Support Policy managed by the AWS Deep Learning Containers service. We highly recommend you to upgrade to the currently supported framework versions, if you are using prior framework versions that are no longer supported.

Note

If you want to use SageMaker Profiler for other framework images or your own Docker images, you can install SageMaker Profiler using the SageMaker Profiler Python package binary files provided in the following section.

SageMaker Profiler Python package binary files

If you want to configure your own Docker container, use SageMaker Profiler in other pre-built containers for PyTorch and TensorFlow, or install the SageMaker Profiler Python package locally, use one the following binary files. Depending on the Python and CUDA versions in your environment, choose one of the following.

PyTorch

- Python3.8, CUDA 11.3: https://smppy.s3.amazonaws.com/pytorch/cu113/smprof-0.3.334-cp38-cp38-linux_x86_64.whl
- Python3.9, CUDA 11.7: https://smppy.s3.amazonaws.com/pytorch/cu117/smprof-0.3.334-cp39-cp39-linux_x86_64.whl
- Python3.10, CUDA 11.8: https://smppy.s3.amazonaws.com/pytorch/cu118/smprof-0.3.334-cp310-cp310-linux_x86_64.whl
- Python3.10, CUDA 12.1: https://smppy.s3.amazonaws.com/pytorch/cu121/smprof-0.3.334-cp310-cp310-linux_x86_64.whl

TensorFlow

- Python3.9, CUDA 11.2: https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.334-cp39-cp39-linux_x86_64.whl
- Python3.10, CUDA 11.8: https://smppy.s3.amazonaws.com/tensorflow/cu118/smprof-0.3.334-cp310-cp310-linux_x86_64.whl

For more information about how to install SageMaker Profiler using the binary files, see the section called "(Optional) Install the SageMaker Profiler Python package".

Supported AWS Regions

SageMaker Profiler is available in the following AWS Regions.

- US East (N. Virginia) (`us-east-1`)
- US East (Ohio) (`us-east-2`)
- US West (Oregon) (`us-west-2`)
- Europe (Frankfurt) (`eu-central-1`)
- Europe (Ireland) (`eu-west-1`)

Supported instance types

SageMaker Profiler supports profiling of training jobs on the following instance types.

CPU and GPU profiling

- `ml.g4dn.12xlarge`
- `ml.g5.24xlarge`
- `ml.g5.48xlarge`
- `ml.p3dn.24xlarge`
- `ml.p4de.24xlarge`
- `ml.p4d.24xlarge`
- `ml.p5.48xlarge`

GPU profiling only

- `ml.g5.2xlarge`
- `ml.g5.4xlarge`
- `ml.g5.8xlarge`
- `ml.g5.16.xlarge`

Prerequisites for SageMaker Profiler

The following list shows the prerequisites to start using SageMaker Profiler.

- A SageMaker AI domain set up with Amazon VPC in your AWS account.

  For instructions on setting up a domain, see [Onboard to Amazon SageMaker AI domain using quick setup]. You also need to add domain user profiles for individual users to access the Profiler UI application. For more information, see [Add user profiles].
- The following list is the minimum set of permissions for using the Profiler UI application.
  - `sagemaker:CreateApp`
  - `sagemaker:DeleteApp`
  - `sagemaker:DescribeTrainingJob`
  - `sagemaker:Search`
  - `s3:GetObject`
  - `s3:ListBucket`

Prepare and run a training job with SageMaker Profiler

Setting up to running a training job with the SageMaker Profiler consists of two steps: adapting the training script and configuring the SageMaker training job launcher.

Topics

- Step 1: Adapt your training script using the SageMaker Profiler Python modules
- Step 2: Create a SageMaker AI framework estimator and activate SageMaker Profiler
- (Optional) Install the SageMaker Profiler Python package

Step 1: Adapt your training script using the SageMaker Profiler Python modules

To start capturing kernel runs on GPUs while the training job is running, modify your training script using the SageMaker Profiler Python modules. Import the library and add the `start_profiling()` and `stop_profiling()` methods to define the beginning and the end of profiling. You can also use optional custom annotations to add markers in the training script to visualize hardware activities during particular operations in each step.

Note that the annotators extract operations from GPUs. For profiling operations in CPUs, you don't need to add any additional annotations. CPU profiling is also activated when you specify the profiling configuration, which you'll practice in the section called "Step 2: Create a SageMaker AI framework estimator and activate SageMaker Profiler".

> **Note**
>
> Profiling an entire training job is not the most efficient use of resources. We recommend profiling at most 300 steps of a training job.

> **Important**
>
> The release on December 14, 2023 involves a breaking change. The SageMaker Profiler Python package name is changed from `smppy` to `smprof`. This is effective in the SageMaker AI Framework Containers for TensorFlow v2.12 and later.
> If you use one of the previous versions of the SageMaker AI Framework Containers such TensorFlow v2.11.0, the SageMaker Profiler Python package is still available as `smppy`. If you are uncertain about which version or the package name you should use, replace the import statement of the SageMaker Profiler package with the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

Approach 1. Use the context manager `smprof.annotate` to annotate full functions

You can wrap full functions with the `smprof.annotate()` context manager. This wrapper is recommended if you want to profile by functions instead of code lines. The following example script shows how to implement the context manager to wrap the training loop and full functions in each iteration.

```
import smprof

SMProf = smprof.SMProfiler.instance()
config = smprof.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        with smprof.annotate("step_"+str(i)):
            inputs, labels = data
            inputs = inputs.to("cuda", non_blocking=True)
            labels = labels.to("cuda", non_blocking=True)

            optimizer.zero_grad()

            with smprof.annotate("Forward"):
                outputs = net(inputs)
            with smprof.annotate("Loss"):
                loss = criterion(outputs, labels)
            with smprof.annotate("Backward"):
```

```
                loss.backward()
            with smprof.annotate("Optimizer"):
                optimizer.step()

SMProf.stop_profiling()
```

Approach 2. Use `smprof.annotation_begin()` and `smprof.annotation_end()` to annotate specific code line in functions

You can also define annotations to profile specific code lines. You can set the exact starting point and end point of profiling at the level of individual code lines, not by the functions. For example, in the following script, the `step_annotator` is defined at the beginning of each iteration and ends at the end of the iteration. Meanwhile, other detailed annotators for each operations are defined and wrap around the target operations throughout each iteration.

```
import smprof

SMProf = smprof.SMProfiler.instance()
config = smprof.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        step_annotator = smprof.annotation_begin("step_" + str(i))

        inputs, labels = data
        inputs = inputs.to("cuda", non_blocking=True)
        labels = labels.to("cuda", non_blocking=True)
        optimizer.zero_grad()

        forward_annotator = smprof.annotation_begin("Forward")
        outputs = net(inputs)
        smprof.annotation_end(forward_annotator)

        loss_annotator = smprof.annotation_begin("Loss")
        loss = criterion(outputs, labels)
```

```
        smprof.annotation_end(loss_annotator)

        backward_annotator = smprof.annotation_begin("Backward")
        loss.backward()
        smprof.annotation_end(backward_annotator)

        optimizer_annotator = smprof.annotation_begin("Optimizer")
        optimizer.step()
        smprof.annotation_end(optimizer_annotator)

        smprof.annotation_end(step_annotator)

SMProf.stop_profiling()
```

After annotating and setting up the profiler initiation modules, save the script to submit using a SageMaker training job launcher in the following Step 2. The sample launcher assumes that the training script is named `train_with_profiler_demo.py`.

Step 2: Create a SageMaker AI framework estimator and activate SageMaker Profiler

The following procedure shows how to prepare a SageMaker AI framework estimator for training using the SageMaker Python SDK.

1. Set up a `profiler_config` object using the `ProfilerConfig` and `Profiler` modules as follows.

   ```
   from sagemaker import ProfilerConfig, Profiler
   profiler_config = ProfilerConfig(
       profile_params = Profiler(cpu_profiling_duration=3600)
   )
   ```

   The following is the description of the `Profiler` module and its argument.

   - `Profiler`: The module for activating SageMaker Profiler with the training job.
     - `cpu_profiling_duration` (int): Specify the time duration in seconds for profiling on CPUs. Default is 3600 seconds.

2. Create a SageMaker AI framework estimator with the `profiler_config` object created in the previous step. The following code shows an example of creating a PyTorch estimator. If you want to create a TensorFlow estimator, import `sagemaker.tensorflow.TensorFlow` instead, and specify one of the [TensorFlow versions](#) supported by SageMaker Profiler. For more

information about supported frameworks and instance types, see the section called "SageMaker AI framework images pre-installed with SageMaker Profiler".

```
import sagemaker
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    framework_version="2.0.0",
    role=sagemaker.get_execution_role(),
    entry_point="train_with_profiler_demo.py", # your training job entry point
    source_dir=source_dir, # source directory for your training script
    output_path=output_path,
    base_job_name="sagemaker-profiler-demo",
    hyperparameters=hyperparameters, # if any
    instance_count=1, # Recommended to test with < 8
    instance_type=ml.p4d.24xlarge,
    profiler_config=profiler_config
)
```

3. Start the training job by running the `fit` method. With `wait=False`, you can silence the training job logs and let it run in the background.

```
estimator.fit(wait=False)
```

While running the training job or after the job has completed, you can go to the next topic at the section called "Open the SageMaker Profiler UI application" and start exploring and visualizing the saved profiles.

If you want to directly access the profile data saved in the Amazon S3 bucket, use the following script to retrieve the S3 URI.

```
import os
# This is an ad-hoc function to get the S3 URI
# to where the profile output data is saved
def get_detailed_profiler_output_uri(estimator):
    config_name = None
    for processing in estimator.profiler_rule_configs:
        params = processing.get("RuleParameters", dict())
        rule = config_name = params.get("rule_to_invoke", "")
        if rule == "DetailedProfilerProcessing":
            config_name = processing.get("RuleConfigurationName")
```

```
            break
    return os.path.join(
        estimator.output_path,
        estimator.latest_training_job.name,
        "rule-output",
        config_name,
    )

print(
    f"Profiler output S3 bucket: ",
    get_detailed_profiler_output_uri(estimator)
)
```

(Optional) Install the SageMaker Profiler Python package

To use SageMaker Profiler on PyTorch or TensorFlow framework images not listed in the section called "SageMaker AI framework images pre-installed with SageMaker Profiler", or on your own custom Docker container for training, you can install SageMaker Profiler by using one of the the section called "SageMaker Profiler Python package binary files".

Option 1: Install the SageMaker Profiler package while launching a training job

If you want to use SageMaker Profiler for training jobs using PyTorch or TensorFlow images not listed in the section called "SageMaker AI framework images pre-installed with SageMaker Profiler", create a `requirements.txt` file and locate it under the path you specify to the `source_dir` parameter of the SageMaker AI framework estimator in Step 2. For more information about setting up a `requirements.txt` file in general, see Using third-party libraries in the *SageMaker Python SDK documentation*. In the `requirements.txt` file, add one of the S3 bucket paths for the the section called "SageMaker Profiler Python package binary files".

```
# requirements.txt
https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.332-cp39-cp39-
linux_x86_64.whl
```

Option 2: Install the SageMaker Profiler package in your custom Docker containers

If you use a custom Docker container for training, add one of the the section called "SageMaker Profiler Python package binary files" to your Dockerfile.

```
# Install the smprof package version compatible with your CUDA version
```

```
RUN pip install https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.332-cp39-
cp39-linux_x86_64.whl
```

For guidance on running a custom Docker container for training on SageMaker AI in general, see Adapting your own training container.

Open the SageMaker Profiler UI application

You can access the SageMaker Profiler UI application through the following options.

Topics

- Option 1: Launch the SageMaker Profiler UI from the domain details page
- Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker AI console
- Option 3: Use the application launcher function in the SageMaker AI Python SDK

Option 1: Launch the SageMaker Profiler UI from the domain details page

If you have access to the SageMaker AI console, you can take this option.

Navigate to the domain details page

The following procedure shows how to navigate to the domain details page.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **domains**.
3. From the list of domains, select the domain in which you want to launch the SageMaker Profiler application.

Launch the SageMaker Profiler UI application

The following procedure shows how to launch the SageMaker Profiler application that is scoped to a user profile.

1. On the domain details page, choose the **User profiles** tab.
2. Identify the user profile for which you want to launch the SageMaker Profiler UI application.
3. Choose **Launch** for the selected user profile, and choose **Profiler**.

Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker AI console

The following procedure describes how to launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker AI console. If you have access to the SageMaker AI console, you can take this option.

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Profiler**.
3. Under **Get started**, select the domain in which you want to launch the Studio Classic application. If your user profile only belongs to one domain, you do not see the option for selecting a domain.
4. Select the user profile for which you want to launch the SageMaker Profiler UI application. If there is no user profile in the domain, choose **Create user profile**. For more information about creating a new user profile, see Add user profiles.
5. Choose **Open Profiler**.

Option 3: Use the application launcher function in the SageMaker AI Python SDK

If you are a SageMaker AI domain user and have access only to SageMaker Studio, you can access the SageMaker Profiler UI application through SageMaker Studio Classic by running the `sagemaker.interactive_apps.detail_profiler_app.DetailProfilerApp` function.

Note that SageMaker Studio Classic is the previous Studio UI experience before re:Invent 2023, and is migrated as an application into a newly designed Studio UI at re:Invent 2023. The SageMaker Profiler UI application is available at SageMaker AI domain level, and thus requires your domain ID and user profile name. Currently, the `DetailedProfilerApp` function only works within the SageMaker Studio Classic application; the function properly takes in the domain and user profile information from SageMaker Studio Classic.

For domain, domain users, and Studio created before re:Invent 2023, Studio Classic would be the default experience unless you have updated it following the instructions at Migrating from Amazon SageMaker Studio Classic. If this is your case, there's no further action needed, and you can directly launch the SageMaker Profiler UI application by running the `DetailProfilerApp` funciton.

If you created a new domain and Studio after re:Invent 2023, launch the Studio Classic application within the Studio UI and then run the `DetailProfilerApp` function to launch the SageMaker Profiler UI application.

Note that the `DetailedProfilerApp` function doesn't work in other SageMaker AI machine learning IDEs, such as the SageMaker Studio JupyterLab application, the SageMaker Studio Code Editor application, and SageMaker Notebook instances. If you run the `DetailedProfilerApp` function in those IDEs, it returns a URL to the Profiler landing page in the SageMaker AI console, instead of a direct link to open the Profiler UI application.

Explore the profile output data visualized in the SageMaker Profiler UI

This section walks through the SageMaker Profiler UI and provides tips for how to use and gain insights from it.

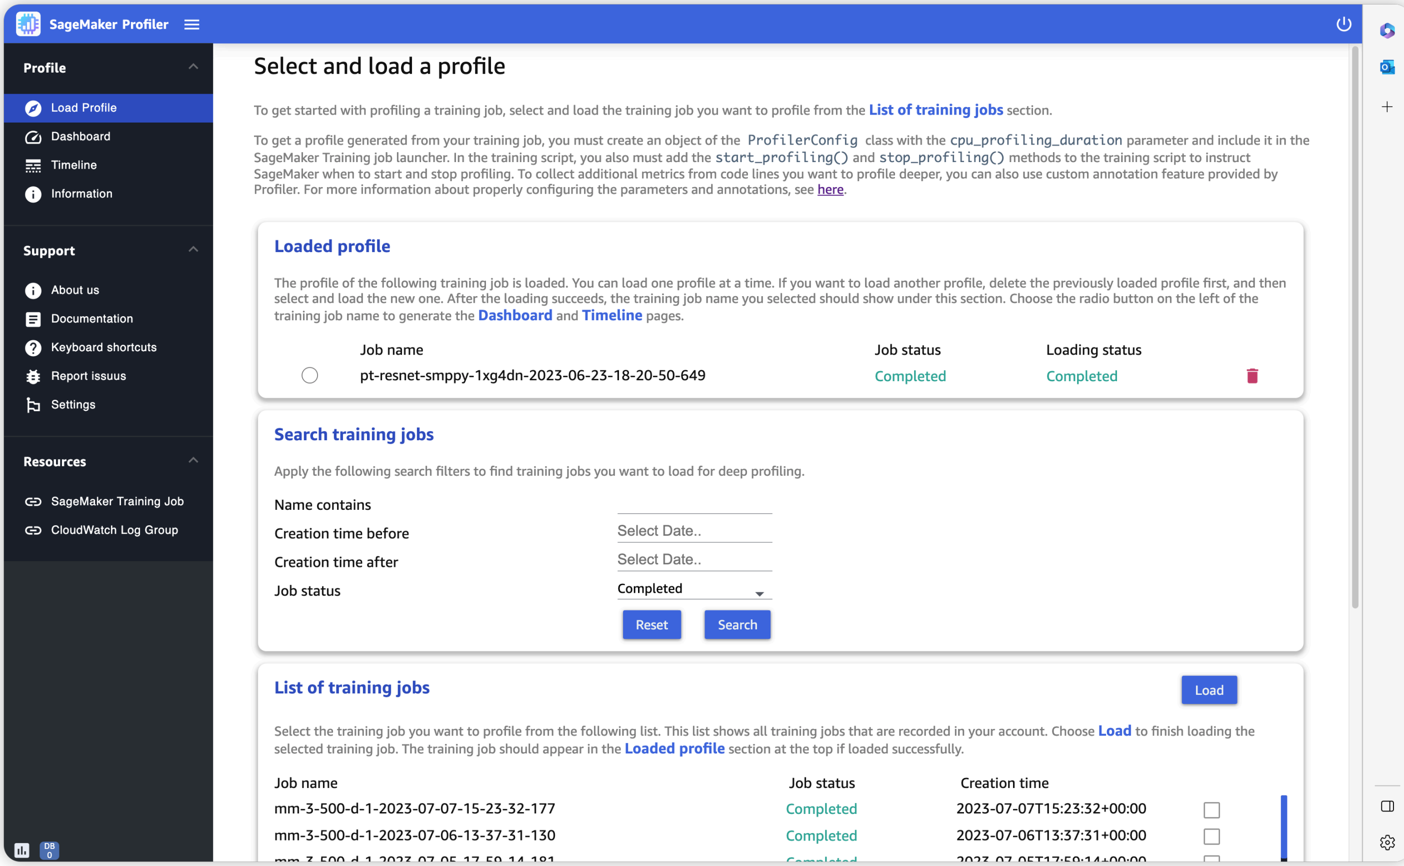
Load profile

When you open the SageMaker Profiler UI, the **Load profile** page opens up. To load and generate the **Dashboard** and **Timeline**, go through the following procedure.

To load the profile of a training job

1. From the **List of training jobs** section, use the check box to choose the training job for which you want to load the profile.
2. Choose **Load**. The job name should appear in the **Loaded profile** section at the top.
3. Choose the radio button on the left of the **Job name** to generate the **Dashboard** and **Timeline**. Note that when you choose the radio button, the UI automatically opens the **Dashboard**. Note also that if you generate the visualizations while the job status and loading status still appear to be in progress, the SageMaker Profiler UI generates **Dashboard** plots and a **Timeline** up to the most recent profile data collected from the ongoing training job or the partially loaded profile data.

> **Tip**
>
> You can load and visualize one profile at a time. To load another profile, you must first unload the previously loaded profile. To unload a profile, use the trash bin icon on the right end of the profile in the **Loaded profile** section.



Dashboard

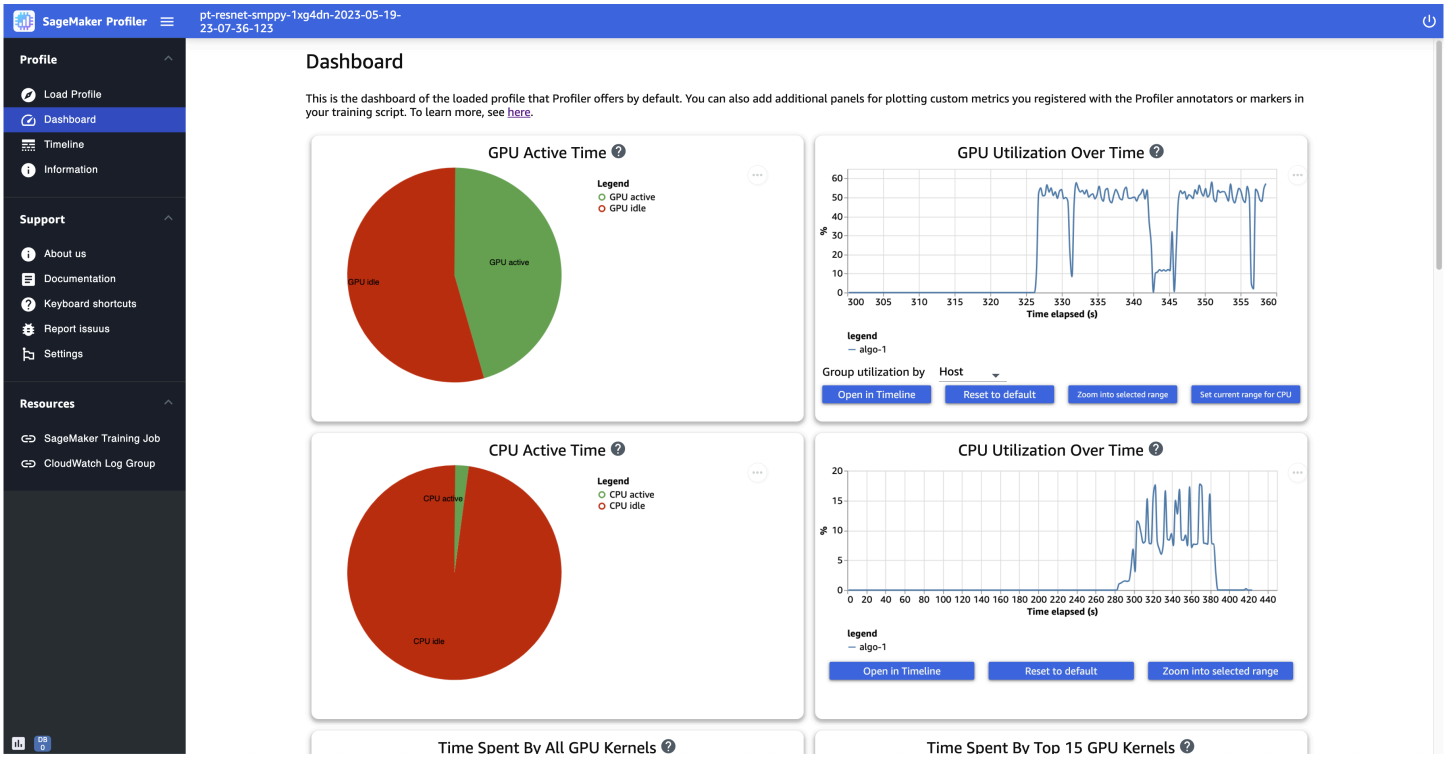
After you finish loading and selecting the training job, the UI opens the **Dashboard** page furnished with the following panels by default.

- **GPU active time** – This pie chart shows the percentage of GPU active time versus GPU idle time. You can check if your GPUs are more active than idle throughout the entire training job. GPU active time is based on the profile data points with a utilization rate greater than 0%, whereas GPU idle time is the profiled data points with 0% utilization.
- **GPU utilization over time** – This timeline graph shows the average GPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the GPUs have an unbalanced workload, under-utilization issues, bottlenecks, or idle issues during certain time intervals. To track the utilization rate at the individual GPU level and related kernel runs, use the the section called "Timeline interface". Note that the GPU activity collection starts from where you added the profiler starter function `SMProf.start_profiling()` in your training script, and stops at `SMProf.stop_profiling()`.

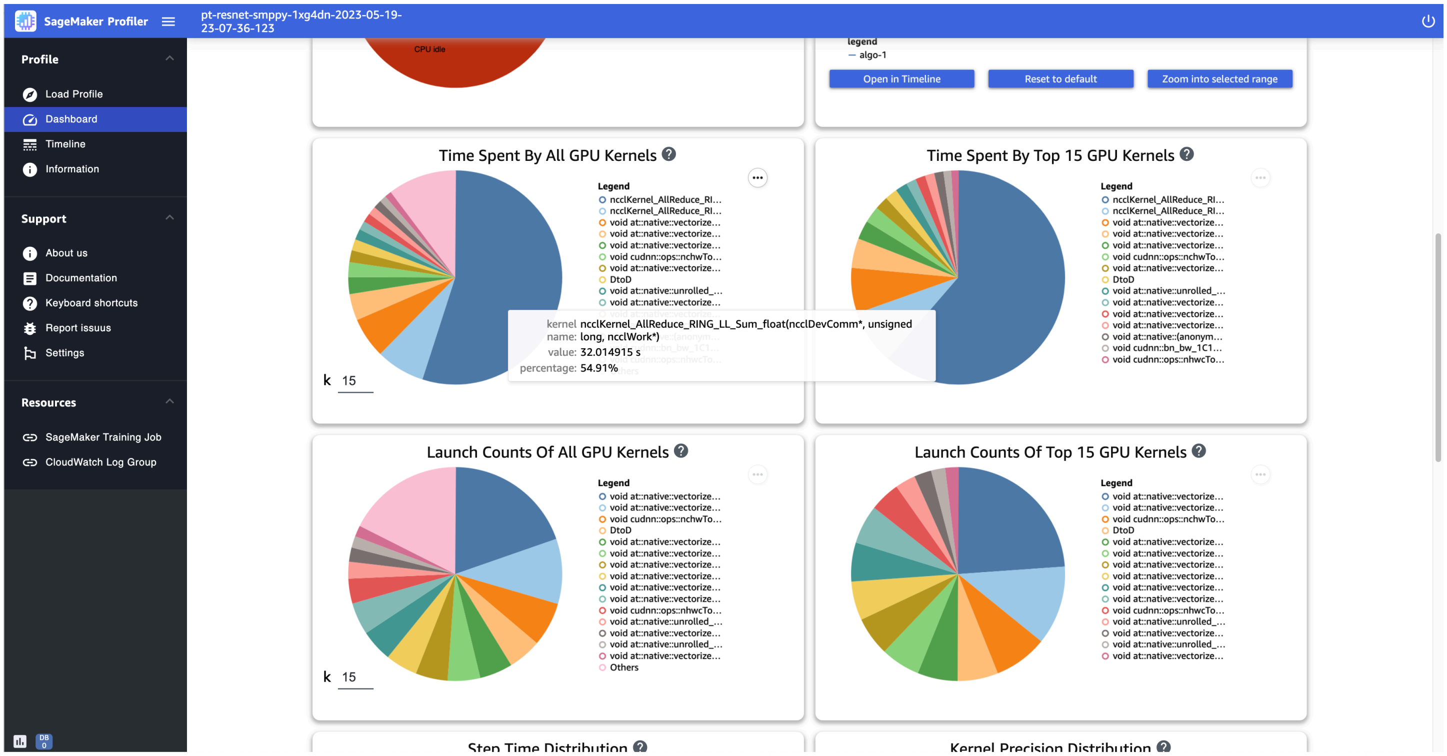
- **CPU active time –** This pie chart shows the percentage of CPU active time versus CPU idle time. You can check if your CPUs are more active than idle throughout the entire training job. CPU active time is based on the profiled data points with a utilization rate greater than 0%, whereas CPU idle time is the profiled data points with 0% utilization.
- **CPU utilization over time –** This timeline graph shows the average CPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the CPUs are bottlenecked or underutilized during certain time intervals. To track the utilization rate of the CPUs aligned with the individual GPU utilization and kernel runs, use the the section called "Timeline interface". Note that the utilization metrics start from the start from the job initialization.
- **Time spent by all GPU kernels –** This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels by default as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.
- **Time spent by top 15 GPU kernels –** This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels as individual sectors. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.
- **Launch counts of all GPU kernels –** This pie chart shows the number of counts for every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.
- **Launch counts of top 15 GPU kernels –** This pie chart shows the number of counts of every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.
- **Step time distribution –** This histogram shows the distribution of step durations on GPUs. This plot is generated only after you add the step annotator in your training script.
- **Kernel precision distribution –** This pie chart shows the percentage of time spent on running kernels in different data types such as FP32, FP16, INT32, and INT8.
- **GPU activity distribution –** This pie chart shows the percentage of time spent on GPU activities, such as running kernels, memory (`memcpy` and `memset`), and synchronization (`sync`).

- **GPU memory operations distribution** – This pie chart shows the percentage of time spent on GPU memory operations. This visualizes the `memcopy` activities and helps identify if your training job is spending excessive time on certain memory operations.
- **Create a new histogram** – Create a new diagram of a custom metric you annotated manually during the section called “Step 1: Adapt your training script using the SageMaker Profiler Python modules”. When adding a custom annotation to a new histogram, select or type the name of the annotation you added in the training script. For example, in the demo training script in Step 1, `step`, `Forward`, `Backward`, `Optimize`, and `Loss` are the custom annotations. While creating a new histogram, these annotation names should appear in the drop-down menu for metric selection. If you choose `Backward`, the UI adds the histogram of the time spent on backward passes throughout the profiled time to the **Dashboard**. This type of histogram is useful for checking if there are outliers taking abnormally longer time and causing bottleneck problems.

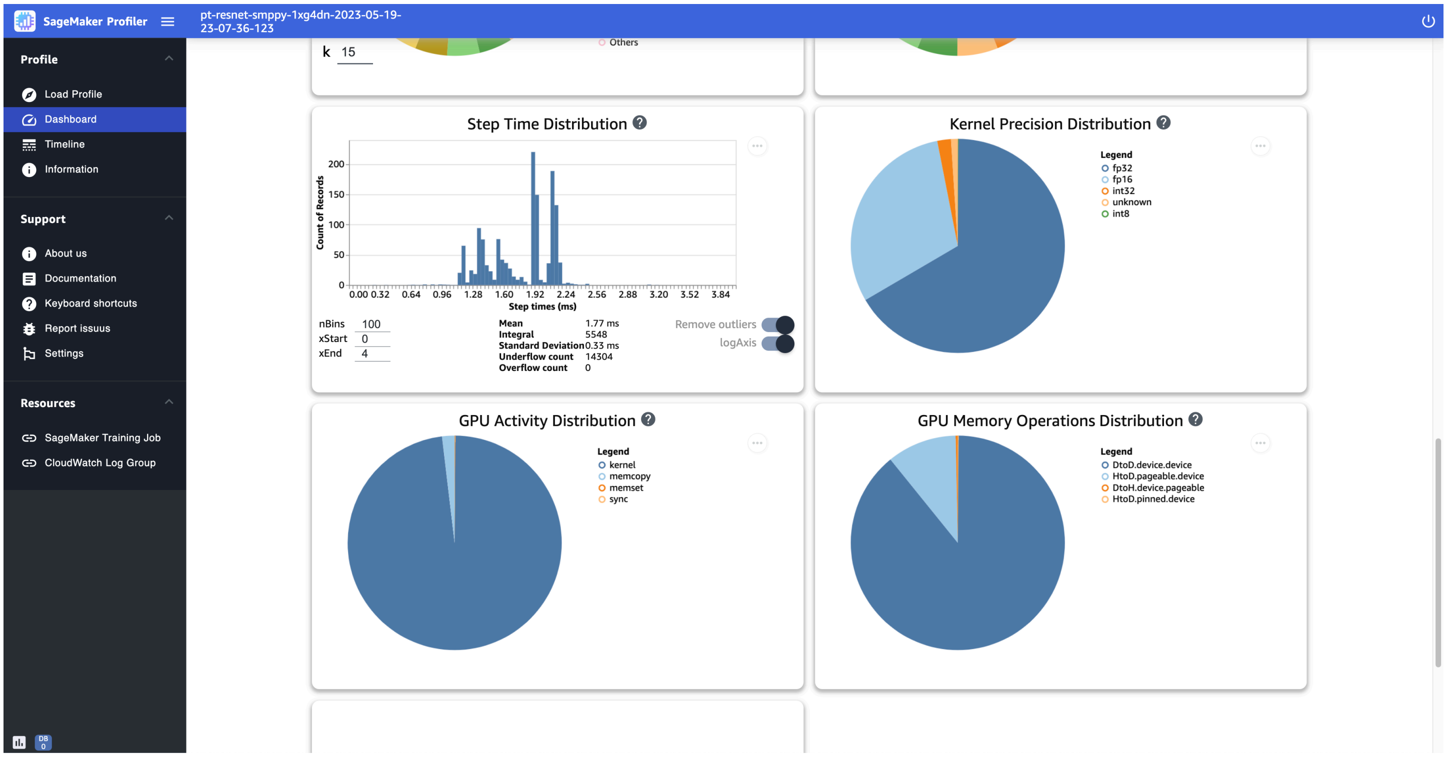
The following screenshots show the GPU and CPU active time ratio and the average GPU and CPU utilization rate with respect to time per compute node.



The following screenshot shows an example of pie charts for comparing how many times the GPU kernels are launched and measuring the time spent on running them. In the **Time spent by all GPU kernels** and **Launch counts of all GPU kernels** panels, you can also specify an integer to the input field for *k* to adjust the number of legend to show in the plots. For example, if you specify 10, the plots show the top 10 most run and launched kernels respectively.



The following screenshot shows an example of step time duration histogram, and pie charts for the kernel precision distribution, GPU activity distribution, and GPU memory operation distribution.



Timeline interface

To gain a detailed view into the compute resources at the level of operations and kernels scheduled on the CPUs and run on the GPUs, use the **Timeline** interface.

You can zoom in and out and pan left or right in the timeline interface using your mouse, the `[w, a, s, d]` keys, or the four arrow keys on the keyboard.

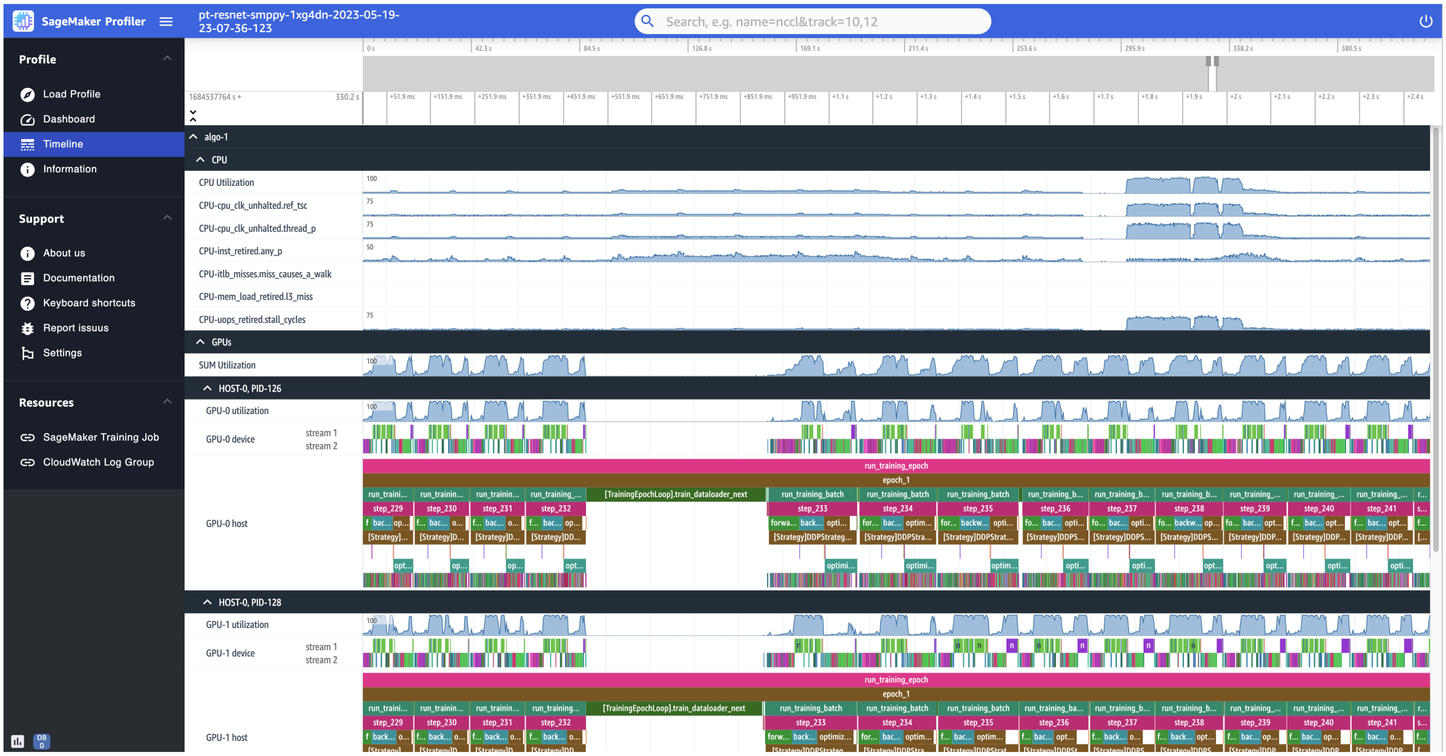
> **Tip**
>
> For more tips on the keyboard shortcuts to interact with the **Timeline** interface, choose **Keyboard shortcuts** in the left pane.

The timeline tracks are organized in a tree structure, giving you information from the host level to the device level. For example, if you run `N` instances with eight GPUs in each, the timeline structure of each instance would be as follows.

- **algo-i_{node}** – This is what SageMaker AI tags to assign jobs to provisioned instances. The digit i_{node} is randomly assigned. For example, if you use 4 instances, this section expands from **algo-1** to **algo-4**.
  - **CPU** – In this section, you can check the average CPU utilization rate and performance counters.
  - **GPUs** – In this section, you can check the average GPU utilization rate, individual GPU utilization rate, and kernels.
    - **SUM Utilization** – The average GPU utilization rates per instance.
    - **HOST-0 PID-123** – A unique name assigned to each process track. The acronym PID is the process ID, and the number appended to it is the process ID number that's recorded during data capture from the process. This section shows the following information from the process.
      - **GPU-i_{num_gpu} utilization** – The utilization rate of the i_{num_gpu}-th GPU over time.
      - **GPU-i_{num_gpu} device** – The kernel runs on the i_{num_gpu}-th GPU device.
        - **stream i_{cuda_stream}** – CUDA streams showing kernel runs on the GPU device. To learn more about CUDA streams, see the slides in PDF at CUDA C/C++ Streams and Concurrency provided by NVIDIA.
      - **GPU-i_{num_gpu} host** – The kernel launches on the i_{num_gpu}-th GPU host.

The following several screenshots show the **Timeline** of the profile of a training job run on `ml.p4d.24xlarge` instances, which are equipped with 8 NVIDIA A100 Tensor Core GPUs in each.

The following is a zoomed-out view of the profile, printing a dozen of steps including an intermittent data loader between `step_232` and `step_233` for fetching the next data batch.



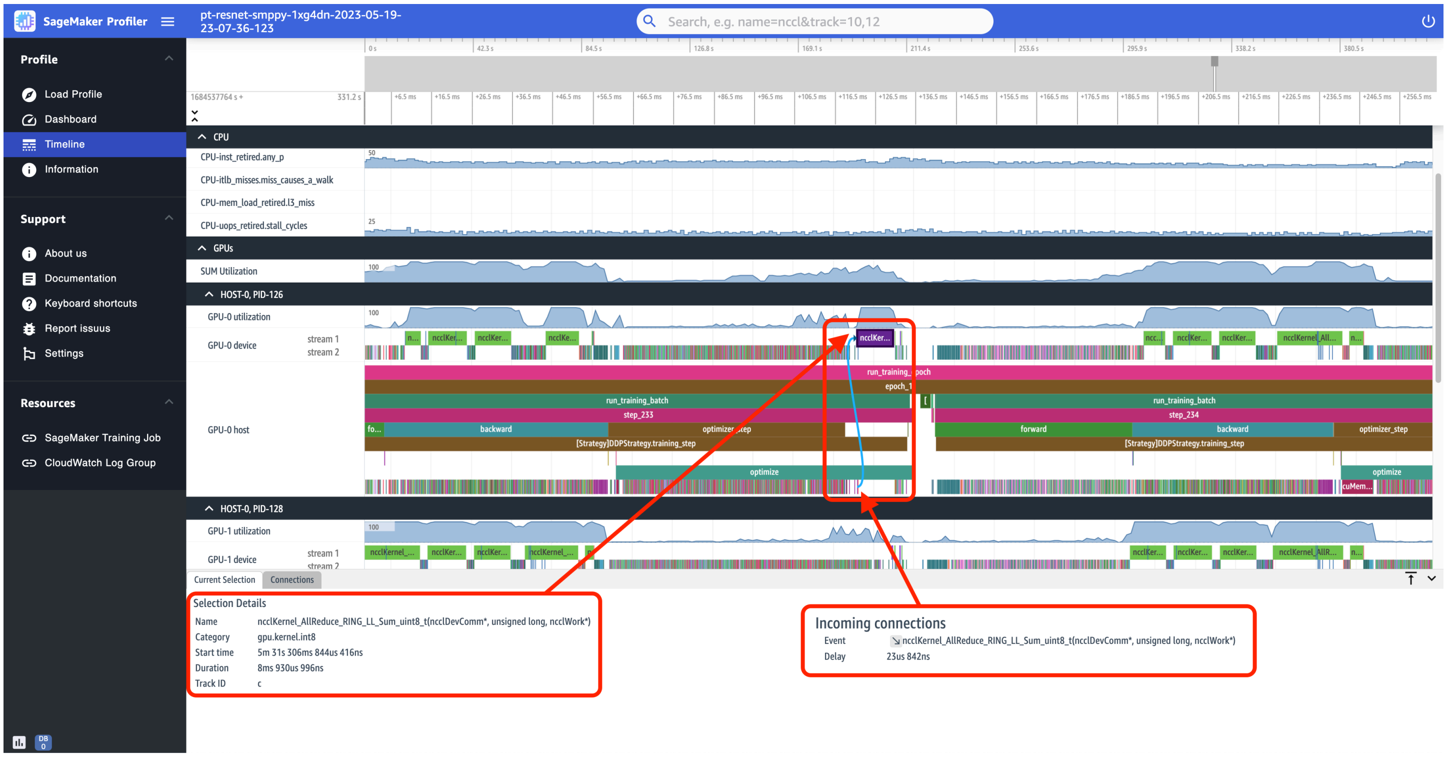
For each CPU, you can track the CPU utilization and performance counters, such as `"clk_unhalted_ref.tsc"` and `"itlb_misses.miss_causes_a_walk"`, which are indicative of instructions run on the CPU.

For each GPU, you can see a host timeline and a device timeline. Kernel launches are on the host timeline and kernel runs are on the device timeline. You can also see annotations (such as forward, backward, and optimize) if you have added in training script in the GPU host timeline.

In the timeline view, you can also track kernel launch-and-run pairs. This helps you understand how a kernel launch scheduled on a host (CPU) is run on the corresponding GPU device.

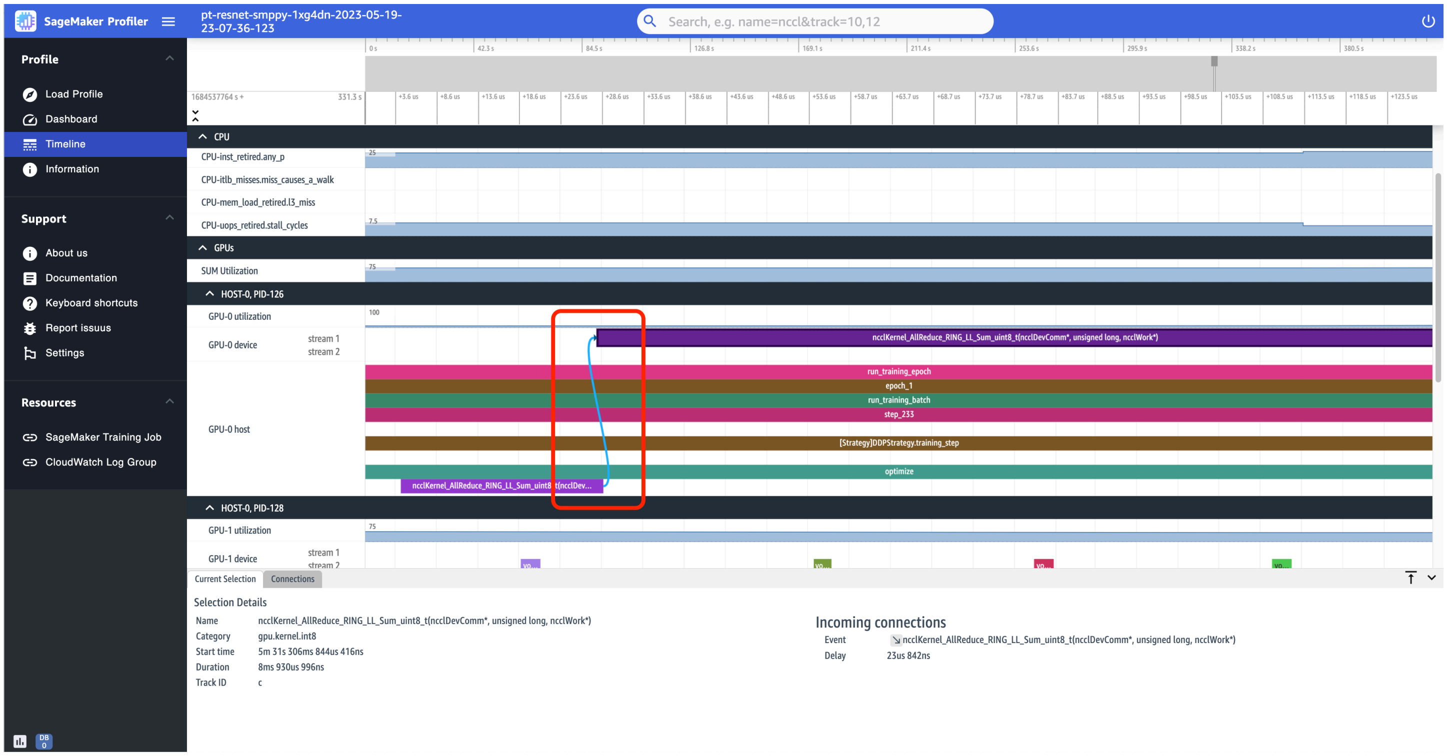
> **Tip**
>
> Press the `f` key to zoom into the selected kernel.

The following screenshot is a zoomed-in view into `step_233` and `step_234` from the previous screenshot. The timeline interval selected in the following screenshot is the `AllReduce` operation, an essential communication and synchronization step in distributed training, run on the GPU-0 device. In the screenshot, note that the kernel launch in the GPU-0 host connects to the kernel run in the GPU-0 device stream 1, indicated with the arrow in cyan color.



Also two information tabs appear in the bottom pane of the UI when you select a timeline interval, as shown in the previous screenshot. The **Current Selection** tab shows the details of the selected kernel and the connected kernel launch from the host. The connection direction is always from host (CPU) to device (GPU) since each GPU kernel is always called from a CPU. The **Connections** tab shows the chosen kernel launch and run pair. You can select either of them to move it to the center of the **Timeline** view.

The following screenshot zooms in further into the `AllReduce` operation launch and run pair.



Information

In **Information**, you can access information about the loaded training job, such as the instance type, Amazon Resource Names (ARNs) of compute resources provisioned for the job, node names, and hyperparameters.

Settings

The SageMaker AI Profiler UI application instance is configured to shut down after 2 hours of idle time by default. In **Settings**, use the following settings to adjust the auto shutdown timer.

- **Enable app auto shutdown** – Choose and set to **Enabled** to let the application automatically shut down after the specified number of hours of idle time. To turn off the auto-shutdown functionality, choose **Disabled**.
- **Auto shutdown threshold in hours** – If you choose **Enabled** for **Enable app auto shutdown**, you can set the threshold time in hours for the application to shut down automatically. This is set to 2 by default.

Troubleshooting for SageMaker Profiler

Use the following question-and-answer pairs to troubleshoot problems while using SageMaker Profiler.

Q. I'm getting an error message, `ModuleNotFoundError: No module named 'smppy'`

Since December 2023, the name of the SageMaker Profiler Python package has changed from `smppy` to `smprof` to resolve a duplicate package name issue; `smppy` is already used by an open source package.

Therefore, if you have been using `smppy` since before December 2023 and experiencing this `ModuleNotFoundError` issue, it might be due to the outdated package name in your training script while having the latested `smprof` package installed or using one of the latest the section called "SageMaker AI framework images pre-installed with SageMaker Profiler". In this case, make sure that you replace all mentions of `smppy` with `smprof` throughout your training script.

While updating the SageMaker Profiler Python package name in your training scripts, to avoid confusion around which version of the package name you should use, consider using a conditional import statement as shown in the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

Also note that if you have been using `smppy` while upgrading to the latest PyTorch or TensorFlow versions, make sure that you install the latest `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I'm getting an error message, `ModuleNotFoundError: No module named 'smprof'`

First, make sure that you use one of the officially supported SageMaker AI Framework Containers. If you don't use one of those, you can install the `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I'm not able to import `ProfilerConfig`

If you are unable to import `ProfilerConfig` in your job launcher script using the SageMaker Python SDK, your local environment or the Jupyter kernel might have a significantly outdated version of the SageMaker Python SDK. Make sure that you upgrade the SDK to the latest version.

```
$ pip install --upgrade sagemaker
```

Q. I'm getting an error message, `aborted: core dumped` when `importing smprof into my training script`

In an earlier version of `smprof`, this issue occurs with PyTorch 2.0+ and PyTorch Lightning. To resolve this issue, also install the latest `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I cannot find the SageMaker Profiler UI from SageMaker Studio. How can I find it?

If you have access to the SageMaker AI console, choose one of the following options.

- the section called "Option 1: Launch the SageMaker Profiler UI from the domain details page"
- the section called "Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker AI console"

If you are a domain user and don't have access to the SageMaker AI console, you can access the application through SageMaker Studio Classic. If this is your case, choose the following option.

- the section called "Option 3: Use the application launcher function in the SageMaker AI Python SDK"

Monitor AWS compute resource utilization in Amazon SageMaker Studio Classic

To track compute resource utilization of your training job, use the monitoring tools offered by Amazon SageMaker Debugger.

For any training job you run in SageMaker AI using the SageMaker Python SDK, Debugger collects basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time every 500 milliseconds. To see the dashbard of the resource utilization metrics of your training job, simply use the SageMaker Debugger UI in SageMaker Studio Experiments.

Deep learning operations and steps might operate in intervals of milliseconds. Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, Debugger provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals so you can dive deep into the metrics at the level of an operation or a step.

If you want to change the metric collection time interval, you can add a paramter for profiling configuration to your training job launcher. For example, if you're using the SageMaker AI Python SDK, you need to pass the `profiler_config` parameter when you create an estimator object. To learn how to adjust the resource utilization metric collection interval, see the section called "Code template for configuring a SageMaker AI estimator object with the SageMaker Debugger Python modules in the SageMaker AI Python SDK" and then the section called "Configure settings for basic profiling of system resource utilization".

Additionally, you can add issue detecting tools called *built-in profiling rules* provided by SageMaker Debugger. The built-in profiling rules run analysis against the resource utilization metrics and detect computational performance issues. For more information, see the section called "Use built-in profiler rules". You can receive rule analysis results through the SageMaker Debugger UI in SageMaker Studio Experiments or the SageMaker Debugger Profiling Report. You can also create custom profiling rules using the SageMaker Python SDK.

To learn more about monitoring functionalities provided by SageMaker Debugger, see the following topics.

Topics

Estimator configuration with parameters for basic profiling using the Amazon SageMaker Debugger Python modules

By default, SageMaker Debugger basic profiling is on by default and monitors resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, Network, and I/O wait time, of all SageMaker training jobs submitted using the Amazon SageMaker Python SDK. SageMaker Debugger collects these resource utilization metrics every 500 milliseconds. You don't need to make any additional changes in your code, training script, or the job launcher for tracking basic resource utilization. If you want to change the metric collection interval for basic profiling, you can specify Debugger-specific parameters while creating a SageMaker training job launcher using the SageMaker Python SDK, AWS SDK for Python (Boto3), or AWS Command Line Interface (CLI). In this guide, we focus on how to change profiling options using the Amazon SageMaker Python SDK. This page gives reference templates for configuring this estimator object.

If you want to access the resource utilization metrics dashboard of your training job in SageMaker Studio, you can jump onto the Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments.

If you want to activate the rules that detect system resource utilization problems automatically, you can add the `rules` parameter in the estimator object for activating the rules.

> **Important**
>
> To use the latest SageMaker Debugger features, you need to upgrade the SageMaker Python SDK and the `SMDebug` client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.
>
> ```
> import sys
> import IPython
> !{sys.executable} -m pip install -U sagemaker smdebug
> IPython.Application.instance().kernel.do_shutdown(True)
> ```

Code template for configuring a SageMaker AI estimator object with the SageMaker Debugger Python modules in the SageMaker AI Python SDK

To adjust the basic profiling configuration (`profiler_config`) or add the profiler rules (`rules`), choose one of the tabs to get the template for setting up a SageMaker AI estimator. In the subsequent pages, you can find more information about how to configure the two parameters.

Note

The following code examples are not directly executable. Proceed to the next sections to learn how to configure each parameter.

PyTorch

```
# An example of constructing a SageMaker AI PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.12.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

TensorFlow

```
# An example of constructing a SageMaker AI TensorFlow estimator
import boto3
```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.8.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```
# An example of constructing a SageMaker AI MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
```

```
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

Note

For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

XGBoost

```
# An example of constructing a SageMaker AI XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
```

```
)

estimator.fit(wait=False)
```

> **Note**
>
> For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

Generic estimator

```
# An example of constructing a SageMaker AI generic estimator using the XGBoost
 algorithm base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule,
 ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)
```

```
estimator.fit(wait=False)
```

The following provides brief descriptions of the parameters.

- `profiler_config` – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. You can set how frequently or loosely collect the system metrics. To learn how to configure the `profiler_config` parameter, see Configure settings for basic profiling of system resource utilization and Estimator configuration for framework profiling.
- `rules` – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in parallel. Make sure that your training job has access to this S3 bucket. The rules runs on processing containers and automatically analyze your training job to find computational and operational performance issues. The ProfilerReport rule is the most integrated rule that runs all built-in profiling rules and saves the profiling results as a report into your secured S3 bucket. To learn how to configure the `rules` parameter, see Use built-in profiler rules managed by Amazon SageMaker Debugger.

Note

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are three subfolders created by Debugger: `debug-output`, `profiler-output`, and `rule-output`. You can also retrieve the default S3 bucket URIs using the SageMaker AI estimator classmethods.

See the following topics to find out how to configure the Debugger-specific parameters in detail.

Topics

- Configure settings for basic profiling of system resource utilization
- Estimator configuration for framework profiling
- Updating Debugger system monitoring and framework profiling configuration while a training job is running
- Turn off Debugger

Configure settings for basic profiling of system resource utilization

To adjust the time interval for collecting the utilization metrics, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker AI framework or generic estimator depending on your preference.

> **Note**
>
> By default, for all SageMaker training jobs, Debugger collects resource utilization metrics from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker AI estimators.
> Debugger saves the system metrics in the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following code example shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open the Amazon SageMaker Debugger Insights dashboard.

Estimator configuration for framework profiling

> **Warning**
>
> In favor of Amazon SageMaker Profiler, SageMaker AI Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

See also March 16, 2023.

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

Note

Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported frameworks and algorithms.

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

Topics

- Default framework profiling
- Default system monitoring and customized framework profiling for target steps or a target time range
- Default system monitoring and customized framework profiling with different profiling options

Default framework profiling

Debugger framework default profiling includes the following options: detailed profiling, data loader profiling, and Python profiling. The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)
```

With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Default system monitoring and customized framework profiling with different profiling options and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

Default system monitoring and customized framework profiling for target steps or a target time range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
)
```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
)
```

- **For a target time range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
 duration=600)
)
```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```

```
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
 duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

Default system monitoring and customized framework profiling with different profiling options

This section gives information about the supported profiling configuration classes, as well as an example configuration. You can use the following profiling configuration classes to manage the framework profiling options:

- DetailedProfilingConfig – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  > **Note**
  >
  > Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- DataloaderProfilingConfig – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

> **Note**
>
> Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps.
>
> Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- PythonProfilingConfig – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
  - *cProfile* – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.
  - *Pyinstrument* – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

> **Note**
>
> Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling

increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```
import time
from sagemaker.debugger import (ProfilerConfig,
                                FrameworkProfile,
                                DetailedProfilingConfig,
                                DataloaderProfilingConfig,
                                PythonProfilingConfig,
                                PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see DetailedProfilingConfig, DataloaderProfilingConfig, and PythonProfilingConfig in the Amazon SageMaker Python SDK.

Updating Debugger system monitoring and framework profiling configuration while a training job is running

If you want to activate or update the Debugger monitoring configuration for a training job that is currently running, use the following SageMaker AI estimator extension methods:

- To activate Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

  ```
  estimator.enable_default_profiling()
  ```

  When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

  For more information, see estimator.enable_default_profiling in the Amazon SageMaker Python SDK.
- To update system monitoring configuration, use the following:

  ```
  estimator.update_profiler(
      system_monitor_interval_millis=500
  )
  ```

  For more information, see estimator.update_profiler in the Amazon SageMaker Python SDK.

Turn off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To turn off profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

> **Warning**
>
> If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

To turn off debugging, set the `debugger_hook_config` parameter to `False`.

> **Warning**
>
> If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```
estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker AI Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the estimator.disable_profiling and estimator.update_profiler classmethods in the Amazon SageMaker Python SDK documentation.

Use built-in profiler rules managed by Amazon SageMaker Debugger

The Amazon SageMaker Debugger built-in profiler rules analyze system metrics and framework operations collected during the training of a model. Debugger offers the `ProfilerRule` API operation that helps configure the rules to monitor training compute resources and operations and to detect anomalies. For example, the profiling rules can help you detect whether there are computational problems such as CPU bottlenecks, excessive I/O wait time, imbalanced workload across GPU workers, and compute resource underutilization. To see a full list of available built-in profiling rules, see List of Debugger built-in profiler rules. The following topics show how to use the Debugger built-in rules with default parameter settings and custom parameter values.

> **Note**
>
> The built-in rules are provided through Amazon SageMaker processing containers and fully managed by SageMaker Debugger at no additional cost. For more information about billing, see the Amazon SageMaker Pricing page.

Topics

- Use SageMaker Debugger built-in profiler rules with their default parameter settings
- Use Debugger built-in profiler rules with custom parameter values

Use SageMaker Debugger built-in profiler rules with their default parameter settings

To add SageMaker Debugger built-in rules in your estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the SageMaker Debugger built-in rules.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),
    ... # You can also append more debugging rules in the
 Rule.sagemaker(rule_configs.*()) format.
]
```

```
estimator=Estimator(
    ...
    rules=rules
)
```

For a complete list of available built-in rules, see List of Debugger built-in profiler rules.

To use the profiling rules and inspect the computational performance and progress of your training job, add the `ProfilerReport` rule of SageMaker Debugger. This rule activates all built-in rules under the Debugger ProfilerRule `ProfilerRule` family. Furthermore, this rule generates an aggregated profiling report. For more information, see Profiling Report Generated Using SageMaker Debugger. You can use the following code to add the profiling report rule to your training estimator.

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.ProfilerReport())
]
```

When you start the training job with the `ProfilerReport` rule, Debugger collects resource utilization data every 500 milliseconds. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger rules.

Use Debugger built-in profiler rules with custom parameter values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` class methods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. For instruction on how to use the `CollectionConfig` class, see Configure tensor collections using the `CollectionConfig` API.

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be initiated.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger built-in profiler rules.

For more information about the Debugger rule class, methods, and parameters, see SageMaker AI Debugger Rule class in the Amazon SageMaker Python SDK.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
                "key": "value"
        }
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger built-in profiler rules.

For a low-level JSON configuration of the Debugger built-in rules using the `CreateTrainingJob` API, see Configure Debugger using SageMaker API.

List of Debugger built-in profiler rules

Use the Debugger built-in profiler rules provided by Amazon SageMaker Debugger and analyze metrics collected while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of running a performant training job. You can call the built-in profiler rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

> **Note**
>
> The maximum numbers of built-in profiler rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Profiler rules

The following rules are the Debugger built-in rules that are callable using the `ProfilerRule.sagemaker` classmethod.

Debugger built-in rule for generating the profiling report

Scope of Validity	Built-in Rules
Profiling Report for any SageMaker training job	• ProfilerReport

Debugger built-in rules for profiling hardware system resource utilization (system metrics)

Scope of Validity	Built-in Rules
Generic system monitoring rules for any SageMaker training job	• BatchSize • CPUBottleneck • GPUMemoryIncrease • IOBottleneck • LoadBalancing • LowGPUUtilization • OverallSystemUsage

Debugger built-in rules for profiling framework metrics

Scope of Validity	Built-in Rules
Profiling rules for deep learning frameworks (TensorFlow and PyTorch)	• MaxInitializationTime • OverallFrameworkMetrics • StepOutlier

Warning

In favor of Amazon SageMaker Profiler, SageMaker AI Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

See also March 16, 2023.

To use the built-in rules with default parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n())
]
```

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
```

```
rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInRuleName(),
        rule_parameters={
                "key": "value"
        }
    )
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger built-in rules example code.
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see Configure Debugger using SageMaker API.

ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

To explore what's in the profiler report, see SageMaker Debugger Profiling Report. Also, because this rule activates all of the profiling rules, you can also check the rule analysis status using the SageMaker Debugger UI in SageMaker Studio Experiments.

Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`<BuiltInRuleName>_<parameter_name>`	Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules. **Optional** Default value: None

BatchSize

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

Parameter Descriptions for the BatchSize Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`cpu_threshold_p95`	Defines the threshold for 95th quantile of CPU utilization in percentage. **Optional** Valid values: Integer Default value: `70` (in percentage)
`gpu_threshold_p95`	Defines the threshold for 95th quantile of GPU utilization in percentage. **Optional** Valid values: Integer Default value: `70` (in percentage)

Parameter Name	Description
`gpu_memory_threshold_p95`	Defines the threshold for 95th quantile of GPU memory utilization in percentage. **Optional** Valid values: Integer Default values: `70` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

CPUBottleneck

The CPUBottleneck rule helps detect if GPU is underutilized due to CPU bottlenecks. Rule returns True if number of CPU bottlenecks exceeds a predefined threshold.

Parameter Descriptions for the CPUBottleneck Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold for proportion of bottlenecked time to the total training time. If the proportion exceeds the percentage specified to the threshold parameter, the rule switches the rule status to True. **Optional** Valid values: Integer Default value: `50` (in percentage)
`gpu_threshold`	A threshold that defines low GPU utilization. **Optional** Valid values: Integer Default value: `10` (in percentage)
`cpu_threshold`	A threshold that defines high CPU utilization. **Optional** Valid values: Integer

Parameter Name	Description
	Default values: `90` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

GPUMemoryIncrease

The GPUMemoryIncrease rule helps detect a large increase in memory usage on GPUs.

Parameter Descriptions for the GPUMemoryIncrease Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`increase`	Defines the threshold for absolute memory increase. **Optional** Valid values: Integer Default value: `10` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

IOBottleneck

This rule helps to detect if GPU is underutilized due to data IO bottlenecks. Rule returns True if number of IO bottlenecks exceeds a predefined threshold.

Parameter Descriptions for the IOBottleneck Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold when Rule to return True. **Optional** Valid values: Integer Default value: `50` (in percentage)
`gpu_threshold`	A threshold that defines when GPU is considered underutilized. **Optional** Valid values: Integer Default value: `70` (in percentage)
`io_threshold`	A threshold that defines high IO wait time. **Optional** Valid values: Integer Default values: `50` (in percentage)

Parameter Name	Description
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `1000`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

LoadBalancing

The LoadBalancing rule helps detect issues in workload balancing among multiple GPUs.

Parameter Descriptions for the LoadBalancing Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String

Parameter Name	Description
threshold	Defines the workload percentage. **Optional** Valid values: Integer Default value: 0.5 (unitless proportion)
patience	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: 10
scan_interval_us	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: 60000000 (in microseconds)

LowGPUUtilization

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

Parameter Descriptions for the LowGPUUtilization Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_p95`	A threshold for 95th quantile below which GPU is considered to be underutilized. **Optional** Valid values: Integer Default value: `70` (in percentage)
`threshold_p5`	A threshold for 5th quantile. Default is 10 percent. **Optional** Valid values: Integer Default values: `10` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer

Parameter Name	Description
	Default values: `1000`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`scan_interval_us`	Time interval to scan timeline files. **Optional**

Parameter Name	Description
	Valid values: Integer Default values: `60000000` (in microseconds)

MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

Parameter Descriptions for the MaxInitializationTime Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold in minutes to wait for the first step to become available. **Optional** Valid values: Integer Default value: `20` (in minutes)
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

OverallFrameworkMetrics

The OverallFrameworkMetrics rule summarizes the time spent on framework metrics, such as forward and backward pass, and data loading.

Parameter Descriptions for the OverallFrameworkMetrics Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`scan_interval_us`	Time interval to scan timeline files. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

StepOutlier

The StepOutlier rule helps detect outliers in step durations. This rule returns `True` if there are outliers with step durations larger than `stddev` sigmas of the entire step durations in a time range.

Parameter Descriptions for the StepOutlier Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`stddev`	Defines a factor by which to multiply the standard deviation. For example, the rule is invoked by default when a step duration is larger or smaller than 5 times the standard deviation. **Optional** Valid values: Integer Default value: 5 (in minutes)
`mode`	Mode under which steps have been saved and on which Rule should run on. Per default rule will run on steps from EVAL and TRAIN phase **Optional** Valid values: Integer Default value: 5 (in minutes)
`n_outliers`	How many outliers to ignore before rule returns True **Optional** Valid values: Integer Default value: `10`

Parameter Name	Description
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments

Use the Amazon SageMaker Debugger Insights dashboard in Amazon SageMaker Studio Classic Experiments to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, GPU memory, network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio Classic UI or using the Amazon SageMaker Python SDK.

Important

If you're using an existing Studio Classic app, delete the app and restart to use the latest Studio Classic features. For instructions on how to restart and update your Studio Classic environment, see Update Amazon SageMaker AI Studio Classic.

Topics

- Open the Amazon SageMaker Debugger Insights dashboard
- Amazon SageMaker Debugger Insights dashboard controller
- Explore the Amazon SageMaker Debugger Insights dashboard
- Shut down the Amazon SageMaker Debugger Insights instance

Open the Amazon SageMaker Debugger Insights dashboard

In the SageMaker Debugger Insights dashboard in Studio Classic, you can see the compute resource utilization, resource utilization, and system bottleneck information of your training job that runs on Amazon EC2 instances in real time and after trainings

> **Note**
>
> The SageMaker Debugger Insights dashboard runs a Studio Classic application on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio Classic application remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

> **Important**
>
> When you are done using the SageMaker Debugger Insights dashboard, you must shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

To open the SageMaker Debugger Insights dashboard

1. On the Studio Classic **Home** page, choose **Experiments** in the left navigation pane.
2. Search your training job in the **Experiments** page. If your training job is set up with an Experiments run, the job should appear in the **Experiments** tab; if you didn't set up an Experiments run, the job should appear in the **Unassigned runs** tab.
3. Choose (click) the link of the training job name to see the job details.
4. Under the **OVERVIEW** menu, choose **Debuggger**. This should show the following two sections.

   - In the **Debugger rules** section, you can browse the status of the Debugger built-in rules associated with the training job.
   - In the **Debugger insights** section, you can find links to open SageMaker Debugger Insights on the dashboard.

5. In the **SageMaker Debugger Insights** section, choose the link of the training job name to open the SageMaker Debugger Insights dashboard. This opens a **Debug [your-training-job-name]** window. In this window, Debugger provides an overview of the computational performance of your training job on Amazon EC2 instances and helps you identify issues in compute resource utilization.

You can also download an aggregated profiling report by adding the built-in ProfilerReport rule of SageMaker Debugger. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.

Amazon SageMaker Debugger Insights dashboard controller

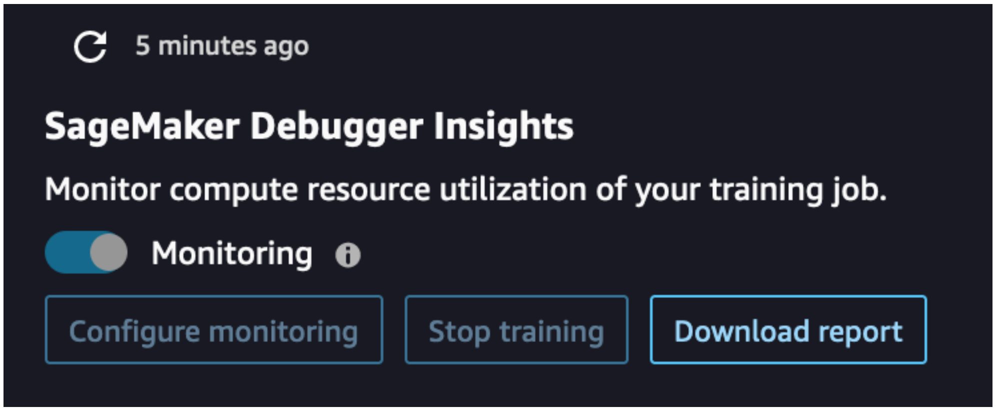
There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

> **Note**
>
> The SageMaker Debugger Insights dashboard runs a Studio Classic app on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio Classic app remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

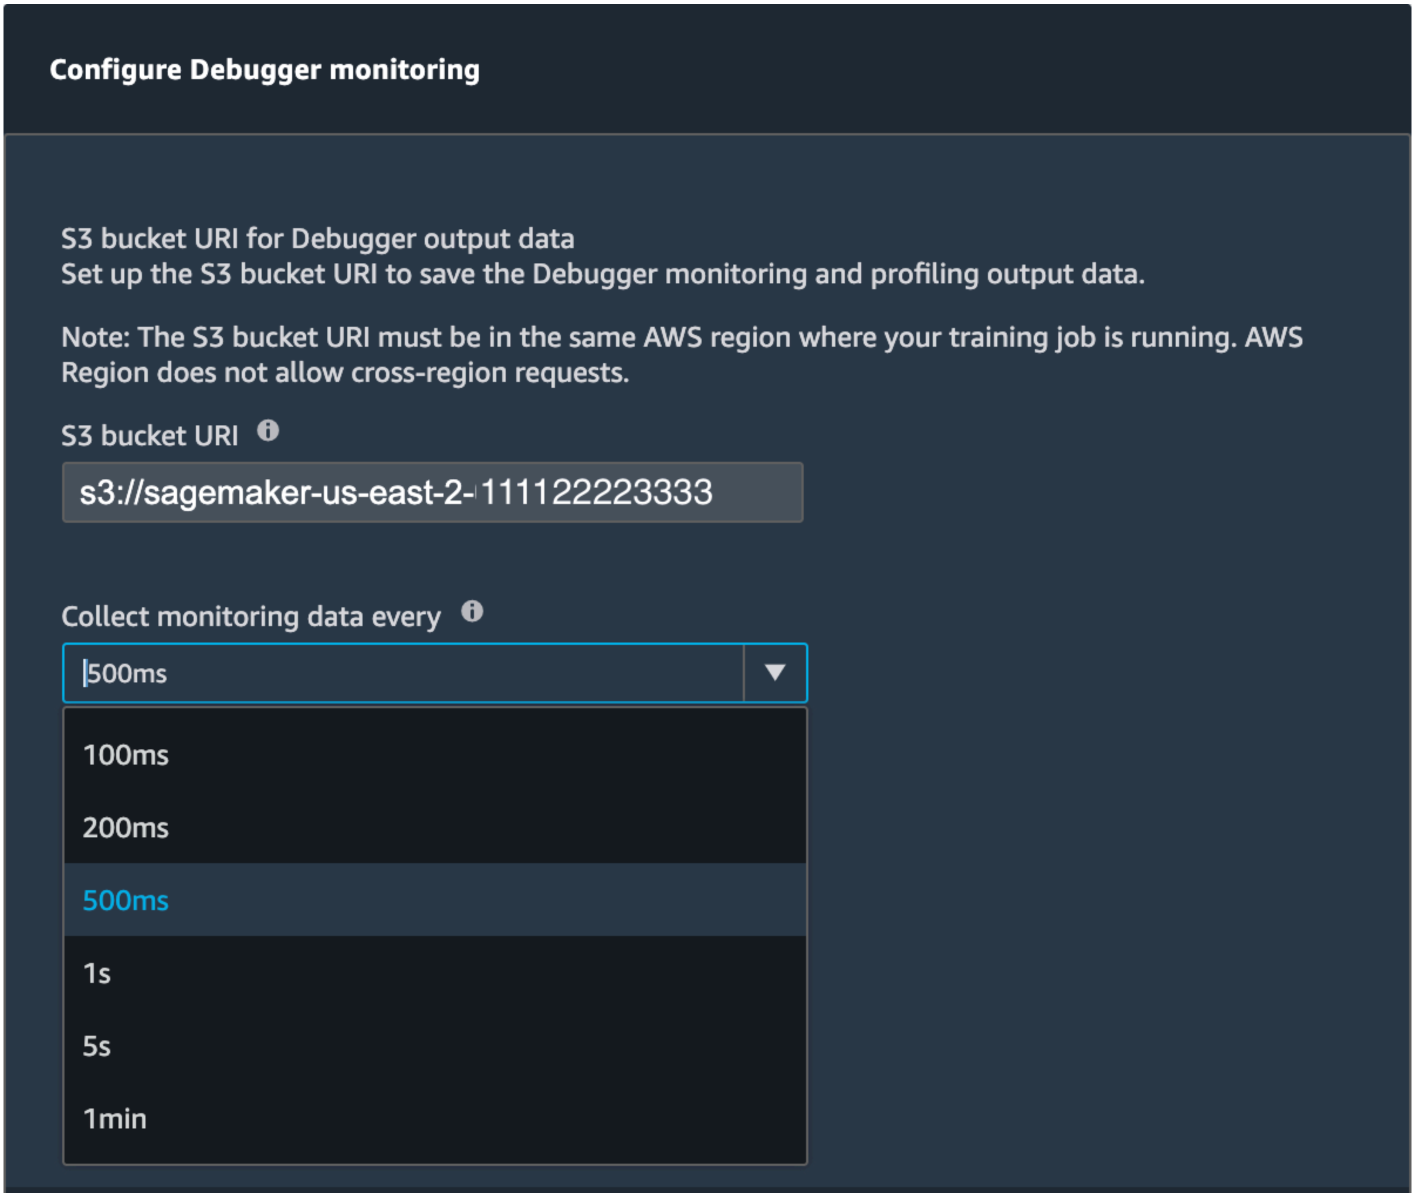
> **Important**
>
> When you are done using the SageMaker Debugger Insights dashboard, shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

SageMaker Debugger Insights controller UI

Using the Debugger controller located at the upper-left corner of the Insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics, stop a training job, and download a Debugger profiling report.



- If you want to manually refresh the dashboard, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- The **Monitoring** toggle button is on by default for any SageMaker training job initiated using the SageMaker Python SDK. If not activated, you can use the toggle button to start monitoring. During monitoring, Debugger only collects resource utilization metrics to detect computational problems such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see [Debugger built-in rules for profiling hardware system resource utilization (system metrics)](#).
- The **Configure monitoring** button opens a pop-up window that you can use to set or update the data collection frequency and the S3 path to save the data.



You can specify values for the following fields.

- **S3 bucket URI**: Specify the base S3 bucket URI.
- **Collect monitoring data every**: Select a time interval to collect system metrics. You can choose one of the monitoring intervals from the dropdown list. Available intervals are 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.

> **Note**
>
> If you choose one of the lower time intervals, you increase the granularity of resource utilization metrics, so you can capture spikes and anomalies with a higher time resolution. However, higher the resolution, larger the size of system metrics to

process. This might introduce additional overhead and impact the overall training and processing time.

- Using the **Stop training** button, you can stop the training job when you find anomalies in resource utilization.
- Using the **Download report** button, you can download an aggregated profiling report by using the built-in ProfilerReport rule of SageMaker Debugger. The button is activated when you add the built-in ProfilerReport rule to the estimator. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.

Explore the Amazon SageMaker Debugger Insights dashboard

When you initiate a SageMaker training job, SageMaker Debugger starts monitoring the resource utilization of the Amazon EC2 instances by default. You can track the system utilization rates, statistics overview, and built-in rule analysis through the Insights dashboard. This guide walks you through the content of the SageMaker Debugger Insights dashboard under the following tabs: **System Metrics** and **Rules**.

> **Note**
>
> The SageMaker Debugger Insights dashboard runs a Studio Classic application on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio Classic application remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

> **Important**
>
> When you are done using the SageMaker Debugger Insights dashboard, shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

> In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics

System metrics

In the **System Metrics** tab, you can use the summary table and timeseries plots to understand resource utilization.

Resource utilization summary

This summary table shows the statistics of compute resource utilization metrics of all nodes (denoted as algo-*n*). The resource utilization metrics include the total CPU utilization, the total GPU utilization, the total CPU memory utilization, the total GPU memory utilization, the total I/O wait time, and the total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.

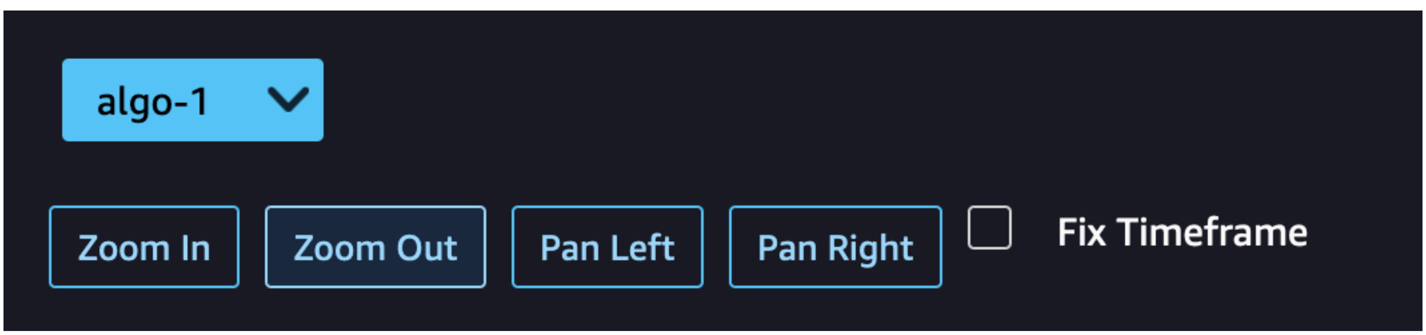
Node	Metric	Unit	Max	p99	p95	p50	Min
algo-1	Network	MB/s	37.82	33.68	32.83	12.39	0
algo-2	Network	MB/s	37.51	33.51	32.69	9.54	0
algo-1	GPU	%	69	20.61	18.27	6.81	0
algo-2	GPU	%	70	20.89	18.68	6.53	0
algo-1	CPU	%	100	94.58	78.95	51.71	0
algo-2	CPU	%	100	94.76	78.48	49.72	0
algo-1	CPU memory	%	5	4.98	4.92	4.16	1
algo-2	CPU memory	%	5	4.98	4.91	4.15	1
algo-1	GPU memory	%	32	9.6	7.71	2.27	0
algo-2	GPU memory	%	33	9.59	7.76	2.21	0
algo-1	I/O	%	100	20.41	0	0	0
algo-2	I/O	%	92	19.45	0	0	0

Resource utilization time series plots

Use the time series graphs to see more details of resource utilization and identify at what time interval each instance shows any undesired utilization rate, such as low GPU utilization and CPU bottlenecks that can cause a waste of the expensive instance.

The time series graph controller UI

The following screenshot shows the UI controller for adjusting the time series graphs.

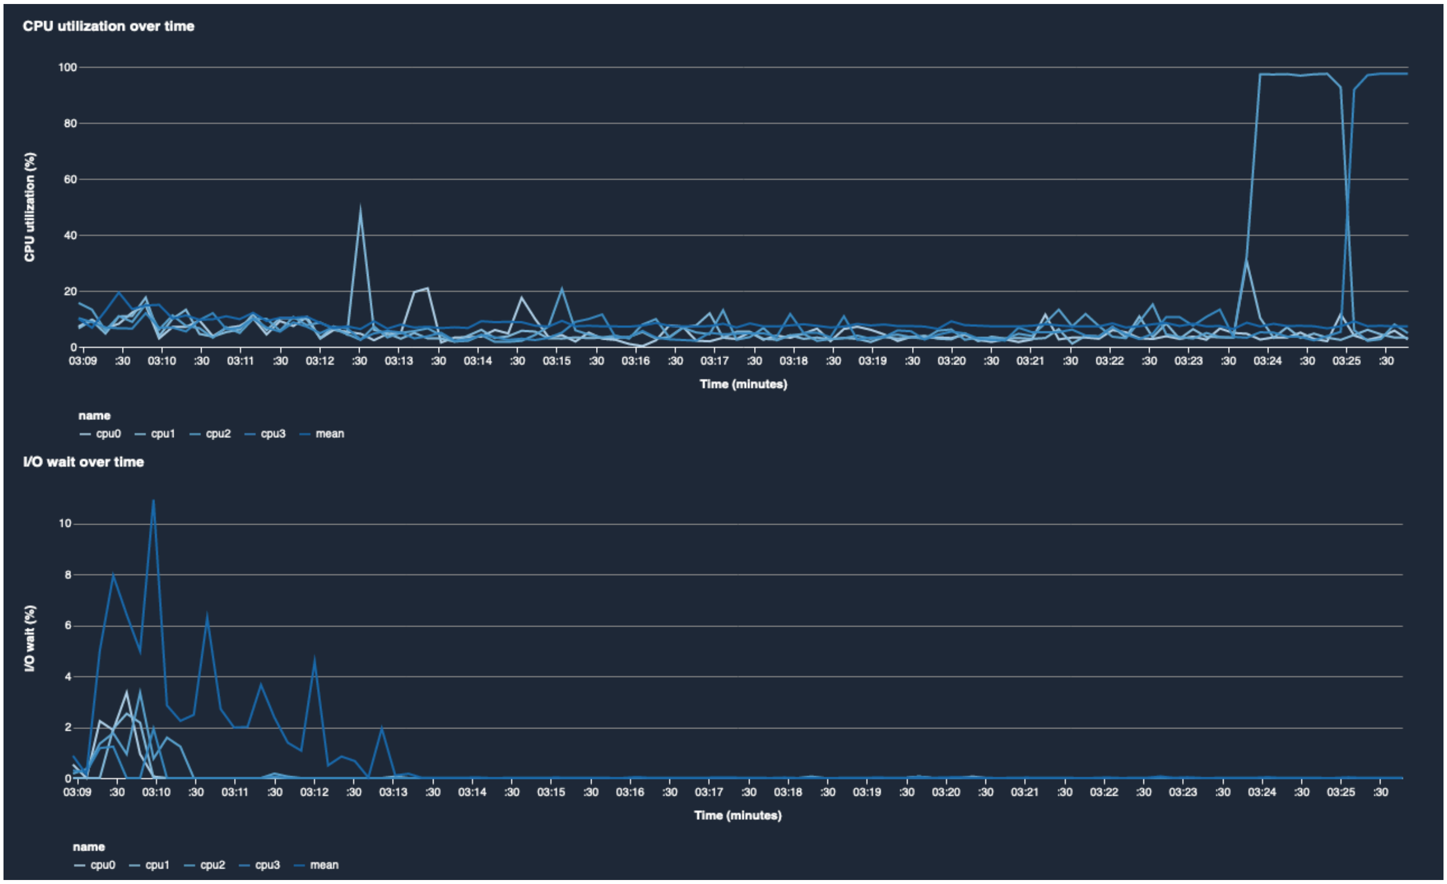


- **algo-1**: Use this dropdown menu to choose the node that you want to look into.
- **Zoom In**: Use this button to zoom in the time series graphs and view shorter time intervals.
- **Zoom Out**: Use this button to zoom out the time series graphs and view wider time intervals.
- **Pan Left**: Move the time series graphs to an earlier time interval.

- **Pan Right**: Move the time series graphs to a later time interval.
- **Fix Timeframe**: Use this check box to fix or bring back the time series graphs to show the whole view from the first data point to the last data point.

CPU utilization and I/O wait time

The first two graphs show CPU utilization and I/O wait time over time. By default, the graphs show the average of CPU utilization rate and I/O wait time spent on the CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. You can drag and zoom in and out to have a closer look at specific time intervals.

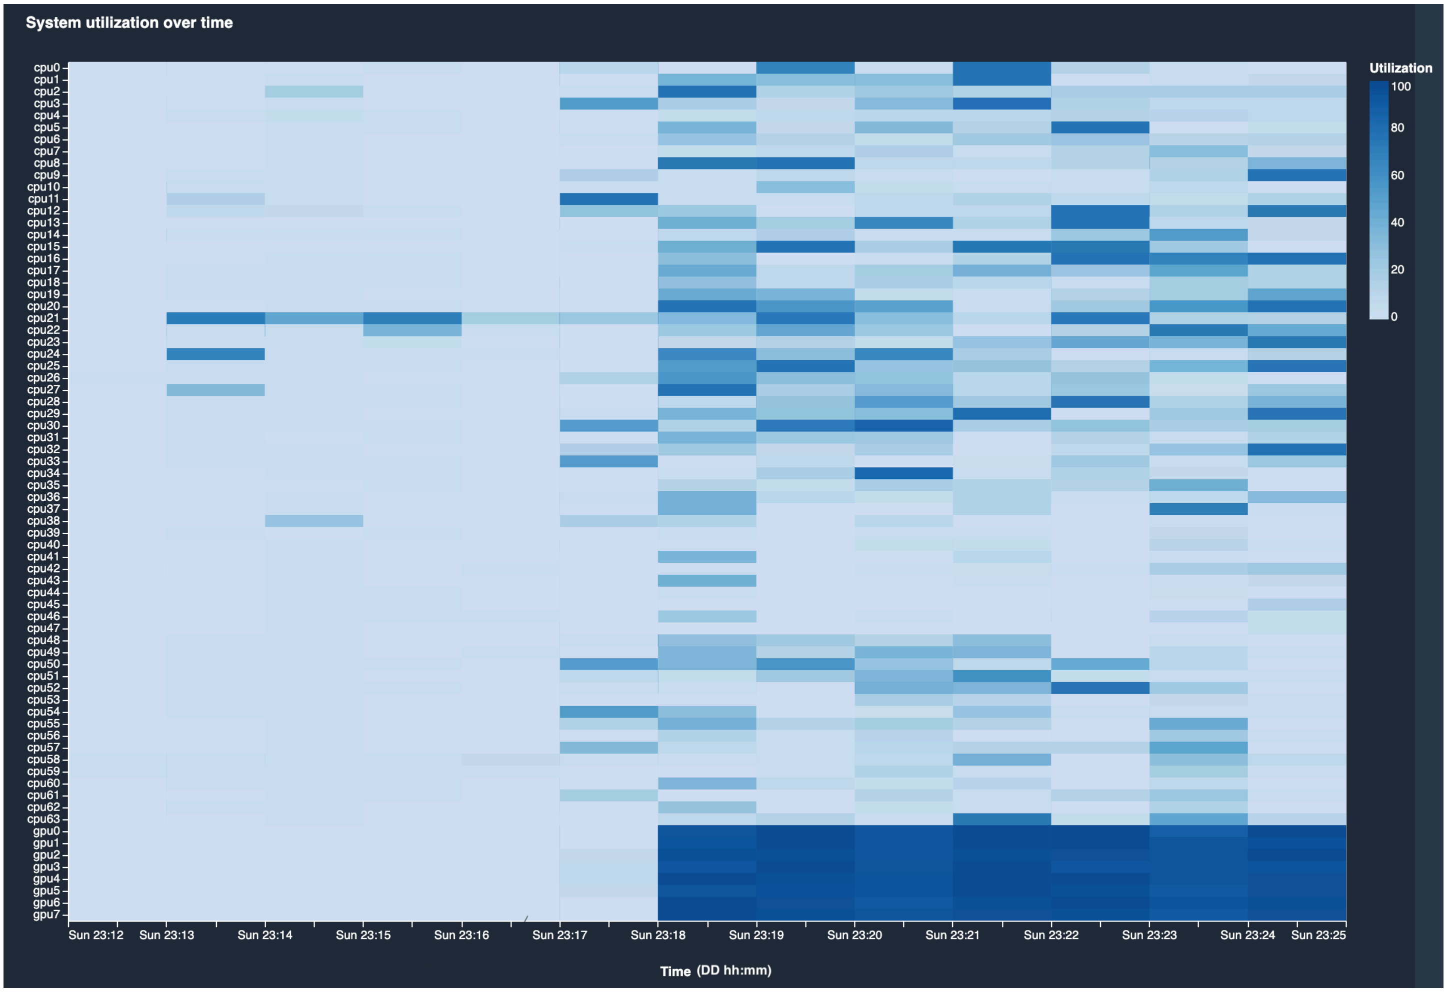


GPU utilization and GPU memory utilization

The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The following figure shows an example training job on an `ml.p3.16xlarge` instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.

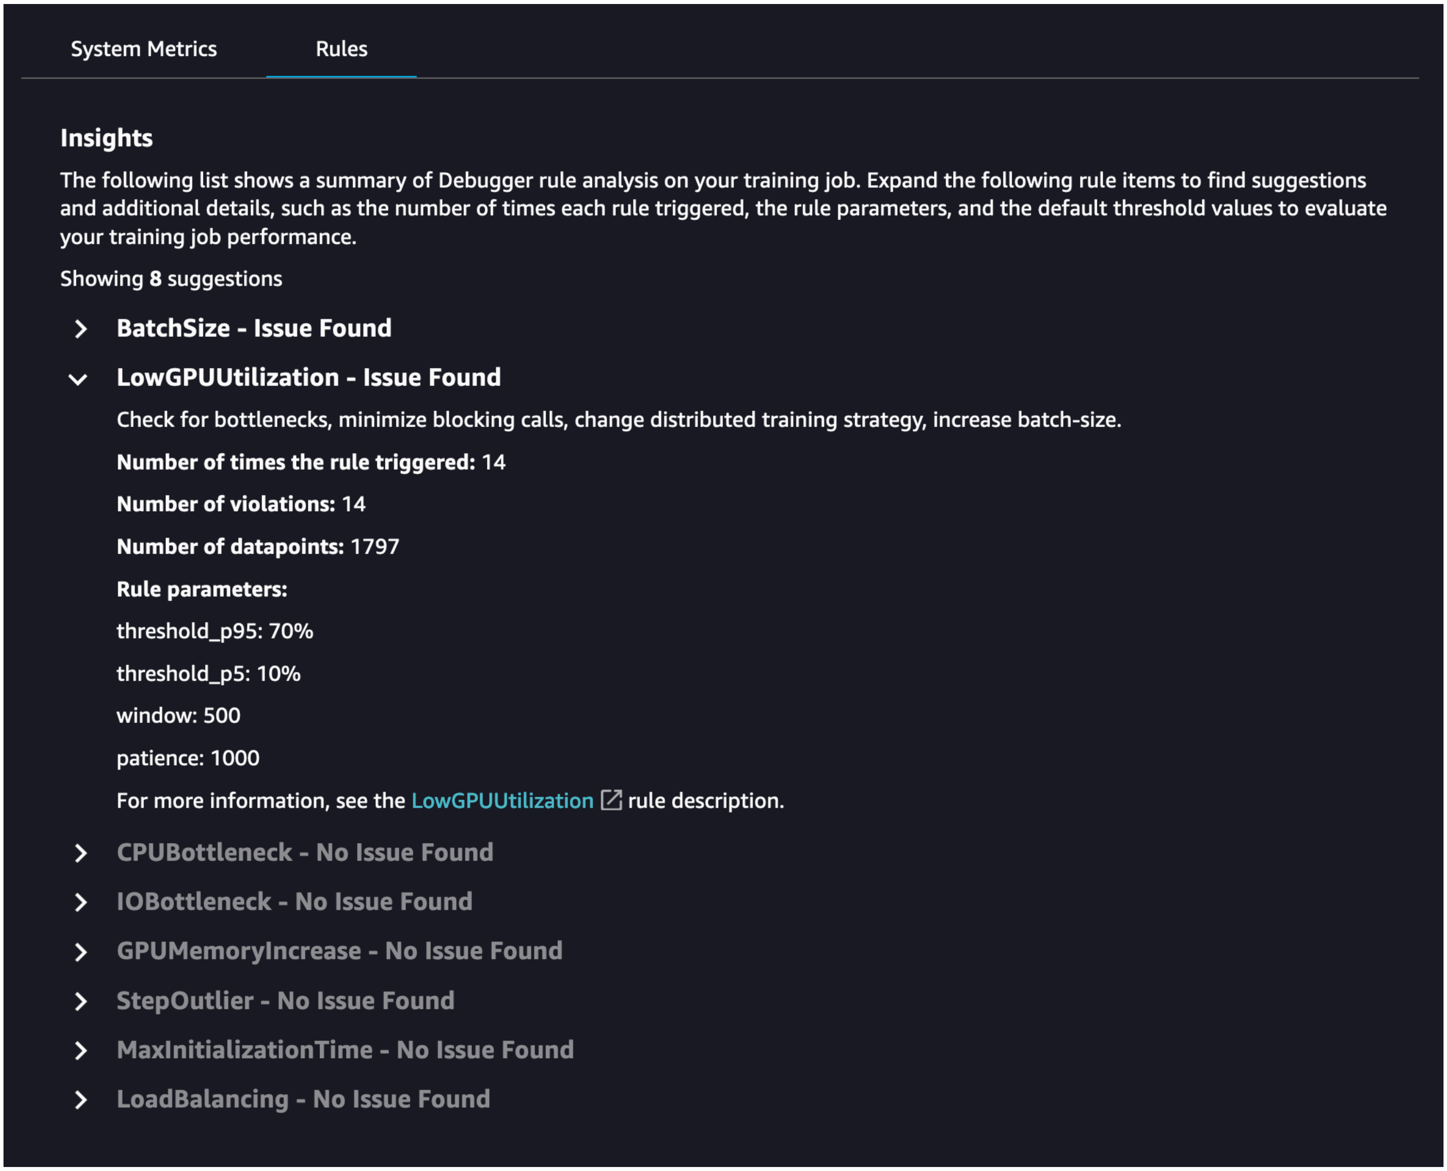
Overall system utilization over time

The following heatmap shows an example of the entire system utilization of an `ml.p3.16xlarge` instance over time, projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with a color scheme, where the bright colors represent low utilization and the darker colors represent high utilization. See the labeled color bar on the right side of the plot to find out which color level corresponds to which utilization rate.



Rules

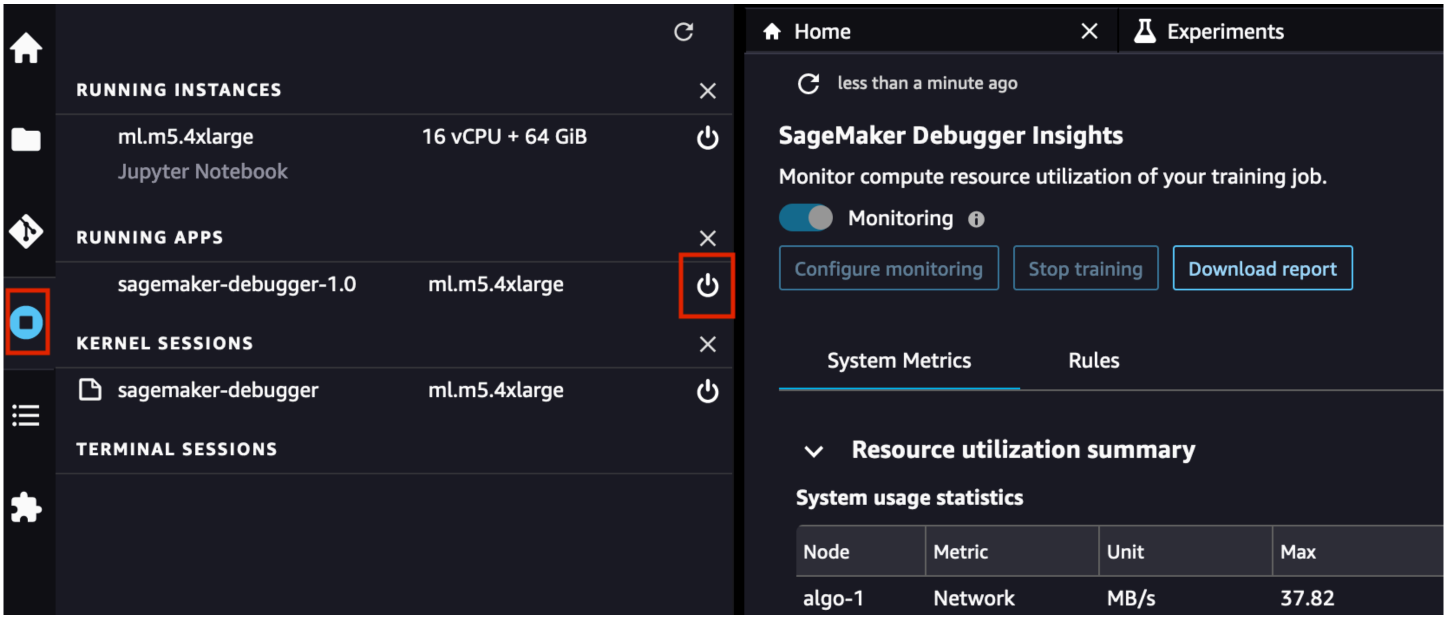
Use the **Rules** tab to find a summary of the profiling rule analysis on your training job. If the profiling rule is activated with the training job, the text appears highlighted with the solid white text. Inactive rules are dimmed in gray text. To activate these rules, follow instructions at the section called "Use built-in profiler rules".



Shut down the Amazon SageMaker Debugger Insights instance

When you are not using the SageMaker Debugger Insights dashboard, you should shut down the app instance to avoid incurring additional fees.

To shut down the SageMaker Debugger Insights app instance in Studio Classic



1. In Studio Classic, select the **Running Instances and Kernels** icon ( ).
2. Under the **RUNNING APPS** list, look for the **sagemaker-debugger-1.0** app. Select the shutdown icon ( ) next to the app. The SageMaker Debugger Insights dashboards run on an `ml.m5.4xlarge` instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the **sagemaker-debugger-1.0** app.

SageMaker Debugger interactive report

Receive profiling reports autogenerated by Debugger. The Debugger report provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger interactive report.

> **Note**
>
> You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the

current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

> **Important**
>
> In the reports, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

For any SageMaker training jobs, the SageMaker Debugger [ProfilerReport](#) rule invokes all of the [monitoring and profiling rules](#) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the [Amazon SageMaker Python SDK](#) or the S3 console, and learn what you can interpret from the profiling results.

> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Download the SageMaker Debugger profiling report

Download the SageMaker Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

> **Note**
>
> To get the profiling report generated by SageMaker Debugger, you must use the built-in ProfilerReport rule offered by SageMaker Debugger. To activate the rule with your training job, see Configure Built-in Profiler Rules.

> **Tip**
>
> You can also download the report with a single click in the SageMaker Studio Debugger insights dashboard. This doesn't require any additional scripting to download the report. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights dashboard.

Download using SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

```
estimator.output_path
```

2. Check the current job name.

```
estimator.latest_training_job.job_name
```

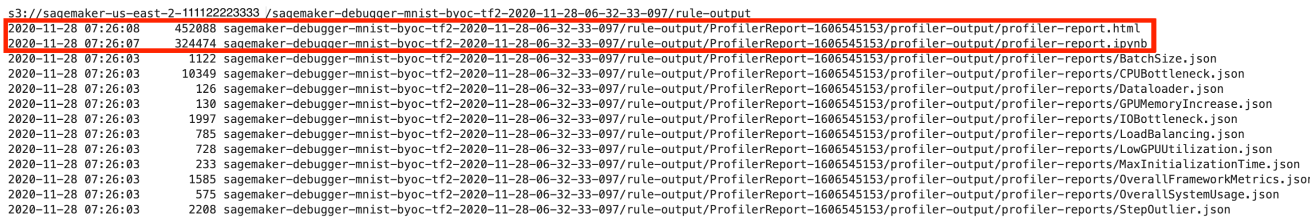
3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/<training-job-name>/rule-output`. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path +
 estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under an autogenerated folder that's named as `ProfilerReport-1234567890`. The folder name is a combination of strings: `ProfilerReport` and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.



```

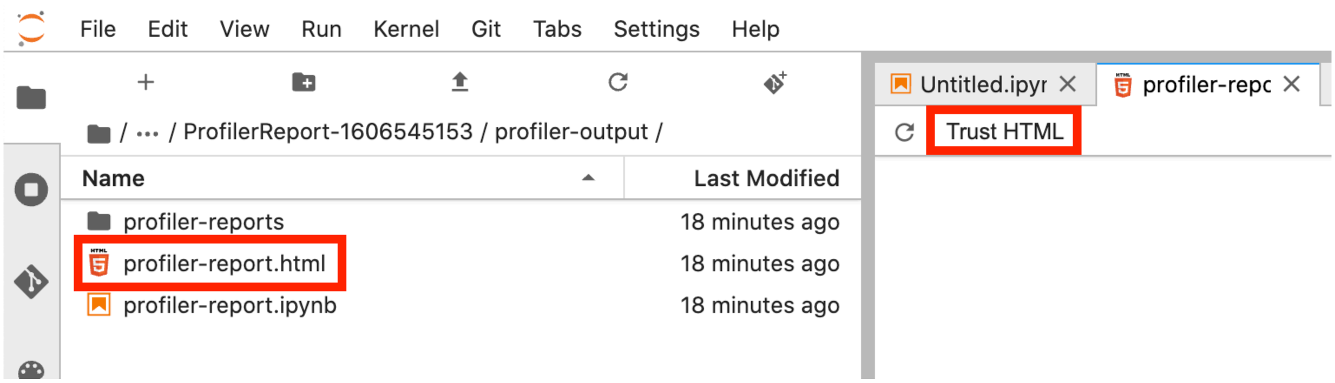
The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

> **Tip**
>
> If using a Jupyter notebook server, run `!pwd` to double check the current working directory.

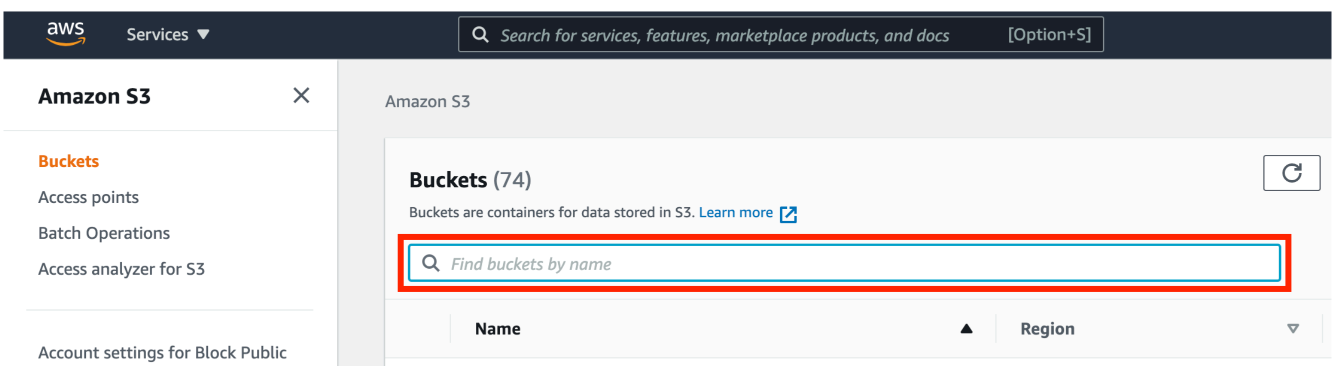
6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.html`. If using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger profiling report.



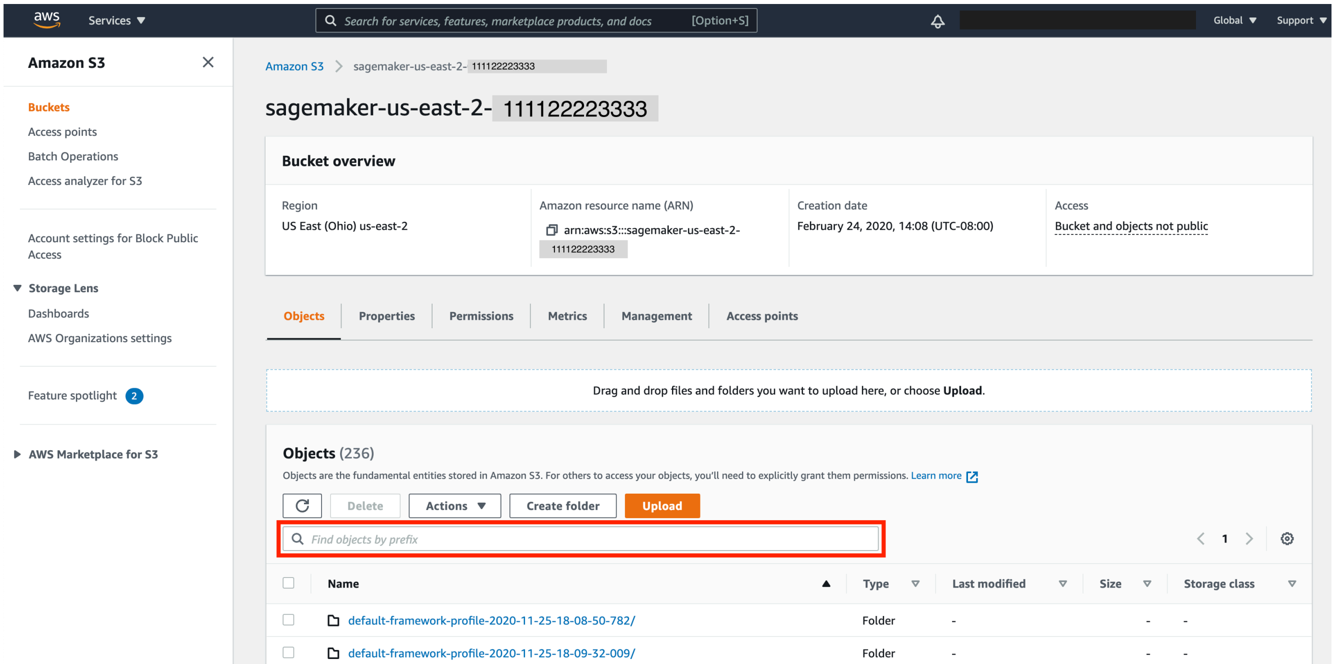
7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

Download using Amazon S3 Console

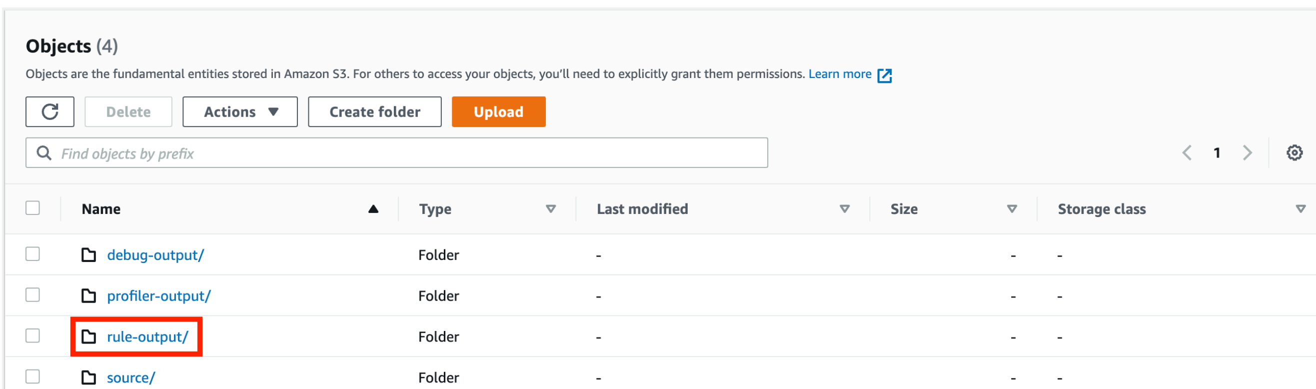
1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the *Find bucket by name* field.



3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the *Find objects by prefix* input field. Choose the training job name.



4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**. Choose **rule-output/**.



5. In the **rule-output/** folder, choose **ProfilerReport-1234567890**, and choose **profiler-output/** folder. The **profiler-output/** folder contains **profiler-report.html** (the autogenerated profiling report in html), **profiler-report.ipynb** (a Jupyter notebook with scripts that are used for generating the report), and a **profiler-report/** folder (contains rule analysis JSON files that are used as components of the report).

6. Select the **profiler-report.html** file, choose **Actions**, and **Download**.

7. Open the downloaded **profiler-report.html** file in a web browser.

> **Note**
>
> If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker AI estimators.
> To learn how to configure the `profiler_config` parameter before starting a training job, see Estimator configuration for framework profiling.
> To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration.

Debugger profiling report walkthrough

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

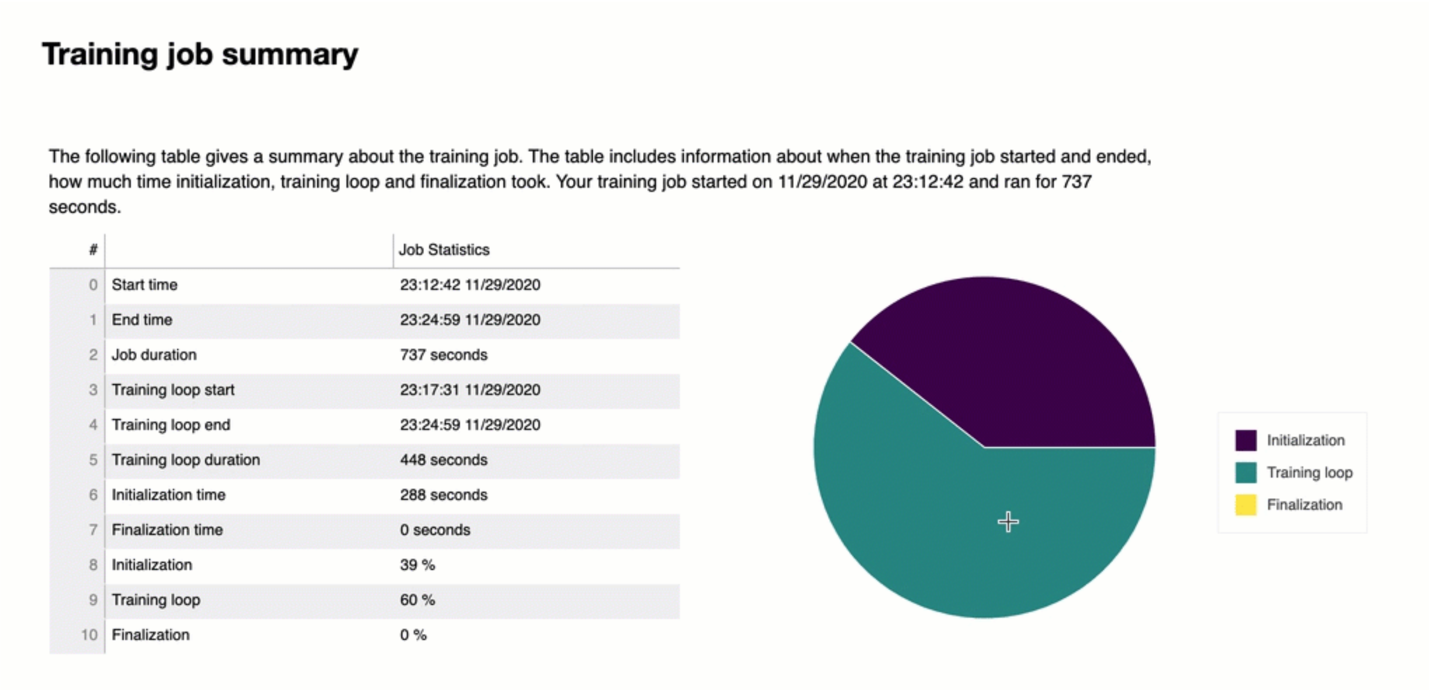
Topics

- Training job summary
- System usage statistics
- Framework metrics summary
- Rules summary
- Analyzing the training loop – step durations
- GPU utilization analysis

- Batch size
- CPU bottlenecks
- I/O bottlenecks
- Load balancing in multi-GPU training
- GPU memory analysis

Training job summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.



The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the **start_time** to the **end_time**.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.

- **initialization_in_seconds –** Time spent on initializing the training job. The initialization phase covers the period from the **start_time** to the **training_loop_start** time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds –** Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the **training_loop_end** time to the **end_time**.
- **initialization (%) –** The percentage of time spent on **initialization** over the total **job_duration_in_seconds**.
- **training loop (%) –** The percentage of time spent on **training loop** over the total **job_duration_in_seconds**.
- **finalization (%) –** The percentage of time spent on **finalization** over the total **job_duration_in_seconds**.

System usage statistics

In this section, you can see an overview of system utilization statistics.

System usage statistics

The 95th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also include total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p90 and p50 percentiles.

#	node	metric	unit	max	p99	p95	p50	min
0	algo-1	Network	bytes	218817581.57	168.02	0	0	0
10	algo-1	I/O	percentage	13.2653125	5.5928312500000	0.1955937499999	0	0
8	algo-1	GPU memory	percentage	32.25	26.25	21	0	0
2	algo-1	GPU	percentage	75	74.5	74.25	0	0
6	algo-1	CPU memory	percentage	5.05	5.01	4.98	2.17	0.55
4	algo-1	CPU	percentage	32.955625	22.6291312500000	17.034	3.7024999999999	0
1	algo-2	Network	bytes	4135.24	0	0	0	0
11	algo-2	I/O	percentage	20.1875	8.1552500000000	1.7478124999999	0	0
9	algo-2	GPU memory	percentage	38	31.75	21.75	0	0
3	algo-2	GPU	percentage	75	74.5	74.25	0	0
7	algo-2	CPU memory	percentage	5.05	5.02	4.99	2.17	0.55
5	algo-2	CPU	percentage	35.0043749999999	25.6999687500000	18.334296875	3.77828125	0

The Debugger profiling report includes the following information:

- **node –** Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of `algo-n`.
- **metric –** The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit –** The unit of the system metrics.
- **max –** The maximum value of each system metric.
- **p99 –** The 99th percentile of each system utilization.
- **p95 –** The 95th percentile of each system utilization.
- **p50 –** The 50th percentile (median) of each system utilization.
- **min –** The minimum value of each system metric.

Framework metrics summary

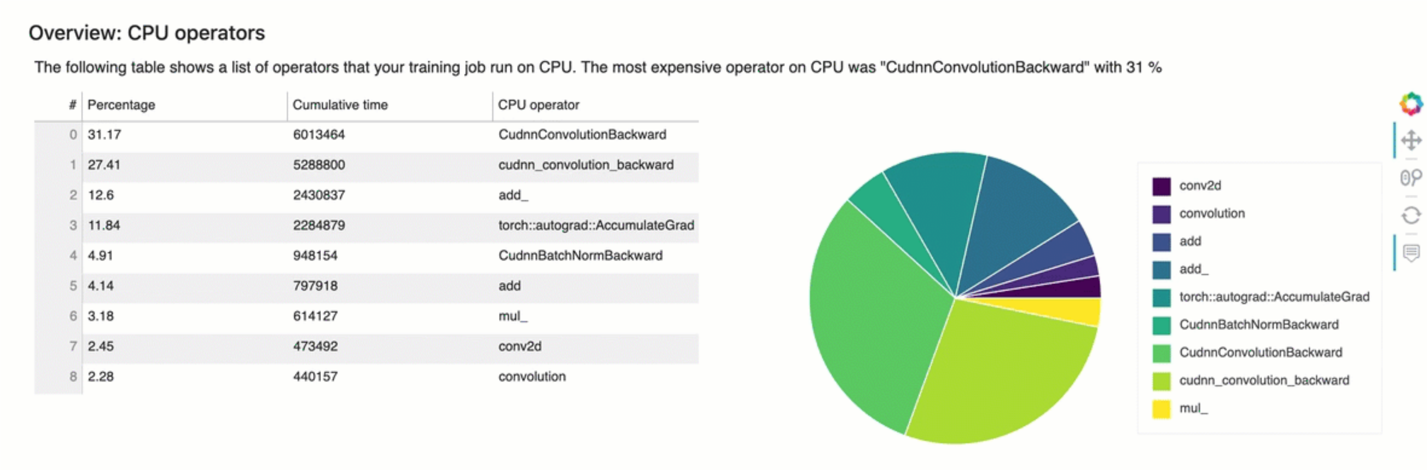
In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

Overview: CPU Operators

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.



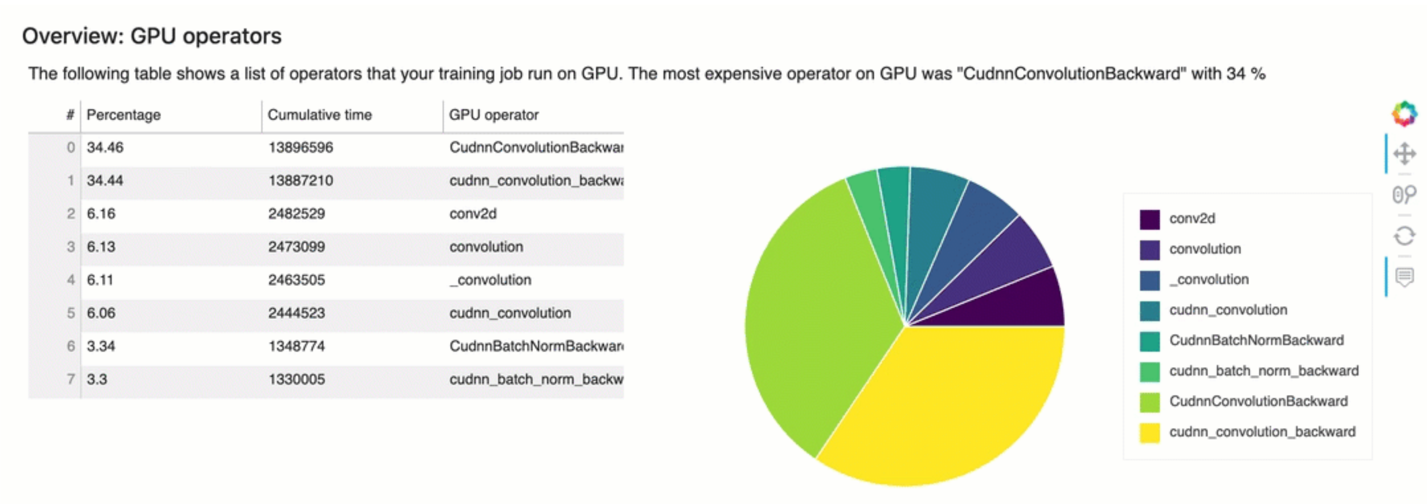
Overview: CPU operators

The following table shows a list of operators that your training job run on CPU. The most expensive operator on CPU was "CudnnConvolutionBackward" with 31 %

#	Percentage	Cumulative time	CPU operator
0	31.17	6013464	CudnnConvolutionBackward
1	27.41	5288800	cudnn_convolution_backward
2	12.6	2430837	add_
3	11.84	2284879	torch::autograd::AccumulateGrad
4	4.91	948154	CudnnBatchNormBackward
5	4.14	797918	add
6	3.18	614127	mul_
7	2.45	473492	conv2d
8	2.28	440157	convolution

Overview: GPU operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.



Overview: GPU operators

The following table shows a list of operators that your training job run on GPU. The most expensive operator on GPU was "CudnnConvolutionBackward" with 34 %

#	Percentage	Cumulative time	GPU operator
0	34.46	13896596	CudnnConvolutionBackwa
1	34.44	13887210	cudnn_convolution_backw
2	6.16	2482529	conv2d
3	6.13	2473099	convolution
4	6.11	2463505	_convolution
5	6.06	2444523	cudnn_convolution
6	3.34	1348774	CudnnBatchNormBackwar
7	3.3	1330005	cudnn_batch_norm_backw

Rules summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.

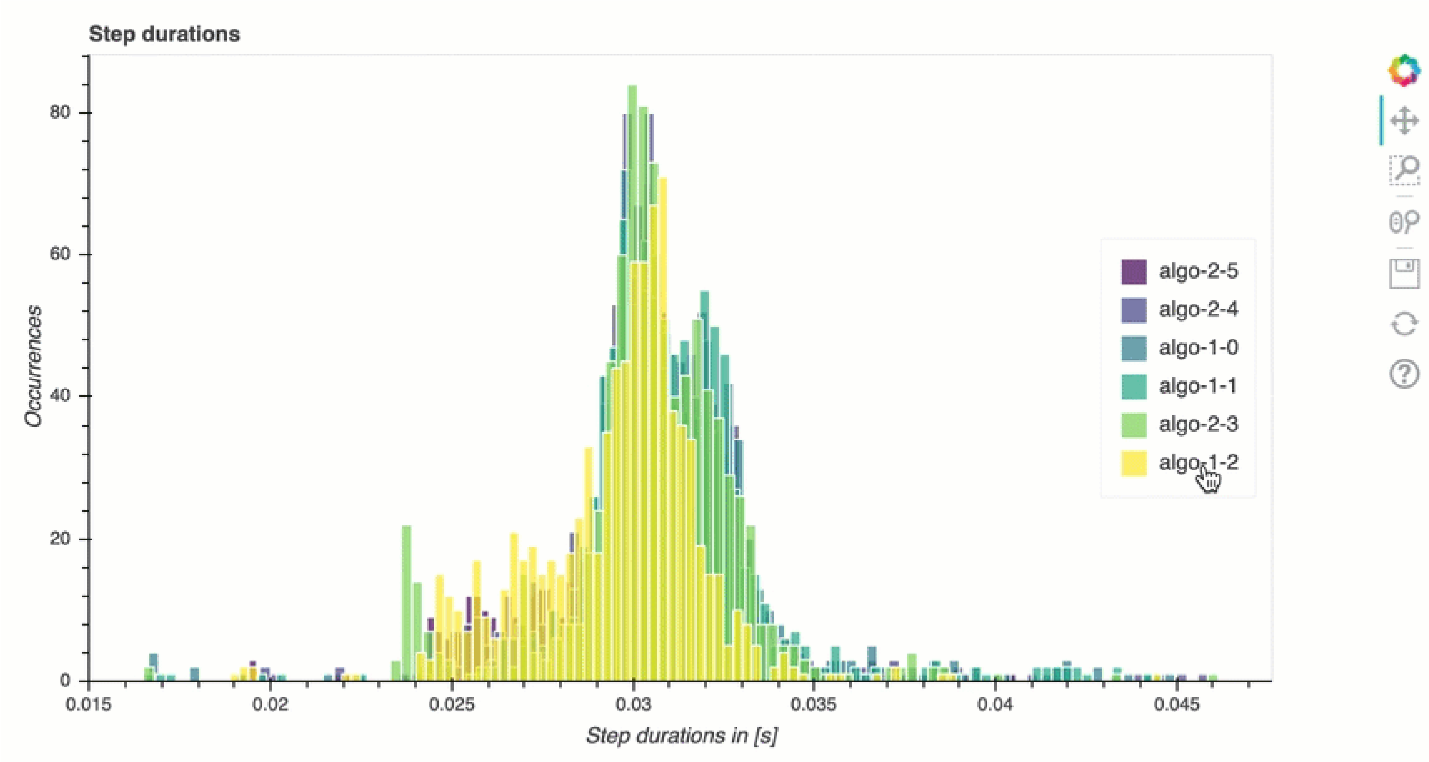
Rules summary

The following table shows a summary of the executed profiler rules. The table is sorted by the rules that triggered most frequently. In your training job this was the case for rule LoadBalancing. It has processed 5467 datapoints and triggered 263 times.

	Description	Recommendation	Number of times rule triggered	Number of datapoints	Rule parameters
LoadBalancing	Detect issues in workload balancing between multiple GPUs. Workload imbalance can for instance occur in data parallel training when gradients are accumulated on primary GPU so this GPU will be overused with regards to other GPUs limiting the effect of parallelization.	Choose different distributed training strategy or different distributed training framework	263	5467	threshold:0.2 patience:1000
LowGPUUtilization	Checks if GPU utilization is low or suffers from fluctuations. This can happen if there are bottlenecks, many blocking calls due to synchronizations or batch size too small.	Check for bottlenecks, minimize blocking calls, change distributed training strategy, increase batch-size.	244	5467	threshold_p95:70 threshold_p5:10 window:500 patience:1000
BatchSize	Checks if GPU is under-utilized because of the batch size being too small. To detect this the rule analyzes the average GPU memory footprint, CPU and GPU utilization.	Run on a smaller instance type or increase batch size	211	5466	cpu_threshold_p95:70 gpu_threshold_p95:70 gpu_memory_threshold_p95:70 patience:1000 window:500
GPUMemoryIncrease	If model and/or batch size is too large then training will run out of memory and crash.	Choose a larger instance type with more memory (if it is not a memory leak) or apply model parallelism (Rubik)	25	5467	increase:5 patience:1000 window:10
CPUBottleneck	Checks if CPU usage is high but GPU usage is low at the same time, it may indicate a CPU bottleneck where GPU is waiting for data to arrive from CPU. The rule triggers if number of CPU bottlenecks exceeds a predefined threshold.	CPU bottlenecks can happen when data preprocessing is very compute intensive. You should consider increasing the number of data-loader processes or apply pre-fetching.	18	10938	threshold:50 cpu_threshold:90 gpu_threshold:10 patience:1000
IOBottleneck	If IO wait time is high but at the same time GPU usage is low, it may indicate an IO bottleneck where GPU is waiting for data to arrive from disk. The rule triggers if number of IO bottlenecks exceeds a predefined threshold.	Pre-fetch data or choose different file formats such as binary formats which improves read performance.	0	10938	threshold:50 io_threshold:50 gpu_threshold:10 patience:1000
StepOutlier	Detect outliers in step duration. Time for forward and backward pass should be roughly the same throughout the training. If there are significant outliers it would indicate an issue due to a system stall or a bottleneck.	Check for bottlenecks	0	4803	threshold:3 mode:None n_outliers:10 stddev:3
MaxInitializationTime	Checks if the training initialization is taking too much time. The rule waits until first step is available. This can happen if you are running in File mode and a lot of data needs to be downloaded from Amazon S3.	Switch from File to Pipe mode	0	4803	threshold:20

Analyzing the training loop – step durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

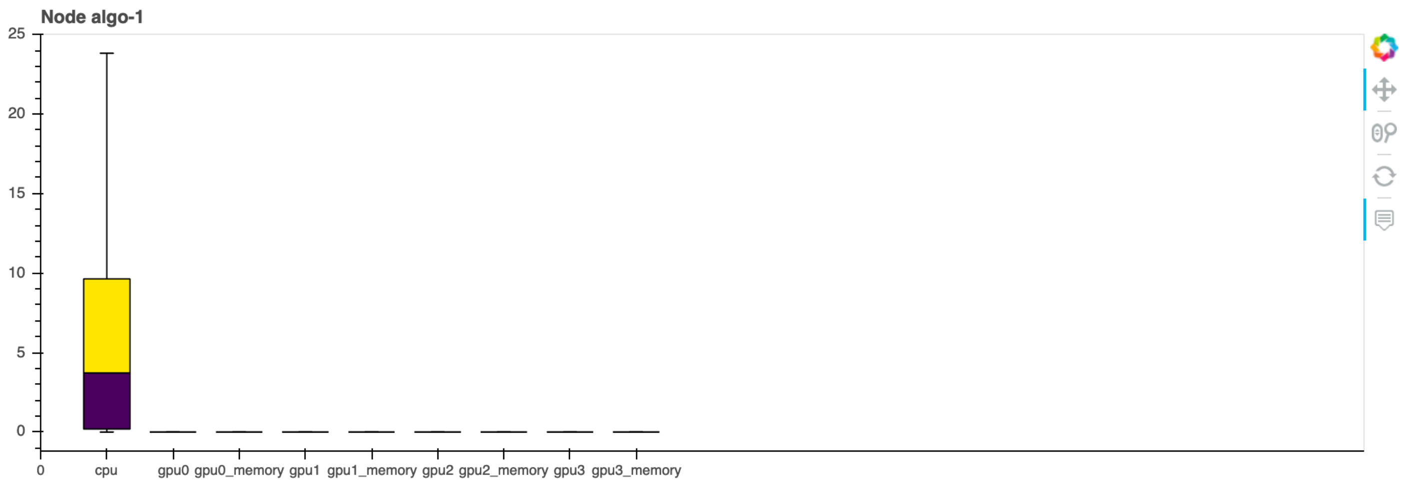


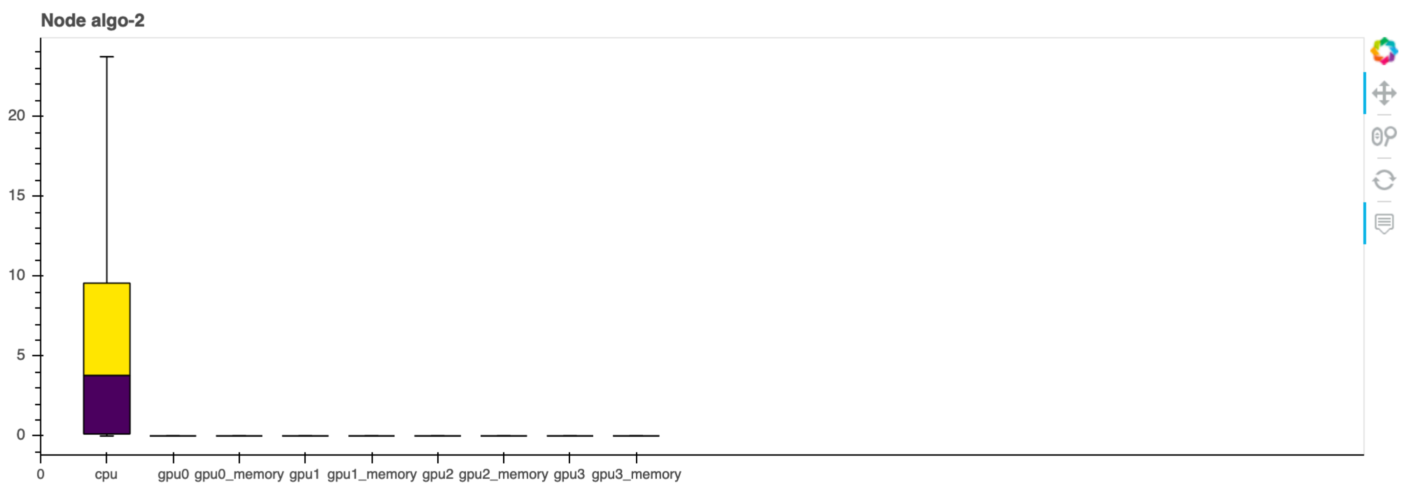
GPU utilization analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch size

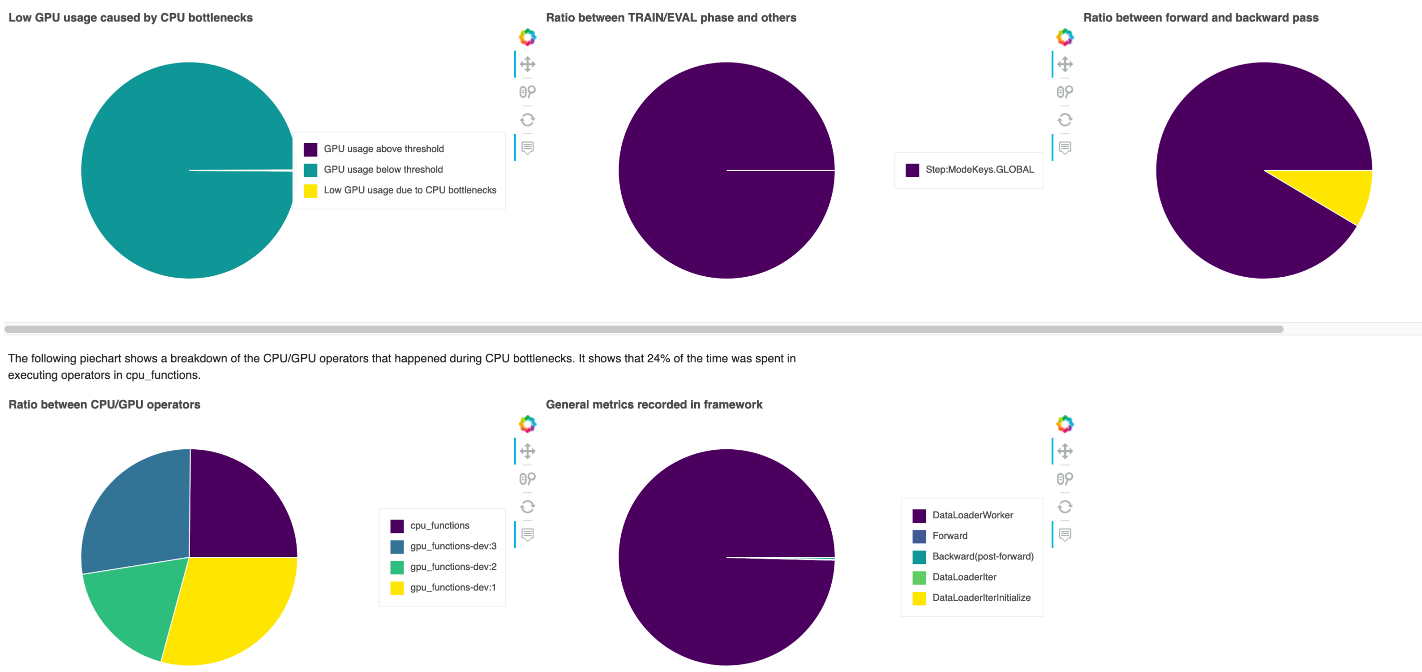
This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.





CPU bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above `cpu_threshold` (90% by default) and also if the GPU utilization is below `gpu_threshold` (10% by default).



The pie charts show the following information:

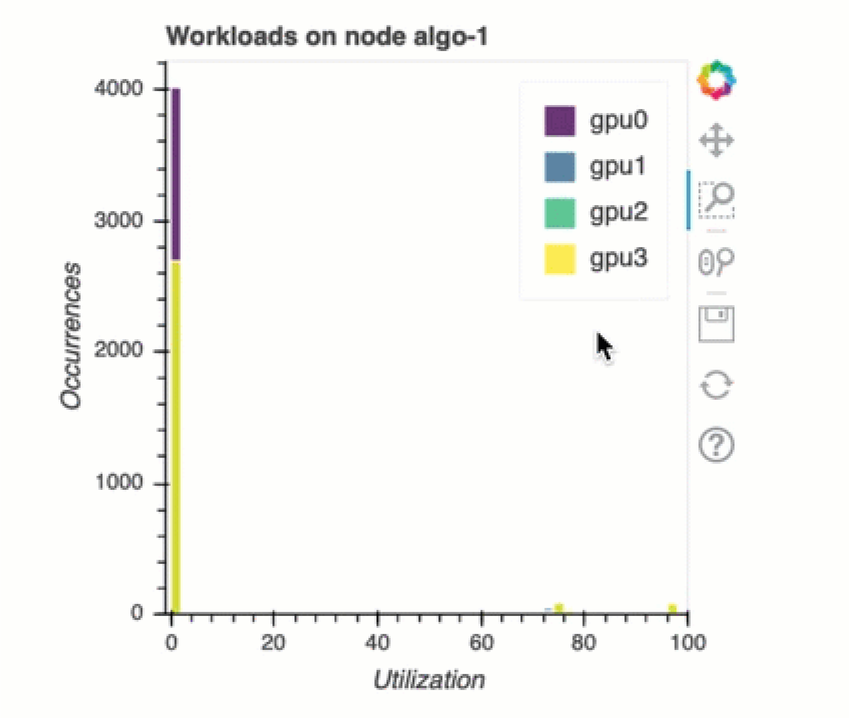
- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.
- **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

I/O bottlenecks

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

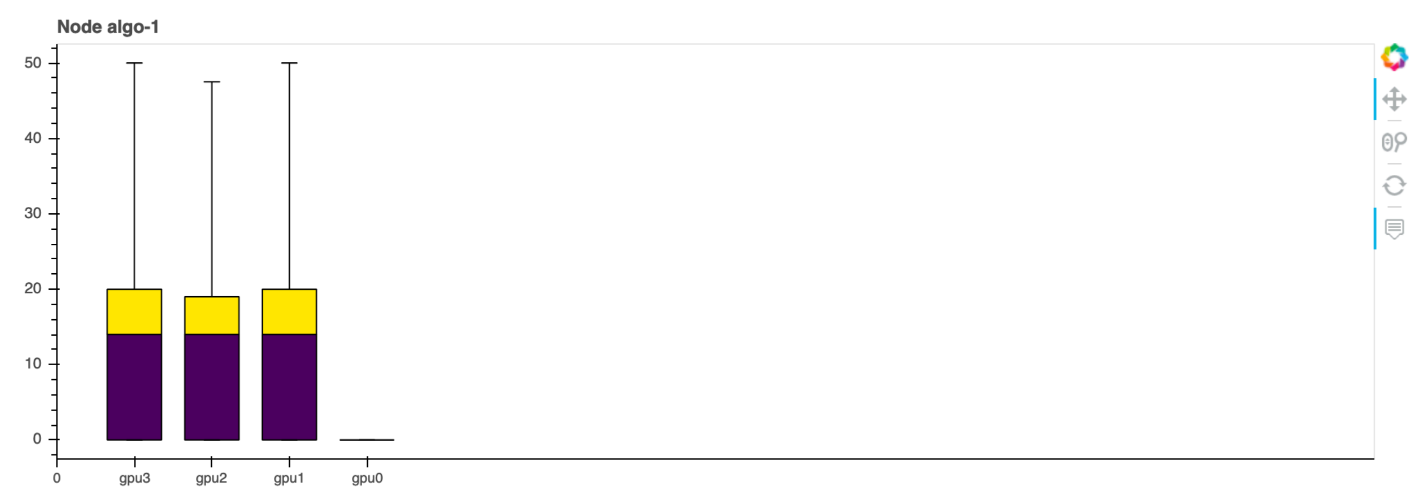
Load balancing in multi-GPU training

In this section, you can identify workload balancing issue across GPUs.



GPU memory analysis

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.



Opt out of the collection of Amazon SageMaker Debugger usage statistics

For all SageMaker training jobs, Amazon SageMaker Debugger runs the ProfilerReport rule and autogenerates a SageMaker Debugger interactive report. The `ProfilerReport` rule provides a Jupyter notebook file (`profiler-report.ipynb`) that generates a corresponding HTML file (`profiler-report.html`).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using one of the following options.

(Recommended) Option 1: Opt out before running a training job

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

SageMaker Python SDK

```
estimator=sagemaker.estimator.Estimator(
    ...

    rules=ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport()
        rule_parameters={"opt_out_telemetry": "True"}
    )
)
```

AWS CLI

```
"ProfilerRuleConfigurations": [ 
    { 
        "RuleConfigurationName": "ProfilerReport-1234567890",
        "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
```

```
                "opt_out_telemetry": "True"
            }
        }
]
```

AWS SDK for Python (Boto3)

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport-1234567890',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'opt_out_telemetry': 'True'
        }
    }
]
```

Option 2: Opt out after a training job has completed

To opt out after training has completed, you need to modify the `profiler-report.ipynb` file.

> **Note**
>
> HTML reports autogenerated without **Option 1** already added to your training job request still report the usage statistics even after you opt out using **Option 2**.

1. Follow the instructions on downloading the Debugger profiling report files in the Download the SageMaker Debugger profiling report page.
2. In the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.ipynb`.
3. Add **opt_out=True** to the `setup_profiler_report()` function in the fifth code cell as shown in the following example code:

```
setup_profiler_report(processing_job_arn, opt_out=True)
```

4. Run the code cell to finish opting out.

Analyze data using the Debugger Python client library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The Debugger Python client library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use its analysis tools (in a JupyterLab notebook or an iPython kernel)

```
! pip install -U smdebug
```

The following topics walk you through how to use the Debugger Python tools to visualize and analyze the training data collected by Debugger.

Analyze system and framework metrics

- Access the profile data
- Plot the system metrics and framework metrics data
- Access the profiling data using the pandas data parsing tool
- Access the Python profiling stats data
- Merge timelines of multiple profile trace files
- Profiling data loaders

Access the profile data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

To set up a `TrainingJob` object and retrieve profiling event files of a training job

```
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

> **Tip**
>
> You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

Note

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.

- If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.
- If you use Studio Classic, turn on profiling using the **Profiling** toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```
tj.wait_for_sys_profiling_data_to_be_available()
```

```
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the system metrics and framework metrics data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

> **Note**
>
> To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=["GPU"]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=["total"]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The `MetricsHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import
 MetricsHistogram

metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
```

```
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                  # optional
)
```

- The `StepTimelineChart` class

```
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import
 StepTimelineChart

view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

- The `StepHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram

step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

- The `TimelineCharts` class

```
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts

view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                  # optional
)

view_timeline_charts.plot_detailed_profiler_data([700,710])
```

- The `Heatmap` class

```
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap

view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
```

```
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"],                 # optional
    plot_height=450
)
```

Access the profiling data using the pandas data parsing tool

The following `PandasFrame` class provides tools to convert the collected profiling data to Pandas data frame.

```
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame
```

The `PandasFrame` class takes the `tj` object's S3 bucket output path, and its methods `get_all_system_metrics()` `get_all_framework_metrics()` return system metrics and framework metrics in the Pandas data format.

```
pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(
    selected_framework_metrics=[
        'Step:ModeKeys.TRAIN',
        'Step:ModeKeys.GLOBAL'
    ]
)
```

Access the Python profiling stats data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker AI deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- PythonProfileModes.TRAIN – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- PythonProfileModes.EVAL – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- PythonProfileModes.PREDICT – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- PythonProfileModes.GLOBAL – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- PythonProfileModes.PRE_STEP_ZERO – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- PythonProfileModes.POST_HOOK_CLOSE – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following StepPhase class:

```
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- StepPhase.START – Use to specify the start point of the initialization phase.
- StepPhase.STEP_START – Use to specify the start step of the training phase.
- StepPhase.FORWARD_PASS_END – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- StepPhase.STEP_END – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- StepPhase.END – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools

Debugger supports the Python profiling with two profiling tools:

- cProfile – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- Pyinstrument – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see [Default system monitoring and customized framework profiling with different profiling options]().

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis,
 cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a `cProfileAnalysis` object, and if you want to use `PyinstrumentAnalysis`, replace the class name.

```
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the `cProfileAnalysis` and `PyinstrumentAnalysis` classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_se` `end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled `step` satisfies `start_step <= step < end_step`.
  - `start_step` and `end_step` (str) – Specify the start step and end step to fetch the Python profiling stats data.

  - `mode` (str) – Specify the mode of training job using the `PythonProfileModes` enumerator class. The default is `PythonProfileModes.TRAIN`. Available options are provided in the Training Modes and Phases for Python Profiling section.
  - `start_phase` (str) – Specify the start phase in the target step(s) using the `StepPhase` enumerator class. This parameter enables profiling between different phases of training. The default is `StepPhase.STEP_START`. Available options are provided in the Training Modes and Phases for Python Profiling section.
  - `end_phase` (str) – Specify the end phase in the target step(s) using the `StepPhase` enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the `start_phase` parameter. The default is `StepPhase.STEP_END`. Available options are provided in the Training Modes and Phases for Python Profiling section.
- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.
- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.
- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.
- `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).
- `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

- `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are `(PRE_STEP_ZERO, TRAIN)`, `(TRAIN, TRAIN)`, `(TRAIN, EVAL)`, `(EVAL, EVAL)`, and `(EVAL, POST_HOOK_CLOSE)`. All stats files within each of these combinations are aggregated.
- `fetch_profile_stats_by_job_phase()` – Fetches and aggregates the Python profiling stats by job phase. The job phases are `initialization` (profiling until step 0), `training_loop` (training and validation), and `finalization` (profiling after the hook is closed).

Merge timelines of multiple profile trace files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

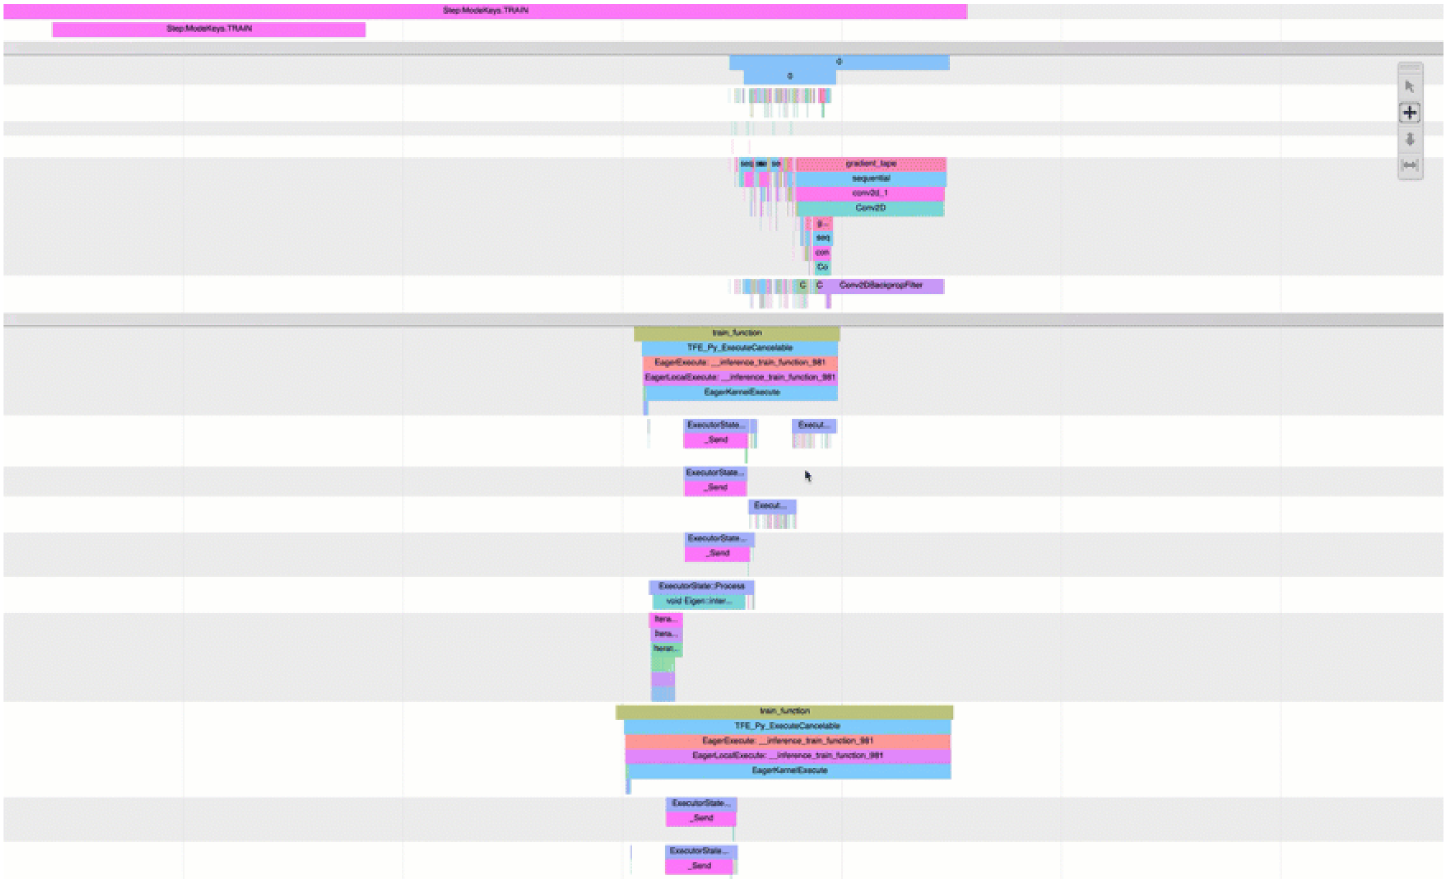
> **Tip**
>
> Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see [Access the profile data](#).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

> **Tip**
>
> If you want to list all of the JSON trace files, use the following AWS CLI command:
>
> ```
> ! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
> ```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.



> **Tip**
>
> To interact with the merged timeline on the traicing app using a keyboard, use the `W` key for zooming in, the `A` key for shifting to the left, the `S` key for zooming out, and the `D` key for shififting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following `MergedTimeline` API operation and class method from the `smdebug.profiler.analysis.utils.merge_timelines` module.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The `MergedTimeline` API operation passes the following parameters:

- `path` (str) – Specify a root folder (`/profiler-output`) that contains system and framework profiling trace files. You can locate the `profiler-output` using the SageMaker AI estimator classmethod or the TrainingJob object. For example, `estimator.latest_job_profiler_artifacts_path()` or `tj.profiler_s3_output_path`.
- `file_suffix_filter` (list) – Specify a list of file suffix filters to merge timelines. Available suffiex filters are `["model_timeline.json", "pythontimeline.json", "trace.json.gz"].` If this parameter is not manually specified, all of the trace files are merged by default.
- `output_directory` (str) – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- `start` (int) – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- `end` (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
- `unit` (str) – Choose between `"time"` and `"step"`. The default is `"time"`.

Using the following example codes, execute the `merge_timeline()` method and download the merged JSON file.

- Merge timeline with the `"time"` unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

- Merge timeline with the `"step"` unit option. The following example code merges all available timelines between step 3 and step 9.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at `chrome://tracing` on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

Profiling data loaders

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import
 PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the [Access the profiling data using the pandas data parsing tool]() section:

```
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The SMDebug `S3SystemMetricsReader` class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

- `pt_analysis.analyze_dataloaderIter_initialization()`

  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.

  The following list shows what analysis is available from this class method:

  - Which type of data loader iterators were initialized.

  - The number of workers per iterator.
  - Inspect whether the iterator was initialized with or without pin_memory.
  - Number of times the iterators were initialized during training.
- `pt_analysis.analyze_dataloaderWorkers()`

  The following list shows what analysis is available from this class method:

  - The number of worker processes that were spun off during the entire training.
  - Median and maximum duration for the worker processes.
  - Start and end time for the worker processes that are outliers.
- `pt_analysis.analyze_dataloader_getnext()`

  The following list shows what analysis is available from this class method:

  - Number of GetNext calls made during the training.
  - Median and maximum duration in microseconds for GetNext calls.
  - Start time, End time, duration and worker id for the outlier GetNext call duration.
- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=[".*"], select_dimensions=[".*"])`

  Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

  The following list shows what analysis is available from this class method:

  - Profile time spent on each data batch, `BatchTime_in_seconds`, by finding the difference between start times of current and subsequent GetNext calls.
  - Find the outliers in `BatchTime_in_seconds` and start and end time for those outliers.
  - Obtain the system and framework metrics during those `BatchTime_in_seconds` timestamps. This indicates where the time was spent.
- `pt_analysis.plot_the_window()`

  Plots a timeline charts between a start timestamp and the end timestamp.

Release notes for profiling capabilities of Amazon SageMaker AI

See the following release notes to track the latest updates for profiling capabilities of Amazon SageMaker AI.

March 21, 2024

Currency updates

SageMaker Profiler has added support for PyTorch v2.2.0, v2.1.0, and v2.0.1.

AWS Deep Learning Containers pre-installed with SageMaker Profiler

SageMaker Profiler is packaged in the following AWS Deep Learning Containers.

- SageMaker AI Framework Container for PyTorch v2.2.0
- SageMaker AI Framework Container for PyTorch v2.1.0
- SageMaker AI Framework Container for PyTorch v2.0.1

December 14, 2023

Currency updates

SageMaker Profiler has added support for TensorFlow v2.13.0.

Breaking changes

This release involves a breaking change. The SageMaker Profiler Python package name is changed from `smppy` to `smprof`. If you have been using the previous version of the package while you have started using the latest SageMaker AI Framework Containers for TensorFlow listed in the following section, make sure that you update the package name from `smppy` to `smprof` in the import statement in your training script.

AWS Deep Learning Containers pre-installed with SageMaker Profiler

SageMaker Profiler is packaged in the following AWS Deep Learning Containers.

- SageMaker AI Framework Container for TensorFlow v2.13.0
- SageMaker AI Framework Container for TensorFlow v2.12.0

If you use the previous versions of the framework containers such TensorFlow v2.11.0, the SageMaker Profiler Python package is still available as `smppy`. If you are uncertain which version or the package name you should use, replace the import statement of the SageMaker Profiler package with the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

August 24, 2023

New features

Released Amazon SageMaker Profiler, a profiling and visualization capability of SageMaker AI to deep dive into compute resources provisioned while training deep learning models and gain visibility into operation-level details. SageMaker Profiler provides Python modules (`smppy`) for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker AI Python SDK and AWS Deep Learning Containers. For any jobs run with the SageMaker Profiler Python modules, you can load the profile data in the SageMaker Profiler UI application that provides a summary dashboard and a detailed timeline. To learn more, see Amazon SageMaker Profiler.

This release of the SageMaker Profiler Python package is integrated into the following SageMaker AI Framework Containers for PyTorch and TensorFlow.

- PyTorch v2.0.0
- PyTorch v1.13.1
- TensorFlow v2.12.0
- TensorFlow v2.11.0

Distributed training in Amazon SageMaker AI

SageMaker AI provides distributed training libraries and supports various distributed training options for deep learning tasks such as computer vision (CV) and natural language processing (NLP). With SageMaker AI's distributed training libraries, you can run highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs. You can also use other distributed training frameworks and packages such as PyTorch DistributedDataParallel (DDP), `torchrun`, MPI (`mpirun`), and parameter server. The following section gives information about fundamental distributed training concepts. Throughout the documentation, instructions and examples focus on how to set up the distributed training options for deep learning tasks using the SageMaker Python SDK.

> **Tip**
>
> To learn best practices for distributed computing of machine learning (ML) training and processing jobs in general, see Distributed computing with SageMaker AI best practices.

Distributed training concepts

SageMaker AI's distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: `global batch size = (the number of model replicas) * (per-replica batch size)`. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size:** When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used , it is a subset of the per-replica sized batch . When you use SageMaker AI's distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library's runtime.

Training

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.
- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

Instances and GPUs

- **Instances**: An AWS machine learning compute instance. These are also referred to as *nodes*.
- **Cluster size**: When using SageMaker AI's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker AI distributed training library is designed to optimize communication between Amazon EC2 ML compute instances, leading to higher device utilization and faster training times.

Distributed Training Solutions

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. Each GPU contains a *replica* of the model, receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.
- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single instance. Each GPU carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model

parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule** (**Pipelining**): The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

Advanced concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data *in memory* for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called *mini-batches*. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an *epoch*. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called *data parallel distributed training*, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called *allreduce* that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called *model-parallel distributed training*.

Get started with distributed training in Amazon SageMaker AI

The following page gives information about the steps needed to get started with distributed training in Amazon SageMaker AI. If you're already familiar with distributed training, choose one of the following options that matches your preferred strategy or framework to get started. If you want to learn about distributed training in general, see the section called "Distributed training concepts".

The SageMaker AI distributed training libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker AI, and improve training speed and throughput. The libraries offer both data parallel and model parallel training strategies. They combine software and hardware technologies to improve inter-GPU and inter-node communications, and extend SageMaker AI's training capabilities with built-in options that require minimal code changes to your training scripts.

Before you get started

SageMaker Training supports distributed training on a single instance as well as multiple instances, so you can run any size of training at scale. We recommend you to use the framework estimator classes such as PyTorch and TensorFlow in the SageMaker Python SDK, which are the training job launchers with various distributed training options. When you create an estimator object, the object sets up distributed training infrastructure, runs the `CreateTrainingJob` API in the backend, finds the Region where your current session is running, and pulls one of the pre-built AWS deep learning container prepackaged with a number of libraries including deep learning frameworks, distributed training frameworks, and the EFA driver. If you want to mount an FSx file system to the training instances, you need to pass your VPC subnet and security group ID to the estimator. Before running your distributed training job in SageMaker AI, read the following general guidance on the basic infrastructure setup.

Availability zones and network backplane

When using multiple instances (also called *nodes*), it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves. For example, when you run a distributed data-parallel training job, a number of factors, such as communication between the nodes of a compute cluster for running the `AllReduce` operation and data transfer between the nodes and data storage in Amazon Simple Storage Service or Amazon FSx for Lustre, play a crucial role to achieve an optimal use of compute resources and a faster training speed. To reduce communication overhead, make sure that you configure instances, VPC subnet, and data storage in the same AWS Region and Availability Zone.

GPU instances with faster network and high-throughput storage

You can technically use any instances for distributed training. For cases where you need to run multi-node distributed training jobs for training large models, such as large language models (LLMs) and diffusion models, which require faster inter-node commutation, we recommend EFA-enabled GPU instances supported by SageMaker AI. Especially, to achieve the most performant distributed training job in SageMaker AI, we recommend P4d and P4de instances equipped with NVIDIA A100 GPUs. These are also equipped with high-throughput low-latency local instance storage and faster intra-node network. For data storage, we recommend Amazon FSx for Lustre that provides high throughput for storing training datasets and model checkpoints.

Use the SageMaker AI distributed data parallelism (SMDDP) library

The SMDDP library improves communication between nodes with implementations of `AllReduce` and `AllGather` collective communication operations that are optimized for AWS network infrastructure and Amazon SageMaker AI ML instance topology. You can use the SMDDP library as the backend of PyTorch-based distributed training packages: PyTorch distributed data parallel (DDP), PyTorch fully sharded data parallelism (FSDP), DeepSpeed, and Megatron-DeepSpeed. The following code example shows how to set a `PyTorch` estimator for launching a distributed training job on two `ml.p4d.24xlarge` instances.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...,
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    # Activate distributed training with SMDDP
```

```
    distribution={ "pytorchddp": { "enabled": True } }  # mpirun, activates SMDDP
 AllReduce OR AllGather
    # distribution={ "torch_distributed": { "enabled": True } }  # torchrun, activates
 SMDDP AllGather
    # distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }  #
 mpirun, activates SMDDP AllReduce OR AllGather
)
```

To learn how to prepare your training script and launch a distributed data-parallel training job on SageMaker AI, see the section called “SageMaker AI distributed data parallelism library”.

Use the SageMaker AI model parallelism library (SMP)

SageMaker AI provides the SMP library and supports various distributed training techniques, such as sharded data parallelism, pipelining, tensor parallelism, optimizer state sharding, and more. To learn more about what the SMP library offers, see the section called “Core Features”.

To use SageMaker AI's model parallelism library, configure the `distribution` parameter of the SageMaker AI framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to construct a framework estimator for distributed training with the model parallelism library on two `ml.p4d.24xlarge` instances.

```
from sagemaker.framework import Framework

distribution={
    "smdistributed": {
        "modelparallel": {
            "enabled":True,
            "parameters": {
                ...   # enter parameter key-value pairs here
            }
        },
    },
    "mpi": {
        "enabled" : True,
        ...           # enter parameter key-value pairs here
    }
}

estimator = Framework(
    ...,
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
```

```
    distribution=distribution
)
```

To learn how to adapt your training script, configure distribution parameters in the `estimator` class, and launch a distributed training job, see SageMaker AI's model parallelism library (see also Distributed Training APIs in the *SageMaker Python SDK documentation*).

Use open source distributed training frameworks

SageMaker AI also supports the following options to operate `mpirun` and `torchrun` in the backend.

- To use PyTorch DistributedDataParallel (DDP) in SageMaker AI with the `mpirun` backend, add `distribution={"pytorchddp": {"enabled": True}}` to your PyTorch estimator. For more information, see also PyTorch Distributed Training and SageMaker AI PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

  > **Note**
  >
  > This option is available for PyTorch 1.12.0 and later.

  ```
  from sagemaker.pytorch import PyTorch

  estimator = PyTorch(
      ...,
      instance_count=2,
      instance_type="ml.p4d.24xlarge",
      distribution={"pytorchddp": {"enabled": True}}  # runs mpirun in the backend
  )
  ```

- SageMaker AI supports the PyTorch `torchrun` launcher for distributed training on GPU-based Amazon EC2 instances, such as P3 and P4, as well as Trn1 powered by the AWS Trainium device.

  To use PyTorch DistributedDataParallel (DDP) in SageMaker AI with the `torchrun` backend, add `distribution={"torch_distributed": {"enabled": True}}` to the PyTorch estimator.

  > **Note**
  >
  > This option is available for PyTorch 1.13.0 and later.

The following code snippet shows an example of constructing a SageMaker AI PyTorch estimator to run distributed training on two `ml.p4d.24xlarge` instances with the `torch_distributed` distribution option.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...,
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution={"torch_distributed": {"enabled": True}}   # runs torchrun in the
 backend
)
```

For more information, see Distributed PyTorch Training and SageMaker AI PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

Notes for distributed training on Trn1

A Trn1 instance consists of up to 16 Trainium devices, and each Trainium device consists of two NeuronCores. For specs of the AWS Trainium devices, see Trainium Architecture in the *AWS Neuron Documentation*.

To train on the Trainium-powered instances, you only need to specify the Trn1 instance code, `ml.trn1.*`, in string to the `instance_type` argument of the SageMaker AI PyTorch estimator class. To find available Trn1 instance types, see AWS Trn1 Architecture in the *AWS Neuron documentation*.

> **Note**
>
> SageMaker Training on Amazon EC2 Trn1 instances is currently available only for the PyTorch framework in the AWS Deep Learning Containers for PyTorch Neuron starting v1.11.0. To find a complete list of supported versions of PyTorch Neuron, see Neuron Containers in the *AWS Deep Learning Containers GitHub repository*.

When you launch a training job on Trn1 instances using the SageMaker Python SDK, SageMaker AI automatically picks up and runs the right container from Neuron Containers provided by AWS

Deep Learning Containers. The Neuron Containers are prepackaged with training environment settings and dependencies for easier adaptation of your training job to the SageMaker Training platform and Amazon EC2 Trn1 instances.

> **Note**
>
> To run your PyTorch training job on Trn1 instances with SageMaker AI, you should modify your training script to initialize process groups with the `xla` backend and use PyTorch/XLA. To support the XLA adoption process, the AWS Neuron SDK provides PyTorch Neuron that uses XLA to make conversion of PyTorch operations to Trainium instructions. To learn how to modify your training script, see Developer Guide for Training with PyTorch Neuron (`torch-neuronx`) in the *AWS Neuron Documentation*.

For more information, see Distributed Training with PyTorch Neuron on Trn1 instances and SageMaker AI PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

- To use MPI in SageMaker AI, add `distribution={"mpi": {"enabled": True}}` to your estimator. The MPI distribution option is available for the following frameworks: MXNet, PyTorch, and TensorFlow.
- To use a parameter server in SageMaker AI, add `distribution={"parameter_server": {"enabled": True}}` to your estimator. The parameter server option is available for the following frameworks: MXNet, PyTorch, and TensorFlow.

> **Tip**
>
> For more information about using the MPI and parameter server options per framework, use the following links to the *SageMaker Python SDK documentation*.
>

Strategies for distributed training

Distributed training is usually split by two approaches: data parallel and model parallel. *Data parallel* is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A *model parallel* approach is used with large models that won't fit in a node's memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms *network* and *model* are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you're also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker AI's distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

Train with data parallel and model parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
- SageMaker AI's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker AI data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
  - Frameworks - PyTorch in the *NVIDIA Deep Learning Performance documentation*
  - Frameworks - TensorFlow in the *NVIDIA Deep Learning Performance documentation*
  - Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
  - Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the *PyTorch Blog*
  - TensorFlow mixed precision APIs in the *TensorFlow documentation*

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

- PyTorch distributed training
- TensorFlow distributed training

Batch Size

SageMaker AI distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

> **Tip**
>
> Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-batch size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

- Deep Gradient Compression, Lin et al.

Scaling training

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources. You may want to scale training in one of the following situations:

- Scaling from a single GPU to many GPUs
- Scaling from a single instance to multiple instances
- Using custom training scripts

Scaling from a single GPU to many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer that you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a `p3.16xlarge` that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on `p3.2xlarge` with one GPU.

Instance type	GPUs
p3.2xlarge	1
p3.8xlarge	4
p3.16xlarge	8
p3dn.24xlarge	8

Note

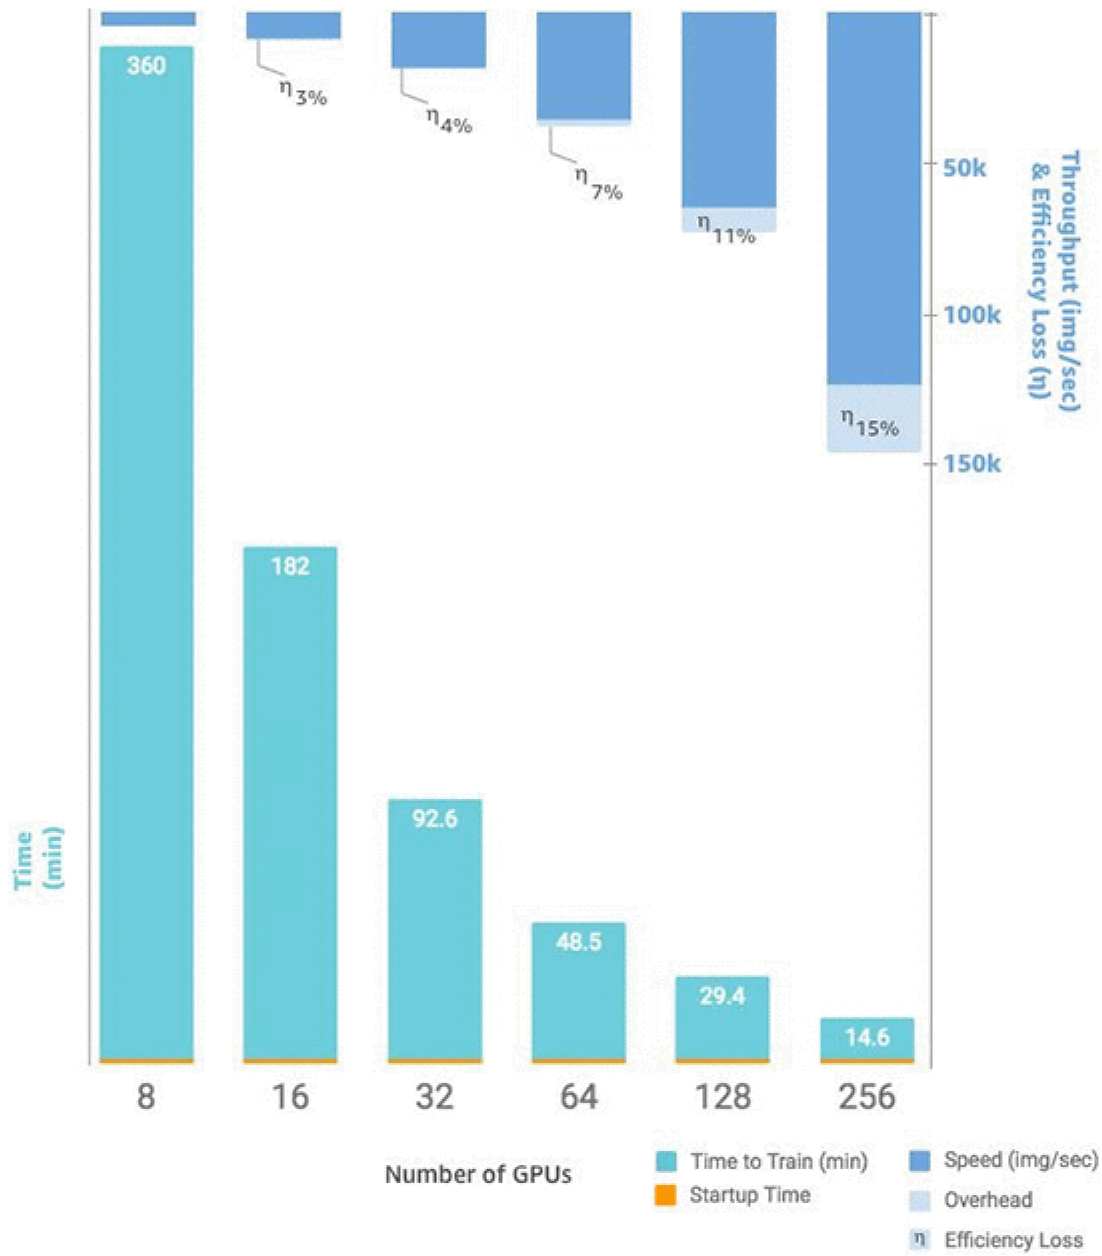
The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, `ml.p3.8xlarge` has the same number of GPUs as `p3.8xlarge` - 4.

Scaling from a single instance to multiple instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a `p3.2xlarge` to four GPUs on a `p3.8xlarge`, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a `p3.16xlarge` before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker AI Python SDK `estimator` function by setting your `instance_count`. For example, you can set `instance_type = p3.16xlarge` and `instance_count = 2`. Instead of the eight GPUs on a single `p3.16xlarge`, you have 16 GPUs across two identical instances. The following chart shows [scaling and throughput starting with eight GPUs](#) on a single instance and increasing to 64 instances for a total of 256 GPUs.



Custom training scripts

While SageMaker AI makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker AI also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker AI's container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

Run distributed training with the SageMaker AI distributed data parallelism library

The SageMaker AI distributed data parallelism (SMDDP) library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency by providing implementations of collective communication operations optimized for AWS infrastructure.

When training large machine learning (ML) models, such as large language models (LLM) and diffusion models, on a huge training dataset, ML practitioners use clusters of accelerators and distributed training techniques to reduce the time to train or resolve memory constraints for models that cannot fit in each GPU memory. ML practitioners often start with multiple accelerators on a single instance and then scale to clusters of instances as their workload requirements increase. As the cluster size increases, so does the communication overhead between multiple nodes, which leads to drop in overall computational performance.

To address such overhead and memory problems, the SMDDP library offers the following.

- The SMDDP library optimizes training jobs for AWS network infrastructure and Amazon SageMaker AI ML instance topology.
- The SMDDP library improves communication between nodes with implementations of `AllReduce` and `AllGather` collective communication operations that are optimized for AWS infrastructure.

To learn more about the details of the SMDDP library offerings, proceed to the section called "Introduction to the SMDDP library".

For more information about training with the model-parallel strategy offered by SageMaker AI, see also (Archived) SageMaker model parallelism library v1.x.

Topics

Introduction to the SageMaker AI distributed data parallelism library

The SageMaker AI distributed data parallelism (SMDDP) library is a collective communication library that improves compute performance of distributed data parallel training. The SMDDP library addresses communications overhead of the key collective communication operations by offering the following.

1. The library offers `AllReduce` optimized for AWS. `AllReduce` is a key operation used for synchronizing gradients across GPUs at the end of each training iteration during distributed data training.
2. The library offers `AllGather` optimized for AWS. `AllGather` is another key operation used in sharded data parallel training, which is a memory-efficient data parallelism technique offered by popular libraries such as the SageMaker AI model parallelism (SMP) library, DeepSpeed Zero Redundancy Optimizer (ZeRO), and PyTorch Fully Sharded Data Parallelism (FSDP).
3. The library performs optimized node-to-node communication by fully utilizing AWS network infrastructure and the Amazon EC2 instance topology.

The SMDDP library can increase training speed by offering performance improvement as you scale your training cluster, with near-linear scaling efficiency.

> **Note**
>
> The SageMaker AI distributed training libraries are available through the AWS deep learning containers for PyTorch and Hugging Face within the SageMaker Training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

SMDDP collective communication operations optimized for AWS compute resources and network infrastructure

The SMDDP library provides implementations of the `AllReduce` and `AllGather` collective operations that are optimized for AWS compute resources and network infrastructure.

SMDDP `AllReduce` collective operation

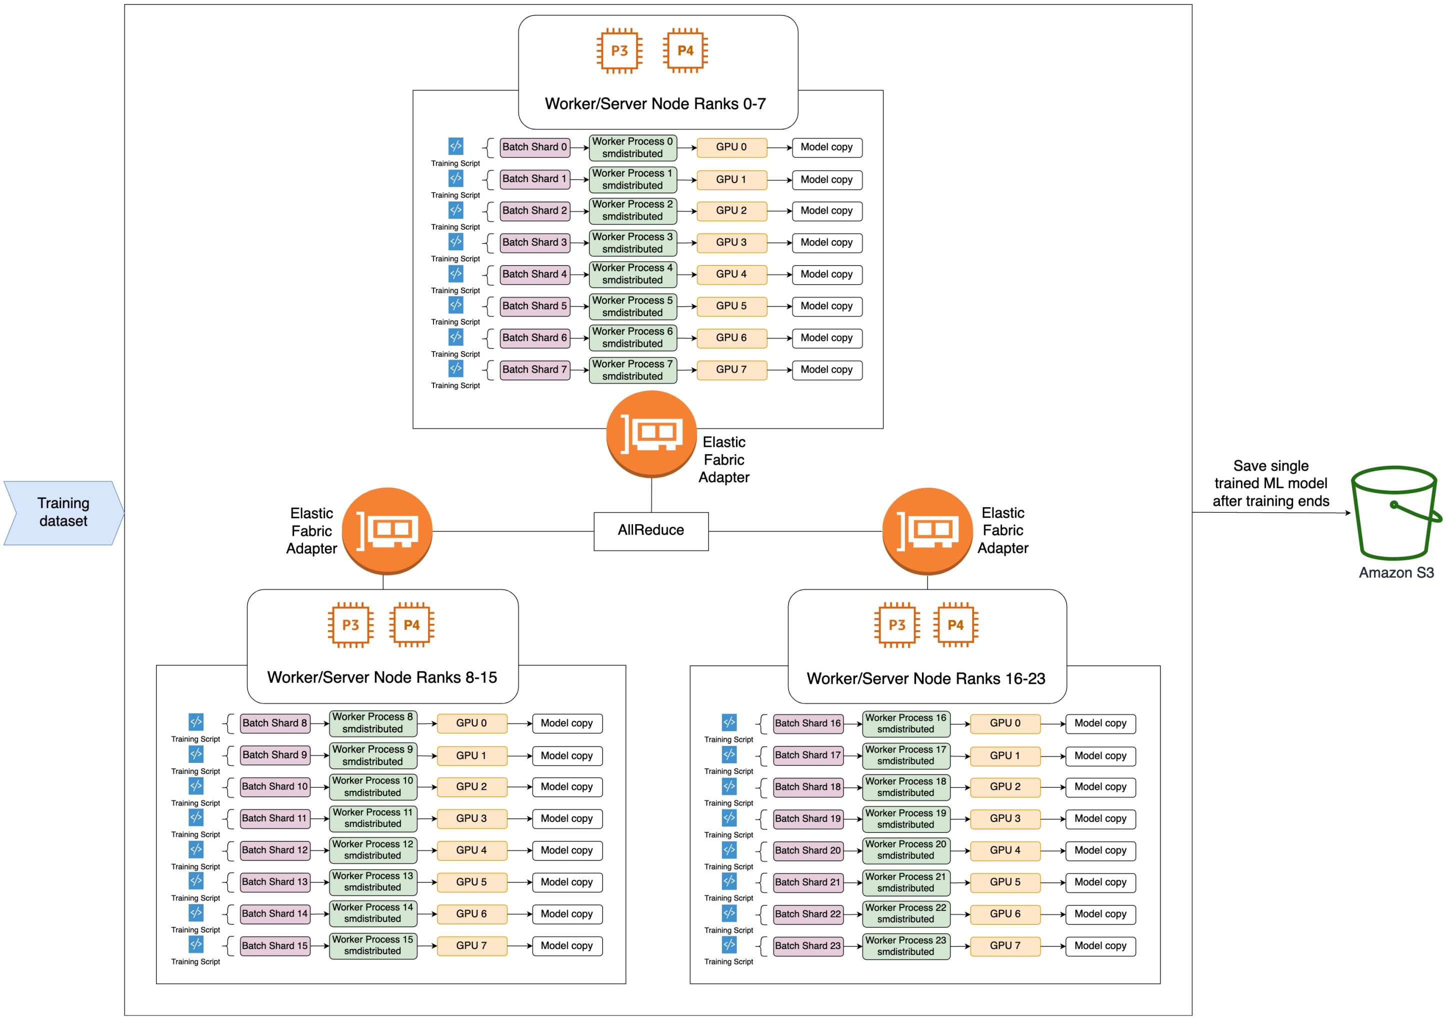
The SMDDP library achieves optimal overlapping of the `AllReduce` operation with the backward pass, significantly improving GPU utilization. It achieves near-linear scaling efficiency and faster training speed by optimizing kernel operations between CPUs and GPUs. The library performs `AllReduce` in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library to achieve faster training.

- *Leverages CPUs*: The library uses CPUs to `AllReduce` gradients, offloading this task from the GPUs.
- *Improved GPU usage*: The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

The following is the high-level workflow of the SMDDP `AllReduce` operation.

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.



SMDDP `AllGather` collective operation

`AllGather` is a collective operation where each worker starts with an input buffer, and then concatenates or *gathers* the input buffers from all other workers into an output buffer.

> **Note**
>
> The SMDDP `AllGather` collective operation is available in `smdistributed-dataparallel>=2.0.1` and AWS Deep Learning Containers (DLC) for PyTorch v2.0.1 and later.

`AllGather` is heavily used in distributed training techniques such as sharded data parallelism where each individual worker holds a fraction of a model, or a sharded layer. The workers call `AllGather` before forward and backward passes to reconstruct the sharded layers. The forward and backward passes continue onward after the parameters are *all gathered*. During the backward pass, each worker also calls `ReduceScatter` to collect (reduce) gradients and break (scatter) them into gradient shards to update the corresponding sharded layer. For more details on the role of these collective operations in sharded data parallelism, see the SMP library's implementati on of sharded data parallelism, ZeRO in the DeepSpeed documentation, and the blog about PyTorch Fully Sharded Data Parallelism.

Because collective operations like AllGather are called in every iteration, they are the main contributors to GPU communication overhead. Faster computation of these collective operations directly translates to a shorter training time with no side effects on convergence. To achieve this, the SMDDP library offers `AllGather` optimized for P4d instances.

SMDDP `AllGather` uses the following techniques to improve computational performance on P4d instances.

1. It transfers data between instances (inter-node) through the Elastic Fabric Adapter (EFA) network with a mesh topology. EFA is the AWS low-latency and high-throughput network solution. A mesh topology for inter-node network communication is more tailored to the characteristics of EFA and AWS network infrastructure. Compared to the NCCL ring or tree topology that involves multiple packet hops, SMDDP avoids accumulating latency from multiple hops as it only needs one hop. SMDDP implements a network rate control algorithm that balances the workload to each communication peer in a mesh topology and achieves a higher global network throughput.
2. It adopts low-latency GPU memory copy library based on NVIDIA GPUDirect RDMA technology (GDRCopy) to coordinate local NVLink and EFA network traffic. GDRCopy, a low-latency GPU memory copy library offered by NVIDIA, provides low-latency communication between CPU processes and GPU CUDA kernels. With this technology, the SMDDP library is able to pipeline the intra-node and inter-node data movement.
3. It reduces the usage of GPU streaming multiprocessors to increase compute power for running model kernels. P4d and P4de instances are equipped with NVIDIA A100 GPUs, which each have 108 streaming multiprocessors. While NCCL takes up to 24 streaming multiprocessors to run collective operations, SMDDP uses fewer than 9 streaming multiprocessors. Model compute kernels pick up the saved streaming multiprocessors for faster computation.

Supported frameworks, AWS Regions, and instances types

Before using the SageMaker AI distributed data parallelism (SMDDP) library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

Supported frameworks

The following tables show the deep learning frameworks and their versions that SageMaker AI and SMDDP support. The SMDDP library is available in SageMaker AI Framework Containers, integrated in Docker containers distributed by the SageMaker model parallelism (SMP) library v2, or downloadable as a binary file.

> **Note**
>
> To check the latest updates and release notes of the SMDDP library, see the the section called "SMDDP release notes".

** The URLs of the binary files are for installing the SMDDP library in custom containers. For more information, see Create your own Docker container with the SageMaker AI distributed data parallel library.

Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the PyTorch DLCs. When you construct a SageMaker AI PyTorch estimator and submit a training job request in Step 2, you need to provide `requirements.txt` to install `pytorch-lightning` and `lightning-bolts` in the SageMaker AI PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see [Using third-party libraries]() in the *Amazon SageMaker AI Python SDK documentation*.

Hugging Face Transformers

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

TensorFlow (deprecated)

Important

The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. The following table lists previous DLCs for TensorFlow with the SMDDP library installed.

TensorFlow version	SMDDP library version
2.9.1, 2.10.1, 2.11.0	`smdistributed-dataparallel==v1.4.1`
2.8.3	`smdistributed-dataparallel==v1.3.0`

AWS Regions

The SMDDP library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker AI and the SMP Docker images are in service.

Supported instance types

The SMDDP library requires one of the following instance types.

Instance type		
ml.p3dn.24xlarge *		
ml.p4d.24xlarge		
ml.p4de.24xlarge		

Tip

To properly run distributed training on the EFA-enabled instance types, you should enable traffic between the instances by setting up the security group of your VPC to allow all inbound and outbound traffic to and from the security group itself. To learn how to set up the security group rules, see [Step 1: Prepare an EFA-enabled security group](#) in the *Amazon EC2 User Guide*.

Important

* The SMDDP library has discontinued support for optimizing its collective communication operations on P3 instances. While you can still utilize the SMDDP optimized `AllReduce` collective on `ml.p3dn.24xlarge` instances, there will be no further development support to enhance performance on this instance type. Note that the SMDDP optimized `AllGather` collective is only available for P4 instances.

For specs of the instance types, see the **Accelerated Computing** section in the [Amazon EC2 Instance Types page](#). For information about instance pricing, see [Amazon SageMaker Pricing](#).

If you encountered an error message similar to the following, follow the instructions at [Request a service quota increase for SageMaker AI resources](#).

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
for training job usage' is 0 Instances, with current utilization of 0 Instances
and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

Distributed training with the SageMaker AI distributed data parallelism library

The SageMaker AI distributed data parallelism (SMDDP) library is designed for ease of use and to provide seamless integration with PyTorch.

When training a deep learning model with the SMDDP library on SageMaker AI, you can focus on writing your training script and model training.

To get started, import the SMDDP library to use its collective operations optimized for AWS. The following topics provide instructions on what to add to your training script depending on which collective operation you want to optimize.

Topics

Adapting your training script to use the SMDDP collective operations

The training script examples provided in this section are simplified and highlight only the required changes to enable the SageMaker AI distributed data parallelism (SMDDP) library in your training script. For end-to-end Jupyter notebook examples that demonstrate how to run a distributed training job with the SMDDP library, see Amazon SageMaker AI data parallelism library examples.

Topics

Use the SMDDP library in your PyTorch training script

Starting from the SageMaker AI distributed data parallelism (SMDDP) library v1.4.0, you can use the library as a backend option for the PyTorch distributed package. To use the SMDDP `AllReduce` and `AllGather` collective operations, you only need to import the SMDDP library at the beginning of your training script and set SMDDP as the the backend of PyTorch distributed modules during process group initialization. With the single line of backend specification, you can keep all the native PyTorch distributed modules and the entire training script unchanged. The following code snippets show how to use the SMDDP library as the backend of PyTorch-based distributed training packages: PyTorch distributed data parallel (DDP), PyTorch fully sharded data parallelism (FSDP), DeepSpeed, and Megatron-DeepSpeed.

For PyTorch DDP or FSDP

Initialize the process group as follows.

```
import torch.distributed as dist
import smdistributed.dataparallel.torch.torch_smddp

dist.init_process_group(backend="smddp")
```

> **Note**
>
> (For PyTorch DDP jobs only) The `smddp` backend currently does not support creating subprocess groups with the `torch.distributed.new_group()` API. You also cannot use the `smddp` backend concurrently with other process group backends such as `NCCL` and `Gloo`.

For DeepSpeed or Megatron-DeepSpeed

Initialize the process group as follows.

```
import deepspeed
import smdistributed.dataparallel.torch.torch_smddp

deepspeed.init_distributed(dist_backend="smddp")
```

> **Note**
>
> To use SMDDP `AllGather` with the `mpirun`-based launchers (`smdistributed` and `pytorchddp`) in the section called "Launching distributed training jobs with SMDDP", you also need to set the following environment variable in your training script.
>
> ```
> export SMDATAPARALLEL_OPTIMIZE_SDP=true
> ```

For general guidance on writing a PyTorch FSDP training script, see Advanced Model Training with Fully Sharded Data Parallel (FSDP) in the PyTorch documentation.

For general guidance on writing a PyTorch DDP training script, see Getting started with distributed data parallel in the PyTorch documentation.

After you have completed adapting your training script, proceed to Launching distributed training jobs with SMDDP using the SageMaker Python SDK.

Use the SMDDP library in your PyTorch Lightning training script

If you want to bring your PyTorch Lightning training script and run a distributed data parallel training job in SageMaker AI, you can run the training job with minimal changes in your training script. The necessary changes include the following: import the `smdistributed.dataparallel` library's PyTorch modules, set up the environment variables for PyTorch Lightning to accept the SageMaker AI environment variables that are preset by the SageMaker training toolkit, and activate the SMDDP library by setting the process group backend to `"smddp"`. To learn more, walk through the following instructions that break down the steps with code examples.

> **Note**
>
> The PyTorch Lightning support is available in the SageMaker AI data parallel library v1.5.0 and later.

PyTorch Lightning == v2.1.0 and PyTorch == 2.0.1

1. Import the `pytorch_lightning` library and the `smdistributed.dataparallel.torch` modules.

```
import lightning as pl
import smdistributed.dataparallel.torch.torch_smddp
```

2. Instantiate the LightningEnvironment.

```
from lightning.fabric.plugins.environments.lightning import LightningEnvironment

env = LightningEnvironment()
env.world_size = lambda: int(os.environ["WORLD_SIZE"])
env.global_rank = lambda: int(os.environ["RANK"])
```

3. **For PyTorch DDP** – Create an object of the DDPStrategy class with "smddp" for process_group_backend and "gpu" for accelerator, and pass that to the Trainer class.

```
import lightning as pl
from lightning.pytorch.strategies import DDPStrategy

ddp = DDPStrategy(
    cluster_environment=env,
    process_group_backend="smddp",
    accelerator="gpu"
)

trainer = pl.Trainer(
    max_epochs=200,
    strategy=ddp,
    devices=num_gpus,
    num_nodes=num_nodes
)
```

For PyTorch FSDP – Create an object of the FSDPStrategy class (with wrapping policy of choice) with "smddp" for process_group_backend and "gpu" for accelerator, and pass that to the Trainer class.

```
import lightning as pl
from lightning.pytorch.strategies import FSDPStrategy

from functools import partial
from torch.distributed.fsdp.wrap import size_based_auto_wrap_policy

policy = partial(
    size_based_auto_wrap_policy,
    min_num_params=10000
)

fsdp = FSDPStrategy(
    auto_wrap_policy=policy,
    process_group_backend="smddp",
    cluster_environment=env
)

trainer = pl.Trainer(
    max_epochs=200,
```

```
    strategy=fsdp,
    devices=num_gpus,
    num_nodes=num_nodes
)
```

After you have completed adapting your training script, proceed to Launching distributed training jobs with SMDDP using the SageMaker Python SDK.

Note

When you construct a SageMaker AI PyTorch estimator and submit a training job request in the section called "Launching distributed training jobs with SMDDP", you need to provide `requirements.txt` to install `pytorch-lightning` and `lightning-bolts` in the SageMaker AI PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the *Amazon SageMaker AI Python SDK documentation*.

Use the SMDDP library in your TensorFlow training script (deprecated)

Important

The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. To find previous TensorFlow DLCs with the SMDDP library installed, see the section called "Supported frameworks".

The following steps show you how to modify a TensorFlow training script to utilize SageMaker AI's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the [SageMaker AI distributed data parallel TensorFlow API documentation]().

Note

SageMaker AI distributed data parallel is adaptable to TensorFlow training scripts composed of `tf` core modules except `tf.keras` modules. SageMaker AI distributed data parallel does not support TensorFlow with Keras implementation.

Note

The SageMaker AI distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker AI data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - TensorFlow in the *NVIDIA Deep Learning Performance documentation*
- Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
- TensorFlow mixed precision APIs in the *TensorFlow documentation*

1. Import the library's TensorFlow client and initialize it.

```
import smdistributed.dataparallel.tensorflow as sdp
sdp.init()
```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you with the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as `sdp.local_rank()`. `set_memory_growth` is not directly related to SageMaker AI distributed, but must be set for distributed training with TensorFlow.

```
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
```

```
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the following code block as `sdp.size()`.

```
learning_rate = learning_rate * sdp.size()
```

4. Use the library's `DistributedGradientTape` to optimize `AllReduce` operations during training. This wraps `tf.GradientTape`.

```
with tf.GradientTape() as tape:
      output = model(input)
      loss_value = loss(label, output)

# SageMaker AI data parallel: Wrap tf.GradientTape with the library's
 DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the following code block as `sdp.broadcast_variables()`.

```
sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

```
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

The following is an example TensorFlow training script for distributed training with the library.

```
import tensorflow as tf
```

```
# SageMaker AI data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker AI data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker AI data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker AI data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

    # SageMaker AI data parallel: Wrap tf.GradientTape with the library's
 DistributedGradientTape
    tape = sdp.DistributedGradientTape(tape)

    grads = tape.gradient(loss_value, mnist_model.trainable_variables)
    opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
       # SageMaker AI data parallel: Broadcast model and optimizer variables
       sdp.broadcast_variables(mnist_model.variables, root_rank=0)
       sdp.broadcast_variables(opt.variables(), root_rank=0)

    return loss_value
```

```
...

# SageMaker AI data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

After you have completed adapting your training script, move on to Launching distributed training jobs with SMDDP using the SageMaker Python SDK.

Launching distributed training jobs with SMDDP using the SageMaker Python SDK

To run a distributed training job with your adapted script from the section called “Adapting your training script to use the SMDDP collective operations”, use the SageMaker Python SDK's framework or generic estimators by specifying the prepared training script as an entry point script and the distributed training configuration.

This page walks you through how to use the SageMaker AI Python SDK in two ways.

- If you want to achieve a quick adoption of your distributed training job in SageMaker AI, configure a SageMaker AI PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the `framework_version` parameter.
- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker AI, use the SageMaker AI generic `Estimator` class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).

Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio Classic app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.

Tip

We recommend that you use Amazon FSx for Lustre instead of Amazon S3 to improve training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Tip

To properly run distributed training on the EFA-enabled instance types, you should enables traffic between the instances by setting up the security group of your VPC to allow all inbound and outbound traffic to and from the security group itself. To learn how to set up the security group rules, see Step 1: Prepare an EFA-enabled security group in the *Amazon EC2 User Guide*.

Choose one of the following topics for instructions on how to run a distributed training job of your training script. After you launch a training job, you can monitor system utilization and model performance using Amazon SageMaker Debugger or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker AI data parallelism library examples to get started.

Topics

Use the PyTorch framework estimators in the SageMaker Python SDK

You can launch distributed training by adding the `distribution` argument to the SageMaker AI framework estimators, `PyTorch` or `TensorFlow`. For more details, choose one of the frameworks supported by the SageMaker AI distributed data parallelism (SMDDP) library from the following selections.

PyTorch

The following launcher options are available for launching PyTorch distributed training.

- `pytorchddp` – This option runs `mpirun` and sets up environment variables needed for running PyTorch distributed training on SageMaker AI. To use this option, pass the following dictionary to the `distribution` parameter.

```
{ "pytorchddp": { "enabled": True } }
```

- `torch_distributed` – This option runs `torchrun` and sets up environment variables needed for running PyTorch distributed training on SageMaker AI. To use this option, pass the following dictionary to the `distribution` parameter.

```
{ "torch_distributed": { "enabled": True } }
```

- `smdistributed` – This option also runs `mpirun` but with `smddprun` that sets up environment variables needed for running PyTorch distributed training on SageMaker AI.

```
{ "smdistributed": { "dataparallel": { "enabled": True } } }
```

If you chose to replace NCCL `AllGather` to SMDDP `AllGather`, you can use all three options. Choose one option that fits with your use case.

If you chose to replace NCCL `AllReduce` with SMDDP `AllReduce`, you should choose one of the `mpirun`-based options: `smdistributed` or `pytorchddp`. You can also add additional MPI options as follows.

```
{
    "pytorchddp": {
        "enabled": True,
        "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
    }
}
```

```
{
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
```

```
        }
    }
}
```

The following code sample shows the basic structure of a PyTorch estimator with distributed training options.

```
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    source_dir="subdirectory-to-your-code",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py310",
    framework_version="2.0.1",

    # For running a multi-node distributed training job, specify a value greater
 than 1
    # Example: 2,3,4,..8
    instance_count=2,

    # Instance types supported by the SageMaker AI data parallel library:
    # ml.p4d.24xlarge, ml.p4de.24xlarge
    instance_type="ml.p4d.24xlarge",

    # Activate distributed training with SMDDP
    distribution={ "pytorchddp": { "enabled": True } }  # mpirun, activates SMDDP
 AllReduce OR AllGather
    # distribution={ "torch_distributed": { "enabled": True } }  # torchrun,
 activates SMDDP AllGather
    # distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }  #
 mpirun, activates SMDDP AllReduce OR AllGather
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the SageMaker AI PyTorch DLCs. Create the following `requirements.txt` file and save in the source directory where you save the training script.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For example, the tree-structured directory should look like the following.

```
### pytorch_training_launcher_jupyter_notebook.ipynb
### sub-folder-for-your-code
    ###  adapted-training-script.py
    ###  requirements.txt
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the *Amazon SageMaker AI Python SDK documentation*.

Considerations for activating SMDDP collective operations and using the right distributed training launcher options

- SMDDP `AllReduce` and SMDDP `AllGather` are not mutually compatible at present.
- SMDDP `AllReduce` is activated by default when using `smdistributed` or `pytorchddp`, which are `mpirun`-based launchers, and NCCL `AllGather` is used.
- SMDDP `AllGather` is activated by default when using `torch_distributed` launcher, and `AllReduce` falls back to NCCL.
- SMDDP `AllGather` can also be activated when using the `mpirun`-based launchers with an additional environment variable set as follows.

```
export SMDATAPARALLEL_OPTIMIZE_SDP=true
```

TensorFlow

Important

The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. To find previous TensorFlow DLCs with the SMDDP library installed, see the section called “TensorFlow (deprecated)”.

```
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.11.0",
    py_version="py38",

    # For running a multi-node distributed training job, specify a value greater
 than 1
    # Example: 2,3,4,..8
    instance_count=2,

    # Instance types supported by the SageMaker AI data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",

    # Training using the SageMaker AI data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

Use the SageMaker AI generic estimator to extend pre-built DLC containers

You can customize SageMaker AI prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker AI Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in [Supported frameworks](#).

> **Note**
>
> From TensorFlow 2.4.1 and PyTorch 1.8.1, SageMaker AI framework DLCs supports EFA-enabled instance types. We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a `FROM` statement similar to the following:

```
# SageMaker AI PyTorch image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/pytorch-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker AI PyTorch container to determine
 our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker AI, use the /code
 subdirectory to store your user code.
COPY train.py /opt/ml/code/train.py

# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM train.py
```

You can further customize your own Docker container to work with SageMaker AI using the [SageMaker Training toolkit](#) and the binary file of the SageMaker AI distributed data parallel library. To learn more, see the instructions in the following section.

Create your own Docker container with the SageMaker AI distributed data parallel library

To build your own Docker container for training and use the SageMaker AI data parallel library, you must include the correct dependencies and the binary files of the SageMaker AI distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker AI using the data parallel library.

> **Note**
>
> This custom Docker option with the SageMaker AI data parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the data parallel library

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

   ```
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   > **Tip**
   >
   > The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker AI data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   To use versions of the third party libraries other than the ones provided in the following code example, we recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find versions that are tested, compatible, and suitable for your application.

   To find URLs for the SMDATAPARALLEL_BINARY argument, see the lookup tables at Supported frameworks.

   ```
   ARG PYTORCH_VERSION=1.10.2
   ARG PYTHON_SHORT_VERSION=3.8
   ARG EFA_VERSION=1.14.1
   ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/
   ${PYTORCH_VERSION}/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-
   linux_x86_64.whl
   ```

```
ARG PT_S3_WHL_GPU=https://aws-s3-plugin.s3.us-west-2.amazonaws.com/
binaries/0.0.1/1c3e69e/awsio-0.0.1-cp38-cp38-manylinux1_x86_64.whl
ARG CONDA_PREFIX="/opt/conda"
ARG BRANCH_OFI=1.1.3-aws
```

3. Set the following environment variables to properly build SageMaker training components and run the data parallel library. You use these variables for the components in the subsequent steps.

```
# Set ENV variables required to build PyTorch
ENV TORCH_CUDA_ARCH_LIST="7.0+PTX 8.0"
ENV TORCH_NVCC_FLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this enviroment variable for SageMaker AI to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add enviroment variable for processes to be able to call fork()
ENV RDMAV_FORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python${PYTHON_SHORT_VERSION}/site-packages/
smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib/:$LD_LIBRARY_PATH
```

4. Install or update `curl`, `wget`, and `git` to download and build packages in the subsequent steps.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update && apt-get install -y  --no-install-recommends \
        curl \
        wget \
        git \
    && rm -rf /var/lib/apt/lists/*
```

5. Install Elastic Fabric Adapter (EFA) software for Amazon EC2 network communication.

```
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa \
    && cd /tmp/efa \
    && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-
${EFA_VERSION}.tar.gz \
    && tar -xf aws-efa-installer-${EFA_VERSION}.tar.gz \
    && cd aws-efa-installer \
    && ./efa_installer.sh -y --skip-kmod -g \
    && rm -rf /tmp/efa
```

6. Install Conda to handle package management.

```
RUN curl -fsSL -v -o ~/miniconda.sh -O  https://repo.anaconda.com/miniconda/
Miniconda3-latest-Linux-x86_64.sh  && \
    chmod +x ~/miniconda.sh && \
    ~/miniconda.sh -b -p $CONDA_PREFIX && \
    rm ~/miniconda.sh && \
    $CONDA_PREFIX/bin/conda install -y python=${PYTHON_SHORT_VERSION} conda-build
 pyyaml numpy ipython && \
    $CONDA_PREFIX/bin/conda clean -ya
```

7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plug-in.

   a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```
RUN DEBIAN_FRONTEND=noninteractive \
    apt-get install -y --no-install-recommends \
        build-essential \
        ca-certificates \
        ccache \
        cmake \
        git \
        libjpeg-dev \
        libpng-dev \
    && rm -rf /var/lib/apt/lists/*

# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
```

```
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch’s common and Linux dependencies.

```
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja pyyaml mkl mkl-include setuptools cmake
 cffi typing_extensions future six requests dataclasses

# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cuda113
```

c. Clone the PyTorch GitHub repository.

```
RUN --mount=type=cache,target=/opt/ccache \
    cd / \
    && git clone --recursive https://github.com/pytorch/pytorch -b v
${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch’s default NCCL folder (`/pytorch/third_party/nccl`) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```
RUN cd /pytorch/third_party/nccl \
    && rm -rf nccl \
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \
    && cd nccl \
    && make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-
gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \
    && make pkg.txz.build \
    && tar -xvf build/pkg/txz/nccl_*.txz -C $CONDA_PREFIX --strip-components=1
```

e. Build and install PyTorch. This process usually takes slightly more than 1 hour to complete. It is built using the NCCL version downloaded in a previous step.

```
RUN cd /pytorch \
    && CMAKE_PREFIX_PATH="$(dirname $(which conda))/../" \
    python setup.py install \
    && rm -rf /pytorch
```

8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker AI data parallel library.

```
RUN DEBIAN_FRONTEND=noninteractive apt-get update \
    && apt-get install -y --no-install-recommends \
        autoconf \
        automake \
        libtool
RUN mkdir /tmp/efa-ofi-nccl \
    && cd /tmp/efa-ofi-nccl \
    && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \
    && cd aws-ofi-nccl \
    && ./autogen.sh \
    && ./configure --with-libfabric=/opt/amazon/efa \
    --with-mpi=/opt/amazon/openmpi \
    --with-cuda=/usr/local/cuda \
    --with-nccl=$CONDA_PREFIX \
    && make \
    && make install \
    && rm -rf /tmp/efa-ofi-nccl
```

9. Build and install [TorchVision](https://github.com/pytorch/vision.git).

```
RUN pip install --no-cache-dir -U \
    packaging \
    mpi4py==3.0.3
RUN cd /tmp \
    && git clone https://github.com/pytorch/vision.git -b v0.9.1 \
    && cd vision \
    && BUILD_VERSION="0.9.1+cu111" python setup.py install \
    && cd /tmp \
    && rm -rf vision
```

10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

```
RUN apt-get update \
    && apt-get install -y  --allow-downgrades --allow-change-held-packages --no-
install-recommends \
    && apt-get install -y --no-install-recommends openssh-client openssh-server \
    && mkdir -p /var/run/sshd \
    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/
ssh_config.new \
    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \
    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \
```

```
    && rm -rf /var/lib/apt/lists/*

# Configure OpenSSH so that nodes can communicate with each other
RUN mkdir -p /var/run/sshd && \
 sed 's@session\s*required\s*pam_loginuid.so@session optional pam_loginuid.so@g' -i /
etc/pam.d/sshd
RUN rm -rf /root/.ssh/ && \
 mkdir -p /root/.ssh/ && \
 ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa && \
 cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys \
 && printf "Host *\n StrictHostKeyChecking no\n" >> /root/.ssh/config
```

11. Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

```
RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU}
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/
tls/certs/ca-bundle.crt
```

12. Install the libboost library. This package is needed for networking the asynchronous IO functionality of the SageMaker AI data parallel library.

```
WORKDIR /
RUN wget https://sourceforge.net/projects/boost/files/boost/1.73.0/
boost_1_73_0.tar.gz/download -O boost_1_73_0.tar.gz \
    && tar -xzf boost_1_73_0.tar.gz \
    && cd boost_1_73_0 \
    && ./bootstrap.sh \
    && ./b2 threading=multi --prefix=${CONDA_PREFIX} -j 64 cxxflags=-fPIC cflags=-
fPIC install || true \
    && cd .. \
    && rm -rf boost_1_73_0.tar.gz \
    && rm -rf boost_1_73_0 \
    && cd ${CONDA_PREFIX}/include/boost
```

13. Install the following SageMaker AI tools for PyTorch training.

```
WORKDIR /root
RUN pip install --no-cache-dir -U \
    smclarify \
    "sagemaker>=2,<3" \
    sagemaker-experiments==0.* \
    sagemaker-pytorch-training
```

14. Finally, install the SageMaker AI data parallel binary and the remaining dependencies.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
  apt-get update && apt-get install -y  --no-install-recommends \
  jq \
  libhwloc-dev \
  libnuma1 \
  libnuma-dev \
  libssl1.1 \
  libtool \
  hwloc \
  && rm -rf /var/lib/apt/lists/*

RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

15. After you finish creating the Dockerfile, see [Adapting Your Own Training Container](#) to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```
# This file creates a docker image with minimum dependencies to run SageMaker AI data
 parallel training
FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04

# Set appropiate versions and location for components
ARG PYTORCH_VERSION=1.10.2

Tip

For more general information about creating a custom Dockerfile for training in SageMaker AI, see Use Your Own Training Algorithms.

Tip

If you want to extend the custom Dockerfile to incorporate the SageMaker AI model parallel library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library.

Amazon SageMaker AI data parallelism library examples

This page provides Jupyter notebooks that present examples of implementing the SageMaker AI distributed data parallelism (SMDDP) library to run distributed training jobs on SageMaker AI.

Blogs and Case Studies

The following blogs discuss case studies about using the SMDDP library.

SMDDP v2 blogs

- Enable faster training with Amazon SageMaker AI data parallel library, *AWS Machine Learning Blog* (December 05, 2023)

SMDDP v1 blogs

- How I trained 10TB for Stable Diffusion on SageMaker AI in *Medium* (November 29, 2022)
- Run PyTorch Lightning and native PyTorch DDP on Amazon SageMaker Training, featuring Amazon Search , *AWS Machine Learning Blog* (August 18, 2022)
- Training YOLOv5 on AWS with PyTorch and the SageMaker AI distributed data parallel library, *Medium* (May 6, 2022)
- Speed up EfficientNet model training on SageMaker AI with PyTorch and the SageMaker AI distributed data parallel library, *Medium* (March 21, 2022)
- Speed up EfficientNet training on AWS with the SageMaker AI distributed data parallel library, *Towards Data Science* (January 12, 2022)
- Hyundai reduces ML model training time for autonomous driving models using Amazon SageMaker AI, *AWS Machine Learning Blog* (June 25, 2021)
- Distributed Training: Train BART/T5 for Summarization using Transformers and Amazon SageMaker AI, the *Hugging Face website* (April 8, 2021)

Example notebooks

Example notebooks are provided in the SageMaker AI examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/data_parallel`.

Note

Clone and run the example notebooks in the following SageMaker AI ML IDEs.

- SageMaker AI JupyterLab (available in Studio created after December 2023)
- SageMaker AI Code Editor (available in Studio created after December 2023)
- Studio Classic (available as an application in Studio created after December 2023)
- SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/data_parallel
```

SMDDP v2 examples

- Train Llama 2 using the SageMaker AI distributed data parallel library (SMDDP) and DeepSpeed
- Train Falcon using the SageMaker AI distributed data parallel library (SMDDP) and PyTorch Fully Sharded Data Parallelism (FSDP)

SMDDP v1 examples

- CNN with PyTorch and the SageMaker AI data parallelism library
- BERT with PyTorch and the SageMaker AI data parallelism library
- CNN with TensorFlow 2.3.1 and the SageMaker AI data parallelism library
- BERT with TensorFlow 2.3.1 and the SageMaker AI data parallelism library
- HuggingFace Distributed Data Parallel Training in PyTorch on SageMaker AI - Distributed Question Answering
- HuggingFace Distributed Data Parallel Training in PyTorch on SageMaker AI - Distributed Text Summarization
- HuggingFace Distributed Data Parallel Training in TensorFlow on SageMaker AI

Configuration tips for the SageMaker AI distributed data parallelism library

Review the following tips before using the SageMaker AI distributed data parallelism (SMDDP) library. This list includes tips that are applicable across frameworks.

Topics

Data preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker AI distributed data parallel uses the CPU for `AllReduce` operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single versus multiple nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library's `AllReduce` operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node `AllReduce` efficiency.

Debug scaling efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as `CPUBottleneck`, `LoadBalancing`, and `LowGPUUtilization`. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS SDK for Python (Boto3) for training on SageMaker AI, you can enable Debugger as shown in Configure SageMaker Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a *Linear Scaling Rule* where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, [Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour](), Sections 2 and 3.

Custom MPI options

The SageMaker AI distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch `Estimator`, the respective container sets up the MPI environment and executes the `mpirun` command to start jobs on the cluster nodes.

You can set custom MPI operations using the `custom_mpi_options` parameter in the `Estimator`. Any `mpirun` flags passed in this field are added to the `mpirun` command and executed by SageMaker AI for training. For example, you may define the `distribution` parameter of an `Estimator` using the following to use the `NCCL_DEBUG` variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options":
 "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the **SCRATCH_2** deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the *Amazon FSx for Lustre documentation*:

- How to increase storage capacity
- Aggregate file system performance

Amazon SageMaker AI distributed data parallelism library FAQ

Use the following to find answers to commonly asked questions about the SMDDP library.

Q: When using the library, how are the `allreduce`-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker AI service create extra C5s for jobs that use the SMDDP library?

The SMDDP library only supports GPU instances, more specificcally, P4d and P4de instances with NVIDIA A100 GPUs and EFA. No additional C5 or CPU instances are launched; if your SageMaker

AI training job is on an 8-node P4d cluster, only 8 `ml.p4d.24xlarge` instances are used. No additional instances are provisioned.

Q: I have a training job taking 5 days on a single `ml.p3.24xlarge` instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker AI's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the SMDDP library?

The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

Q: Does the SMDDP library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called "TensorFlow (deprecated)" and the section called "PyTorch".

Q: Is the SMDDP library relevant in a single-host, multi-device setup?

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

Q: Where should the training dataset be stored?

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.

Q: When using the SMDDP library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

Q: Can the library be used with CPU nodes?

No. To find instance types supported by the SMDDP library, see the section called "Supported instance types".

Q: What frameworks and framework versions are currently supported by the SMDDP library at launch?

the SMDDP library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the SMDDP library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, the SMDDP library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker AI data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the *NVIDIA Deep Learning Performace documentation*
- Frameworks - TensorFlow in the *NVIDIA Deep Learning Performace documentation*
- Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the *PyTorch Blog*
- TensorFlow mixed precision APIs in the *TensorFlow documentation*

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement and more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the *FSx for Lustre User Guide*.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity.

Q: (For the library v1.4.0 or later) How do I resolve the `Invalid backend` error while initializing process group.

If you encounter the error message `ValueError: Invalid backend: 'smddp'` when calling `init_process_group`, this is due to the breaking change in the SMDDP library v1.4.0 and later. You must import the PyTorch client of the library, `smdistributed.dataparallel.torch.torch_smddp`, which registers `smddp` as a backend for PyTorch. To learn more, see the section called "PyTorch".

Q: (For the SMDDP library v1.4.0 or later) I would like to call the collective primitives of the `torch.distributed` interface. Which primitives does the `smddp` backend support?

In v1.4.0, the SMDDP library supports `all_reduce`, `broadcast`, `reduce`, `all_gather`, and `barrier` of of the `torch.distributed` interface.

Q: (For the SMDDP library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SMDDP library is tested with other third-party distributed data parallel libraries and framework implementations that use the `torch.distribtued` modules. Using the SMDDP library with custom DDP classes works as long as the collective operations used by the custom DDP classes are supported by the SMDDP library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker AI team through the AWS Support Center or AWS Developer Forums for Amazon SageMaker AI.

Q: Does the SMDDP library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SMDDP library and its minimum dependencies into your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker AI generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker AI with the SMDDP library, see Create your own Docker container with the SageMaker AI distributed data parallel library.

Troubleshooting for distributed training in Amazon SageMaker AI

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker AI team through AWS Support Center or AWS Developer Forums for Amazon Amazon SageMaker AI.

Topics

Using SageMaker AI distributed data parallel with Amazon SageMaker Debugger and checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker AI distributed data parallel, use Amazon SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker AI distributed data parallel, and SageMaker AI checkpoints, you might see an error that looks like the following example.

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker AI distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework `estimator` example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name,
 checkpoint_in_bucket)

estimator = TensorFlow(
    ...

    distribution={"smdistributed": {"dataparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
```

```
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

- If you want to keep using both SageMaker AI distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see [Saving Checkpoints](#).

An unexpected prefix attached to model parameter keys

For PyTorch distributed training jobs, an unexpected prefix (`model` for example) might be attached to `state_dict` keys (model parameters). The SageMaker AI data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker AI data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each `state_dict` key as a string value, separates the string at the first occurrence of `'model.'`, and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the *PyTorch discussion forum*.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the *PyTorch documentation*.

SageMaker AI distributed training job stalling during initialization

If your SageMaker AI distributed data parallel training job stalls during initialization when using EFA-enabled instances, this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

To configure inbound and outbound rules for the security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Security Groups** in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the **Details** section, copy the **Security group ID**.
5. On the **Inbound rules** tab, choose **Edit inbound rules**.
6. On the **Edit inbound rules** page, do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Source**, choose **Custom**, paste the security group ID into the search box, and select the security group that pops up.
7. Choose **Save rules** to finish configuring the inbound rule for the security group.
8. On the **Outbound rules** tab, choose **Edit outbound rules**.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.

After you complete the preceding steps for configuring the security group with the inbound and outbound rules, re-run the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

SageMaker AI distributed training job stalling at the end of training

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.

Observing scaling efficiency degradation due to Amazon FSx throughput bottlenecks

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see [Aggregate file system performance] and [Managing storage and throughput capacity] in the *Amazon FSx for Lustre User Guide*.

SageMaker AI distributed training job with PyTorch returns deprecation warnings

Since v1.4.0, the SageMaker AI distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the `smdistributed` APIs for the PyTorch distributed package are deprecated. The warning message should be similar to the following:

```
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker AI distributed
 data parallel library v1.4.0+.
Please use torch.distributed and specify 'smddp' as a backend when initializing process
 group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at
https://docs.aws.amazon.com/sagemaker/latest/dg/data-parallel-modify-sdp-pt.html
```

In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See [Use the SMDDP library in your PyTorch training script] to learn about the breaking changes and the new way to use the library with PyTorch.

SageMaker AI data parallelism library release notes

See the following release notes to track the latest updates for the SageMaker AI distributed data parallelism (SMDDP) library.

The SageMaker AI distributed data parallelism library v2.5.0

Date: October 17, 2024

New features

- Added support for PyTorch v2.4.1 with CUDA v12.1.

Integration into Docker containers distributed by the SageMaker AI model parallelism (SMP) library

This version of the SMDDP library is migrated to the section called “SMP v2.6.0”.

```
658645717510.dkr.ecr.<us-west-2>.amazonaws.com/smdistributed-modelparallel:2.4.1-gpu-py311-cu121
```

For Regions where the SMP Docker images are available, see the section called “AWS Regions”.

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.4.1/cu121/2024-10-09/smdistributed_dataparallel-2.5.0-cp311-cp311-linux_x86_64.whl
```

The SageMaker AI distributed data parallelism library v2.3.0

Date: June 11, 2024

New features

- Added support for PyTorch v2.3.0 with CUDA v12.1 and Python v3.11.
- Added support for PyTorch Lightning v2.2.5. This is integrated into the SageMaker AI framework container for PyTorch v2.3.0.
- Added instance type validation during import to prevent loading the SMDDP library on unsupported instance types. For a list of instance types compatible with the SMDDP library, see the section called “Supported frameworks, AWS Regions, and instances types”.

Integration into SageMaker AI Framework Containers

This version of the SMDDP library is migrated to the following SageMaker AI Framework Container.

- PyTorch v2.3.0

```
763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.3.0-gpu-py311-cu121-
ubuntu20.04-sagemaker
```

For a complete list of versions of the SMDDP library and the pre-built containers, see the section called "Supported frameworks, AWS Regions, and instances types".

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.3.0/cu121/2024-05-23/
smdistributed_dataparallel-2.3.0-cp311-cp311-linux_x86_64.whl
```

Other changes

- The SMDDP library v2.2.0 is integrated into the SageMaker AI framework container for PyTorch v2.2.0.

The SageMaker AI distributed data parallelism library v2.2.0

Date: March 4, 2024

New features

- Added support for PyTorch v2.2.0 with CUDA v12.1.

Integration into Docker containers distributed by the SageMaker AI model parallelism (SMP) library

This version of the SMDDP library is migrated to the section called "SMP v2.2.0".

```
658645717510.dkr.ecr.<region>.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-
py310-cu121
```

For Regions where the SMP Docker images are available, see the section called "AWS Regions".

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.2.0/cu121/2024-03-04/
smdistributed_dataparallel-2.2.0-cp310-cp310-linux_x86_64.whl
```

The SageMaker AI distributed data parallelism library v2.1.0

Date: March 1, 2024

New features

- Added support for PyTorch v2.1.0 with CUDA v12.1.

Bug fixes

- Fixed the CPU memory leak issue in SMDDP v2.0.1.

Integration into SageMaker AI Framework Containers

This version of the SMDDP library passed benchmark testing and is migrated to the following SageMaker AI Framework Container.

- PyTorch v2.1.0

  ```
  763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-
  ubuntu20.04-sagemaker
  ```

Integration into Docker containers distributed by the SageMaker AI model parallelism (SMP) library

This version of the SMDDP library is migrated to the section called “SMP v2.1.0”.

```
658645717510.dkr.ecr.<region>.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-
py310-cu121
```

For Regions where the SMP Docker images are available, see the section called “AWS Regions”.

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.1.0/cu121/2024-02-04/
smdistributed_dataparallel-2.1.0-cp310-cp310-linux_x86_64.whl
```

The SageMaker AI distributed data parallelism library v2.0.1

Date: December 7, 2023

New features

- Added a new SMDDP-implementation of `AllGather` collective operation optimized for AWS compute resources and network infrastructure. To learn more, see the section called "SMDDP `AllGather` collective operation".
- The SMDDP `AllGather` collective operation is compatible with PyTorch FSDP and DeepSpeed. To learn more, see the section called "PyTorch".
- Added support for PyTorch v2.0.1

Known issues

- There's a CPU memory leak issue from a gradual CPU memory increase while training with SMDDP `AllReduce` in DDP mode.

Integration into SageMaker AI Framework Containers

This version of the SMDDP library passed benchmark testing and is migrated to the following SageMaker AI Framework Container.

- PyTorch v2.0.1

  ```
  763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu118-
  ubuntu20.04-sagemaker
  ```

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.0.1/cu118/2023-12-07/
smdistributed_dataparallel-2.0.2-cp310-cp310-linux_x86_64.whl
```

Other changes

- Starting from this release, documentation for the SMDDP library is fully available in this *Amazon SageMaker AI Developer Guide*. In favor of the complete developer guide for SMDDP v2 housed in the *Amazon SageMaker AI Developer Guide*, documentation for the additional reference for SMDDP v1.x in the *SageMaker AI Python SDK documentation* is no longer supported. If you still need SMP v1.x documentation, see the following snapshot of the documentation at SageMaker Python SDK v2.212.0 documentation.

SageMaker model parallelism library v2

> **Note**
>
> Since the release of the SageMaker model parallelism (SMP) library v2.0.0 on December 19, 2023, this documentation is renewed for the SMP library v2. For previous versions of the SMP library, see the section called "(Archived) SageMaker model parallelism library v1.x".

The Amazon SageMaker AI model parallelism library is a capability of SageMaker AI that enables high performance and optimized large scale training on SageMaker AI accelerate compute instances. The the section called "Core features of SMP v2" include techniques and optimizations to accelerate and simplify large model training, such as hybrid sharded data parallelism, tensor parallelism, activation checkpointing, and activation offloading. You can use the SMP library to accelerate the training and fine-tuning of large language models (LLMs), large vision models (LVMs), and foundation models (FMs) with hundreds of billions of parameters.

The SageMaker model parallelism library v2 (SMP v2) aligns the library's APIs and methods with open source PyTorch Fully Sharded Data Parallelism (FSDP), which gives you the benefit of SMP performance optimizations with minimal code changes. With SMP v2, you can improve the computational performance of training a state-of-the-art large model on SageMaker AI by bringing your PyTorch FSDP training scripts to SageMaker AI.

You can use SMP v2 for the general SageMaker Training jobs and distributed training workloads on the section called "HyperPod" clusters.

Topics

- Model parallelism concepts
- Supported frameworks and AWS Regions

Model parallelism concepts

Model parallelism is a distributed training method in which the deep learning (DL) model is partitioned across multiple GPUs and instances. The SageMaker model parallel library v2 (SMP v2) is compatible with the native PyTorch APIs and capabilities. This makes it convenient for you to adapt your PyTorch Fully Sharded Data Parallel (FSDP) training script to the SageMaker Training platform and take advantage of the performance improvement that SMP v2 provides. This introduction page provides a high-level overview about model parallelism and a description of how it can help overcome issues that arise when training deep learning (DL) models that are typically very large in size. It also provides examples of what the SageMaker model parallel library offers to help manage model parallel strategies and memory consumption.

What is model parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model that you can train, because the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker AI provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve optimized distributed training using

EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate memory requirements before using model parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses automatic mixed precision such as `float16` (FP16) or `bfloat16` (BF16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 or BF16 parameter ~ 2 bytes
- An FP16 or BF16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the `optimizer apply` (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory) available on a single GPU. On top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P4 and P5 instances that have NVIDIA A100 and H100 Tensor Core GPUs respectively. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the *Accelerated Computing* section in the Amazon EC2 Instance Types page. For instance types that SMP v2 supports, see the section called “Supported instance types”.

Even with the accelerated computing instances, models with about 10 billion parameters such as Megatron-LM and T5, and even larger models with hundreds of billions of parameters such as GPT-3, cannot fit model replicas in each GPU device.

How the library employs model parallelism and memory saving techniques

The library consists of various types of model parallelism features and memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models that consist of hundreds of billions of parameters.

Topics

Sharded data parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs within a data-parallel group.

SMP v2 implements sharded data parallelism through FSDP, and extends it to implement the scale aware hybrid sharding strategy discussed in the blog post Near-linear scaling of gigantic-model training on AWS.

You can apply sharded data parallelism to your model as a standalone strategy. Furthermore, if you are using the most performant GPU instances equipped with NVIDIA A100 Tensor Core GPUs, `ml.p4d.24xlarge` and `ml.p4de.24xlarge`, you can take the advantage of improved training speed from the `AllGather` operation offered by the SageMaker data parallelism (SMDDP) library.

To dive deep into sharded data parallelism and learn how to set it up or use a combination of sharded data parallelism with other techniques like tensor parallelism and mixed precision training, see the section called “Hybrid sharded data parallelism”.

Expert parallelism

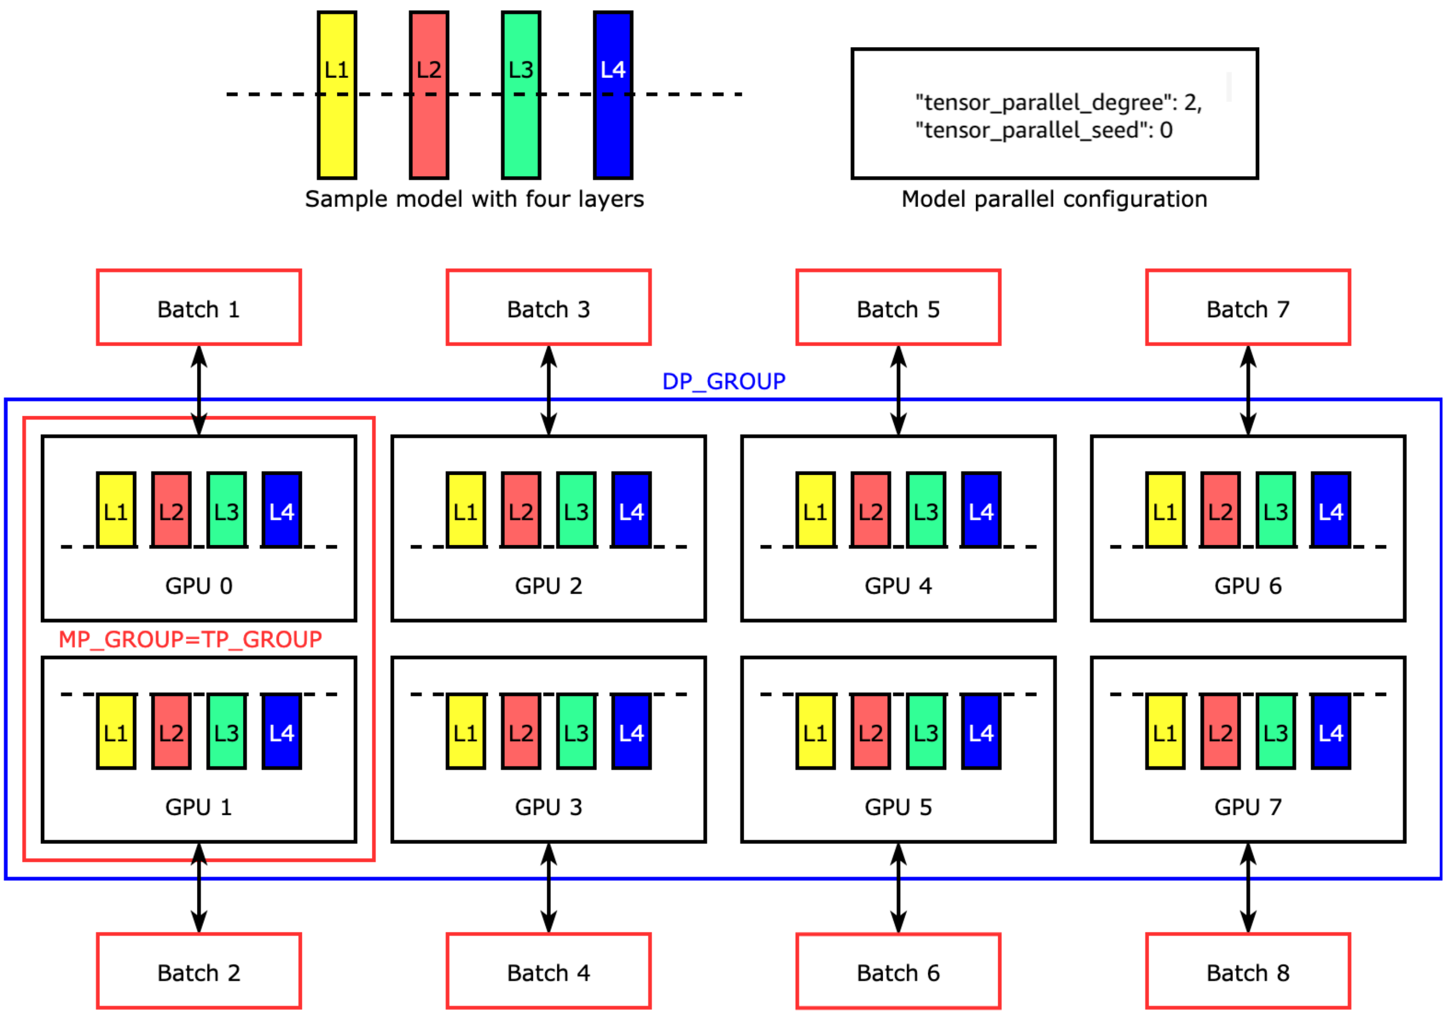
SMP v2 integrates with NVIDIA Megatron for implementing *expert parallelism* on top of its support for the native PyTorch FSDP APIs. You can keep your PyTorch FSDP training code as is and apply SMP expert parallelism for training *Mixture of Experts* (MoE) models within SageMaker AI.

An MoE model is a type of transformer model that consists of multiple *experts*, each consisting of a neural network, typically a feed-forward network (FFN). A gate network called *router* determines which tokens are sent to which expert. These experts specialize in processing specific aspects of the input data, enabling the model to train faster, reduce compute cost, while achieving the same performance quality as its counterpart dense model. And *expert parallelism* is a parallelism technique that handles splitting experts of an MoE model across GPU devices.

To learn how to train MoE models with SMP v2, see [the section called “Expert parallelism”](#).

Tensor parallelism

Tensor parallelism splits individual layers, or `nn.Modules`, across devices to run in parallel. The following figure shows the simplest example of how the SMP library splits a model with four layers to achieve two-way tensor parallelism (`"tensor_parallel_degree": 2`). In the following figure, the notations for model parallel group, tensor parallel group, and data parallel group are `MP_GROUP`, `TP_GROUP`, and `DP_GROUP` respectively. The layers of each model replica are bisected and distributed into two GPUs. The library manages communication across the tensor-distributed model replicas.



To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of the core features, see [the section called “Tensor parallelism”](#).

Activation checkpointing and offloading

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, with activation offloading, it offloads the stored activations to CPU memory and fetches them back to GPU during the backward pass to further reduce the activation memory footprint. For more information about how to use these features, see the section called “Activation checkpointing” and the section called “Activation offloading”.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see the section called “Best practices”.

Supported frameworks and AWS Regions

Before using the SageMaker model parallelism library v2 (SMP v2), check the supported frameworks and instance types and determine if there are enough quotas in your AWS account and AWS Region.

> **Note**
>
> To check the latest updates and release notes of the library, see the section called “SMP release notes”.

Supported frameworks

SMP v2 supports the following deep learning frameworks and available through SMP Docker containers and an SMP Conda channel. When you use the framework estimator classes in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use SMP v2, we recommend that you always keep the SageMaker Python SDK up to date in your development environment.

PyTorch versions that the SageMaker model parallelism library supports

PyTorch version	SageMaker model parallelism library version	SMP Docker image URI	SMP Enroot image URI
v2.5.1	`smdistributed-modelparallel==v2.8.0`	`658645717510.dkr.ecr.` *<us-west-2>* `.amazonaws.com/smdistributed-modelparallel:2.5.1-gpu-py311-cu124`	`https://sagemaker-distributed-model-parallel.s3.` *<us-west-2>* `.amazonaws.com/enroot/2.5.1-gpu-py311-cu124.sqsh`
v2.4.1	`smdistributed-modelparallel==v2.7.0`	`658645717510.dkr.ecr.` *<us-west-2>* `.amazonaws.com/smdistributed-modelparallel:2.4.1-gpu-py311-cu121`	`https://sagemaker-distributed-model-parallel.s3.` *<us-west-2>* `.amazonaws.com/enroot/2.4.1-gpu-py311-cu121.sqsh`
	`smdistributed-modelparallel==v2.6.1`		N/A
	`smdistributed-modelparallel==v2.6.0`		N/A
v2.3.1	`smdistributed-modelparallel==v2.5.0`	`658645717510.dkr.ecr.` *us-west-2*	N/A

PyTorch version	SageMaker model parallelism library version	SMP Docker image URI	SMP Enroot image URI
	`smdistributed-modelparallel==v2.4.0`	`.amazonaws.com/smdistributed-modelparallel:2.3.1-gpu-py311-cu121`	
v2.2.0	`smdistributed-modelparallel==v2.3.0`	`658645717510.dkr.ecr.` *`us-west-2`* `.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121`	N/A
	`smdistributed-modelparallel==v2.2.0`		
v2.1.2	`smdistributed-modelparallel==v2.1.0`	`658645717510.dkr.ecr.` *`us-west-2`* `.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-py310-cu121`	N/A

PyTorch version	SageMaker model parallelism library version	SMP Docker image URI	SMP Enroot image URI
v2.0.1	smdistributed-modelparallel==v2.0.0	658645717510.dkr.ecr. *us-west-2* .amazonaws.com/smdistributed-modelparallel:2.0.1-gpu-py310-cu121	N/A

SMP Conda channel

The following Amazon S3 bucket is a public Conda channel hosted by the SMP service team. If you want to install the SMP v2 library in an environment such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

```
https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/
```

For more information about Conda channels in general, see Channels in the *Conda documentation*.

Note

To find previous versions of the SMP library v1.x and pre-packaged DLCs, see the section called "Supported Frameworks" in the *SMP v1 documentation*.

Use SMP v2 with open source libraries

The SMP v2 library works with other PyTorch-based open source libraries such as PyTorch Lightning, Hugging Face Transformers, and Hugging Face Accelerate, because SMP v2 is compatible with the PyTorch FSDP APIs. If you have further questions on using the SMP library with other third party libraries, contact the SMP service team at `sm-model-parallel-feedback@amazon.com`.

AWS Regions

SMP v2 is available in the following AWS Regions. If you'd like to use the SMP Docker image URIs or the SMP Conda channel, check the following list and choose the AWS Region matching with yours, and update the image URI or the channel URL accordingly.

- ap-northeast-1
- ap-northeast-2
- ap-northeast-3
- ap-south-1
- ap-southeast-1
- ap-southeast-2
- ca-central-1
- eu-central-1
- eu-north-1
- eu-west-1
- eu-west-2
- eu-west-3
- sa-east-1
- us-east-1
- us-east-2
- us-west-1
- us-west-2

Supported instance types

SMP v2 requires one of the following ML instance types.

Instance type
`ml.p4d.24xlarge`
`ml.p4de.24xlarge`
`ml.p5.48xlarge`

Instance type
ml.p5e.48xlarge

Tip

Starting from SMP v2.2.0 supporting PyTorch v2.2.0 and later, the section called "Mixed precision training with FP8 on P5 instances using Transformer Engine" is available.

For specs of the SageMaker machine learning instance types in general, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker AI Pricing.

If you encountered an error message similar to the following, follow the instructions at Requesting a quota increase in the *AWS Service Quotas User Guide*.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
    the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
    for training job usage' is 0 Instances, with current utilization of 0 Instances
    and a request delta of 1 Instances.
    Please contact AWS support to request an increase for this limit.
```

Use the SageMaker model parallelism library v2

On this page, you'll learn how to use the SageMaker model parallelism library v2 APIs and get started with running a PyTorch Fully Sharded Data Parallel (FSDP) training job in the SageMaker Training platform or on a SageMaker HyperPod cluster.

There are various scenarios for running a PyTorch training job with SMP v2.

1. For SageMaker training, use one of the pre-built SageMaker Framework Containers for PyTorch v2.0.1 and later, which are pre-packaged with SMP v2.
2. Use the SMP v2 binary file to set up a Conda environment for running a distributed training workload on a SageMaker HyperPod cluster.
3. Extend the pre-built SageMaker Framework Containers for PyTorch v2.0.1 and later to install any additional functional requirements for your use case. To learn how to extend a pre-built container, see Extend a Pre-built Container.

4. You can also bring your own Docker container and manually set up all SageMaker Training environment using the SageMaker Training toolkit and install the SMP v2 binary file. This is the least recommended option due to the complexity of dependencies. To learn how to run your own Docker container, see Adapting Your Own Training Container.

This getting started guide covers the first two scenarios.

Topics

Step 1: Adapt your PyTorch FSDP training script

To activate and configure the SMP v2 library, start with importing and adding the `torch.sagemaker.init()` module at the top of the script. This module takes in the SMP configuration dictionary of the section called “SMP v2 core feature configuration parameters” that you'll prepare in the section called “Step 2: Launch a training job”. Also, for using the various core features offered by SMP v2, you might need to make few more changes to adapt your training script. More detailed instructions on adapting your training script for using the SMP v2 core features are provided at the section called “Core features of SMP v2”.

SageMaker Training

In your training script, add the following two lines of code, which is the minimal requirement to start training with SMP v2. In the section called “Step 2: Launch a training job”, you'll set up an object of the SageMaker `PyTorch` estimator class with an SMP configuration dictionary through the `distribution` argument of the estimator class.

```
import torch.sagemaker as tsm
tsm.init()
```

Note

You can also directly pass a configuration dictionary of the the section called “SMP v2 core feature configuration parameters” to the `torch.sagemaker.init()` module. However, the parameters passed to the PyTorch estimator in the section called

"Step 2: Launch a training job" take priority and override the ones specified to the `torch.sagemaker.init()` module.

SageMaker HyperPod

In your training script, add the following two lines of code. In the section called "Step 2: Launch a training job", you'll set up a `smp_config.json` file for setting up SMP configurations in JSON format, and upload it to a storage or a file system mapped with your SageMaker HyperPod cluster. We recommend that you keep the configuration file under the same directory where you upload your training script.

```
import torch.sagemaker as tsm
tsm.init("/dir_to_training_files/smp_config.json")
```

Note

You can also directly pass a configuration dictionary of the the section called "SMP v2 core feature configuration parameters" into the `torch.sagemaker.init()` module.

Step 2: Launch a training job

Learn how to configure SMP distribution options for launching a PyTorch FSDP training job with SMP core features.

SageMaker Training

When you set up a training job launcher object of the PyTorch framework estimator class in the SageMaker Python SDK, configure the section called "SMP v2 core feature configuration parameters" through `distribution` argument as follows.

Note

The `distribution` configuration for SMP v2 is integrated in the SageMaker Python SDK starting from v2.200. Make sure that you use the SageMaker Python SDK v2.200 or later.

> **Note**
>
> In SMP v2, you should configure `smdistributed` with `torch_distributed` for the `distribution` argument of the SageMaker `PyTorch` estimator. With `torch_distributed`, SageMaker AI runs `torchrun`, which is the default multi-node job launcher of [PyTorch Distributed](https://pytorch.org/tutorials/beginner/dist_overview.html).

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    framework_version=2.2.0,
    py_version="310"
    # image_uri="<smp-docker-image-uri>" # For using prior versions, specify the SMP
 image URI directly.
    entry_point="your-training-script.py", # Pass the training script you adapted
 with SMP from Step 1.
    ... # Configure other required and optional parameters
    distribution={
        "torch_distributed": { "enabled": True },
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    "hybrid_shard_degree": Integer,
                    "sm_activation_offloading": Boolean,
                    "activation_loading_horizon": Integer,
                    "fsdp_cache_flush_warnings": Boolean,
                    "allow_empty_shards": Boolean,
                    "tensor_parallel_degree": Integer,
                    "expert_parallel_degree": Integer,
                    "random_seed": Integer
                }
            }
        }
    }
)
```

> **Important**
>
> For using one of the prior versions of PyTorch or SMP instead of the latest, you need to specify the SMP Docker image directly using the `image_uri` argument instead of the `framework_version` and `py_version` pair. The following is an example of
>
> ```
> estimator = PyTorch(
>     ...,
>     image_uri="658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-
> modelparallel:2.2.0-gpu-py310-cu121"
> )
> ```
>
> To find SMP Docker image URIs, see the section called "Supported frameworks".

SageMaker HyperPod

Before you start, make sure if the following prerequisites are met.

- An Amazon FSx shared directory mounted (`/fsx`) to your HyperPod cluster.
- Conda installed in the FSx shared directory. To learn how to install Conda, use the instructions at Installing on Linux in the *Conda User Guide*.
- `cuda11.8` or `cuda12.1` installed on the head and compute nodes of your HyperPod cluster.

If the prerequisites are all met, proceed to the following instructions on launching a workload with SMP v2 on a HyperPod cluster.

1. Prepare an `smp_config.json` file that contains a dictionary of the section called "SMP v2 core feature configuration parameters". Make sure that you upload this JSON file to where you store your training script, or the path you specified to the `torch.sagemaker.init()` module in Step 1. If you've already passed the configuration dictionary to the `torch.sagemaker.init()` module in the training script in Step 1, you can skip this step.

   ```
   // smp_config.json
   {
       "hybrid_shard_degree": Integer,
       "sm_activation_offloading": Boolean,
       "activation_loading_horizon": Integer,
   ```

```
    "fsdp_cache_flush_warnings": Boolean,
    "allow_empty_shards": Boolean,
    "tensor_parallel_degree": Integer,
    "expert_parallel_degree": Integer,
    "random_seed": Integer
}
```

2. Upload the `smp_config.json` file to a directory in your file system. The directory path must match with the path you specified in [Step 1](). If you've already passed the configuration dictionary to the `torch.sagemaker.init()` module in the training script, you can skip this step.

3. On the compute nodes of your cluster, start a terminal session with the following command.

```
sudo su -l ubuntu
```

4. Create a Conda environment on the compute nodes. The following code is an example script of creating a Conda environment and installing SMP, [SMDDP](), CUDA, and other dependencies.

```
# Run on compute nodes
SMP_CUDA_VER=<11.8 or 12.1>

source /fsx/<path_to_miniconda>/miniconda3/bin/activate

export ENV_PATH=/fsx/<path to miniconda>/miniconda3/envs/<ENV_NAME>
conda create -p ${ENV_PATH} python=3.10

conda activate ${ENV_PATH}

# Verify aws-cli is installed: Expect something like "aws-cli/2.15.0*"
aws --version
# Install aws-cli if not already installed
# https://docs.aws.amazon.com/cli/latest/userguide/getting-started-
install.html#cliv2-linux-install

# Install the SMP library
conda install pytorch="2.0.1=sm_py3.10_cuda${SMP_CUDA_VER}*" packaging --override-
channels \
  -c https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/
smp-2.0.0-pt-2.0.1/2023-12-11/smp-v2/ \
  -c pytorch -c numba/label/dev \
  -c nvidia -c conda-forge
```

```
# Install dependencies of the script as below
python -m pip install packaging transformers==4.31.0 accelerate ninja tensorboard
 h5py datasets \
    && python -m pip install expecttest hypothesis \
    && python -m pip install "flash-attn>=2.0.4" --no-build-isolation

# Install the SMDDP wheel
SMDDP_WHL="smdistributed_dataparallel-2.0.2-cp310-cp310-linux_x86_64.whl" \
  && wget -q https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.0.1/
cu118/2023-12-07/${SMDDP_WHL} \
  && pip install --force ${SMDDP_WHL} \
  && rm ${SMDDP_WHL}

# cuDNN installation for Transformer Engine installation for CUDA 11.8
# Please download from below link, you need to agree to terms
# https://developer.nvidia.com/downloads/compute/cudnn/secure/8.9.5/
local_installers/11.x/cudnn-linux-x86_64-8.9.5.30_cuda11-archive.tar.xz

    && rm -rf /usr/local/cuda-$SMP_CUDA_VER/include/cudnn* /usr/local/cuda-
$SMP_CUDA_VER/lib/cudnn* \
    && cp ./cudnn-linux-x86_64-8.9.7.29_cuda12-archive/include/* /usr/local/cuda-
$SMP_CUDA_VER/include/ \
    && cp ./cudnn-linux-x86_64-8.9.7.29_cuda12-archive/lib/* /usr/local/cuda-
$SMP_CUDA_VER/lib/ \
    && rm -rf cudnn-linux-x86_64-8.9.7.29_cuda12-archive.tar.xz \
    && rm -rf cudnn-linux-x86_64-8.9.7.29_cuda12-archive/

# TransformerEngine installation
export CUDA_HOME=/usr/local/cuda-$SMP_CUDA_VER
```

```
export CUDNN_PATH=/usr/local/cuda-$SMP_CUDA_VER/lib
export CUDNN_LIBRARY=/usr/local/cuda-$SMP_CUDA_VER/lib
export CUDNN_INCLUDE_DIR=/usr/local/cuda-$SMP_CUDA_VER/include
export PATH=/usr/local/cuda-$SMP_CUDA_VER/bin:$PATH
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/local/cuda-$SMP_CUDA_VER/lib

python -m pip install --no-build-isolation git+https://github.com/NVIDIA/
TransformerEngine.git@v1.0
```

5. Run a test training job.

   a. In the shared file system (`/fsx`), clone the [Awsome Distributed Training GitHub repository](), and go to the `3.test_cases/11.modelparallel` folder.

   ```
   git clone https://github.com/aws-samples/awsome-distributed-training/
   cd awsome-distributed-training/3.test_cases/11.modelparallel
   ```

   b. Submit a job using `sbatch` as follows.

   ```
   conda activate <ENV_PATH>
   sbatch -N 16 conda_launch.sh
   ```

   If the job submission is successful, the output message of this `sbatch` command should be similar to `Submitted batch job ABCDEF`.

   c. Check the log file in the current directory under `logs/`.

   ```
   tail -f ./logs/fsdp_smp_ABCDEF.out
   ```

Core features of the SageMaker model parallelism library v2

The Amazon SageMaker AI model parallelism library v2 (SMP v2) offers distribution strategies and memory-saving techniques, such as sharded data parallelism, tensor parallelism, and checkpointing. The model parallelism strategies and techniques offered by SMP v2 help distribute large models across multiple devices while optimizing training speed and memory consumption. SMP v2 also provides a Python package `torch.sagemaker` to help adapt your training script with few lines of code change.

This guide follows the basic two-step flow introduced in [the section called "Use the SMP v2"](). To dive deep into the core features of SMP v2 and how to use them, see the following topics.

Note

These core features are available in SMP v2.0.0 and later and the SageMaker Python SDK v2.200.0 and later, and works for PyTorch v2.0.1 and later. To check the versions of the packages, see the section called "Supported frameworks and AWS Regions".

Topics

Hybrid sharded data parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across devices. This helps you fit a larger model or increase the batch size using the freed-up GPU memory. The SMP library offers a capability of running sharded data parallelism with PyTorch Fully Sharded Data Parallel (FSDP). PyTorch FSDP by default shards across the whole set of GPUs being used. In SMP v2, the library offers this sharded data parallelism on top of PyTorch FSDP by extending PyTorch hybrid sharding (`HYBRID_SHARD`), which is one of the sharding strategies provided by PyTorch FSDP: `FULL_SHARD`, `SHARD_GRAD_OP`, `HYBRID_SHARD`, `_HYBRID_SHARD_ZERO2`. Extending hybrid sharding in this manner helps implement scale-aware-sharding as described in the blog Near-linear scaling of gigantic-model training on AWS for PyTorch FSDP.

The SMP library makes it easy to use HYBRID_SHARD and _HYBRID_SHARD_ZERO2 across any configurable number of GPUs, extending the native PyTorch FSDP that supports sharding across a single node (HYBRID_SHARD) or all GPUs (FULL_SHARD). PyTorch FSDP calls can stay as is, and you only need to add the `hybrid_shard_degree` argument to the SMP configuration, as shown in the following code example. You don't need to change the value of the `sharding_strategy` argument in the PyTorch FSDP wrapper around your PyTorch model. You can pass `ShardingStrategy.HYBRID_SHARD` as the value. Alternatively, the SMP library overrides the strategy in the script and sets it to `ShardingStrategy.HYBRID_SHARD` if you specify a value equal to or greater than 2 to the `hybrid_shard_degree` parameter.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Use the SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `hybrid_shard_degree` parameter, see the section called "SMP v2 core feature configuration parameters".

SMP configuration dictionary

```
{ "hybrid_shard_degree": 16 }
```

In training script

```
import torch.sagemaker as tsm
tsm.init()

# Set up a PyTorch model
model = ...

# Wrap the PyTorch model using the PyTorch FSDP module
model = FSDP(
    model,
    ...
)

# Optimizer needs to be created after FSDP wrapper
optimizer = ...
```

Expert parallelism

A *Mixture of Experts* (MoE) model is a type of transformer model that employs a *sparse* approach, making it lighter for training compared to training traditional dense models. In this MoE neural network architecture, only a subset of the model's components called *experts* are utilized for each input. This approach offers several advantages, including more efficient training and faster inference, even with a larger model size. In other words, with the same compute budget for training a full dense model, you can fit a larger model or dataset when using MoE.

An MoE model consists of multiple *experts*, each consisting of a neural network, typically a feed-forward network (FFN). A gate network called *router* determines which tokens are sent to which expert. These experts specialize in processing specific aspects of the input data, enabling the model to train faster, reduce compute cost, while achieving the same performance quality as its counterpart dense model. To learn more about Mixture of Experts in general, refer to the blog [Applying Mixture of Experts in LLM Architectures](#) in the *NVIDIA developer website*.

Expert parallelism is a type of parallelism that handles splitting experts of an MoE model across GPU devices.

SMP v2 integrates with [NVIDIA Megatron](#) for implementing expert parallelism to support training MoE models, and runs on top of PyTorch FSDP APIs. You keep using your PyTorch FSDP training code as is and activate SMP expert parallelism for training MoE models.

Hugging Face Transformer models compatible with SMP expert parallelism

SMP v2 currently offers expert parallelism support for the following Hugging Face transformer models.

- [Mixtral](#)

Configure expert parallelism

For `expert_parallel_degree`, you select a value for the degree of expert parallelism. The value must evenly divide the number of GPUs in your cluster. For example, to shard your model while using an instance with 8 GPUs, choose 2, 4, or 8. We recommend that you start with a small number, and gradually increase it until the model fits in the GPU memory.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Use the SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `expert_parallel_degree` parameter, see the section called "SMP v2 core feature configuration parameters".

> **Note**
>
> You can use expert parallelism with the section called "Hybrid sharded data parallelism". Note that expert parallelism is currently not compatible with tensor parallelism.

> **Note**
>
> This expert parallelism training feature is available in the following combination of libraries of SageMaker and the PyTorch library:
>
> - SMP v2.3.0 and later
> - The SageMaker Python SDK v2.214.4 and later
> - PyTorch v2.2.0 and later

In your training script

As part of Step 1, initialize your script with `torch.sagemaker.init()` to activate SMP v2 and wrap your model with the section called "`torch.sagemaker.transform`" API, adding the `config` parameter to the API to activate MoE. The following code snippet shows how to activate SMP MoE for the generic model class `AutoModelForCausalLM` pulling an MoE transformer model configuration using the `from_config` method for training from scratch, or the `from_pretrained` method for fine-tuning. To learn more about the SMP `MoEConfig` class, see the section called "`torch.sagemaker.moe.moe_config.MoEConfig`".

```
# Import the torch.sagemaker.transform API and initialize.
import torch.sagemaker as tsm
tsm.init()

# Import transformers AutoModelForCausalLM class.
from transformers import AutoModelForCausalLM

# Import the SMP-implementation of MoE configuration class.
```

```
from torch.sagemaker.moe.moe_config import MoEConfig

# Define a transformer model with an MoE model configuration
model = AutoModelForCausalLM.from_config(MoEModelConfig)

# Wrap it by torch.sagemaker.transform with the SMP MoE configuration.
model = tsm.transform(
    model,
    config=MoEConfig(
        smp_moe=True,
        random_seed=12345,
        moe_load_balancing="sinkhorn",
        global_token_shuffle=False,
        moe_all_to_all_dispatcher=True,
        moe_aux_loss_coeff=0.001,
        moe_z_loss_coeff=0.001
    )
)
```

SMP configuration

As part of Step 2, add the following parameter to the SMP configuration dictionary for the SageMaker PyTorch estimator.

```
{
    ..., # other SMP config parameters
    "expert_parallel_degree": 8
}
```

Context parallelism

Context parallelism is a type of model parallelism that partitions the model activations along the sequence dimension. Unlike other sequence parallelism techniques, which only partition the `LayerNorm` and `RMSNorm`, context parallelism partitions the network inputs and all intermediate activations along the sequence dimension.

SMP v2 integrates with Transformer Engine for context parallelism and can be used in conjunction with PyTorch FSDP and SMP the section called “Tensor parallelism”. You can enable all three parallelisms simultaneously for model training. Context parallelism is beneficial for training models with large activation sizes and long sequence lengths. It accelerates the computation of attention scores and attention outputs, by allowing each device to computes only a part of the scores and outputs along the sequence dimension. While tensor parallelism also accelerates computation through partitioning along the hidden dimension, the advantage of context parallelism is more substantial since computational requirements increase quadratically with sequence dimension.

Hugging Face Transformer models compatible with SMP context parallelism

SMP v2 currently offers context parallelism support for the following Hugging Face transformer models.

- GPT-NeoX
- Llama 2 and Llama 3
- Mistral 7B

Configure context parallelism

Set an integer value to the `context_parallel_degree` parameter that evenly divides the number of GPUs in your cluster. For example, if you have an 8-GPU instance, use 2, 4, or 8 for `context_parallel_degree`. We recommend starting with a small `context_parallel_degree` value and gradually increasing it until the model fits in the GPU memory with the required input sequence length.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called “Use the SMP v2”. You don’t need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `context_parallel_degree` parameter, see the section called “SMP v2 core feature configuration parameters”.

In your training script

As part of Step 1, initialize your script with `torch.sagemaker.init()` to activate SMP v2 and wrap your model with the the section called “torch.sagemaker.transform” API.

Starting from SMP v2.6.0, you can use the argument `cp_comm_type` to determine which context parallelism implementation to use. The SMP library currently supports two implementations: `p2p` and `all_gather`. The `p2p` implementation uses peer-to-peer send-receive calls for key-value accumulation during the attention implementation and runs asynchronously, allowing overlaps with compute. `all_gather` implementation, instead, uses the `AllGather` collective operation and runs synchronously.

```
import torch.sagemaker as tsm
tsm.init()

from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_config(..)
model = tsm.transform(model, cp_comm_type="p2p")
```

SMP configuration

As part of Step 2, add the following parameter to the SMP configuration dictionary for the SageMaker PyTorch estimator.

```
{
    ..., # other SMP config parameters
    "context_parallel_degree": 2
}
```

Compatibility with the SMDDP library optimized for AWS infrastructure

You can use the SageMaker model parallelism library v2 (SMP v2) in conjunction with the SageMaker distributed data parallelism (SMDDP) library that offers the `AllGather` collective communication operation optimized for AWS infrastructure. In distributed training, collective communication operations are designed for synchronizing multiple GPU workers and exchange information between them. `AllGather` is one of the core collective communication operations typically used in sharded data parallelism. To learn more about the SMDDP `AllGather` operation, see the section called "SMDDP `AllGather` collective operation" Optimizing such collective communication operations would directly contribute to a faster end-to-end training without side effects on convergence.

> **Note**
>
> The SMDDP library supports P4 and P4de instances (see also the section called "Supported frameworks, AWS Regions, and instances types" by the SMDDP library).

The SMDDP library integrates natively with PyTorch through the process group layer. To use the SMDDP library, you only need to add two lines of code to your training script. It supports any training frameworks such as SageMaker Model Parallelism Library, PyTorch FSDP, and DeepSpeed.

To activate SMDDP and use its `AllGather` operation, you need to add two lines of code to your training script as part of the section called "Step 1: Adapt your PyTorch FSDP training script". Note that you need to initialize PyTorch Distributed with the SMDDP backend first, and then run the SMP initialization.

```
import torch.distributed as dist

# Initialize with SMDDP
import smdistributed.dataparallel.torch.torch_smddp
dist.init_process_group(backend="smddp") # Replacing "nccl"

 # Initialize with SMP
import torch.sagemaker as tsm
tsm.init()
```

SageMaker Framework Containers for PyTorch (see also the section called "Supported frameworks and AWS Regions" by SMP v2 and the section called "Supported frameworks, AWS Regions, and instances types" by the SMDDP library) are pre-packaged with the SMP binary and the SMDDP binary. To learn more about the SMDDP library, see the section called "SageMaker AI distributed data parallelism library".

Mixed precision training

The SageMaker model parallelism (SMP) library v2 supports mixed precision training out of the box by integrating with open source frameworks such as PyTorch FSDP and Transformer Engine. To learn more, see the following topics.

Topics

- Mixed precision training with FP8 on P5 instances using Transformer Engine
- Mixed precision training with half-precision data types using PyTorch FSDP

Mixed precision training with FP8 on P5 instances using Transformer Engine

Starting from the SageMaker model parallelism (SMP) library v2.2.0, the SMP library integrates with Transformer Engine and supports FP8 mixed precision training out of the box, keeping compatibility with PyTorch FSDP `MixedPrecision`. This means that you can use both PyTorch FSDP for mixed precision training and Transformer Engine for FP8 training. For model layers not supported by Transformer Engine's FP8 training feature, those layers fall back to PyTorch FSDP mixed precision.

Note

SMP v2 offers FP8 support for the following Hugging Face Transformer models:

- GPT-NeoX (available in SMP v2.2.0 and later)
- Llama 2 (available in SMP v2.2.0 and later)
- Mixtral 8x7b and Mixtral 8x22b (available in SMP v2.5.0 and later)

Note

This FP8 training on the P5 feature is available in the following combination of libraries of SageMaker and the PyTorch library:

- The SageMaker Python SDK v2.212.0 and later
- PyTorch v2.2.0 and later

FP8 (8-bit floating point precision) is a data type that has emerged as another paradigm to accelerate deep learning training of LLM models. With the release of NVIDIA H100 GPUs supporting FP8 data types, you can benefit from the advantages from the performance improvements on P5 instances equipped with the H100 GPUs, while accelerating distributed training with FP8 mixed precision training.

The FP8 data type further branches down to E4M3 and E5M2 formats. *E4M3* offers a better precision, has a limited dynamic range, and is ideal for the forward pass in model training. *E5M2* has a broader dynamic range, but reduced precision, and is better suited for the backward pass, where precision is less critical and a wider dynamic range becomes beneficial. Hence, we recommend that you use the hybrid FP8 strategy recipe to leverage these characteristics effectively.

For half-precision data types (FP16 and BF16), global loss-scaling techniques such as static loss-scaling or dynamic loss-scaling handle convergence issues that arise from information loss due to rounding gradients in half-precision. However, the dynamic range of FP8 is even narrower, and the global loss scaling techniques are not sufficient. At this point, we need a finer-grained per-tensor scaling technique. *Delayed scaling* is a strategy that selects a scaling factor based on the maximum absolute values observed in a number of tensors form previous iterations. There's a trade-off in this strategy; it uses the full performance benefits of FP8 computation but requires memory for keeping the maximum value history of tensors. To learn more about the delayed scaling strategy in general, see the paper *FP8 Formats for Deep Learning*.

In practice, using FP8 is helpful in all training scenarios on P5 instances. We strongly recommend enabling FP8 whenever possible for enhancing training performance.

SMP v2 supports Transformer Engine out of the box. Therefore, when running FP8 training with SMP v2 on P5 instances of SageMaker AI (`ml.p5.48xlarge`), the only thing you need to do is to import `torch.sagemaker` in your training script and keep using the native Transformer Engine Python package. To learn more about using Transformer Engine for FP8 training in general, see Using FP8 with Transformer Engine in the *NVIDIA Transformer Engine documentation*. The following code snippet shows how the code lines for importing the SMP library and setting up FP8 in your training script should look.

```
import torch.sagemaker as tsm
import transformer_engine.pytorch as te
from transformer_engine.common.recipe import DelayedScaling, Format

# Initialize the SMP torch.sagemaker API.
tsm.init()

# Define a transformer model and wrap it with the torch.sagemaker.transform API.
from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_config(ModelConfig)
model = tsm.transform(model)

# Enable E4M3 during forward pass, E5M2 during backward pass.
fp8_format = Format.HYBRID

# Create an FP8 recipe.
fp8_recipe = DelayedScaling(fp8_format=fp8_format, amax_history_len=32,
 amax_compute_algo="max")

# Enable FP8 autocasting.
with te.fp8_autocast(enabled=True, fp8_recipe=fp8_recipe,
 fp8_group=tsm.state.world_process_group):
    out = model(inp)

loss = out.sum()
loss.backward()
```

To find a practical example of FP8 training with SMP v2 on P5 instances, see the example notebook at Accelerate SageMaker PyTorch FSDP Training of Llama-v2 (or GPT-NeoX) with FP8 on P5 instances.

Mixed precision training with half-precision data types using PyTorch FSDP

SMP v2 supports PyTorch FSDP `MixedPrecision` for training jobs on P4 and P5 instances. PyTorch FSDP provides various configurations for mixed precision for both performance improvement and memory reduction.

> **Note**
>
> This mixed precision training with the PyTorch FSDP feature is available in the following combination of libraries of SageMaker and the PyTorch library.
>
> - SMP v2.0.0 and later
> - the SageMaker Python SDK v2.200.0 and later
> - PyTorch v2.0.1 and later

The standard way to configure a model for mixed precision is to create the model in `float32`, and then allow FSDP to cast the parameters to `float16` or `bfloat16` on the fly by passing a `MixedPrecision` policy, as shown in the following code snippet. For more information about options to change the `dtype` for parameters, reduction, or buffers for mixed precision in PyTorch, see PyTorch FSDP `MixedPrecision` API in the *PyTorch documentation*.

```
# Native PyTorch API
from torch.distributed.fsdp import MixedPrecision

dtype = torch.bfloat16
mixed_precision_policy = MixedPrecision(
    param_dtype=dtype, reduce_dtype=dtype, buffer_dtype=dtype
)

model = FSDP(
    model,
    ...,
    mixed_precision=mixed_precision_policy
)
```

Note that certain models (such as the Hugging Face Transformers Llama model) expect buffers as `float32`. To use `float32`, replace `torch.bfloat16` with `torch.float32` in the line defining the `dtype` object.

Delayed parameter initialization

Initialization of a large model for training is not always possible with the limited GPU memory. To resolve this problem of insufficient GPU memory, you can initialize the model on CPU memory. However, for larger models with more than 20 or 40 billion parameters, even CPU memory might not be enough. For such case, we recommend that you initialize the model on what PyTorch calls a *meta device*, which allows the creation of tensors without any data attached to them. A tensor on a meta device only needs the shape information, and this allows to create a large model with its parameters on meta devices. [Hugging Face Accelerate](https://huggingface.co/docs/accelerate) provides the context manager `init_empty_weights` to help create such model on meta devices while initializing the buffers on a regular device. Before training starts, PyTorch FSDP initializes the model parameters. This delayed parameter initialization feature of SMP v2 delays this creation of model parameters to happen after PyTorch FSDP performs parameter sharding. PyTorch FSDP accepts a parameter initialization function (`param_init_fn`) when sharding the modules, and it calls `param_init_fn` for each module. The `param_init_fn` API takes a module as an argument and initializes all the parameters in it, not including the parameters of any child module. Note that this behavior *differs* from the native PyTorch v2.0.1 which has a bug causing the parameters to be initialized multiple times.

SMP v2 provides the the section called "`torch.sagemaker.delayed_param.DelayedParamIniter`" API for applying delayed parameter initialization.

The following code snippets show how to apply the `torch.sagemaker.delayed_param.DelayedParamIniter` API to your training script.

Assume that you have a PyTorch FSDP training script as follows.

```
# Creation of model on meta device
from accelerate import init_empty_weights
with init_empty_weights():
    model = create_model()

# Define a param init fn, below is an example for Hugging Face GPTNeoX.
def init_weights(module):
    d = torch.cuda.current_device()
```

```
    # Note that below doesn't work if you have buffers in the model
    # buffers will need to reinitialized after this call
    module.to_empty(device=d, recurse=False)
    if isinstance(module, (nn.Linear, Conv1D)):
        module.weight.data.normal_(mean=0.0, std=args.initializer_range)
        if module.bias:
            module.bias.data.zero_()
    elif isinstance(module, nn.Embedding):
        module.weight.data.normal_(mean=0.0, std=args.initializer_range)
        if module.padding_idx:
            module.weight.data[module.padding_idx].zero_()
    elif isinstance(module, nn.LayerNorm):
        module.bias.data.zero_()
        module.weight.data.fill_(1.0)

# Changes to FSDP wrapper.
model = FSDP(
    model,
    ...,
    param_init_fn=init_weights
)

# At this point model is initialized and sharded for sharded data parallelism.
```

Note that the delayed parameter initialization approach is not model agnostic. To resolve this issue, you need to write an `init_weights` function as shown in the preceding example to match the initialization in the original model definition, and it should cover all the parameters of the model. To simplify this process of preparing such `init_weights` function, SMP v2 implements this initialization function for the following models: GPT-2, GPT-J, GPT-NeoX, and Llama from Hugging Face Transformers. The `torch.sagemaker.delayed_param.DelayedParamIniter` API also works with the SMP tensor parallel implementation, `torch.sagemaker.tensor_parallel.transformer.TransformerLMHead` model, that you can call after the the section called "`torch.sagemaker.transform`" API call.

Using the `torch.sagemaker.delayed_param.DelayedParamIniter` API, you can adapt your PyTorch FSDP script as follows. After creating a model with empty weights, register the `torch.sagemaker.delayed_param.DelayedParamIniter` API to the model, and define an object of it. Pass the object to the `param_init_fn` of the PyTorch FSDP class.

```
from torch.sagemaker.delayed_param import DelayedParamIniter
```

```
from accelerate import init_empty_weights

with init_empty_weights():
    model = create_model()

delayed_initer = DelayedParamIniter(model)

with delayed_initer.validate_params_and_buffers_inited():
    model = FSDP(
        model,
        ...,
        param_init_fn=delayed_initer.get_param_init_fn()
    )
```

Notes on tied weights

When training models with tied weights, we need to take special care to tie the weights after initializing the weights with delayed parameter initialization. PyTorch FSDP does not have a mechanism to tie the weights after initializing them using `param_init_fn` as above. To address such cases we added API to allow a `post_init_hook_fn`, which can be used to tie the weights. You can pass any function in there which accepts the module as argument, but we also have a predefined `post_param_init_fn` defined in `DelayedParamIniter` which calls `tie_weights` method of the module if it exists. Note that it's safe to always pass in `post_param_init_fn` even if there's no `tie_weights` method for the module.

```
with delayed_initer.validate_params_and_buffers_inited():
    model = FSDP(
        model,
        ...,
        param_init_fn=delayed_initer.get_param_init_fn(),
        post_param_init_fn=delayed_initer.get_post_param_init_fn()
    )
```

Activation checkpointing

Activation checkpointing is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during the backward pass. Effectively, this trades extra computation time for reducing memory usage. If a module is checkpointed, at the end of a forward pass, only the initial inputs to the module and final outputs from the module stay in memory. PyTorch releases any intermediate tensors that are part of the computation inside that module during the forward pass. During the backward pass of the checkpointed modules, PyTorch recomputes these tensors. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing becomes lower.

SMP v2 supports the PyTorch activation checkpointing module, [apply_activation_checkpointing](). The following are examples of activation checkpointing of the Hugging Face GPT-NeoX model.

Checkpointing Transformer layers of the Hugging Face GPT-NeoX model

```
from transformers.models.gpt_neox import GPTNeoXLayer
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing
)

# check_fn receives a module as the arg,
# and it needs to return whether the module is to be checkpointed
def is_transformer_layer(module):
    from transformers.models.gpt_neox import GPTNeoXLayer
    return isinstance(submodule, GPTNeoXLayer)

apply_activation_checkpointing(model, check_fn=is_transformer_layer)
```

Checkpointing every other Transformer layer of the Hugging Face GPT-NeoX model

```
# check_fn receives a module as arg,
# and it needs to return whether the module is to be checkpointed
# here we define that function based on global variable (transformer_layers)
from transformers.models.gpt_neox import GPTNeoXLayer
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing
)

transformer_layers = [
    m for m model.modules() if isinstance(m, GPTNeoXLayer)
]

def is_odd_transformer_layer(module):
    return transformer_layers.index(module) % 2 == 0

apply_activation_checkpointing(model, check_fn=is_odd_transformer_layer)
```

Alternatively, PyTorch also has the `torch.utils.checkpoint` module for checkpointing, which is used by a subset of Hugging Face Transformers models. This module also works with SMP v2. However, it requires you to have access to the model definition for adding the checkpoint wrapper. Therefore, we recommend you to use the `apply_activation_checkpointing` method.

Activation offloading

> **Important**
>
> In SMP v2.2.0, the activation offloading functionality of the SMP library doesn't work. Use the native PyTorch activation offloading instead.

Typically, the forward pass computes activations at each layer and keeps them in GPU memory until the backward pass for the corresponding layer finishes. Offloading these tensors to CPU memory after forward pass and fetching them back to GPU when they are needed can save substantial GPU memory usage. PyTorch supports offloading activations, but the implementation causes GPUs to be idle while activations are fetched back from CPU during backward pass. This causes a major performance degradation when using activation offloading.

SMP v2 improves this activation offloading. It pre-fetches activations ahead of time before the activations are needed for the GPU to start backward pass on those activations. The pre-fetching feature helps training progresses be run more efficiently without idle GPUs. This results in offering benefits from lower memory usage without a performance degradation.

You can keep the native PyTorch modules for offloading activations in your training script. The following is an example structure of applying the SMP activation offloading feature in your script. Note that activation offloading is applicable *only* when used together with the section called "Activation checkpointing". To learn more about the native PyTorch checkpoint tools for activation offloading, see:

- checkpoint_wrapper.py in the *PyTorch GitHub repository*
- Activation Checkpointing in the PyTorch blog *Scaling Multi-modal Foundation Models in TorchMultimodal with PyTorch Distributed*.

You can apply the SMP activation offloading feature on PyTorch activation checkpointing. This is done by adding the `sm_activation_offloading` and `activation_loading_horizon` parameters to the SMP configuration dictionary during the section called “Step 2: Launch a training job”.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called “Use the SMP v2”. You don’t need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `sm_activation_offloading` and `activation_loading_horizon` parameters, see the section called “SMP v2 core feature configuration parameters”.

SMP configuration

```
{
    "activation_loading_horizon": 2,
    "sm_activation_offloading": True
}
```

In training script

> **Note**
>
> While activating the SMP activation offloading feature, make sure that you also use the PyTorch `offload_wrapper` function and apply it to the root module. The SMP activation offloading feature uses the root module to determine when forward pass is done to start pre-fetching.

```
import torch.sagemaker as tsm
tsm.init()

# Native PyTorch module for activation offloading
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing,
    offload_wrapper,
)

model = FSDP(...)

# Activation offloading requires activation checkpointing.
```

```
apply_activation_checkpointing(
    model,
    check_fn=checkpoint_transformer_layers_policy,
)

model = offload_wrapper(model)
```

Tensor parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the *set* of weights, gradients, or optimizer across devices, tensor parallelism shards *individual* weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

SMP v2 integrates with [Transformer Engine](https://docs.nvidia.com/deeplearning/transformer-engine) for the implementation for tensor parallelism, and runs on top of PyTorch FSDP APIs. You can enable PyTorch FSDP and SMP tensor parallelism simultaneously, and determine the best model parallelism for best performance.

In practice, tensor parallelism is especially helpful in the following scenarios.

- When training with long context lengths as that leads to high activation memory with FSDP alone.
- When training with really large clusters on which the global batch size exceeds desired limits.

Hugging Face Transformer models compatible with the SMP tensor parallelism

SMP v2 currently offers tensor parallelism support for the following Hugging Face transformer models.

- GPT-NeoX
- Llama 2
- Llama 3
- Mistral 7B

- Mixtral 8x7B
- Mixtral 8x22B

For reference configuration for applying tensor parallelism on these models, see the section called "Configuration tips".

Configure tensor parallelism

For `tensor_parallel_degree`, you select a value for the degree of tensor parallelism. The value must evenly divide the number of GPUs in your cluster. For example, to shard your model while using an instance with 8 GPUs, choose 2, 4, or 8. We recommend that you start with a small number, and gradually increase it until the model fits in the GPU memory.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Use the SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `tensor_parallel_degree` and `random_seed` parameters, see the section called "SMP v2 core feature configuration parameters".

SMP configuration

```
{
    "tensor_parallel_degree": 8,
    "random_seed": 0
}
```

In your training script

Initialize with `torch.sagemaker.init()` to activate SMP v2 and wrap your model with the section called "`torch.sagemaker.transform`" API.

```
import torch.sagemaker as tsm
tsm.init()

from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_config(..)
model = tsm.transform(model)
```

Saving and loading Hugging Face Transformer checkpoints

After the SMP library transforms a model, it changes the state dictionary (`state_dict`) of the model. This means that the model becomes incompatible with the original Hugging Face Transformer checkpointing functionalities. To handle this, the SMP library provides APIs to save checkpoints from a transformed model in Hugging Face Transformer representation, and the `torch.sagemaker.transform` API to load a Hugging Face Transformer model checkpoint for fine-tuning.

For more information about saving checkpoints while using the tensor parallelism feature of SMP v2, see the section called “Checkpointing using SMP”.

For more information about fine-tuning a model applying the tensor parallelism feature of SMP v2, see the section called “Fine-tuning”.

Fine-tuning

Fine-tuning is a process of continuously training pre-trained models to improve performance for specific use cases.

Fine-tuning small models that fit fully on a single GPU, or those that fit 8 copies of model fully on CPUs is straightforward. It requires no special change to regular FSDP training. In the realm of models larger than this, you need to consider using the delayed parameter initialization functionality, which can be tricky.

To address this, the SMP library loads the full model on one of the ranks while the rest of the ranks create models with empty weights on a meta device. Then, PyTorch FSDP initializes the weights on non-zero ranks using the `init_weights` function, and synchronizes the weights on all ranks to the weights on the 0th rank with `sync_module_states` set to `True`. The following code snippet shows how you should set it up in your training script.

```
import torch.distributed as dist
from transformers import AutoModelForCasalLM
from accelerate import init_empty_weights
from torch.sagemaker.delayed_param import DelayedParamIniter

if dist.get_rank() == 0:
    model = AutoModelForCasalLM.from_pretrained(..., low_cpu_mem_usage=True)
else:
    with init_empty_weights():
```

```
        model = AutoModelForCasalLM.from_config(AutoConfig.from_pretrained(...))
    delayed_initer = DelayedParamIniter(model)

model = FSDP(
    model,
    ...,
    sync_module_states=True,
    param_init_fn=delayed_initer.get_param_init_fn() if dist.get_rank() > 0 else None
)
```

Fine-tuning a pre-trained Hugging Face Transformer model with SMP tensor parallelism

This section discusses loading Transformer models for two use cases: fine-tuning small Transformer models and fine-tuning large Transformer models. For smaller models without delayed parameter initialization, wrap the model with the `torch.sagemaker.transform` API before wrapping it with PyTorch FSDP.

```
import functools
from transformers import AutoModelForCausalLM
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp.wrap import transformer_auto_wrap_policy
from torch.sagemaker import transform

model = AutoModelForCausalLM.from_pretrained("meta-llama/Llama-2-7b-hf",
 low_cpu_mem_usage=True)

# Transform model while loading state dictionary from rank 0.
tp_model = transform(model, load_state_dict_from_rank0=True)

# Wrap with FSDP.
model = FSDP(
    tp_model,
    ...
    sync_module_states=True,
)
```

For larger models, the preceding approach causes to run out of CPU memory. We recommend that you use delayed parameter initialization to avoid such CPU memory issues. In this case, you can apply the `torch.sagemaker.transform` API and the `torch.sagemaker.delayed_param.DelayedParamIniter` API as shown in the following code example.

```
from transformers import AutoModelForCausalLM
from torch.sagemaker import transform
from torch.sagemaker.delayed_param import DelayedParamIniter

# Create one instance of model without delayed param
# on CPU, on one rank.
if dist.get_rank() == 0:
    model = AutoModelForCasalLM.from_pretrained(...,low_cpu_mem_usage=True)
else:
    with init_empty_weights():
        model = AutoModelForCasalLM.from_config(AutoConfig.from_pretrained(...))

# Transform model while loading state dictionary from rank 0
model = transform(model, load_state_dict_from_rank0=True)

if dist.get_rank() != 0: # For fine-tuning, delayed parameter on non-zero ranks
    delayed_initer = DelayedParamIniter(model)
else:
    delayed_initer = None

with (
    delayed_initer.validate_params_and_buffers_inited() if delayed_initer else
 nullcontext()
):
    # Wrap the model with FSDP
    model = FSDP(
        model,
        ...,
        sync_module_states=True,
        param_init_fn=delayed_initer.get_param_init_fn() if delayed_initer else None
    )
```

FlashAttention

SMP v2 supports FlashAttention kernels and makes it easy to apply them to various scenarios for Hugging Face Transformer models. Note that if you use FlashAttention package v2.0 or later, SMP uses FlashAttention v2; however, the Triton flash attention defaults to the flash attention kernel in FlashAttention v1.x, making it exclusively supported in FlashAttention v1.

The module (`nn.Module`) is a low level API that defines the attention layers of a model. It should be applied right after model creation, from the `AutoModelForCausalLM.from_config()` API for example, and before the model is being transformed or wrapped with FSDP.

Use FlashAttention kernels for self attention

The following code snippet shows how to use the the section called "torch.sagemaker.nn.attn.FlashSelfAttention" API provided by SMP v2.

```
def new_attn(self, q, k, v, attention_mask=None, head_mask=None):
    return (
        self.flashmod((q, k, v), causal=True, cast_dtype=torch.bfloat16, layout="b h s
 d"),
        None,
    )

for layer in model.gpt_neox.layers:
    layer.attention.flash_mod = torch.sagemaker.nn.attn.FlashSelfAttention()
    layer.attention._attn = functools.partial(new_attn, layer.attention)
```

Use FlashAttention kernels for grouped-query attention

SMP v2 also supports FlashAttention kernels for grouped-query attention (GQA) and makes it easy to apply them to various scenarios for Hugging Face Transformer models. Different from original attention architecture, GQA equally partitions query heads into groups, and query heads in the same group share the same key and value heads. Therefore, q and kv heads are passed into forward call separately. Note: The number of q heads needs to be divisible by the number of kv heads.

Example of using FlashGroupedQueryAttention

The following code snippet shows how to use the the section called "torch.sagemaker.nn.attn.FlashGroupedQueryAttention" API provided by SMP v2.

```
from transformers.models.llama.modeling_llama import LlamaAttention
from torch.sagemaker.nn.attn import FlashGroupedQueryAttention

class LlamaFlashAttention(LlamaAttention):
    def __init__(self, config: LlamaConfig):
        super().__init__(config)

        self.flash_attn = FlashGroupedQueryAttention(
            attention_dropout_prob=0.0,
        )
```

```
    def forward(
        self,
        hidden_states: torch.Tensor,
        attention_mask: Optional[torch.Tensor] = None,
        position_ids: Optional[torch.LongTensor] = None,
        ...
    ):
        query_states = self.q_proj(hidden_states)
        key_states = self.k_proj(hidden_states)
        value_states = self.v_proj(hidden_states)
        ...
        kv = (key_states, value_states)
        attn_output = self.flash_attn(
            query_states,
            kv,
            attn_mask=attention_mask,
            causal=True,
            layout="b h s d",
        )
        ...
        attn_output = self.o_proj(attn_output)
        ...
        return attn_output
```

The SMP library also provides the section called "`torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention`", which uses the the section called "`torch.sagemaker.nn.attn.FlashGroupedQueryAttention`" API at low level. Hugging Face Transformers has a similar implementation called `LlamaFlashAttention2` from v4.36.0. The following code snippet shows how to use the SMP v2 `LlamaFlashAttention` API or the Transformers `LlamaFlashAttention2` API to replace the attention layers of an existing Llama model.

```
from torch.sagemaker.nn.huggingface.llama_flashattn import LlamaFlashAttention
from transformers.models.llama.modeling_llama import LlamaFlashAttention2

flash_attn_class = LlamaFlashAttention # or flash_attn_class = LlamaFlashAttention2

attn_name = "self_attn"
for layer in model.model.layers:
    prev_layer = getattr(layer, attn_name)
    setattr(layer, attn_name, flash_attn_class(model.config))
```

Checkpointing using SMP

The SageMaker model parallelism (SMP) library supports PyTorch APIs for checkpoints, and provides APIs that help checkpoint properly while using the SMP library.

PyTorch FSDP (Fully Sharded Data Parallelism) supports three types of checkpoints: full, sharded, and local, each serving different purposes. Full checkpoints are used when exporting the model after training is completed, as generating a full checkpoint is a computationally expensive process. Sharded checkpoints help save and load the state of a model sharded for each individual rank. With sharded checkpoints, you can resume training with different hardware configurations, such as a different number of GPUs. However, loading sharded checkpoints can be slow due to the communication involved among multiple devices. The SMP library provides local checkpointing functionalities, which allow faster retrieval of the model's state without additional communication overhead. Note that checkpoints created by FSDP require writing to a shared network file system such as Amazon FSx.

Async local checkpoints

When training machine learning models, there is no need for subsequent iterations to wait for the checkpoint files to be saved to disk. With the release of SMP v2.5, the library supports saving checkpoint files asynchronously. This means that the subsequent training iteration can run simultaneously with the input and output (I/O) operations for creating checkpoints, without being slowed down or held back by those I/O operations. Also, the process of retrieving sharded model and optimizer paramemeters in PyTorch can be time-consuming due to the additional collective communication required to exchange distributed tensor metadata across ranks. Even when using `StateDictType.LOCAL_STATE_DICT` to save local checkpoints for each rank, PyTorch still invokes hooks that perform collective communication. To mitigate this issue and reduce the time required for checkpoint retrieval, SMP introduces `SMStateDictType.SM_LOCAL_STATE_DICT`, which allows for faster retrieval of model and optimizer checkpoints by bypassing the collective communication overhead.

> **Note**
>
> Maintaining consistency in the FSDP `SHARD_DEGREE` is a requirement for utilizing the `SMStateDictType.SM_LOCAL_STATE_DICT`. Ensure that the `SHARD_DEGREE` remains unchanged. While the number of model replications can vary, the model shard degree needs to be identical to the previous training setup when resuming from a checkpoint.

```
import os
import torch.distributed as dist
import torch.sagemaker as tsm
from torch.sagemaker import state
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.sagemaker.distributed.checkpoint.state_dict_saver import (
    async_save,
    maybe_finalize_async_calls,
)
from torch.sagemaker.distributed.checkpoint.state_dict_utils import (
    sm_state_dict_type,
    SMStateDictType,
)

global_rank = dist.get_rank()
save_dir = "/opt/ml/checkpoints"
sub_dir = f"tp{state.tp_rank}_ep{state.ep_rank}_fsdp{model.rank}"

# 1. Get replication ranks and group
current_replication_group = None
current_replication_ranks = None
for replication_ranks in state.ranker.get_rep_groups():
    rep_group = dist.new_group(replication_ranks)
    if global_rank in replication_ranks:
        current_replication_group = rep_group
        current_replication_ranks = replication_ranks

coordinator_rank = min(current_replication_ranks)

# 2. Wait for the previous checkpointing done
maybe_finalize_async_calls(
    blocking=True, process_group=current_replication_group
)

# 3. Get model local checkpoint
with sm_state_dict_type(model, SMStateDictType.SM_LOCAL_STATE_DICT):
    state_dict = {
       "model": model.state_dict(),
       "optimizer": optimizer.state_dict(),
        # Potentially add more customized state dicts.
    }

# 4. Save a local checkpoint
```

```
async_save(
    state_dict,
    checkpoint_id=os.path.join(save_dir, sub_dir),
    process_group=current_replication_group,
    coordinator_rank=coordinator_rank,
)
```

The following code snippet demonstrates how to load a checkpoint utilizing `SMStateDictType.SM_LOCAL_STATE_DICT`.

```
import os
import torch.sagemaker as tsm
from torch.sagemaker import state
from torch.sagemaker.distributed.checkpoint.state_dict_loader import load
from torch.sagemaker.distributed.checkpoint.state_dict_utils import (
    sm_state_dict_type,
    SMStateDictType,
    init_optim_state
)
from torch.sagemaker.distributed.checkpoint.filesystem import (
    DistributedFileSystemReader,
)

load_dir = "/opt/ml/checkpoints"
sub_dir = f"tp{state.tp_rank}_ep{state.ep_rank}_fsdp{model.rank}"
global_rank = dist.get_rank()
checkpoint_id = os.path.join(load_dir, sub_dir)
storage_reader = DistributedFileSystemReader(checkpoint_id)

# 1. Get replication ranks and group
current_replication_group = None
current_replication_ranks = None
for replication_ranks in state.ranker.get_rep_groups():
    rep_group = dist.new_group(replication_ranks)
    if global_rank in replication_ranks:
        current_replication_group = rep_group
        current_replication_ranks = replication_ranks

coordinator_rank = min(current_replication_ranks)

# 2. Create local state_dict
with sm_state_dict_type(model, SMStateDictType.SM_LOCAL_STATE_DICT):
    state_dict = {
```

```
        "model": model.state_dict(),
        # Potentially add more customized state dicts.
    }

    # Init optimizer state_dict states by setting zero grads and step.
    init_optim_state(optimizer, skip_empty_param=True)
    state_dict["optimizer"] = optimizer.state_dict()

# 3. Load a checkpoint
load(
    state_dict=state_dict,
    process_group=current_replication_group,
    coordinator_rank=coordinator_rank,
    storage_reader=storage_reader,
)
```

Storing checkpoints for large language models (LLMs) can be expensive as it often requires creating a large filesystem volume. To reduce costs, you have the option to save checkpoints directly to Amazon S3 without the need for additional filesystem services such as Amazon FSx. You can leverage the previous example with the following code snippet to save checkpoints to S3 by specifying an S3 URL as the destination.

```
key = os.path.join(checkpoint_dir, sub_dir)
checkpoint_id= f"s3://{your_s3_bucket}/{key}"
async_save(state_dict, checkpoint_id=checkpoint_id, **kw)
load(state_dict, checkpoint_id=checkpoint_id, **kw)
```

Async sharded checkpoints

There may be situations where you need to continue training with different hardware configurations, such as changing the number of GPUs. In these cases, your training processes must load checkpoints while resharding, which means resuming subsequent training with a different number of `SHARD_DEGREE`. In order to address the scenario where you need to resume training with a different number of `SHARD_DEGREE`, you must save your model checkpoints using the sharded state dictionary type, which is represented by `StateDictType.SHARDED_STATE_DICT`. Saving checkpoints in this format allows you to properly handle the resharding process when continuing the training with a modified hardware configuration. The provided code snippet illustrates how to use the `tsm` API to asynchronously save sharded checkpoints, enabling a more efficient and streamlined training process.

```
import os
import torch.sagemaker as tsm
from torch.sagemaker import state
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp import StateDictType
from torch.sagemaker.utils.process_group_utils import get_global_ranks
from torch.sagemaker.distributed.checkpoint.state_dict_saver import (
    async_save,
    maybe_finalize_async_calls,
)

save_dir = "/opt/ml/checkpoints"
sub_dir = f"tp{state.tp_rank}_ep{state.ep_rank}"
checkpoint_id = os.path.join(save_dir, sub_dir)

# To determine whether curreto take part in checkpointing.
global_rank = dist.get_rank()
action_rank = state.ranker.get_rep_rank(global_rank) == 0
process_group = model.process_group
coordinator_rank = min(get_global_ranks(process_group))

# 1. wait for the previous checkpointing done
maybe_finalize_async_calls(blocking=True, process_group=process_group)

# 2. retrieve model & optimizer sharded state_dict
with FSDP.state_dict_type(model, StateDictType.SHARDED_STATE_DICT):
    state_dict = {
        "model": model.state_dict(),
        "optimizer": FSDP.optim_state_dict(model, optimizer),
        # Potentially add more customized state dicts.
    }

# 3. save checkpoints asynchronously using async_save
if action_rank:
    async_save(
        state_dict,
        checkpoint_id=checkpoint_id,
        process_group=process_group,
        coordinator_rank=coordinator_rank,
    )
```

The process of loading shared checkpoints is similar to the previous section, but it involves using the `torch.sagemaker.distributed.checkpoint.filesystem.DistributedFileSystemReader` and its `load` method. The `load` method of this class allows you to load the shared checkpoint data, following a process analogous to the one described earlier.

```
import os
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp import StateDictType
from torch.distributed.checkpoint.optimizer import load_sharded_optimizer_state_dict
from torch.sagemaker.distributed.checkpoint.state_dict_loader import load
from torch.sagemaker.utils.process_group_utils import get_global_ranks
from torch.sagemaker.distributed.checkpoint.filesystem import (
    DistributedFileSystemReader,
)

 load_dir = "/opt/ml/checkpoints"
sub_dir = f"tp{state.tp_rank}_ep{state.ep_rank}"
checkpoint_id = os.path.join(load_dir, sub_dir)
reader = DistributedFileSystemReader(checkpoint_id)

process_group = model.process_group
coordinator_rank = min(get_global_ranks(process_group))

with FSDP.state_dict_type(model, StateDictType.SHARDED_STATE_DICT):
   # 1. Load model and everything else except the optimizer.
   state_dict = {
        "model": model.state_dict()
        # Potentially more customized state dicts.
   }
   load(
        state_dict,
        storage_reader=reader,
        process_group=process_group,
        coordinator_rank=coordinator_rank,
   )
   model.load_state_dict(state_dict["model"])

   # 2. Load optimizer.
   optim_state = load_sharded_optimizer_state_dict(
        model_state_dict=state_dict["model"],
        optimizer_key="optimizer",
        storage_reader=reader,
        process_group=process_group,
    )
```

```
    flattened_optimizer_state = FSDP.optim_state_dict_to_load(
         optim_state["optimizer"], model, optimizer,
          group=model.process_group
    )
    optimizer.load_state_dict(flattened_optimizer_state)
```

Full model checkpoints

At the end of training, you can save a full checkpoint that combines all shards of a model into a single model checkpoint file. The SMP library fully supports the PyTorch full model checkpoints API, so you don't need to make any changes.

Note that if you use the SMP the section called “Tensor parallelism”, the SMP library transforms the model. When checkpointing the full model in this case, the SMP library translates the model back to the Hugging Face Transformers checkpoint format by default.

In cases where you train with the SMP tensor parallelism and turn off the SMP translation process, you can use the `translate_on_save` argument of the PyTorch `FullStateDictConfig` API to switch the SMP auto-translation on or off as needed. For example, if you are focusing on training a model, you don’t need to add the translation process which adds overhead. In that case, we recommend you to set `translate_on_save=False`. Also, if you plan to keep using the SMP translation of the model for further training in future, you can switch it off to save the SMP translation of the model for later use. Translating the model back to the Hugging Face Transformers model checkpoint format is needed when you wrap up the training of your model and use that for inference.

```
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp import FullStateDictConfig
import torch.sagemaker as tsm

# Save checkpoints.
with FSDP.state_dict_type(
    model,
    StateDictType.FULL_STATE_DICT,
    FullStateDictConfig(
        rank0_only=True, offload_to_cpu=True,
        # Default value is to translate back to Hugging Face Transformers format,
        # when saving full checkpoints for models trained with SMP tensor parallelism.
        # translate_on_save=True
    ),
):
```

```
    state_dict = model.state_dict()
    if dist.get_rank() == 0:
        logger.info("Processed state dict to save. Starting write to disk now.")
        os.makedirs(save_dir, exist_ok=True)
        # This name is needed for HF from_pretrained API to work.
        torch.save(state_dict, os.path.join(save_dir, "pytorch_model.bin"))
        hf_model_config.save_pretrained(save_dir)
    dist.barrier()
```

Note that the option `FullStateDictConfig(rank0_only=True, offload_to_cpu=True)` is to gather the model on the CPU of the 0th rank device to save memory when training large models.

To load the model back for inference, you do so as shown in the following code example. Note that the class `AutoModelForCausalLM` might change to other factor builder classes in Hugging Face Transformers, such as `AutoModelForSeq2SeqLM`, depending on your model. For more information, see Hugging Face Transformers documentation.

```
from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_pretrained(save_dir)
```

Amazon SageMaker AI model parallelism library v2 examples

This page provides a list of blogs and Jupyter notebooks that present practical examples of implementing the SageMaker model parallelism (SMP) library v2 to run distributed training jobs on SageMaker AI.

Blogs and Case Studies

The following blogs discuss case studies about using SMP v2.

- Amazon SageMaker AI model parallel library now accelerates PyTorch FSDP workloads by up to 20%

PyTorch example notebooks

Example notebooks are provided in the SageMaker AI examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/model_parallel_v2`.

Note

Clone and run the example notebooks in the following SageMaker AI ML IDEs.

- SageMaker JupyterLab (available in Studio created after December 2023)
- SageMaker Code Editor (available in Studio created after December 2023)
- Studio Classic (available as an application in Studio created after December 2023)
- SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/model_parallel_v2
```

SMP v2 example notebooks

- Accelerate training of Llama v2 with SMP v2, PyTorch FSDP, and Transformer Engine by running FP8 training on P5 instances
- Fine-tune Llama v2 with SMP v2 and PyTorch FSDP at large-scale using tensor parallelism, hybrid sharding, and activation offloading
- Train GPT-NeoX with SMP v2 and PyTorch FSDP at large scale
- Fine-tune GPT-NeoX with SMP v2 and PyTorch FSDP at large-scale using tensor parallelism, hybrid sharding, and activation offloading

SageMaker distributed model parallelism best practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library v2 (SMP v2).

Setting up the right configuration for distributed training

To estimate and find the best starting point to apply distributed training techniques that SMP v2 provides, review the following list. Each list item discusses the advantage of using the the section called "Core features of SMP v2" along with potential tradeoffs.

Configuration tips

This section provides guidelines on how to decide on the best model configurations for optimal throughput with global batch size requirements.

First, we recommend the following setups regardless of the size of your model.

1. Use the most powerful instance type that you can use.
2. Turn on mixed precision all the time, as it provides substantial benefits for performance and memory reduction. We recommend you to use `bfloat16` as it's more precise than `float16`.
3. Turn on the SageMaker distributed data parallelism library (instead of using NCCL) whenever it's applicable, as shown in the section called "Compatibility with the SMDDP library". One exception is for tensor-parallelism-only use cases (`hybrid_shard_degree = 1` and `tensor_paralle_degree > 1`).
4. If your model has more than about 60 billion parameters, we recommend using the section called "Delayed parameter initialization". You can also use delayed parameter initialization to speed up the initialization for any model.
5. We recommend you to enable the section called "Activation checkpointing".

Depending on the size of you model, we recommend that you start with the following guidance.

1. Use sharded data parallelism.
   a. Depending on the batch size you intend to fit in the GPU memory, choose the appropriate sharded data parallel degree. Normally, you should start with the lowest degree to fit your model in the GPU memory while minimizing overhead from network communication. If you see a warning that cache flushes are happening, we recommend that you increase the sharding degree.
   b. Determine `world_size` based on the maximum local batch size and required global batch size, if any.
   c. You can experiment with activation offloading. Depending on scenarios, it can address your memory needs without having to increase the sharding degree, which means less communication.
2. Use sharded data parallelism of PyTorch FSDP and tensor parallelism of SMP v2 simultaneously, as introduced in the section called "Tensor parallelism".
   a. When training on large clusters, with FSDP alone the global batch size can become too large, causing convergence issues for the model. Typically, most research work keeps the batch size under 4 million tokens. In this case, you can resolve the problem by composing PyTorch FSDP with tensor parallelism of SMP v2 to reduce the batch size.

For example, if you have 256 nodes and sequence length 4096, even a batch size of 1 per GPU leads to global batch size of 8M tokens. However, when you use tensor parallelism with degree 2 and batch size of 1 per tensor parallel group, this becomes 1/2 batch size per GPU, which translates to 4 million tokens.

b. When training with long context lengths such as 8k, 16k activation memory can become very high. FSDP doesn't shard activations, and activations can cause GPUs to go out of memory. In such scenarios, you can train efficiently by composing PyTorch FSDP with tensor parallelism of SMP v2.

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the Llama 2 model transformed to the SMP transformer model using the section called "`torch.sagemaker.transform`", and trained on `ml.p4d.24xlarge` instance(s) with sequence length 4096 and mixed precision (FP16 or BF16).

Model	Model size (the number of model parameters)	The number of instances	Sharded data parallel degree	Tensor parallel degree	Activation checkpointing	Activation offloading	Batch size
Llama 2	7B	1	8	1	TRUE	FALSE	4
	70B	32	256	1	TRUE	FALSE	2
	175B	64	128	4	TRUE	TRUE	6

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn't fit, try increasing the degree of tensor parallelism.

Monitoring and logging a training job using the SageMaker AI console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker AI console.

1. In the left navigation pane, choose **Training**.
2. Choose **Training jobs**.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the **Monitor** section to see the automated visualization.
5. To see training job logs, choose **View logs** in the **Monitor** section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of **algo-n-1234567890**. The **algo-1** log stream tracks training logs from the main (0th) node.

For more information, see Amazon CloudWatch Metrics for Monitoring and Analyzing Training Jobs.

Permissions

To run a SageMaker training job with model parallelism, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add `AmazonFSxFullAccess`.
- To use Amazon S3 as a data channel, add `AmazonS3FullAccess`.
- To use Docker, build your own container, and push it to Amazon ECR, add `AmazonEC2ContainerRegistryFullAccess`.
- To have a full access to use the entire suite of SageMaker AI features, add `AmazonSageMakerFullAccess`.

The SageMaker model parallel library v2 reference

The following are references for the SageMaker model parallel library v2 (SMP v2).

Topics

- SMP v2 core feature configuration parameters
- Reference for the SMP v2 torch.sagemaker package

- [Upgrade from SMP v1 to SMP v2]

SMP v2 core feature configuration parameters

The following is a complete list of parameters to activate and configure the [the section called "Core features of SMP v2"]. These must be written in JSON format and passed to the PyTorch estimator in the SageMaker Python SDK or saved as a JSON file for SageMaker HyperPod.

```
{
    "hybrid_shard_degree": Integer,
    "sm_activation_offloading": Boolean,
    "activation_loading_horizon": Integer,
    "fsdp_cache_flush_warnings": Boolean,
    "allow_empty_shards": Boolean,
    "tensor_parallel_degree": Integer,
    "context_parallel_degree": Integer,
    "expert_parallel_degree": Integer,
    "random_seed": Integer
}
```

- `hybrid_shard_degree` (Integer) – Specifies a sharded parallelism degree. The value must be an integer between `0` and `world_size`. The default value is `0`.
  - If set to `0`, it falls back to the native PyTorch implementation and API in the script when `tensor_parallel_degree` is 1. Otherwise, it computes the largest possible `hybrid_shard_degree` based on `tensor_parallel_degree` and `world_size`. When falling back to the native PyTorch FSDP use cases, if `FULL_SHARD` is the strategy you use, it shards across the whole cluster of GPUs. If `HYBRID_SHARD` or `_HYBRID_SHARD_ZERO2` was the strategy, it is equivalent to `hybrid_shard_degree` of 8. When tensor parallelism is enabled, it shards based on the revised `hybrid_shard_degree`.
  - If set to 1, it falls back to the native PyTorch implementation and API for `NO_SHARD` in the script when `tensor_parallel_degree` is 1. Otherwise, it's equivalent to `NO_SHARD` within any given tensor parallel groups.
  - If set to an integer between 2 and `world_size`, sharding happens across the specified number of GPUs. If you don't set up `sharding_strategy` in the FSDP script, it gets overridden to `HYBRID_SHARD`. If you set `_HYBRID_SHARD_ZERO2`, the `sharding_strategy` you specify is used.

- `sm_activation_offloading` (Boolean) – Specifies whether to enable the SMP activation offloading implementation. If `False`, offloading uses the native PyTorch implementation. If `True`, it uses the SMP activation offloading implementation. You also need to use the PyTorch activation offload wrapper (`torch.distributed.algorithms._checkpoint.checkpoint_wrapper.offload_wrapper`) in your script. To learn more, see the section called "Activation offloading". The default value is `True`.
- `activation_loading_horizon` (Integer) – An integer specifying the activation offloading horizon type for FSDP. This is the maximum number of checkpointed or offloaded layers whose inputs can be in the GPU memory simultaneously. To learn more, see the section called "Activation offloading". The input value must be a positive integer. The default value is 2.
- `fsdp_cache_flush_warnings` (Boolean) – Detects and warns if cache flushes happen in the PyTorch memory manager, because they can degrade computational performance. The default value is `True`.
- `allow_empty_shards` (Boolean) – Whether to allow empty shards when sharding tensors if tensor is not divisible. This is an experimental fix for crash during checkpointing in certain scenarios. Disabling this falls back to the original PyTorch behavior. The default value is `False`.
- `tensor_parallel_degree` (Integer) – Specifies a tensor parallelism degree. The value must be between 1 and `world_size`. The default value is 1. Note that passing a value greater than 1 does not enable context parallelism automatically; you also need to use the the section called "`torch.sagemaker.transform`" API to wrap the model in your training script. To learn more, see the section called "Tensor parallelism".
- `context_parallel_degree` (Integer) – Specifies the context parallelism degree. The value must be between 1 and `world_size` , and must be `<= hybrid_shard_degree`. The default value is 1. Note that passing a value greater than 1 does not enable context parallelism automatically; you also need to use the the section called "`torch.sagemaker.transform`" API to wrap the model in your training script. To learn more, see the section called "Context parallelism".
- `expert_parallel_degree` (Integer) – Specifies a expert parallelism degree. The value must be between 1 and `world_size`. The default value is 1. Note that passing a value greater than 1 does not enable context parallelism automatically; you also need to use the the section called "`torch.sagemaker.transform`" API to wrap the model in your training script. To learn more, see the section called "Expert parallelism".
- `random_seed` (Integer) – A seed number for the random operations in distributed modules by SMP tensor parallelism or expert parallelism. This seed is added to tensor-parallel or expert-

parallel ranks to set the actual seed for each rank. It is unique for each tensor-parallel and expert-parallel rank. SMP v2 makes sure that the random number generated across tensor-parallel and expert-parallel ranks matches the non-tensor-parallelism and non-expert-parallelism cases respectively.

Reference for the SMP v2 `torch.sagemaker` package

This section is a reference for the `torch.sagemaker` package provided by SMP v2.

Topics

`torch.sagemaker.delayed_param.DelayedParamIniter`

An API for applying the section called “Delayed parameter initialization” to a PyTorch model.

```
class torch.sagemaker.delayed_param.DelayedParamIniter(
    model: nn.Module,
    init_method_using_config : Callable = None,
    verbose: bool = False,
)
```

Parameters

- `model` (`nn.Module`) – A PyTorch model to wrap and apply the delayed parameter initialization functionality of SMP v2.

- `init_method_using_config` (Callable) – If you use the tensor parallel implementation of SMP v2 or supported the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism", keep this parameter at the default value, which is `None`. By default, the `DelayedParamIniter` API finds out how to initialize the given model correctly. For any other models, you need to create a custom parameter initialization function and add it to your script. The following code snippet is the default `init_method_using_config` function that SMP v2 implemented for the the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism". Use the following code snippet as a reference for creating your own initialization configuration function, adding it to your script, and passing it to the `init_method_using_config` parameter of the SMP `DelayedParamIniter` API.

```
from torch.sagemaker.utils.module_utils import empty_module_params,
 move_buffers_to_device

# Define a custom init config function.
def custom_init_method_using_config(module):
    d = torch.cuda.current_device()
    empty_module_params(module, device=d)
    if isinstance(module, (nn.Linear, Conv1D)):
        module.weight.data.normal_(mean=0.0, std=config.initializer_range)
        if module.bias is not None:
            module.bias.data.zero_()
    elif isinstance(module, nn.Embedding):
        module.weight.data.normal_(mean=0.0, std=config.initializer_range)
        if module.padding_idx is not None:
            module.weight.data[module.padding_idx].zero_()
    elif isinstance(module, nn.LayerNorm):
        module.weight.data.fill_(1.0)
        module.bias.data.zero_()
    elif isinstance(module, LlamaRMSNorm):
        module.weight.data.fill_(1.0)
    move_buffers_to_device(module, device=d)

delayed_initer = DelayedParamIniter(model,
 init_method_using_config=custom_init_method_using_config)
```

  For more information about the `torch.sagemaker.module_util` functions in the preceding code snippet, see the section called "`torch.sagemaker` util functions and properties".

- `verbose` (Boolean) – Whether to enable more detailed logging during initialization and validation. The default value is `False`.

Methods

- `get_param_init_fn()` – Returns the parameter initialization function that you can pass to the `param_init_fn` argument of the PyTorch FSDP wrapper class.
- `get_post_param_init_fn()` – Returns the parameter initialization function that you can pass to the `post_param_init_fn` argument of the PyTorch FSDP wrapper class. This is needed when you have tied weights in the model. The model must implement the method `tie_weights`. For more information, see the **Notes on tied weight** in the section called "Delayed parameter initialization".
- `count_num_params` (`module: nn.Module, *args: Tuple[nn.Parameter]`) – Tracks how many parameters are being initialized by the parameter initialization function. This helps implement the following `validate_params_and_buffers_inited` method. You usually don't need to call this function explicitly, because the `validate_params_and_buffers_inited` method implicitly calls this method in the backend.
- `validate_params_and_buffers_inited` (`enabled: bool=True`) – This is a context manager that helps validate that the number of parameters initialized matches the total number of parameters in the model. It also validates that all parameters and buffers are now on GPU devices instead of meta devices. It raises `AssertionErrors` if these conditions are not met. This context manager is only optional and you're not required to use this context manager to initialize parameters.

`torch.sagemaker.distributed.checkpoint.state_dict_saver.async_save`

Entry API for asynchronous save. Use this method to save a `state_dict` asynchronously to a specified `checkpoint_id`.

```
def async_save(
    state_dict: STATE_DICT_TYPE,
    *,
    checkpoint_id: Union[str, os.PathLike, None] = None,
    storage_writer: Optional[StorageWriter] = None,
    planner: Optional[SavePlanner] = None,
    process_group: Optional[dist.ProcessGroup] = None,
    coordinator_rank: int = 0,
    queue : AsyncCallsQueue = None,
    sharded_strategy: Union[SaveShardedStrategy, Tuple[str, int], None] = None,
    wait_error_handling: bool = True,
    force_check_all_plans: bool = True,
```

```
    s3_region: Optional[str] = None,
    s3client_config: Optional[S3ClientConfig] = None
) -> None:
```

Parameters

- `state_dict` (dict) - Required. The state dict to save.
- `checkpoint_id` (str) - Required. The storage path to save checkpoints to.
- `storage_writer` (StorageWriter) - Optional. An instance of [`StorageWriter`] in PyTorch to perform write operations. If this is not specificed, the default configuration of [`StorageWriter`] is used.
- `planner` (SavePlanner) - Optional. An instance of [`SavePlanner`] in PyTorch. If this is not specificed, the default configuration of [`SavePlanner`] is used.
- `process_group` (ProcessGroup) - Optional. The process group to work on. If `None`, the default (global) process group is used.
- `coordinator_rank` (int) - Optional. The rank of the coordinator when performing collective communication operators such as `AllReduce`.
- `queue` (AsyncRequestQueue) - Optional. The async scheduler to use. By default, it takes the global parameter `DEFAULT_ASYNC_REQUEST_QUEUE`.
- `sharded_strategy` (PyTorchDistSaveShardedStrategy) - Optional. The sharded strategy to use for saving checkpoints. If this is is not specified, `torch.sagemaker.distributed.checkpoint.state_dict_saver.PyTorchDistSaveShardedS` is used by default.
- `wait_error_handling` (bool) - Optional. A flag specifying whether to wait for all ranks to finish error handling. The default value is `True`.
- `force_check_all_plans` (bool) - Optional. A flag that determines whether to forcibly synchronize plans across ranks, even in the case of a cache hit. The default value is `True`.
- `s3_region` (str) - Optional. The region where the S3 bucket is located. If not specified, the region is inferred from the `checkpoint_id`.
- `s3client_config` (S3ClientConfig) - Optional. The dataclass exposing configurable parameters for the S3 client. If not provided, the default configuration of [S3ClientConfig] is used. The `part_size` parameter is set to 64MB by default.

torch.sagemaker.distributed.checkpoint.state_dict_saver.maybe_finalize_async_cal

This function allows a training process to monitor multiple asynchronous requests to be done.

```
def maybe_finalize_async_calls(
    blocking=True,
    process_group=None
) -> List[int]:
```

Parameters

- `blocking` (bool) - Optional. If `True`, it will wait until all active requests are completed. Otherwise, it finalizes only the asynchronous requests that have already finished. The default value is `True`.
- `process_group` (ProcessGroup) - Optional. The process group to operate on. If set to `None`, the default (global) process group is utilized.

Returns

- A list containing the indices of asynchronous calls are successfully finalized.

torch.sagemaker.distributed.checkpoint.state_dict_saver.save

Use this method to save a `state_dict` synchronously to a specified `checkpoint_id`.

```
def save(
    state_dict: STATE_DICT_TYPE,
    *,
    checkpoint_id: Union[str, os.PathLike, None] = None,
    storage_writer: Optional[StorageWriter] = None,
    planner: Optional[SavePlanner] = None,
    process_group: Optional[dist.ProcessGroup] = None,
    coordinator_rank: int = 0,
    wait_error_handling: bool = True,
    force_check_all_plans: bool = True,
    s3_region: Optional[str] = None,
    s3client_config: Optional[S3ClientConfig] = None
) -> None:
```

Parameters

- `state_dict` (dict) - Required. The state dict to save.
- `checkpoint_id` (str) - Required. The storage path to save checkpoints to.
- `storage_writer` (StorageWriter) - Optional. An instance of [`StorageWriter`] in PyTorch to perform write operations. If this is not specificed, the default configuration of [`StorageWriter`] is used.
- `planner` (SavePlanner) - Optional. An instance of [`SavePlanner`] in PyTorch. If this is not specificed, the default configuration of [`SavePlanner`] is used.
- `process_group` (ProcessGroup) - Optional. The process group to work on. If `None`, the default (global) process group is used.
- `coordinator_rank` (int) - Optional. The rank of the coordinator when performing collective communication operators such as `AllReduce`.
- `wait_error_handling` (bool) - Optional. A flag specifying whether to wait for all ranks to finish error handling. The default value is `True`.
- `force_check_all_plans` (bool) - Optional. A flag that determines whether to forcibly synchronize plans across ranks, even in the case of a cache hit. The default value is `True`.
- `s3_region` (str) - Optional. The region where the S3 bucket is located. If not specified, the region is inferred from the `checkpoint_id`.
- `s3client_config` (S3ClientConfig) - Optional. The dataclass exposing configurable parameters for the S3 client. If not provided, the default configuration of [S3ClientConfig] is used. The `part_size` parameter is set to 64MB by default.

`torch.sagemaker.distributed.checkpoint.state_dict_loader.load`

Load the state dictionary of a distributed model (`state_dict`).

```
def load(
    state_dict: Dict[str, Any],
    *,
    checkpoint_id: Union[str, os.PathLike, None] = None,
    storage_reader: Optional[StorageReader] = None,
    planner: Optional[LoadPlanner] = None,
    process_group: Optional[dist.ProcessGroup] = None,
    check_keys_matched: bool = True,
    coordinator_rank: int = 0,
    s3_region: Optional[str] = None,
    s3client_config: Optional[S3ClientConfig] = None
```

```
) -> None:
```

Parameters

- `state_dict` (dict) - Required. The `state_dict` to load.
- `checkpoint_id` (str) - Required. The ID of a checkpoint. The meaning of the `checkpoint_id` depends on the storage. It can be a path to a folder or to a file. It can also be a key if the storage is a key-value store.
- `storage_reader` (StorageReader) - Optional. An instance of [`StorageReader`] in PyTorch to perform read operations. If not specified, distributed checkpointing will automatically infer the reader based on the `checkpoint_id`. If `checkpoint_id` is also None, an exception error is raised.
- `planner` (StorageReader) - Optional. An instance of [`LoadPlanner`] in PyTorch. If not specificed, the default configuration of [`LoadPlanner`] is used.
- `check_keys_matched` (bool) - Optional. If enabled, checks whether the `state_dict` keys of all ranks are matched using `AllGather`.
- `s3_region` (str) - Optional. The region where the S3 bucket is located. If not specified, the region is inferred from the `checkpoint_id`.
- `s3client_config` (S3ClientConfig) - Optional. The dataclass exposing configurable parameters for the S3 client. If not provided, the default configuration of [S3ClientConfig] is used. The `part_size` parameter is set to 64MB by default.

`torch.sagemaker.moe.moe_config.MoEConfig`

A configuration class for setting up the SMP-implementation of Mixture-of-Experts (MoE). You can specify MoE configuration values through this class and pass it to the [`torch.sagemaker.transform`] API call. To learn more about the usage of this class for training MoE models, see [the section called “Expert parallelism”].

```
class torch.sagemaker.moe.moe_config.MoEConfig(
    smp_moe=True,
    random_seed=12345,
    moe_load_balancing="sinkhorn",
    global_token_shuffle=False,
    moe_all_to_all_dispatcher=True,
    moe_aux_loss_coeff=0.001,
    moe_z_loss_coeff=0.001
```

```
)
```

Parameters

- `smp_moe` (Boolean) - Whether to use the SMP-implementation of MoE. The default value is `True`.
- `random_seed` (Integer) - A seed number for the random operations in expert-parallel distributed modules. This seed is added to the expert parallel rank to set the actual seed for each rank. It is unique for each expert parallel rank. The default value is `12345`.
- `moe_load_balancing` (String) - Specify the load balancing type of the MoE router. Valid options are `aux_loss`, `sinkhorn`, `balanced`, and none. The default value is `sinkhorn`.
- `global_token_shuffle` (Boolean) - Whether to shuffle tokens across EP ranks within the same EP group. The default value is `False`.
- `moe_all_to_all_dispatcher` (Boolean) - Whether to use all-to-all dispatcher for the communications in MoE. The default value is `True`.
- `moe_aux_loss_coeff` (Float) - A coefficient for auxiliary load balancing loss. The default value is `0.001`.
- `moe_z_loss_coeff` (Float) - Coefficient for z-loss. The default value is `0.001`.

`torch.sagemaker.nn.attn.FlashSelfAttention`

An API for using the section called “FlashAttention” with SMP v2.

```
class torch.sagemaker.nn.attn.FlashSelfAttention(
   attention_dropout_prob: float = 0.0,
   scale: Optional[float] = None,
   triton_flash_attention: bool = False,
   use_alibi: bool = False,
)
```

Parameters

- `attention_dropout_prob` (float) – The dropout probability to apply to attention. The default value is `0.0`.
- `scale` (float) – If passed, this scale factor is applied for softmax. If set to None (which is also the default value), the scale factor is `1 / sqrt(attention_head_size)`. The default value is None.

- `triton_flash_attention` (bool) – If passed, Triton implementation of flash attention is used. This is necessary to supports Attention with Linear Biases (ALiBi) (see the following `use_alibi` parameter). This version of the kernel doesn't support dropout. The default value is `False`.
- `use_alibi` (bool) – If passed, it enables Attention with Linear Biases (ALiBi) using the mask provided. When using ALiBi, it needs an attention mask prepared as follows. The default value is `False`.

```
def generate_alibi_attn_mask(attention_mask, batch_size, seq_length,
    num_attention_heads, alibi_bias_max=8):
    device, dtype = attention_mask.device, attention_mask.dtype
    alibi_attention_mask = torch.zeros(
        1, num_attention_heads, 1, seq_length, dtype=dtype, device=device
    )

    alibi_bias = torch.arange(1 - seq_length, 1, dtype=dtype, device=device).view(
        1, 1, 1, seq_length
    )
    m = torch.arange(1, num_attention_heads + 1, dtype=dtype, device=device)
    m.mul_(alibi_bias_max / num_attention_heads)
    alibi_bias = alibi_bias * (1.0 / (2 ** m.view(1, num_attention_heads, 1, 1)))

    alibi_attention_mask.add_(alibi_bias)
    alibi_attention_mask = alibi_attention_mask[..., :seq_length, :seq_length]
    if attention_mask is not None and attention_mask.bool().any():
        alibi_attention_mask.masked_fill(
            attention_mask.bool().view(batch_size, 1, 1, seq_length), float("-inf")
        )

    return alibi_attention_mask
```

Methods

- `forward(self, qkv, attn_mask=None, causal=False, cast_dtype=None, layout="b h s d")` – A regular PyTorch module function. When a `module(x)` is called, SMP runs this function automatically.
  - `qkv` – `torch.Tensor` of the following form: `(batch_size x seqlen x (3 x num_heads) x head_size)` or `(batch_size, (3 x num_heads) x seqlen x head_size)`, a tuple of `torch.Tensors` each of which might be of shape `(batch_size`

`x seqlen x num_heads x head_size`), or (`batch_size x num_heads x seqlen x head_size`). An appropriate layout arg must be passed based on the shape.

- `attn_mask` – `torch.Tensor` of the following form (`batch_size x 1 x 1 x seqlen`). To enable this attention mask parameter, it requires `triton_flash_attention=True` and `use_alibi=True`. To learn how to generate an attention mask using this method, see the code examples at the section called "FlashAttention". The default value is None.
- `causal` – When set to `False`, which is the default value of the argument, no mask is applied. When set to `True`, the `forward` method uses the standard lower triangular mask. The default value is `False`.
- `cast_dtype` – When set to a particular `dtype`, it casts the `qkv` tensors to that `dtype` before `attn`. This is useful for implementations such as the Hugging Face Transformer GPT-NeoX model, which has `q` and `k` with `fp32` after rotary embeddings. If set to None, no cast is applied. The default value is None.
- `layout` (string) – Available values are `b h s d` or `b s h d`. This should be set to the layout of `qkv` tensors passed, so appropriate transformations can be applied for `attn`. The default value is `b h s d`.

Returns

A single `torch.Tensor` with shape (`batch_size x num_heads x seq_len x head_size`).

torch.sagemaker.nn.attn.FlashGroupedQueryAttention

An API for using `FlashGroupedQueryAttention` with SMP v2. To learn more about the usage of this API, see the section called "Use FlashAttention kernels for grouped-query attention".

```
class torch.sagemaker.nn.attn.FlashGroupedQueryAttention(
    attention_dropout_prob: float = 0.0,
    scale: Optional[float] = None,
)
```

Parameters

- `attention_dropout_prob` (float) – The dropout probability to apply to attention. The default value is `0.0`.
- `scale` (float) – If passed, this scale factor is applied for softmax. If set to None, `1 / sqrt(attention_head_size)` is used as the scale factor. The default value is None.

Methods

- `forward(self, q, kv, causal=False, cast_dtype=None, layout="b s h d")` – A regular PyTorch module function. When a `module(x)` is called, SMP runs this function automatically.
  - `q` – `torch.Tensor` of the following form `(batch_size x seqlen x num_heads x head_size)` or `(batch_size x num_heads x seqlen x head_size)`. Appropriate layout arg must be passed based on the shape.
  - `kv` – `torch.Tensor` of the following form `(batch_size x seqlen x (2 x num_heads) x head_size)` or `(batch_size, (2 x num_heads) x seqlen x head_size)`, or a tuple of two `torch.Tensor`s, each of which might be of shape `(batch_size x seqlen x num_heads x head_size)` or `(batch_size x num_heads x seqlen x head_size)`. Appropriate `layout` argument must also be passed based on the shape.
  - `causal` – When set to `False`, which is the default value of the argument, no mask is applied. When set to `True`, the `forward` method uses the standard lower triangular mask. The default value is `False`.
  - `cast_dtype` – When set to a particular dtype, it casts the `qkv` tensors to that dtype before `attn`. This is useful for implementations such as Hugging Face Transformers GPT-NeoX, which has `q,k` with `fp32` after rotary embeddings. If set to `None`, no cast is applied. The default value is `None`.
  - layout (string) – Available values are `"b h s d"` or `"b s h d"`. This should be set to the layout of `qkv` tensors passed, so appropriate transformations can be applied for `attn`. The default value is `"b h s d"`.

Returns

Returns a single `torch.Tensor (batch_size x num_heads x seq_len x head_size)` that represents the output of attention computation.

`torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention`

An API that supports FlashAttention for the Llama model. This API uses the the section called “`torch.sagemaker.nn.attn.FlashGroupedQueryAttention`” API at low level. To learn how to use this, see the section called “Use FlashAttention kernels for grouped-query attention”.

```
class torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention(
    config: LlamaConfig
```

```
)
```

Parameters

- `config` – A FlashAttention configuration for the Llama model.

Methods

- `forward(self, hidden_states, attention_mask, position_ids, past_key_value, output_attentions, use_cache)`
  - `hidden_states` (`torch.Tensor`) – Hidden states of a tensor in form of `(batch_size x seq_len x num_heads x head_size)`.
  - `attention_mask` (`torch.LongTensor`) – Mask to avoid performing attention on padding token indices in form of `(batch_size x seqlen)`. The default value is `None`.
  - `position_ids` (`torch.LongTensor`) – When not being `None`, it is in form of `(batch_size x seqlen)`, indicating the indices of positions of each input sequence token in the position embeddings. The default value is `None`.
  - `past_key_value` (Cache) – Pre-computed hidden-states (key and values in the self-attention blocks and in the cross-attention blocks). The default value is `None`.
  - `output_attentions` (bool) – Indicates whether to return the attentions tensors of all attention layers. The default value is `False`.
  - `use_cache` (bool) – Indicates whether to return `past_key_values` key value states. The default value is `False`.

Returns

Returns a single `torch.Tensor (batch_size x num_heads x seq_len x head_size)` that represents the output of attention computation.

`torch.sagemaker.transform`

SMP v2 provides this `torch.sagemaker.transform()` API for transforming Hugging Face Transformer models to SMP model implementations and enabling the SMP tensor parallelism.

```
torch.sagemaker.transform(
    model: nn.Module,
    device: Optional[torch.device] = None,
```

```
    dtype: Optional[torch.dtype] = None,
    config: Optional[Dict] = None,
    load_state_dict_from_rank0: bool = False,
    cp_comm_type: str = "p2p"
)
```

SMP v2 maintains transformation policies for the the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism" by converting the configuration of the Hugging Face Transformer models to the SMP transformer configuration.

Parameters

- `model` (`torch.nn.Module`) – A model from the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism" to transform and apply the tensor parallelism feature of the SMP library.
- `device` (`torch.device`) – If passed, a new model is created on this device. If the original module has any parameter on meta device (see the section called "Delayed parameter initialization"), then the transformed module will also be created on meta device, ignoring the argument passed here. The default value is `None`.
- `dtype` (`torch.dtype`) – If passed, sets this as the dtype context manager for the creation of the model and creates a model with this dtype. This is typically unnecessary, as we want to create the model with `fp32` when using `MixedPrecision`, and `fp32` is the default dtype in PyTorch. The default value is `None`.
- `config` (dict) – This is a dictionary for configuring the SMP transformer. The default value is `None`.
- `load_state_dict_from_rank0` (Boolean) – By default, this module creates a new instance of the model with new weights. When this argument is set to `True`, SMP tries to load the state dictionary of the original PyTorch model from the 0th rank into transformed model for the tensor parallel group that the 0th rank is part of. When this is set to `True`, rank 0 can't have any parameters on meta device. Only the first tensor parallel group populates the weights from the 0th rank after this transform call. You need to set `sync_module_states` to `True` in the FSDP wrapper to get these weights from the first tensor parallel group to all other processes. With this activated, the SMP library loads the state dictionary from the original model. The SMP library takes the `state_dict` of the model before transform, converts it to match the structure of the transformed model, shards it for each tensor parallel rank, communicates this state from the 0th rank to other ranks in the tensor parallel group that the 0th rank is part of, and loads it. The default value is `False`.

- `cp_comm_type` (str) – Determines the context parallelism implementation and is only applicable when the `context_parallel_degree` is greater than 1. Available values for this parameter are `p2p` and `all_gather`. The `p2p` implementation utilizes peer-to-peer send-receive calls for key-and-value (KV) tensor accumulation during the attention computation, running asynchronously and allowing communication to overlap with computation. On the other hand, the `all_gather` implementation employs the `AllGather` communication collective operation for KV tensor accumulation. The default value is `"p2p"`.

Returns

Returns a transformed model that you can wrap with PyTorch FSDP. When `load_state_dict_from_rank0` is set to `True`, the tensor parallel group that involves rank 0 has weights loaded from the original state dictionary on rank 0. When using the section called “Delayed parameter initialization” on the original model, only these ranks have the actual tensors on CPUs for the parameters and buffers of the transformed model. The rest of the ranks continue to have the parameters and buffers on the meta device to save memory.

`torch.sagemaker` util functions and properties

torch.sagemaker util functions

- `torch.sagemaker.init(config: Optional[Union[str, Dict[str, Any]]] = None) -> None` – Initializes the PyTorch training job with SMP.
- `torch.sagemaker.is_initialized() -> bool` – Checks whether the training job is initialized with SMP. When falling back to the native PyTorch while the job is initialized with SMP, some of the properties are not relevant and become `None`, as indicated in the following **Properties** list.
- `torch.sagemaker.utils.module_utils.empty_module_params(module: nn.Module, device: Optional[torch.device] = None, recurse: bool = False) -> nn.Module` – Creates empty parameters on the given `device` if any, and it can be recursive for all nested modules if specified.
- `torch.sagemaker.utils.module_utils.move_buffers_to_device(module: nn.Module, device: torch.device, recurse: bool = False) -> nn.Module` – Moves module buffers to the given `device`, and it can be recursive for all nested modules if specified.

Properties

`torch.sagemaker.state` holds multiple useful properties after the initialization of SMP with `torch.sagemaker.init`.

- `torch.sagemaker.state.hybrid_shard_degree` (int) – The sharded data parallelism degree, a copy from user input in the SMP configuration passed to `torch.sagemaker.init()`. To learn more, see the section called "Use the SMP v2".
- `torch.sagemaker.state.rank` (int) – The global rank for the device, in the range of `[0, world_size)`.
- `torch.sagemaker.state.rep_rank_process_group` (`torch.distributed.ProcessGroup`) – The process group including all devices with the same replication rank. Note the subtle but fundamental difference with `torch.sagemaker.state.tp_process_group`. When falling back to native PyTorch, it returns `None`.
- `torch.sagemaker.state.tensor_parallel_degree` (int) – The tensor parallelism degree, a copy from user input in the SMP configuration passed to `torch.sagemaker.init()`. To learn more, see the section called "Use the SMP v2".
- `torch.sagemaker.state.tp_size` (int) – An alias to `torch.sagemaker.state.tensor_parallel_degree`.
- `torch.sagemaker.state.tp_rank` (int) – The tensor parallelism rank for the device in the range of `[0, tp_size)`, determined by the tensor parallelism degree and the ranking mechanism.
- `torch.sagemaker.state.tp_process_group` (`torch.distributed.ProcessGroup`) – The tensor parallel process group including all devices with the same rank in other dimensions (for example, sharded data parallelism and replication) but unique tensor parallel ranks. When falling back to native PyTorch, it returns `None`.
- `torch.sagemaker.state.world_size` (int) – The total number of devices used in training.

Upgrade from SMP v1 to SMP v2

To move from SMP v1 to SMP v2, you must make script changes to remove the SMP v1 APIs and apply the SMP v2 APIs. Instead of starting from your SMP v1 script, we recommend you start from a PyTorch FSDP script, and follow the instructions at the section called "Use the SMP v2".

To bring SMP v1 *models* to SMP v2, in SMP v1 you must collect the full model state dictionary and apply the translation functions on the model state dictionary to convert it into the Hugging Face Transformers model checkpoint format. Then in SMP v2, as discussed in the section called "Checkpointing using SMP", you can load the Hugging Face Transformers model checkpoints, and then continue with using the PyTorch checkpoint APIs with SMP v2. To use SMP with your PyTorch FSDP model, make sure that you move to SMP v2 and make changes to your training script to use PyTorch FSDP and other latest features.

```
import smdistributed.modelparallel.torch as smp

# Create model
model = ...
model = smp.DistributedModel(model)

# Run training
...

# Save v1 full checkpoint
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True) # save the full model
    # Get the corresponding translation function in smp v1 and translate
    if model_type == "gpt_neox":
        from smdistributed.modelparallel.torch.nn.huggingface.gptneox import
 translate_state_dict_to_hf_gptneox
        translated_state_dict = translate_state_dict_to_hf_gptneox(state_dict,
 max_seq_len=None)

    # Save the checkpoint
    checkpoint_path = "checkpoint.pt"
    if smp.rank() == 0:
        smp.save(
            {"model_state_dict": translated_state_dict},
            checkpoint_path,
            partial=False,
        )
```

To find available translation functions in SMP v1, see the section called "Support for Hugging Face Transformer Models".

For instruction on model checkpoints saving and loading in SMP v2, see the section called "Checkpointing using SMP".

Release notes for the SageMaker model parallelism library

See the following release notes to track the latest updates for the SageMaker model parallelism (SMP) library. If you have further questions about the SMP library, contact the SMP service team at `sm-model-parallel-feedback@amazon.com`.

The SageMaker model parallelism library v2.8.0

Date: April 01, 2025

SMP library updates

Bug fixes

- SMP gradient norm clipping now supports activation offloading.

SMP Docker and Enroot containers

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to `v2.243.0` or later.

Currency updates

- Added support for PyTorch v2.5.1
- Upgraded CUDA support to v12.4
- Upgraded NCCL support to v2.23.4
- Upgraded SMDDP library to 2.6.0

Container details

- SMP Docker container for PyTorch v2.5.1 with CUDA v12.4

```
658645717510.dkr.ecr.<us-west-2>.amazonaws.com/smdistributed-modelparallel:2.5.1-gpu-py311-cu124
```

- SMP Enroot container for PyTorch v2.5.1 with CUDA v12.4

```
https://sagemaker-distributed-model-parallel.s3.<us-west-2>.amazonaws.com/
enroot/2.5.1-gpu-py311-cu124.sqsh
```

- Pre-installed packages
  - The SMP library v2.8.0
  - The SMDDP library v2.6.0
  - CUDNN v9.4.0
  - FlashAttention v2.5.8
  - TransformerEngine v1.10
  - Megatron v0.8.0
  - Hugging Face Transformers v4.44.2
  - Hugging Face Datasets library v2.19.0
  - EFA v1.36.0
  - NCCL v2.23.4
  - AWS-OFI-NCCL v1.13.2

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in an environment such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.7.0

Date: December 04, 2024

SMP library updates

New features

- Added support for the section called “HyperPod recipes”.

SMP Docker and Enroot containers

The SMP library team distributes Docker and Enroot containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to `v2.237.0` or later.

Container details

- SMP Docker container for PyTorch v2.4.1 with CUDA v12.1

```
658645717510.dkr.ecr.<us-west-2>.smdistributed-modelparallel:2.4.1-gpu-py311-cu121
```

- SMP Enroot container for PyTorch v2.4.1 with CUDA v12.1

```
https://sagemaker-distributed-model-parallel.s3.<us-west-2>.amazonaws.com/
enroot/2.4.1-gpu-py311-cu121.sqsh
```

- Pre-installed packages
  - The SMP library v2.7.0
  - The SMDDP library v2.5.0
  - CUDNN v9.4.0
  - FlashAttention v2.5.8
  - TransformerEngine v1.10
  - Megatron v0.8.0
  - Hugging Face Transformers v4.44.2
  - Hugging Face Datasets library v2.19.0
  - EFA v1.32.0
  - NCCL v2.21.5

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in a Conda environment such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.6.1

Date: October 31, 2024

SMP library updates

Bug fixes

- Fixed an `ImportError` issue that occurred when using older training scripts with SMP v2.6.0. This fixes the backward incompatibility with SMP v2.6.0.
- Added a `DeprecationWarning` for `torch.sagemaker.distributed.fsdp.checkpoint`. This module will be deprecated and removed in SMP v2.7.0. If you're currently using `torch.sagemaker.distributed.fsdp.checkpoint` in your code, you should plan to update your scripts before the release of SMP v2.7.0 to avoid issues in the future.
- Fixed a backward compatibility issue identified in SMP v2.6.0. This issue was related to the deprecation of the `USE_PG_WITH_UTIL` checkpoint method in SMP v2.6.0, which broke backward compatibility with previous versions of training scripts. To resolve this issue, re-run your PyTorch training jobs to pick up the latest SMP container packaged with SMP v2.6.1.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers.

Container details

- SMP Docker container for PyTorch v2.4.1 with CUDA v12.1

```
658645717510.dkr.ecr.<us-west-2>.amazonaws.com/smdistributed-modelparallel:2.4.1-gpu-py311-cu121
```

- Pre-installed packages

- The SMP library v2.6.1
- The SMDDP library v2.5.0
- CUDNN v9.4.0
- FlashAttention v2.5.8
- TransformerEngine v1.10
- Megatron v0.8.0
- Hugging Face Transformers v4.44.2
- Hugging Face Datasets library v2.19.0
- EFA v1.32.0
- NCCL v2.21.5

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.6.0

Date: October 17, 2024

SMP library updates

New features

- Added support for the following LLM model configurations. You can start using the section called "Context parallelism" and the section called "Tensor parallelism".
  - Llama3.1 8B
  - Llama3.1 70B
  - Mistral 7B

- Added the section called “Tensor parallelism” support for the following Mixtral model configurations.
  - Mixtral 8x7B
  - Mixtral 8x22B
- Added support for an AllGather-based context parallelism implementation that utilizes the AllGather communication collective to obtain the full sequence of key-and-value tensors. Available implementations are `p2p` and `all_gather`. The `p2p` implementation utilizes peer-to-peer send-receive calls for key-and-value (KV) tensor accumulation during the attention computation, running asynchronously and allowing communication to overlap with computation. On the other hand, the `all_gather` implementation employs the `AllGather` communication collective operation for KV tensor accumulation. To learn how to apply these context parallelism implementation, see the section called “Context parallelism”.
- Added support for tuning the Rotary Position Embedding (RoPE) theta value.

Bug fixes

- Fixed a bug where Rotary Position Embedding (RoPE) isn’t properly initialized during pre-training when delayed parameter is enabled.

Known issues

- Transformer Engine does not currently support context parallelism or FP8 with sliding window attention enabled. Thus, the SMP version of Mistral transformers don’t support context parallelism or FP8 training when sliding window configuration is set to a non-null value.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers.

Currency updates

- Upgraded PyTorch to v2.4.1
- Upgraded Megatron to v0.8.0

- Upgraded the TransformerEngine library to v1.10
- Upgraded Transformers to v4.44.2
- Upgraded cuDNN to v9.4.0.58

Container details

- SMP Docker container for PyTorch v2.4.1 with CUDA v12.1

  ```
  658645717510.dkr.ecr.<us-west-2>.amazonaws.com/smdistributed-modelparallel:2.4.1-gpu-py311-cu121
  ```
- Pre-installed packages
  - The SMP library v2.6.0
  - The SMDDP library v2.5.0
  - CUDNN v9.4.0
  - FlashAttention v2.5.8
  - TransformerEngine v1.10
  - Megatron v0.8.0
  - Hugging Face Transformers v4.44.2
  - Hugging Face Datasets library v2.19.0
  - EFA v1.32.0
  - NCCL v2.21.5

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.5.0

Date: August 28, 2024

SMP library updates

New features

- Added support for mixed-precision training using FP8 data format on P5 instances for the Mixtral model.
  - Supported Mixtral configurations are 8x7B and 8x22B. To learn more, see the section called "Mixed precision training with FP8 on P5 instances using Transformer Engine".
- Added support for the section called "Context parallelism" for the following model configurations.
  - Llama-v2: 7B and 70B
  - Llama-v3: 8B and 70B
  - GPT-NeoX: 20B
- Added support for saving checkpoints asynchronously. To learn more, see the section called "Checkpointing using SMP".
  - Support for saving checkpoints to S3 directly without using Amazon EBS or file servers.

Bug fixes

- Resolved an issue that caused unexpectedly high initial loss during Llama fine-tuning when loading a pre-trained model checkpoint and utilizing tensor parallelism.

Notes

- To use activation checkpointing for Mixtral with FP8 mixed precision, you will need to checkpoint the attention and expert layers separately. For an example of setting it up properly, see the example training script in the *Amazon SageMaker AI Examples repository*.

Known issues

- The balanced load balancing type in the MoE configuration (the section called "`torch.sagemaker.moe.moe_config.MoEConfig`") is currently incompatible with activation checkpointing.

- With context parallelism, GPT-NeoX shows performance regression in both pre-training and fine-tuning.
- For GPT-NeoX on P4 instances, directly loading weights from a delayed parameter initialized transformed model into a Hugging Face transformer model leads to a loss mismatch on the first step.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.224.0 or later.

Currency updates

- Upgraded the FlashAttention library to v2.5.8
- Upgraded the Transformer Engine library to v1.8
  - If you want to install Transformer Engine in a Conda environment, you need to build from the source and cherry-pick the specific upstream fixes (744624d, 27c6342, 7669bf3).

Container details

- SMP Docker container for PyTorch v2.3.1 with CUDA v12.1

  ```
  658645717510.dkr.ecr.<region>.amazonaws.com/smdistributed-modelparallel:2.3.1-gpu-py311-cu121
  ```

  For a complete list of supported regions, see the section called “AWS Regions”.
- Pre-installed packages
  - The SMP library v2.5.0
  - The SMDDP library v2.3.0
  - CUDNN v8.9.7.29
  - FlashAttention v2.5.8
  - TransformerEngine v1.8
  - Megatron v0.7.0

- Hugging Face Transformers v4.40.1
- Hugging Face Datasets library v2.19.0
- EFA v1.32.0
- NCCL v2.21.5

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see [Channels] in the *Conda documentation*.

The SageMaker model parallelism library v2.4.0

Date: June 20, 2024

SMP library updates

Bug fixes

- Fixed a bug that causes incorrect logit shapes when labels are not passed in the forward pass while using the SMP Transformer.

Currency updates

- Added support for PyTorch v2.3.1.
- Added support for Python v3.11.
- Added support for the Hugging Face Transformers library v4.40.1.

Deprecations

- Discontinued support for Python v3.10.

- Discontinued support for the Hugging Face Transformers library versions before v4.40.1.

Other changes

- Included a patch to toggle saving de-duplicated tensors on different ranks. To learn more, see the discussion threadin the PyTorch GitHub repository.

Known issues

- There is a known issue that the loss might spike and then resume at a higher loss value while fine-tuning Llama-3 70B with tensor parallelism.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.224.0 or later.

Currency updates

- Upgraded the SMDDP library to v2.3.0.
- Upgraded the NCCL library to v2.21.5.
- Upgraded the EFA software to v1.32.0.

Deprecations

- Discontinued the installation of the Torch Distributed Experimental (torchdistX) library.

Container details

- SMP Docker container for PyTorch v2.3.1 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.3.1-gpu-py311-cu121
```

- Pre-installed packages

- The SMP library v2.4.0
- The SMDDP library v2.3.0
- CUDNN v8.9.7.29
- FlashAttention v2.3.3
- TransformerEngine v1.2.1
- Hugging Face Transformers v4.40.1
- Hugging Face Datasets library v2.19.0
- EFA v1.32.0
- NCCL v2.21.5

SMP Conda channel

The following S3 bucket is the public Conda channel of the SMP library hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.3.1

Date: May 9, 2024

Bug fixes

- Fixed an `ImportError` issue when using `moe_load_balancing=balanced` in the section called "`torch.sagemaker.moe.moe_config.MoEConfig`" for expert parallelism.
- Fixed a fine-tuning issue where the the section called "`torch.sagemaker.transform`" call raised `KeyError` when `load_state_dict_from_rank0` is enabled.
- Fixed an out-of-memory (OOM) error raised when loading large Mixture of Experts (MoE) models, such as Mixtral 8x22B, for fine-tuning.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. This release incorporates the aforementioned bug fixes into the following SMP Docker image.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121
```

The SageMaker model parallelism library v2.3.0

Date: April 11, 2024

New features

- Added a new core feature, *expert parallelism*, to support Mixture of Experts transformer models. To learn more, see the section called “Expert parallelism”.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.214.4 or later.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121
```

  - Pre-installed packages in this Docker container
    - The SMDDP library v2.2.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1

  - Hugging Face Datasets library v2.16.1
  - Megatron-core 0.5.0
  - EFA v1.30.0
  - NCCL v2.19.4

The SageMaker model parallelism library v2.2.0

Date: March 7, 2024

New Features

- Added support for FP8 training of the following Hugging Face transformer models on P5 instances with Transformer Engine integration:
  - GPT-NeoX
  - Llama 2

Bug Fixes

- Fixed a bug where tensors were not guaranteed to be contiguous before the `AllGather` collective call during tensor parallelism training.

Currency Updates

- Added support for PyTorch v2.2.0.
- Upgraded the SMDDP library to v2.2.0.
- Upgraded the FlashAttention library to v2.3.3.
- Upgraded the NCCL library to v2.19.4.

Deprecation

- Discontinued support for Transformer Engine versions before v1.2.0.

Known issues

- The SMP the section called "Activation offloading" feature currently does not work. Use the native PyTorch activation offloading instead.

Other changes

- Included a patch to fix the performance regression discussed in the issue thread at https://github.com/pytorch/pytorch/issues/117748 in the PyTorch GitHub repository.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.212.0 or later.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

  ```
  658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121
  ```

  - Available for P4d, P4de, and P5 instances
  - Pre-installed packages in this Docker container
    - The SMDDP library v2.2.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1
    - Hugging Face Datasets library v2.16.1
    - EFA v1.30.0
    - NCCL v2.19.4

The SageMaker model parallelism library v2.1.0

Date: February 6, 2024

Currency Updates

- Added support for PyTorch v2.1.2.

Deprecation

- Discontinued support for Hugging Face Transformers v4.31.0.

Known issues

- An issue is discovered that fine-tuning of the Hugging Face Llama 2 model with `attn_implementation=flash_attention_2` and FSDP causes the model to diverge. For reference, see the issue ticket in the *Hugging Face Transformers GitHub repository*. To avoid the divergence issue, use `attn_implementation=sdpa`. Alternatively, use the SMP transformer model implementation by setting up `use_smp_implementation=True`.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.207.0 or later.

- SMP Docker container for PyTorch v2.1.2 with CUDA v12.1

  ```
  658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-py310-cu121
  ```

  - Available for P4d, P4de, and P5 instances
  - Pre-installed packages in this Docker container
    - The SMDDP library v2.1.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1
    - Hugging Face Datasets library v2.16.1
    - EFA v1.30.0

SMP Conda channel

The following S3 bucket is a public Conda channel hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.0.0

Date: December 19, 2023

New features

Released the SageMaker model parallelism (SMP) library v2.0.0 with the following new offerings.

- A new `torch.sagemaker` package, entirely revamped from the previous `smdistributed.modelparallel.torch` package in SMP v1.x.
- Support for PyTorch 2.0.1.
- Support for PyTorch FSDP.
- Tensor parallelism implementation by integrating with the Transformer Engine library.
- Support for both SageMaker Training and SageMaker HyperPod.

Breaking changes

- SMP v2 revamped the APIs entirely and provides the `torch.sagemaker` package. Mostly, you only need to initialize with the `torch.sagemaker.init()` module and pass model parallel configuration parameters. With this new package, you can significantly simplify code modifications in your training script. To learn more about adapting your training script to use SMP v2, see the section called "Use the SMP v2".
- If you've used SMP v1 for training Hugging Face Transformer models and want to reuse the models in SMP v2, see the section called "Upgrade from SMP v1 to SMP v2".
- For PyTorch FSDP training, you should use SMP v2.

Known issues

- Activation checkpointing currently only works with the following wrapping policies with FSDP.
  - `auto_wrap_policy = functools.partial(transformer_auto_wrap_policy, ...)`
- To use the section called “Activation offloading”, FSDP activation checkpointing type must be REENTRANT.
- When running with tensor parallel enabled with the sharded data parallel degree set to 1, you must use `backend = nccl`. The `smddp` backend option is not supported in this scenario.
- Transformer Engine is required to use PyTorch with the SMP library even when not using tensor parallelism.

Other changes

- Starting from this release, the documentation for the SageMaker model parallelism library is fully available in this *Amazon SageMaker AI Developer Guide*. In favor of this complete developer guide for SMP v2 in the *Amazon SageMaker AI Developer Guide*, the additional reference for SMP v1.x in the *SageMaker Python SDK documentation* is deprecated. If you still need the documentation for SMP v1.x, the developer guide for SMP v1.x is available at the section called “(Archived) SageMaker model parallelism library v1.x”, and the SMP Python library v1.x reference is available in the SageMaker Python SDK v2.199.0 documentation.

Deprecations

- Discontinued support for TensorFlow.
- There is no pipeline parallelism support in SMP v2.
- There is no support for the DeepSpeed library in favor of native PyTorch FSDP.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker AI automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.207.0 or later.

- SMP Docker container for PyTorch v2.0.1 with CUDA v12.1

```

(Archived) SageMaker model parallelism library v1.x

Important

As of December 19, 2023, the SageMaker model parallelism (SMP) library v2 is released. In favor of the SMP library v2, the SMP v1 capabilites are no longer supported in future releases. The following section and topics are archived and specific to using the SMP library v1. For information about using the SMP library v2, see the section called “SageMaker model parallelism library v2”.

Use Amazon SageMaker AI's model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.

You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the *SageMaker Python SDK v2.199.0 documentation*.

- Model Parallel Troubleshooting

Introduction to Model Parallelism

Model parallelism is a distributed training method in which the deep learning model is partitioned across multiple devices, within or across instances. This introduction page provides a high-level overview about model parallelism, a description of how it can help overcome issues that arise when training DL models that are typically very large in size, and examples of what the SageMaker model parallel library offers to help manage model parallel strategies as well as memory consumption.

What is Model Parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model you can train, since the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve most optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate Memory Requirements Before Using Model Parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses AMP (FP16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 parameter ~ 2 bytes

- An FP16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the `optimizer apply` (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory and V100 with 16/32 GB) available on a single GPU. Note that on top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P3 and P4 instances that have NVIDIA V100 and A100 Tensor Core GPUs respectively. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the *Accelerated Computing* section in the Amazon EC2 Instance Types page.

Even with the accelerated computing instances, it is obvious that models with about 10 billion parameters such as Megatron-LM and T5 and even larger models with hundreds of billions of parameters such as GPT-3 cannot fit model replicas in each GPU device.

How the Library Employs Model Parallelism and Memory Saving Techniques

The library consists of various types of model parallelism features and memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models that consist of hundreds of billions of parameters.

Topics

Sharded data parallelism (available for PyTorch)

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs within a data-parallel group.

SageMaker AI implements sharded data parallelism through the implementation of MiCS, which is a library that **mi**nimizes **c**ommunication **s**cale and discussed in the blog post [Near-linear scaling of gigantic-model training on AWS](https://www.amazon.science/blog/near-linear-scaling-of-gigantic-model-training-on-aws).

You can apply sharded data parallelism to your model as a stand-alone strategy. Furthermore, if you are using the most performant GPU instances equipped with NVIDIA A100 Tensor Core GPUs, `ml.p4d.24xlarge`, you can take the advantage of improved training speed from the `AllGather` operation offered by SMDDP Collectives.

To dive deep into sharded data parallelism and learn how to set it up or use a combination of sharded data parallelism with other techniques like tensor parallelism and FP16 training, see the section called “Sharded Data Parallelism”.

Pipeline parallelism (available for PyTorch and TensorFlow)

Pipeline parallelism partitions the set of layers or operations across the set of devices, leaving each operation intact. When you specify a value for the number of model partitions (`pipeline_parallel_degree`), the total number of GPUs (`processes_per_host`) must be divisible by the number of the model partitions. To set this up properly, you have to specify the correct values for the `pipeline_parallel_degree` and `processes_per_host` parameters. The simple math is as follows:

```
(pipeline_parallel_degree) x (data_parallel_degree) = processes_per_host
```

The library takes care of calculating the number of model replicas (also called `data_parallel_degree`) given the two input parameters you provide.

For example, if you set `"pipeline_parallel_degree": 2` and `"processes_per_host": 8` to use an ML instance with eight GPU workers such as `ml.p3.16xlarge`, the library automatically sets up the distributed model across the GPUs and four-way data parallelism. The following image illustrates how a model is distributed across the eight GPUs achieving four-way data parallelism and two-way pipeline parallelism. Each model replica, where we define it as a *pipeline parallel group* and label it as `PP_GROUP`, is partitioned across two GPUs. Each partition of the model is assigned to four GPUs, where the four partition replicas are in a *data parallel group* and labeled as

DP_GROUP. Without tensor parallelism, the pipeline parallel group is essentially the model parallel group.

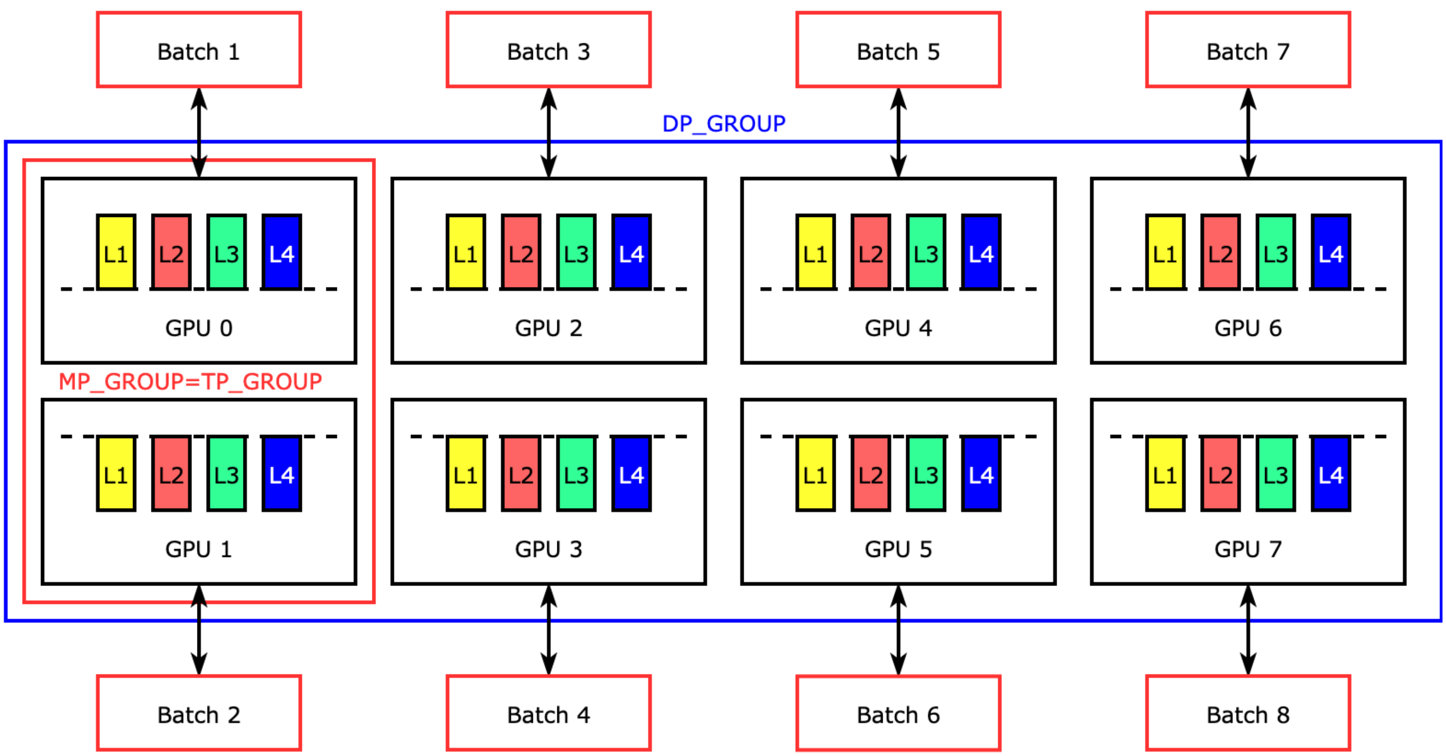
To dive deep into pipeline parallelism, see Core Features of the SageMaker Model Parallelism Library.

To get started with running your model using pipeline parallelism, see Run a SageMaker Distributed Training Job with the SageMaker Model Parallel Library.

Tensor parallelism (available for PyTorch)

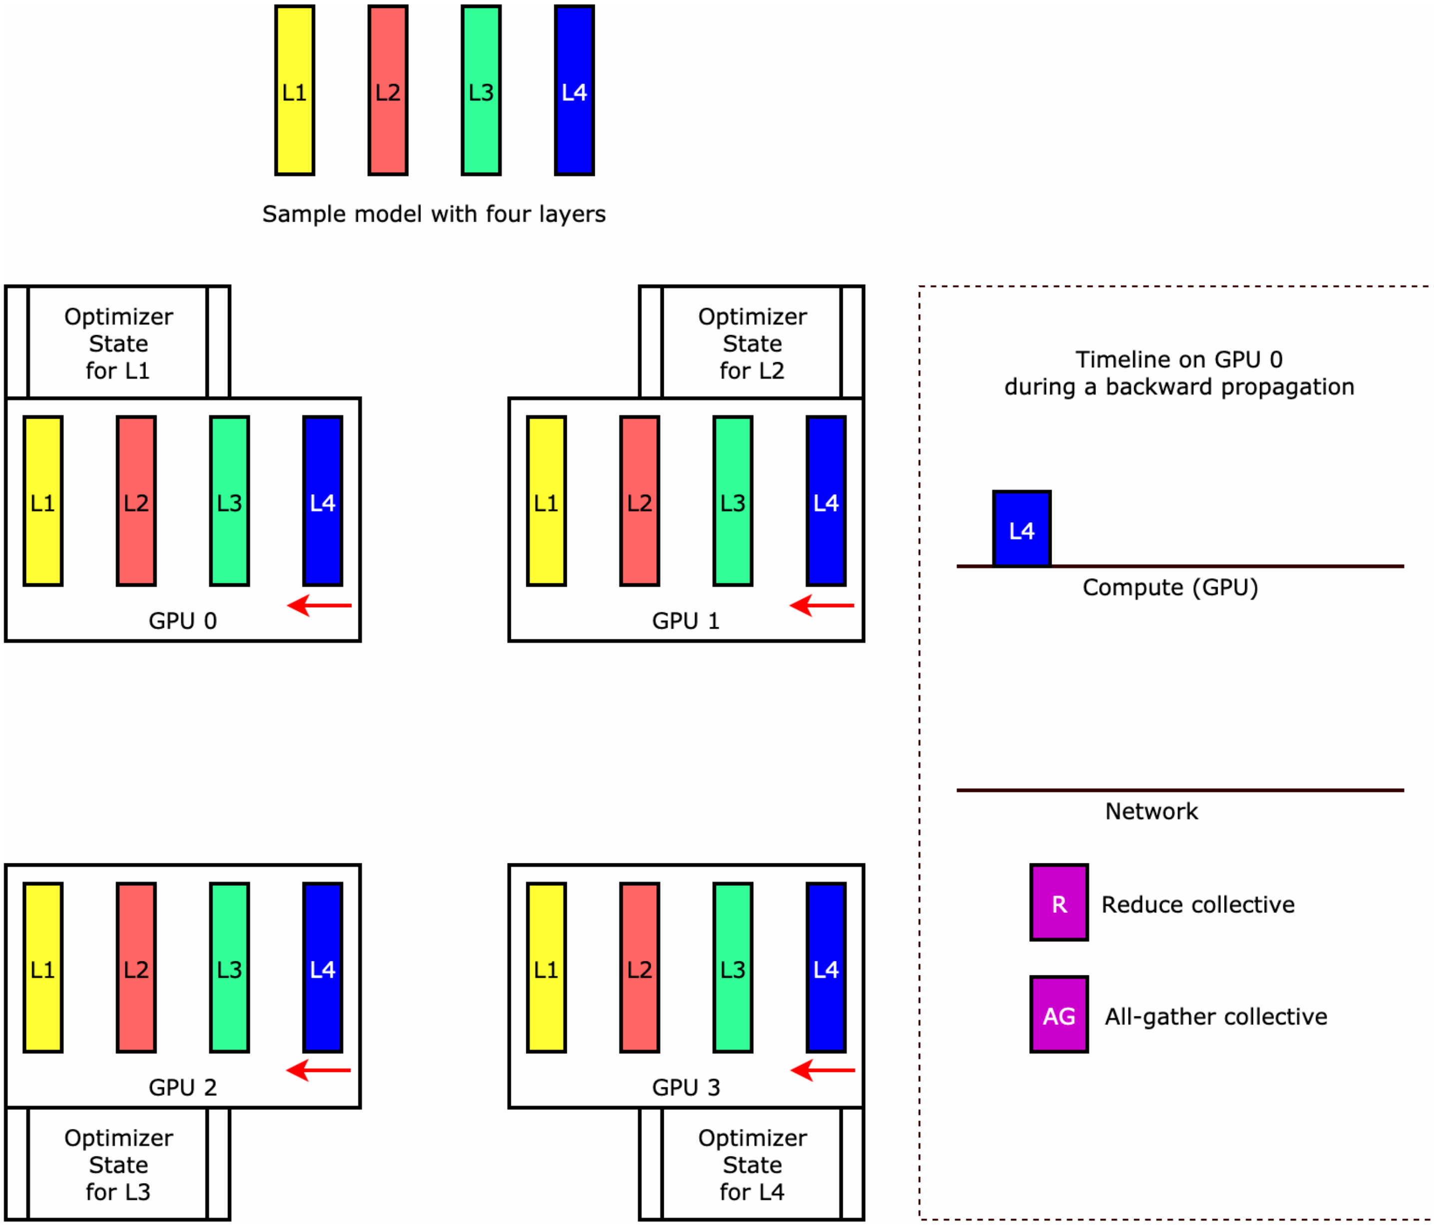
Tensor parallelism splits individual layers, or `nn.Modules`, across devices, to be run in parallel. The following figure shows the simplest example of how the library splits a model with four layers to achieve two-way tensor parallelism (`"tensor_parallel_degree": 2`). The layers of each model replica are bisected and distributed into two GPUs. In this example case, the model parallel configuration also includes `"pipeline_parallel_degree": 1` and `"ddp": True` (uses PyTorch DistributedDataParallel package in the background), so the degree of data parallelism becomes eight. The library manages communication across the tensor-distributed model replicas.



The usefulness of this feature is in the fact that you can select specific layers or a subset of layers to apply tensor parallelism. To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of pipeline and tensor parallelism, see Tensor Parallelism.

Optimizer state sharding (available for PyTorch)

To understand how the library performs *optimizer state sharding*, consider a simple example model with four layers. The key idea in optimizing state sharding is you don't need to replicate your optimizer state in all of your GPUs. Instead, a single replica of the optimizer state is sharded across data-parallel ranks, with no redundancy across devices. For example, GPU 0 holds the optimizer state for layer one, the next GPU 1 holds the optimizer state for L2, and so on. The following animated figure shows a backward propagation with the optimizer state sharding technique. At the end of the backward propagation, there's compute and network time for the `optimizer apply` (OA) operation to update optimizer states and the `all-gather` (AG) operation to update the model parameters for the next iteration. Most importantly, the `reduce` operation can overlap with the compute on GPU 0, resulting in a more memory-efficient and faster backward propagation. In the current implementation, AG and OA operations do not overlap with `compute`. It can result in an extended computation during the AG operation, so there might be a tradeoff.



For more information about how to use this feature, see Optimizer State Sharding.

Activation offloading and checkpointing (available for PyTorch)

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, the activation offloading feature offloads the stored activations to CPU memory and fetches back to GPU during the backward pass to further reduce activation memory footprint. For more information about how to use these features, see Activation Checkpointing and Activation Offloading.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see SageMaker Distributed Model Parallel Best Practices and Configuration Tips and Pitfalls.

Supported Frameworks and AWS Regions

Before using the SageMaker model parallelism library, check the supported frameworks and instance types, and determine if there are enough quotas in your AWS account and AWS Region.

> **Note**
>
> To check the latest updates and release notes of the library, see the SageMaker Model Parallel Release Notes in the *SageMaker Python SDK documentation*.

Supported Frameworks

The SageMaker model parallelism library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

PyTorch versions supported by SageMaker AI and the SageMaker model parallelism library

PyTorch version	SageMaker model parallelism library version	`smdistributed-modelparallel` integrated DLC image URI	URL of the binary file**

Hugging Face Transformers versions supported by SageMaker AI and the SageMaker distributed data parallel library

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

AWS Regions

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

Supported Instance Types

The SageMaker model parallelism library requires one of the following ML instance types.

Instance type
ml.g4dn.12xlarge
ml.p3.16xlarge
ml.p3dn.24xlarge
ml.p4d.24xlarge
ml.p4de.24xlarge

For specs of the instance types, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker AI Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker AI resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
    the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
    for training job usage' is 0 Instances, with current utilization of 0 Instances
    and a request delta of 1 Instances.
    Please contact AWS support to request an increase for this limit.
```

Core Features of the SageMaker Model Parallelism Library

Amazon SageMaker AI's model parallelism library offers distribution strategies and memory-saving techniques, such as sharded data parallelism, tensor parallelism, model partitioning by layers for pipeline scheduling, and checkpointing. The model parallelism strategies and techniques help distribute large models across multiple devices while optimizing training speed and memory consumption. The library also provides Python helper functions, context managers, and wrapper functions to adapt your training script for automated or manual partitioning of your model.

When you implement model parallelism to your training job, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism section. For adapting your training script, you'll add zero or few additional code lines to your training script. For launching a training job of the adapted training script, you'll need to set the distribution configuration parameters to activate the memory-saving features or to pass values for the degree of parallelism.

To get started with examples, see the following Jupyter notebooks that demonstrate how to use the SageMaker model parallelism library.

- PyTorch example notebooks
- TensorFlow example notebooks

To dive deep into the core features of the library, see the following topics.

Note

The SageMaker distributed training libraries are available through the AWS deep learning containers for PyTorch, Hugging Face, and TensorFlow within the SageMaker Training platform. To utilize the features of the distributed training libraries, we recommend that you use the SageMaker Python SDK. You can also manually configure in JSON request syntax if you use SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Important

The SageMaker model parallelism library supports all the core features for PyTorch, and supports pipeline parallelism for TensorFlow.

Topics

- Sharded Data Parallelism
- Pipelining a Model
- Tensor Parallelism
- Optimizer State Sharding
- Activation Checkpointing
- Activation Offloading
- FP16 Training with Model Parallelism
- Support for FlashAttention

Sharded Data Parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs in a data parallel group.

> **Note**
>
> Sharded data parallelism is available for PyTorch in the SageMaker model parallelism library v1.11.0 and later.

When scaling up your training job to a large GPU cluster, you can reduce the per-GPU memory footprint of the model by sharding the training state of the model over multiple GPUs. This returns two benefits: you can fit larger models, which would otherwise run out of memory with standard data parallelism, or you can increase the batch size using the freed-up GPU memory.

The standard data parallelism technique replicates the training states across the GPUs in the data parallel group, and performs gradient aggregation based on the `AllReduce` operation. Sharded data parallelism modifies the standard data-parallel distributed training procedure to account for the sharded nature of the optimizer states. A group of ranks over which the model and optimizer states are sharded is called a *sharding group*. The sharded data parallelism technique shards the trainable parameters of a model and corresponding gradients and optimizer states across the GPUs in the *sharding group*.

SageMaker AI achieves sharded data parallelism through the implementation of MiCS, which is discussed in the AWS blog post [Near-linear scaling of gigantic-model training on AWS](). In this implementation, you can set the sharding degree as a configurable parameter, which must be less than the data parallelism degree. During each forward and backward pass, MiCS temporarily recombines the model parameters in all GPUs through the `AllGather` operation. After the forward or backward pass of each layer, MiCS shards the parameters again to save GPU memory. During the backward pass, MiCS reduces gradients and simultaneously shards them across GPUs through the `ReduceScatter` operation. Finally, MiCS applies the local reduced and sharded gradients to their corresponding local parameter shards, using the local shards of optimizer states. To bring down communication overhead, the SageMaker model parallelism library prefetches the upcoming layers in the forward or backward pass, and overlaps the network communication with the computation.

The training state of the model is replicated across the sharding groups. This means that before gradients are applied to the parameters, the `AllReduce` operation must take place across the sharding groups, in addition to the `ReduceScatter` operation that takes place within the sharding group.

In effect, sharded data parallelism introduces a tradeoff between the communication overhead and GPU memory efficiency. Using sharded data parallelism increases the communication cost, but the memory footprint per GPU (excluding the memory usage due to activations) is divided by the sharded data parallelism degree, thus larger models can be fit in the GPU cluster.

Selecting the degree of sharded data parallelism

When you select a value for the degree of sharded data parallelism, the value must evenly divide the degree of data parallelism. For example, for an 8-way data parallelism job, choose 2, 4, or 8 for the sharded data parallelism degree. While choosing the sharded data parallelism degree, we recommend that you start with a small number, and gradually increase it until the model fits in the memory together with the desired batch size.

Selecting the batch size

After setting up sharded data parallelism, make sure you find the most optimal training configuration that can successfully run on the GPU cluster. For training large language models (LLM), start from the batch size 1, and gradually increase it until you reach the point to receive the out-of-memory (OOM) error. If you encounter the OOM error even with the smallest batch size, apply a higher degree of sharded data parallelism or a combination of sharded data parallelism and tensor parallelism.

Topics

How to apply sharded data parallelism to your training job

To get started with sharded data parallelism, apply required modifications to your training script, and set up the SageMaker PyTorch estimator with the sharded-data-parallelism-specific parameters. Also consider to take reference values and example notebooks as a starting point.

Adapt your PyTorch training script

Follow the instructions at Step 1: Modify a PyTorch Training Script to wrap the model and optimizer objects with the smdistributed.modelparallel.torch wrappers of the torch.nn.parallel and torch.distributed modules.

(Optional) Additional modification to register external model parameters

If your model is built with torch.nn.Module and uses parameters that is not defined within the module class, you should register them to the module manually for SMP to gather the full parameters while . To register parameters to a module, use smp.register_parameter(module, parameter).

```
class Module(torch.nn.Module):
    def __init__(self, *args):
        super().__init__(self, *args)
        self.layer1 = Layer1()
        self.layer2 = Layer2()
        smp.register_parameter(self, self.layer1.weight)

    def forward(self, input):
        x = self.layer1(input)
        # self.layer1.weight is required by self.layer2.forward
        y = self.layer2(x, self.layer1.weight)
        return y
```

Set up the SageMaker PyTorch estimator

When configuring a SageMaker PyTorch estimator in the section called "Step 2: Launch a Training Job", add the parameters for sharded data parallelism.

To turn on sharded data parallelism, add the sharded_data_parallel_degree parameter to the SageMaker PyTorch Estimator. This parameter specifies the number of GPUs over which the training state is sharded. The value for sharded_data_parallel_degree must be an integer between one and the data parallelism degree and must evenly divide the data parallelism degree. Note that the library automatically detects the number of GPUs so thus the data parallel degree. The following additional parameters are available for configuring sharded data parallelism.

- "sdp_reduce_bucket_size" *(int, default: 5e8)* – Specifies the size of PyTorch DDP gradient buckets in number of elements of the default dtype.

- `"sdp_param_persistence_threshold"` *(int, default: 1e6)* – Specifies the size of a parameter tensor in number of elements that can persist at each GPU. Sharded data parallelism splits each parameter tensor across GPUs of a data parallel group. If the number of elements in the parameter tensor is smaller than this threshold, the parameter tensor is not split; this helps reduce communication overhead because the parameter tensor is replicated across data-parallel GPUs.
- `"sdp_max_live_parameters"` *(int, default: 1e9)* – Specifies the maximum number of parameters that can simultaneously be in a recombined training state during the forward and backward pass. Parameter fetching with the `AllGather` operation pauses when the number of active parameters reaches the given threshold. Note that increasing this parameter increases the memory footprint.
- `"sdp_hierarchical_allgather"` *(bool, default: True)* – If set to `True`, the `AllGather` operation runs hierarchically: it runs within each node first, and then runs across nodes. For multi-node distributed training jobs, the hierarchical `AllGather` operation is automatically activated.
- `"sdp_gradient_clipping"` *(float, default: 1.0)* – Specifies a threshold for gradient clipping the L2 norm of the gradients before propagating them backward through the model parameters. When sharded data parallelism is activated, gradient clipping is also activated. The default threshold is `1.0`. Adjust this parameter if you have the exploding gradients problem.

The following code shows an example of how to configure sharded data parallelism.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        # "pipeline_parallel_degree": 1,    # Optional, default is 1
        # "tensor_parallel_degree": 1,      # Optional, default is 1
        "ddp": True,
        # parameters for sharded data parallelism
        "sharded_data_parallel_degree": 2,              # Add this to activate sharded
 data parallelism
        "sdp_reduce_bucket_size": int(5e8),             # Optional
        "sdp_param_persistence_threshold": int(1e6),    # Optional
        "sdp_max_live_parameters": int(1e9),            # Optional
        "sdp_hierarchical_allgather": True,             # Optional
```

```
        "sdp_gradient_clipping": 1.0                        # Optional
    }
}

mpi_options = {
    "enabled" : True,                         # Required
    "processes_per_host" : 8                  # Required
}

smp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-job"
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Reference configurations

The SageMaker distributed training team provides the following reference configurations that you can use as a starting point. You can extrapolate from the following configurations to experiment and estimate the GPU memory usage for your model configuration.

Sharded data parallelism with SMDDP Collectives

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree
GPT-NEOX-20B	2	ml.p4d.24xlarge	2048	64	4	16

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree
GPT-NEOX-20B	8	ml.p4d.24xlarge	2048	768	12	32

For example, if you increase the sequence length for a 20-billion-parameter model or increase the size of the model to 65 billion parameters, you need to try reducing the batch size first. If the model still doesn't fit with the smallest batch size (the batch size of 1), try increasing the degree of model parallelism.

Sharded data parallelism with tensor parallelism and NCCL Collectives

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree	Tensor parallel degree	Activation offloading
GPT-NEOX-65B	64	ml.p4d.24xlarge	2048	512	8	16	8	Y
GPT-NEOX-65B	64	ml.p4d.24xlarge	4096	512	2	64	2	Y

The combined usage of sharded data parallelism and tensor parallelism is useful when you want to fit a large language model (LLM) into a large-scale cluster while using text data with a longer sequence length, which leads to use a smaller batch size, and consequently handling the GPU memory usage to train LLMs against longer text sequences. To learn more, see the section called "Sharded data parallelism with tensor parallelism".

For case studies, benchmarks, and more configuration examples, see the blog post New performance improvements in Amazon SageMaker AI model parallel library.

Sharded data parallelism with SMDDP Collectives

The SageMaker data parallelism library offers collective communication primitives (SMDDP collectives) optimized for the AWS infrastructure. It achieves optimization by adopting an all-to-all-type communication pattern by making use of Elastic Fabric Adapter (EFA), resulting in high-throughput and less latency-sensitive collectives, offloading the communication-related processing to the CPU, and freeing up GPU cycles for computation. On large clusters, SMDDP Collectives can offer improvements in distributed training performance by up to 40% compared to NCCL. For case studies and benchmark results, see the blog New performance improvements in the Amazon SageMaker AI model parallelism library.

> **Note**
>
> Sharded data parallelism with SMDDP Collectives is available in the SageMaker model parallelism library v1.13.0 and later, and the SageMaker data parallelism library v1.6.0 and later. See also Supported configurations to use sharded data parallelism with SMDDP Collectives.

In sharded data parallelism, which is a commonly used technique in large-scale distributed training, the `AllGather` collective is used to reconstitute the sharded layer parameters for forward and backward pass computations, in parallel with GPU computation. For large models, performing the `AllGather` operation efficiently is critical to avoid GPU bottleneck problems and slowing down training speed. When sharded data parallelism is activated, SMDDP Collectives drops into these performance-critical `AllGather` collectives, improving training throughput.

Train with SMDDP Collectives

When your training job has sharded data parallelism activated and meets the Supported configurations, SMDDP Collectives are automatically activated. Internally, SMDDP Collectives optimize the `AllGather` collective to be performant on the AWS infrastructure and falls back to NCCL for all other collectives. Furthermore, under unsupported configurations, all collectives, including `AllGather`, automatically use the NCCL backend.

Since the SageMaker model parallelism library version 1.13.0, the `"ddp_dist_backend"` parameter is added to the `modelparallel` options. The default value for this configuration parameter is "auto", which uses SMDDP Collectives whenever possible, and falls back to NCCL otherwise. To force the library to always use NCCL, specify "nccl" to the "ddp_dist_backend" configuration parameter.

The following code example shows how to set up a PyTorch estimator using the sharded data parallelism with the "ddp_dist_backend" parameter, which is set to "auto" by default and, therefore, optional to add.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled":True,
    "parameters": {
        "partitions": 1,
        "ddp": True,
        "sharded_data_parallel_degree": 64
        "bf16": True,
        "ddp_dist_backend": "auto"  # Specify "nccl" to force to use NCCL.
    }
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8               # Required
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Supported configurations

The `AllGather` operation with SMDDP Collectives are activated in training jobs when all the following configuration requirements are met.

- The sharded data parallelism degree greater than 1
- `Instance_count` greater than 1
- `Instance_type` equal to `ml.p4d.24xlarge`
- SageMaker training container for PyTorch v1.12.1 or later
- The SageMaker data parallelism library v1.6.0 or later
- The SageMaker model parallelism library v1.13.0 or later

Performance and memory tuning

SMDDP Collectives utilize additional GPU memory. There are two environment variables to configure the GPU memory usage depending on different model training use cases.

- `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` – During the SMDDP `AllGather` operation, the `AllGather` input buffer is copied into a temporary buffer for inter-node communication. The `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` variable controls the size (in bytes) of this temporary buffer. If the size of the temporary buffer is smaller than the `AllGather` input buffer size, the `AllGather` collective falls back to use NCCL.
  - Default value: 16 * 1024 * 1024 (16 MB)
  - Acceptable values: any multiple of 8192
- `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` – The `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` variable is to size the temporary buffer (in bytes) to hold data gathered from inter-node communication. If the size of this temporary buffer is smaller than `1/8 * sharded_data_parallel_degree * AllGather input size`, the `AllGather` collective falls back to use NCCL.
  - Default value: 128 * 1024 * 1024 (128 MB)
  - Acceptable values: any multiple of 8192

Tuning guidance on the buffer size variables

The default values for the environment variables should work well for most use cases. We recommend tuning these variables only if training runs into the out-of-memory (OOM) error.

The following list discusses some tuning tips to reduce the GPU memory footprint of SMDDP Collectives while retaining the performance gain from them.

- Tuning `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES`
  - The `AllGather` input buffer size is smaller for smaller models. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for models with fewer parameters.
  - The `AllGather` input buffer size decreases as `sharded_data_parallel_degree` increases, because the model gets sharded across more GPUs. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for training jobs with large values for `sharded_data_parallel_degree`.
- Tuning `SMDDP_AG_SORT_BUFFER_SIZE_BYTES`
  - The amount of data gathered from inter-node communication is less for models with fewer parameters. Hence, the required size for `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` can be smaller for such models with fewer number of parameters.

Some collectives might fall back to use NCCL; hence, you might not get the performance gain from the optimized SMDDP collectives. If additional GPU memory is available for use, you can consider increasing the values of `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` and `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` to benefit from the performance gain.

The following code shows how you can configure the environment variables by appending them to `mpi_options` in the distribution parameter for the PyTorch estimator.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    .... # All modelparallel configuration options go here
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8               # Required
```

```
}

# Use the following two lines to tune values of the environment variables for buffer
mpioptions += " -x SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES=8192"
mpioptions += " -x SMDDP_AG_SORT_BUFFER_SIZE_BYTES=8192"

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo-with-tuning",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Mixed precision training with sharded data parallelism

To further save GPU memory with half-precision floating point numbers and sharded data parallelism, you can activate 16-bit floating point format (FP16) or Brain floating point format (BF16) by adding one additional parameter to the distributed training configuration.

> **Note**
>
> Mixed precision training with sharded data parallelism is available in the SageMaker model parallelism library v1.11.0 and later.

For FP16 Training with Sharded Data Parallelism

To run FP16 training with sharded data parallelism, add `"fp16": True"` to the `smp_options` configuration dictionary. In your training script, you can choose between the static and dynamic loss scaling options through the `smp.DistributedOptimizer` module. For more information, see the section called “FP16 Training with Model Parallelism”.

```
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "fp16": True
    }
}
```

For BF16 Training with Sharded Data Parallelism

The sharded data parallelism feature of SageMaker AI supports training in BF16 data type. The BF16 data type uses 8 bits to represent the exponent of a floating point number, while the FP16 data type uses 5 bits. Preserving the 8 bits for the exponent allows to keep the same representation of the exponent of a 32-bit single precision floating point (FP32) number. This makes the conversion between FP32 and BF16 simpler and significantly less prone to cause overflow and underflow issues that arise often in FP16 training, especially when training larger models. While both data types use 16 bits in total, this increased representation range for the exponent in the BF16 format comes at the expense of reduced precision. For training large models, this reduced precision is often considered an acceptable trade-off for the range and training stability.

> **Note**
>
> Currently, BF16 training works only when sharded data parallelism is activated.

To run BF16 training with sharded data parallelism, add `"bf16": True` to the `smp_options` configuration dictionary.

```
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "bf16": True
    }
}
```

Sharded data parallelism with tensor parallelism

If you use sharded data parallelism and also need to reduce the global batch size, consider using tensor parallelism with sharded data parallelism. When training a large model with sharded data parallelism on a very large compute cluster (typically 128 nodes or beyond), even a small batch size per GPU results in a very large global batch size. It might lead to convergence issues or low computational performance issues. Reducing the batch size per GPU sometimes is not possible with sharded data parallelism alone when a single batch is already large and cannot be reduced further. In such cases, using sharded data parallelism in combination with tensor parallelism helps reduce the global batch size.

Choosing the optimal sharded data parallel and tensor parallel degrees depends on the scale of the model, the instance type, and the global batch size that is reasonable for the model to converge. We recommend that you start from a low tensor parallel degree to fit the global batch size into the compute cluster to resolve CUDA out-of-memory errors and achieve the best performance. See the following two example cases to learn how the combination of tensor parallelism and sharded data parallelism helps you adjust the global batch size by grouping GPUs for model parallelism, resulting in a lower number of model replicas and a smaller global batch size.

> **Note**
>
> This feature is available from the SageMaker model parallelism library v1.15, and supports PyTorch v1.13.1.

> **Note**
>
> This feature is available for the supported models by the tensor parallelism functionality of the library. To find the list of the supported models, see Support for Hugging Face Transformer Models. Also note that you need to pass `tensor_parallelism=True` to the `smp.model_creation` argument while modifying your training script. To learn more, see the training script `train_gpt_simple.py` in the *SageMaker AI Examples GitHub repository*.

Example 1

Assume that we want to train a model over a cluster of 1536 GPUs (192 nodes with 8 GPUs in each), setting the degree of sharded data parallelism to 32 (`sharded_data_parallel_degree=32`) and the batch size per GPU to 1, where each batch has a sequence length of 4096 tokens. In this case, there are 1536 model replicas, the global batch size becomes 1536, and each global batch contains about 6 million tokens.

```
(1536 GPUs) * (1 batch per GPU) = (1536 global batches)
(1536 batches) * (4096 tokens per batch) = (6,291,456 tokens)
```

Adding tensor parallelism to it can lower the global batch size. One configuration example can be setting the tensor parallel degree to 8 and the batch size per GPU to 4. This forms 192 tensor parallel groups or 192 model replicas, where each model replica is distributed across 8 GPUs. The batch size of 4 is the amount of training data per iteration and per tensor parallel group; that is, each model replica consumes 4 batches per iteration. In this case, the global batch size becomes 768, and each global batch contains about 3 million tokens. Hence, the global batch size is reduced by half compared to the previous case with sharded data parallelism only.

```
(1536 GPUs) / (8 tensor parallel degree) = (192 tensor parallelism groups)
(192 tensor parallelism groups) * (4 batches per tensor parallelism group) = (768
 global batches)
(768 batches) * (4096 tokens per batch) = (3,145,728 tokens)
```

Example 2

When both sharded data parallelism and tensor parallelism are activated, the library first applies tensor parallelism and shards the model across this dimension. For each tensor parallel rank, the data parallelism is applied as per `sharded_data_parallel_degree`.

For example, assume that we want to set 32 GPUs with a tensor parallel degree of 4 (forming groups of 4 GPUs), a sharded data parallel degree of 4, ending up with a replication degree of 2. The assignment creates eight GPU groups based on the tensor parallel degree as follows: `(0,1,2,3)`, `(4,5,6,7)`, `(8,9,10,11)`, `(12,13,14,15)`, `(16,17,18,19)`, `(20,21,22,23)`, `(24,25,26,27)`, `(28,29,30,31)`. That is, four GPUs form one tensor parallel group. In this case, the reduced data parallel group for the 0th rank GPUs of the tensor parallel groups would be `(0,4,8,12,16,20,24,28)`. The reduced data parallel group is sharded based on the sharded data parallel degree of 4, resulting in two replication groups for data parallelism. GPUs `(0,4,8,12)` form one sharding group, which collectively hold a complete copy of all parameters for the 0th tensor parallel rank, and GPUs `(16,20,24,28)` form another such group. Other tensor parallel ranks also have similar sharding and replication groups.

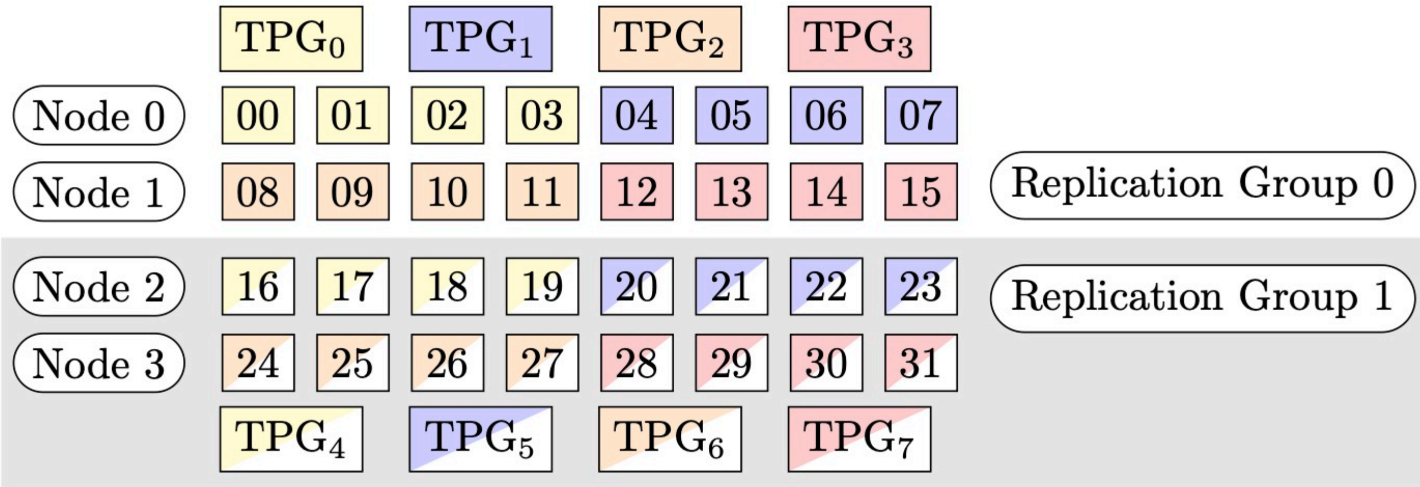

Figure 1: Tensor parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form tensor parallelism groups from TPG_0 to TPG_7. Replication groups are ({TPG_0, TPG_4}, {TPG_1, TPG_5}, {TPG_2, TPG_6} and {TPG_3, TPG_7}); each replication group pair shares the same color but filled differently.

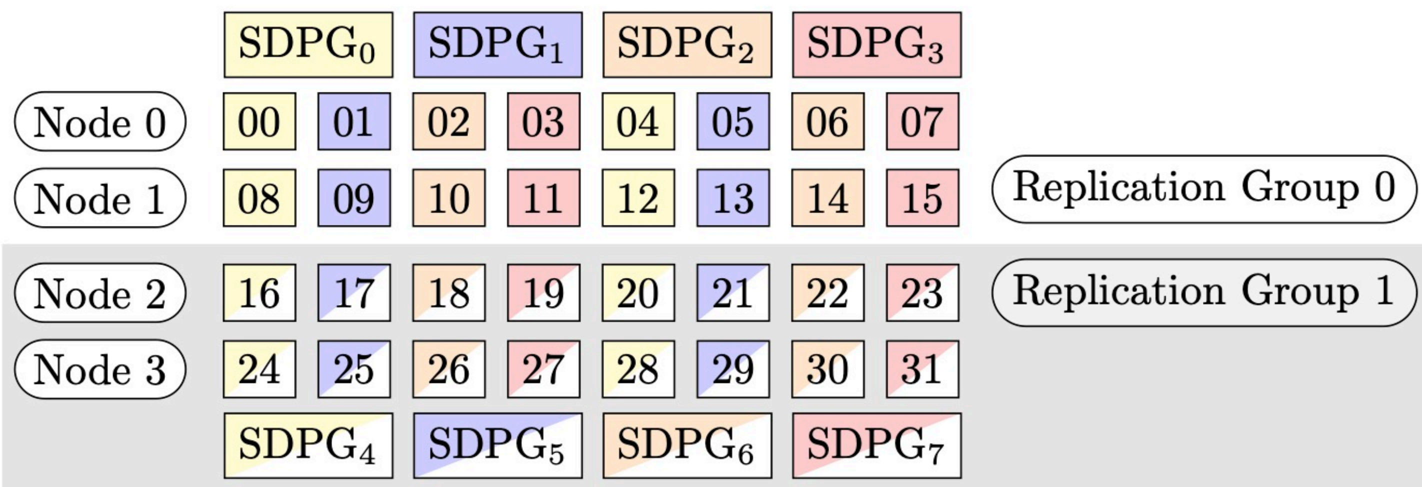

Figure 2: Sharded data parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form sharded data parallelism groups from $SDPG_0$ to $SDPG_7$. Replication groups are ({$SDPG_0$, $SDPG_4$}, {$SDPG_1$, $SDPG_5$}, {$SDPG_2$, $SDPG_6$} and {$SDPG_3$, $SDPG_7$}); each replication group pair shares the same color but filled differently.

How to activate sharded data parallelism with tensor parallelism

To use sharded data parallelism with tensor parallelism, you need to set both `sharded_data_parallel_degree` and `tensor_parallel_degree` in the configuration for `distribution` while creating an object of the SageMaker PyTorch estimator class.

You also need to activate `prescaled_batch`. This means that, instead of each GPU reading its own batch of data, each tensor parallel group collectively reads a combined batch of the chosen batch size. Effectively, instead of dividing the dataset into parts equal to the number of GPUs (or data parallel size, `smp.dp_size()`), it divides into parts equal to the number of GPUs divided by `tensor_parallel_degree` (also called reduced data parallel size, `smp.rdp_size()`). For more details on prescaled batch, see [Prescaled Batch](#) in the *SageMaker Python SDK documentation*. See also the example training script [`train_gpt_simple.py`](#) for GPT-2 in the *SageMaker AI Examples GitHub repository*.

The following code snippet shows an example of creating a PyTorch estimator object based on the aforementioned scenario in [the section called “Example 2”](#).

```
mpi_options = "-verbose --mca orte_base_help_aggregate 0 "
smp_parameters = {
    "ddp": True,
    "fp16": True,
    "prescaled_batch": True,
    "sharded_data_parallel_degree": 4,
    "tensor_parallel_degree": 4
}

pytorch_estimator = PyTorch(
    entry_point="your_training_script.py",
    role=role,
    instance_type="ml.p4d.24xlarge",
    volume_size=200,
    instance_count=4,
    sagemaker_session=sagemaker_session,
    py_version="py3",
    framework_version="1.13.1",
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": smp_parameters,
            }
        },
        "mpi": {
            "enabled": True,
            "processes_per_host": 8,
            "custom_mpi_options": mpi_options,
        },
```

```
    },
    source_dir="source_directory_of_your_code",
    output_path=s3_output_location
)
```

Tips and considerations for using sharded data parallelism

Consider the following when using the SageMaker model parallelism library's sharded data parallelism.

- Sharded data parallelism is compatible with FP16 training. To run FP16 training, see the the section called "FP16 Training with Model Parallelism" section.
- Sharded data parallelism is compatible with tensor parallelism. The following items are what you might need to consider for using sharded data parallelism with tensor parallelism.
  - When using sharded data parallelism with tensor parallelism, the embedding layers are also automatically distributed across the tensor parallel group. In other words, the `distribute_embedding` parameter is automatically set to `True`. For more information about tensor parallelism, see the section called "Tensor Parallelism".
  - Note that sharded data parallelism with tensor parallelism currently uses the NCCL collectives as the backend of the distributed training strategy.

  To learn more, see the the section called "Sharded data parallelism with tensor parallelism" section.
- Sharded data parallelism currently is not compatible with pipeline parallelism or optimizer state sharding. To activate sharded data parallelism, turn off optimizer state sharding and set the pipeline parallel degree to 1.
- The activation checkpointing and activation offloading features are compatible with sharded data parallelism.
- To use sharded data parallelism with gradient accumulation, set the `backward_passes_per_step` argument to the number of accumulation steps while wrapping your model with the `smdistributed.modelparallel.torch.DistributedModel` module. This ensures that the gradient `AllReduce` operation across the model replication groups (sharding groups) takes place at the boundary of gradient accumulation.
- You can checkpoint your models trained with sharded data parallelism using the library's checkpointing APIs, `smp.save_checkpoint` and `smp.resume_from_checkpoint`. For more information, see the section called "Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)".

- The behavior of the `delayed_parameter_initialization` configuration parameter changes under sharded data parallelism. When these two features are simultaneously turned on, parameters are immediately initialized upon model creation in a sharded manner instead of delaying the parameter initialization, so that each rank initializes and stores its own shard of parameters.
- When sharded data parallelism is activated, the library performs gradient clipping internally when the `optimizer.step()` call runs. You don't need to use utility APIs for gradient clipping, such as `torch.nn.utils.clip_grad_norm_()`. To adjust the threshold value for gradient clipping, you can set it through the `sdp_gradient_clipping` parameter for the distribution parameter configuration when you construct the SageMaker PyTorch estimator, as shown in the the section called "How to apply sharded data parallelism to your training job" section.

Pipelining a Model

One of the core features of SageMaker's model parallelism library is *pipeline parallelism*, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation. When you use pipeline parallelism, training job is executed in a pipelined fashion over microbatches to maximize GPU usage.

> **Note**
>
> Pipeline parallelism, also called model partitioning, is available for both PyTorch and TensorFlow. For supported versions of the frameworks, see the section called "Supported Frameworks and AWS Regions".

Pipeline Execution Schedule

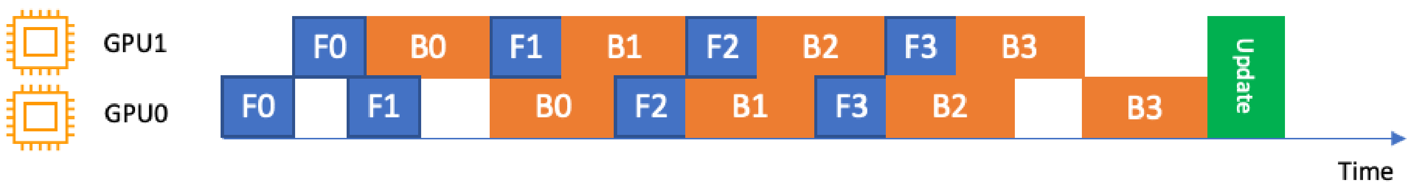
Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A *microbatch* is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU `i` might perform (forward or backward) computation on microbatch `b` while GPU `i+1` performs computation on microbatch b+1, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

Interleaved Pipeline

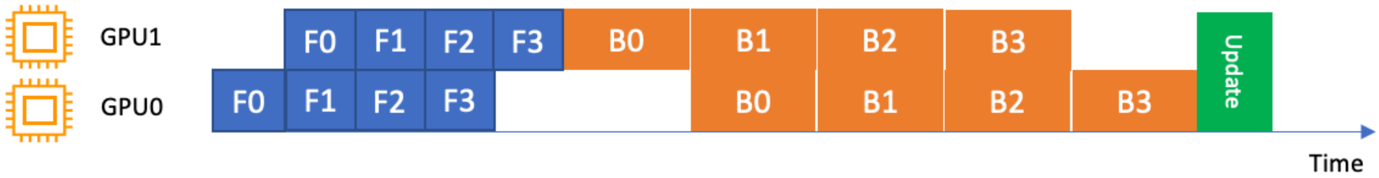
In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.



The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

Simple Pipeline

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

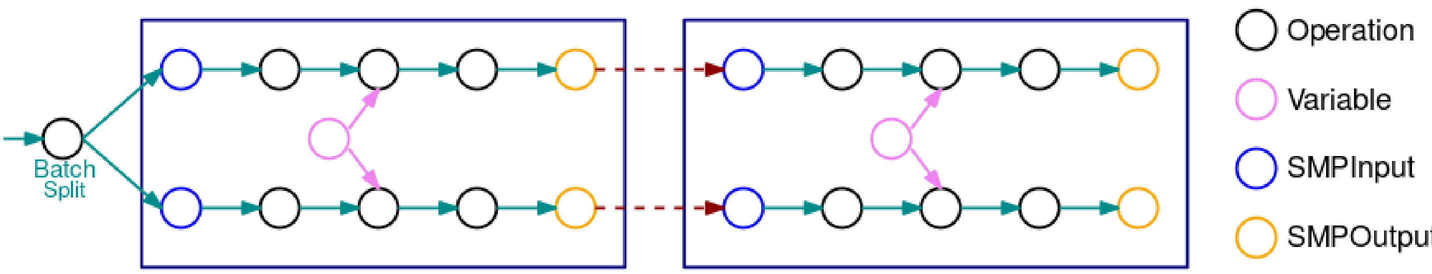


Pipelining Execution in Specific Frameworks

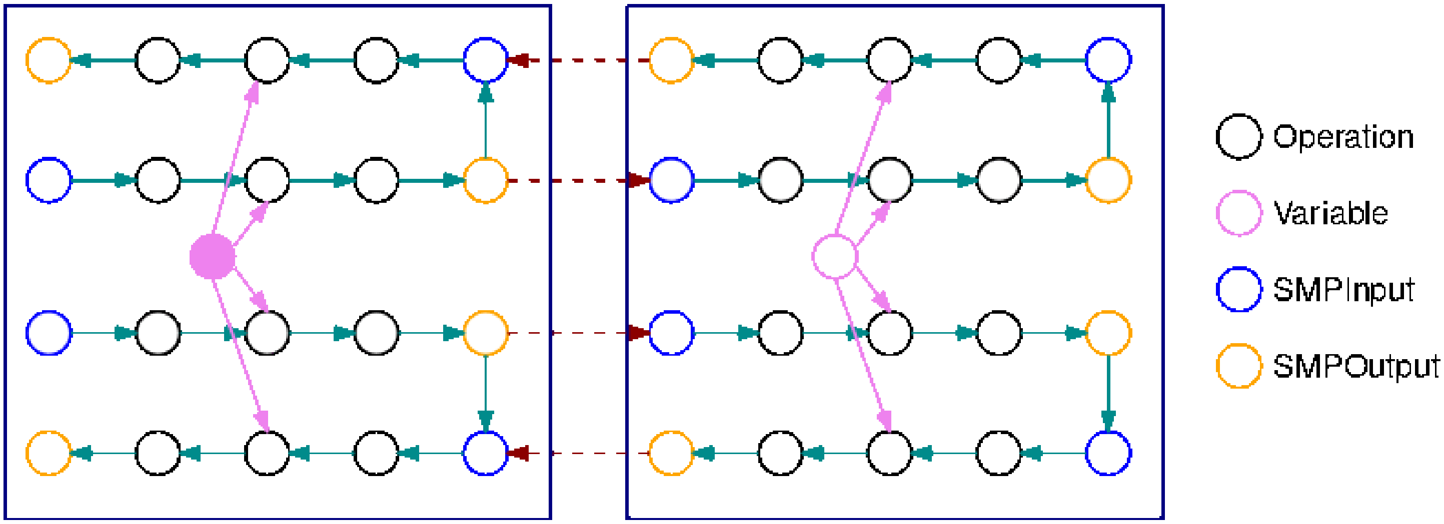
Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's model parallelism library makes for TensorFlow and PyTorch.

Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallelism library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An `SMPInput` operation is inserted at each input of a subgraph, and an `SMPOutput` operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.



The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a `SMPInput` op is a `SMPOutput` op, and vice versa. This enables the gradients to flow backwards during back-propagation.



This GIF demonstrates an example interleaved pipeline execution schedule with B=2 microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As B grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue `SMPInput` operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

Pipeline Execution with PyTorch

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallelism library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the *set* of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

> **Note**
>
> Tensor parallelism is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

Topics

How Tensor Parallelism Works

Tensor parallelism takes place at the level of `nn.Modules`; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the *set of modules* used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules. The modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does **not** have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a partition of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.

```
A
### B
|   ### E
|   ### F
### C
### D
    ### G
    ### H
```

Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

```
dp_rank 0 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 1 (tensor parallel rank 1): A, B:1, C, D, G:1, H
dp_rank 2 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 3 (tensor parallel rank 1): A, B:1, C, D, G:1, H
```

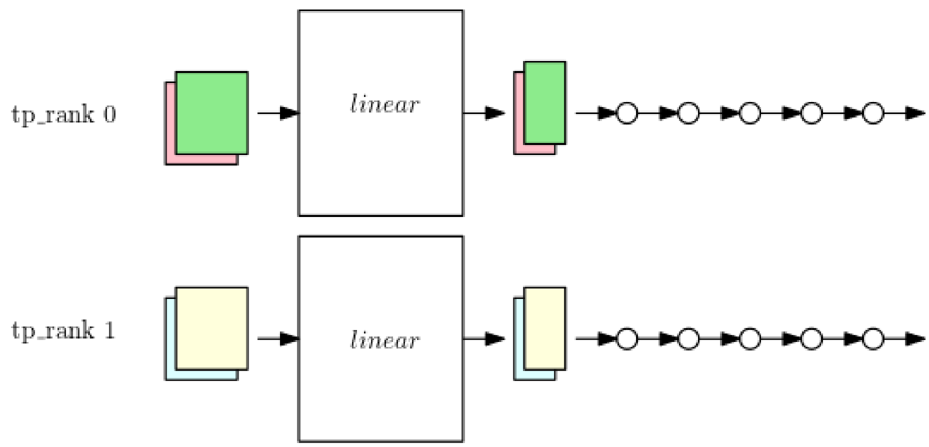
Each line represents the set of modules stored in that `dp_rank`, and the notation `X:y` represents the `y`th fraction of the module `X`. Note the following:

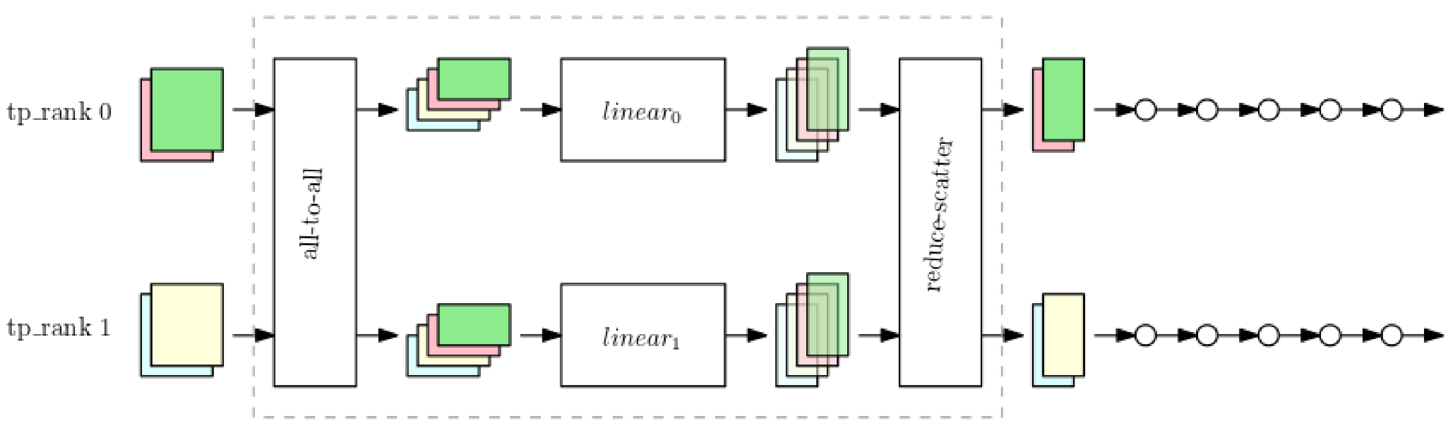
1. Partitioning takes place across subsets of data parallel ranks, which we call `TP_GROUP`, not the entire `DP_GROUP`, so that the exact model partition is replicated across `dp_rank` 0 and `dp_rank` 2, and similarly across `dp_rank` 1 and `dp_rank` 3.
2. The modules `E` and `F` are no longer part of the model, since their parent module `B` is partitioned, and any execution that is normally a part of `E` and `F` takes place within the (partitioned) `B` module.

3. Even though H is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

How the library adapts tensor parallelism to PyTorch nn.Linear module

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices *for the modules that are partitioned*. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of *all data samples* across peer devices in the same tensor parallelism group. The device then runs the local fraction of the module on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned `nn.Linear` module.





The first figure shows a small model with a large `nn.Linear` module with data parallelism over the two tensor parallelism ranks. The `nn.Linear` module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the `nn.Linear` module. Each `tp_rank` holds half the linear module, and the entirety of the rest of the operations. While the linear module runs, each `tp_rank` collects the relevant half of all data samples and passes it through their half of the `nn.Linear` module. The result needs to be reduce-scattered (with summation as the reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended `smdistributed.modelparallel` modules for tensor parallelism.

To learn more about the `smdistributed.modelparallel` modules, see the [SageMaker model parallel APIs](#) in the *SageMaker Python SDK documentation*.

Topics

- [Tensor parallelism alone](#)
- [Tensor parallelism combined with pipeline parallelism](#)

Tensor parallelism alone

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the `mpi_options` and `smp_options` dictionaries to specify distributed training options to the SageMaker `PyTorch` estimator.

> **Note**
>
> Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "pipeline_parallel_degree": 1,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4,      # tp over 4 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.13.1',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

> **Tip**
>
> To find a complete list of parameters for `distribution`, see Configuration Parameters for Model Parallelism in the SageMaker Python SDK documentation.

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. In this example, it is assumed that the script is named `your_training_script.py`.

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        loss.backward()
```

```
        optimizer.step()

# smdistributed: Initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

# smdistributed: Enable tensor parallelism for all supported modules in the model
# i.e., nn.Linear in this case. Alternatively, we can use
# smp.set_tensor_parallelism(model.fc1, True)
# to enable it only for model.fc1
with smp.tensor_parallelism():
    model = Net()

# smdistributed: Use the DistributedModel wrapper to distribute the
# modules for which tensor parallelism is enabled
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Tensor parallelism combined with pipeline parallelism

The following is an example of a distributed training option that enables tensor parallelism combined with pipeline parallelism. Set up the `mpi_options` and `smp_options` parameters to specify model parallel options with tensor parallelism when you configure a SageMaker `PyTorch` estimator.

> **Note**
>
> Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
    "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.13.1',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
```

```
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. Note that the training script now includes the `smp.step` decorator:

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

# smdistributed: Define smp.step. Return any tensors needed outside.
```

```
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: Initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
```

```
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = Net()

# smdistributed: enable tensor parallelism only for model.fc1
smp.set_tensor_parallelism(model.fc1, True)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Support for Hugging Face Transformer Models

The SageMaker model parallelism library's tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallelism library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallelism library v1.8.0 and later)
- GPT-Neo (Available in the SageMaker model parallelism library v1.10.0 and later)

> **Note**
>
> For any other Transformers models, you need to use the smdistributed.modelparallel.torch.tp_register_with_module() API to apply tensor parallelism.

> **Note**
>
> To use tensor parallelism for training Hugging Face Transformer models, make sure you use Hugging Face Deep Learning Containers for PyTorch that has the SageMaker model

parallelism library v1.7.0 and later. For more information, see the SageMaker model parallelism library release notes.

Supported Models Out of the Box

For the Hugging Face transformer models supported by the library out of the box, you don't need to manually implement hooks to translate Transformer APIs to `smdistributed` transformer layers. You can activate tensor parallelism by using the context manager smdistributed.modelparallel.torch.tensor_parallelism() and wrapping the model by smdistributed.modelparallel.torch.DistributedModel(). You don't need to manually register hooks for tensor parallelism using the `smp.tp_register` API.

The `state_dict` translation functions between Hugging Face Transformers and `smdistributed.modelparallel` can be accessed as follows.

- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_state_dict_to_h` `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_hf_state_dict_t`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_state_dict_to_h` `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_hf_state_dict_t`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_state_dict_t` `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_hf_state_dic`
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_state_dict_to_h` `max_seq_len=None)` (Available in the SageMaker model parallelism library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_hf_gptj_state_d` (Available in the SageMaker model parallelism library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_state_dict_to` `max_seq_len=None)` (Available in the SageMaker model parallelism library v1.10.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_hf_state_dict` (Available in the SageMaker model parallelism library v1.10.0 and later)

Example usage of the GPT-2 translation function

Start with wrapping the model as shown in the following code.

```
from transformers import AutoModelForCausalLM

with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)

model = smp.DistributedModel(model)
```

Given a `state_dict` from the `DistributedModel` object, you can load the weights into the original Hugging Face GPT-2 model using the `translate_state_dict_to_hf_gpt2` function as shown in the following code.

```
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 \
                                      import translate_state_dict_to_hf_gpt2
max_seq_len = 1024

# [... code block for training ...]

if smp.rdp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)

    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

Example usage of the RoBERTa translation function

Similarly, given a supported HuggingFace model `state_dict`, you can use the `translate_hf_state_dict_to_smdistributed` function to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:

```
from smdistributed.modelparallel.torch.nn.huggingface.roberta \
                                      import translate_state_dict_to_smdistributed

model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)

pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
translated_state_dict =
        translate_state_dict_to_smdistributed(pretrained_model.state_dict())
```

```
# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)

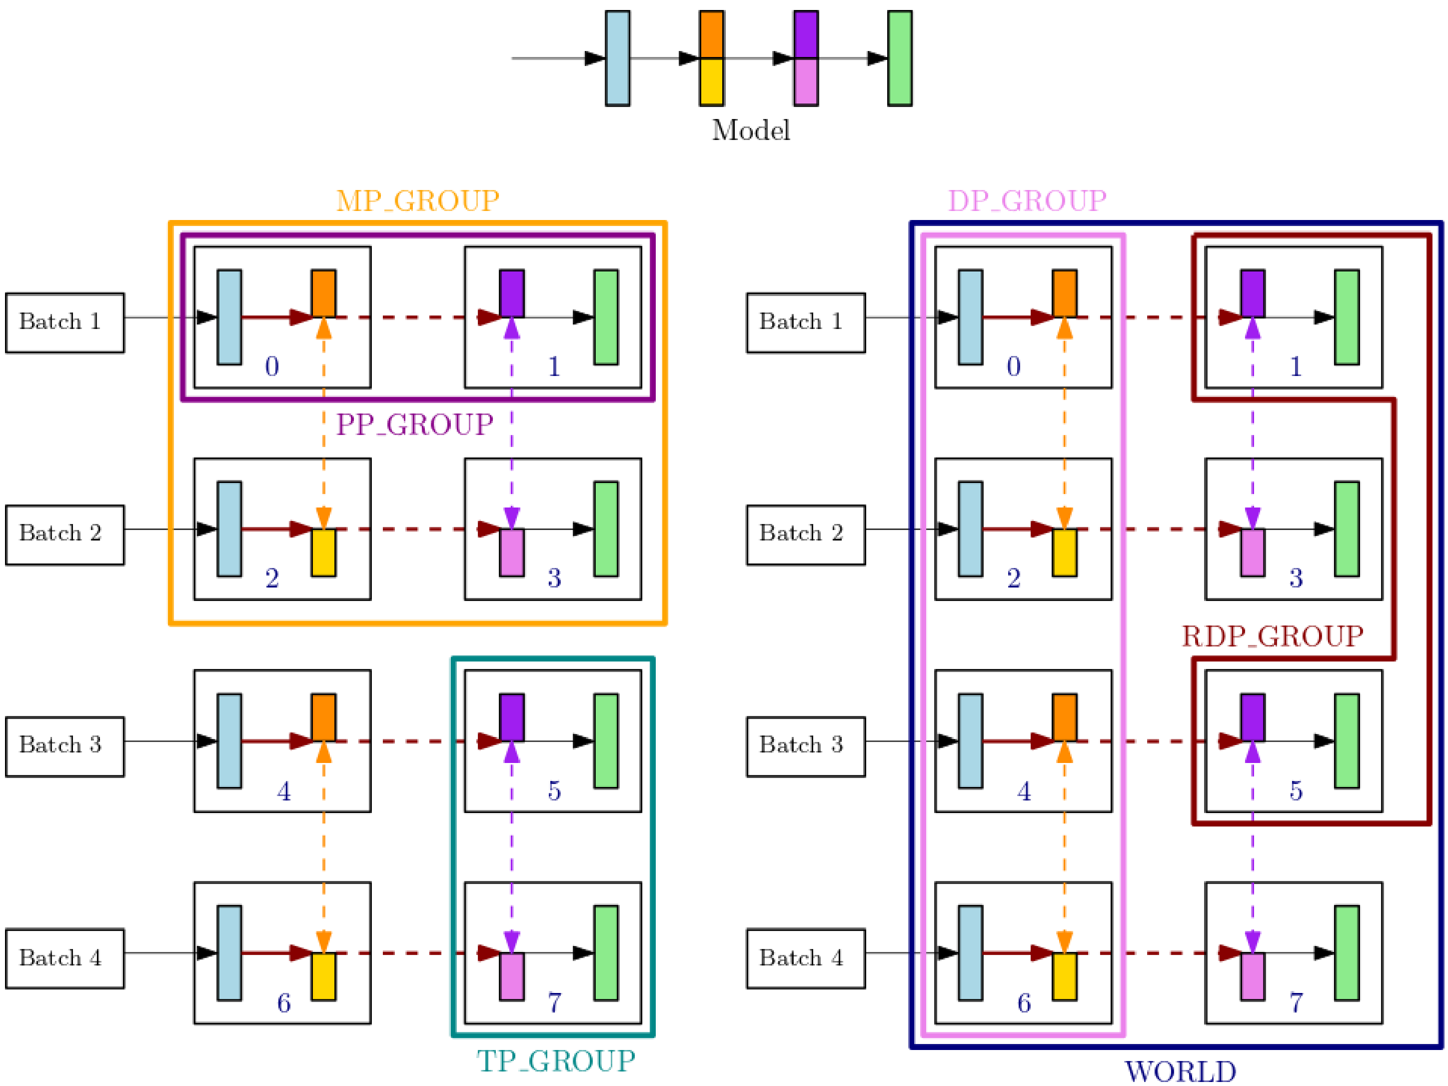
# start fine-tuning...
```

Ranking Mechanism when Using a Combination of Pipeline Parallelism and Tensor Parallelism

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the Ranking Basics for Core Features of the SageMaker Model Parallelism Library. With tensor parallelism, the library introduces three types of ranking and process group APIs: `smp.tp_rank()` for tensor parallel rank, `smp.pp_rank()` for pipeline parallel rank, and `smp.rdp_rank()` for reduced-data parallel rank. The corresponding communication process groups are tensor parallel group (`TP_GROUP`), pipeline parallel group (`PP_GROUP`), and reduced-data parallel group (`RDP_GROUP`). These groups are defined as follows:

- A *tensor parallel group* (`TP_GROUP`) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, `TP_GROUP` is the same as *model parallel group* (`MP_GROUP`).
- A *pipeline parallel group* (`PP_GROUP`) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, `PP_GROUP` is the same as `MP_GROUP`.
- A *reduced-data parallel group* (`RDP_GROUP`) is a set of processes that hold both the same pipeline parallelism partitions and the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, `DP_GROUP`. For the model parameters that are distributed within the `TP_GROUP` , the gradient `allreduce` operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient `allreduce` takes place over the entire `DP_GROUP`.
- A model parallel group (`MP_GROUP`) refers to a group of processes that collectively store the entire model. It consists of the union of the `PP_GROUP`s of all the ranks that are in the `TP_GROUP` of the current process. When the degree of tensor parallelism is 1, `MP_GROUP` is equivalent to `PP_GROUP`. It is also consistent with the existing definition of `MP_GROUP` from previous `smdistributed` releases. Note that the current `TP_GROUP` is a subset of both the current `DP_GROUP` and the current `MP_GROUP`.

To learn more about the communication process APIs in the SageMaker model parallelism library, see the Common API and the PyTorch-specific APIs in the *SageMaker Python SDK documentation*.



For example, consider process groups for a single node with 8 GPUs, where the degree of tensor parallelism is 2, the degree of pipeline parallelism is 2, and the degree of data parallelism is 4. The upper center part of the preceding figure shows an example of a model with 4 layers. The lower left and lower right parts of figure illustrate the 4-layer model distributed across 4 GPUs using both pipeline parallelism and tensor parallelism, where tensor parallelism is used for the middle two layers. These two lower figures are simple copies to illustrate different group boundary lines. The partitioned model is replicated for data parallelism across GPUs 0-3 and 4-7. The lower left figure shows the definitions of `MP_GROUP`, `PP_GROUP`, and `TP_GROUP`. The lower right figure shows `RDP_GROUP`, `DP_GROUP`, and `WORLD` over the same set of GPUs. The gradients for the layers and layer slices that have the same color are `allreduced` together for data parallelism. For example, the first layer (light blue) gets the `allreduce` operations across `DP_GROUP`, whereas the dark orange slice in the second layer only gets the `allreduce` operations within the `RDP_GROUP` of its process. The bold dark red arrows represent tensors with the batch of its entire `TP_GROUP`.

```
GPU0: pp_rank 0, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 0
GPU1: pp_rank 1, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 1
GPU2: pp_rank 0, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 2
GPU3: pp_rank 1, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 3
GPU4: pp_rank 0, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 0
GPU5: pp_rank 1, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 1
GPU6: pp_rank 0, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 2
GPU7: pp_rank 1, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 3
```

In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, data parallelism (`allreduce`) takes place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of `DP_GROUP`s, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).

Optimizer State Sharding

Optimizer state sharding is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

> **Note**
>
> Optimizer state sharding is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Optimizer State Sharding

You can turn on *optimizer state sharding* by setting `"shard_optimizer_state": True` in the `modelparallel` configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the `i`th partition get reduced only at the `i`th data parallel rank. At the end of the first call to an `smp.step` decorator function, the optimizer wrapped by `smp.DistributedOptimizer` redefines its parameters to be only limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called *virtual parameters* and share underlying storage with the original parameters. During the first call to `optimizer.step`, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, the AllGather operation (as part of the `optimizer.step` call) runs across the data parallel ranks to achieve consistent parameter states.

> **Tip**
>
> Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.
> The degree of data parallelism is calculated by `(processes_per_host * instance_count / pipeline_parallel_degree)`, and the `smp.dp_size()` function handles the sizing in the background.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True,
        "shard_optimizer_state": True
    }
}
```

Adapt your PyTorch training script

See [Adapt your PyTorch training script](#) in the *Tensor parallelism combined with pipeline parallelism* section. There's no additional modification required for the script.

Activation Checkpointing

Activation checkpointing (or *gradient checkpointing*) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

> **Note**
>
> This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Checkpointing

With `smdistributed.modelparallel`, you can use activation checkpointing at the granularity of a module. For all `torch.nn` modules except `torch.nn.Sequential`, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the `torch.nn.Sequential` module, each module tree inside the sequential module must lie completely within one partition for activation checkpointing to work. When you use manual partitioning, be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with `Partition assignments:` in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

> **Note**
>
> The SageMaker model parallelism library supports both overlapping and non-overlapping `allreduce` operation in combination with checkpointing.

Note

PyTorch's native checkpointing API is not compatible with `smdistributed.modelparallel`.

Example 1: The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```
import torch.nn as nn
import torch.nn.functional as F

from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = self.conv2(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        # This call of fc1 will be checkpointed
        x = checkpoint(self.fc1, x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)
```

Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.

```
import torch.nn as nn
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint_sequential

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
```

```
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU()
        )

    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)
```

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, do the following:

1. Wrap the model by `smp.DistributedModel()`.
2. Define an object for sequential layers.
3. Wrap the sequential layer object by `smp.set_activation_checkpointig()`.

```
import smdistributed.modelparallel.torch as smp
from transformers import AutoModelForCausalLM

smp.init()
model = AutoModelForCausalLM(*args, **kwargs)
model = smp.DistributedModel(model)

# Call set_activation_checkpointing API
transformer_layers = model.module.module.module.transformer.seq_layers
smp.set_activation_checkpointing(
    transformer_layers, pack_args_as_tuple=True, strategy='each')
```

Activation Offloading

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, *activation offloading* is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch's backward pass, this functionality prefetches the offloaded activations back from the CPU.

Note

This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Offloading

Use activation offloading to reduce memory usage when **the number of microbatches is greater than 1, and activation checkpointing is turned on** (see Activation Checkpointing). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.

To use activation offloading, set `"offload_activations": True` in the `modelparallel` configuration.

Activation offloading moves the checkpointed activations in `nn.Sequential` modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter `"activation_loading_horizon"` (default is set to 4, must be `int` larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

Tip

Activation offloading can be useful for large models with over a hundred billion parameters.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
```

```
    "enabled" : True,
    "processes_per_host" : 8,              # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True,
        "offload_activations": True,
        "activation_loading_horizon": 4   # optional. default is 4.
    }
}
```

FP16 Training with Model Parallelism

For FP16 training, apply the following modifications to your training script and estimator.

> **Note**
>
> This feature is available for PyTorch in the SageMaker model parallelism library v1.10.0 and later.

Adapt your PyTorch training script

1. Wrap your model using the smdistributed.modelparallel.torch.model_creation() context manager.

```
# fp16_training_script.py

import torch
import smdistributed.modelparallel.torch as smp

with smp.model_creation(
    dtype=torch.float16 if args.fp16 else torch.get_default_dtype()
):
    model = ...
```

Tip

If you are using tensor parallelism, add `tensor_parallelism=smp.tp_size() > 1` to the `smp.model_creation` context manager. Adding this line also helps automatically detect whether tensor parallelism is activated or not.

```
with smp.model_creation(
    ... ,
    tensor_parallelism=smp.tp_size() > 1
):
    model = ...
```

2. When you wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`, set either the `static_loss_scaling` or `dynamic_loss_scaling` argument. By default, `static_loss_scaling` is set to `1.0`, and `dynamic_loss_scaling` is set to `False`. If you set `dynamic_loss_scale=True`, you can feed dynamic loss scaling options as a dictionary through the `dynamic_loss_args` argument. In most cases, we recommend you use dynamic loss scaling with the default options. For more information, options, and examples of the optimizer wrapper function, see the smdistributed.modelparallel.torch.DistributedOptimizer API.

   The following code is an example of wrapping an `Adadelta` optimizer object with dynamic loss scaling for FP16 training.

```
optimizer = torch.optim.Adadelta(...)
optimizer = smp.DistributedOptimizer(
    optimizer,
    static_loss_scale=None,
    dynamic_loss_scale=True,
    dynamic_loss_args={
        "scale_window": 1000,
        "min_scale": 1,
        "delayed_shift": 2
    }
)
```

Configure a SageMaker PyTorch estimator

Add the FP16 parameter ("`fp16`") to the distribution configuration for model parallelism when creating a SageMaker PyTorch estimator object. For a complete list of the configuration parameters for model parallelism, see [Parameters for `smdistributed`].

```
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters":  {
        "microbatches":  4,
        "pipeline_parallel_degree":  2,
        "tensor_parallel_degree":  2,
        ...,

        "fp16": True
    }
}

fp16_estimator = PyTorch(
    entry_point="fp16_training_script.py", # Specify your train script
    ...,

    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": {...}
    }
)

fp16_estimator.fit(...)
```

When FP16 training starts, the model and the optimizer are wrapped by `FP16_Module` and `FP16_Optimizer` respectively, which are modified `smdistributed` versions of the [Apex utils]. `FP16_Module` converts the model to FP16 dtype and deals with the forward pass in FP16.

Tip

You can apply gradient clipping by calling `clip_master_grads` before `optimizer.step`.

```
optimizer.clip_master_grads(max_norm)     # max_norm(float or int): max norm of
 the gradients
```

> **Tip**
>
> When using `torch.optim.lr_scheduler` and FP16 training, you need to pass `optimizer.optimizer` to the LR scheduler rather than the optimizer. See the following example code.
>
> ```
> from torch.optim.lr_scheduler import StepLR
>
> scheduler = StepLR(
>     optimizer.optimizer if smp.state.cfg.fp16 else optimizer,
>     step_size=1,
>     gamma=args.gamma
> )
> ```

Support for FlashAttention

Support for FlashAttention is a feature of the library only applicable for the *distributed transformer* model, which is a Transformer model wrapped by `smp.DistributedModel()` for model-parallel training. This feature is also compatible with the section called "Tensor Parallelism".

The FlashAttention library only supports models when `attention_head_size` is set to a value that's a multiple of 8 and less than 128. Therefore, when you train a distributed transformer and make sure that FlashAttention works properly, you should adjust parameters to make the attention head size comply the requirements. For more information, see also Installation and features in the *FlashAttention GitHub repository*.

For example, assume that you configure a Transformer model with `hidden_width=864` and `num_heads=48`. The head size of FlashAttention is calculated as `attention_head_size = hidden_width / num_heads = 864 / 48 = 18`. To enable FlashAttention, you need to adjust the `num_heads` parameter to 54, so that `attention_head_size = hidden_width / num_heads = 864 / 54 = 16`, which is a multiple of 8.

Run a SageMaker Distributed Training Job with Model Parallelism

Learn how to run a model-parallel training job of your own training script using the SageMaker Python SDK with the SageMaker model parallelism library.

There are three use-case scenarios for running a SageMaker training job.

1. You can use one of the pre-built AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see the example notebooks at PyTorch training with Amazon SageMaker AI's model parallelism library.
2. You can extend the pre-built containers to handle any additional functional requirements for your algorithm or model that the pre-built SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see Extend a Pre-built Container.
3. You can adapt your own Docker container to work with SageMaker AI using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker `TensorFlow` or `PyTorch` estimator to activate the library. To learn more, see the following topics.

Topics

- Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library
- Step 2: Launch a Training Job Using the SageMaker Python SDK

Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker AI model parallelism library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker model parallel library APIs in the *SageMaker Python SDK documentation*.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker AI model parallelism library v2 examples.

Topics

- Split the model of your training script using the SageMaker model parallelism library
- Modify a TensorFlow training script

- [Modify a PyTorch Training Script]

Split the model of your training script using the SageMaker model parallelism library

There are two ways to modify your training script to set up model splitting: automated splitting or manual splitting.

Automated model splitting

When you use SageMaker's model parallelism library, you can take advantage of *automated model splitting*, also referred to as *automated model partitioning*. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

How it works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.

Automated model splitting with PyTorch

During the first training step, the model parallelism library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameters`, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called “Automated splitting with PyTorch”.

Automated model splitting with TensorFlow

The model parallelism library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallelism parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called “Automated splitting with TensorFlow”.

Comparison of automated model splitting between frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore the model parallelism library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how to partition your model across devices, use the `smp.partition` context manager. For instructions on how to set the context manager for manual partitioning, see the following pages.

- the section called "Manual splitting with TensorFlow"
- the section called "Manual splitting with PyTorch"

To use this option after making modifications, in Step 2, you'll need to set `auto_partition` to `False`, and define a `default_partition` in the framework estimator class of the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallelism library creates a pipelined execution schedule automatically.

Modify a TensorFlow training script

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

> **Note**
>
> To find which TensorFlow versions are supported by the library, see the section called "Supported Frameworks and AWS Regions".

The required modifications you must make to your training script to use the library are listed in Automated splitting with TensorFlow.

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism.

If you want to use manual partitioning, also review Manual splitting with TensorFlow.

The following topics show examples of training scripts that you can use to configure SageMaker's model parallelism library for auto-partitioning and manual partitioning TensorFlow models.

> **Note**
>
> Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics

Automated splitting with TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's model parallelism library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.

4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Perform post-processing on the outputs across microbatches using [`StepOutput`]() methods such as `reduce_mean`. The [`smp.step`]() function must have a return value that depends on the output of `smp.DistributedModel`.
7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using [`StepOutput` API]().

To learn more about the SageMaker's model parallelism library API, refer to the [API documentation]().

The following Python script is an example of a training script after the changes are made.

```
import tensorflow as tf

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)
```

```
# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return the model output

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
```

```
    accuracy = train_accuracy.result()
```

If you are done preparing your training script, proceed to Step 2: Launch a Training Job Using the SageMaker Python SDK. If you want to run a hybrid model and data parallel training job, continue to the next section.

Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism

You can use the SageMaker model parallelism library with Horovod for hybrid model and data parallelism. To read more about how the library splits a model for hybrid parallelism, see Pipeline parallelism (available for PyTorch and TensorFlow).

In this step, we focus on how to modify your training script to adapt the SageMaker model parallelism library.

To properly set up your training script to pick up the hybrid parallelism configuration that you'll set in Step 2: Launch a Training Job Using the SageMaker Python SDK, use the library's helper functions, `smp.dp_rank()` and `smp.mp_rank()`, which automatically detect the data parallel rank and model parallel rank respectively.

To find all MPI primitives the library supports, see MPI Basics in the SageMaker Python SDK documentation.

The required changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

> **Note**
>
> When you use Horovod, you must not directly call `hvd.init` in your training script. Instead, you'll have to set `"horovod"` to `True` in the SageMaker Python SDK `modelparallel` parameters in Step 2: Launch a Training Job Using the SageMaker Python SDK. This allows the library to internally initialize Horovod based on the device assignments of model partitions. Calling `hvd.init()` directly in your training script can cause problems.

Note

Using the `hvd.DistributedOptimizer` API directly in your training script might result in a poor training performance and speed, because the API implicitly places the `AllReduce` operation inside `smp.step`. We recommend you to use the model parallelism library with Horovod by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as will be shown in the following example.

To learn more about the SageMaker's model parallelism library API, refer to the [API documentation](https://sagemaker.readthedocs.io/en/stable/api/training/smd_model_parallel.html).

```
import tensorflow as tf
import horovod.tensorflow as hvd

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
```

```
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: AllReduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()
```

```
for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()

    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))
```

Manual splitting with TensorFlow

Use `smp.partition` context managers to place operations in specific partition. Any operation not placed in any `smp.partition` contexts is placed in the `default_partition`. To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import tensorflow as tf

# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers
```

```
    def call(self, x):
        with smp.partition(0):
            x = self.layer0(x)
        with smp.partition(1):
            return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
    accuracy = train_accuracy.result()
```

Unsupported framework features

The following TensorFlow features are not supported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
- The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

Modify a PyTorch Training Script

In this section, you learn how to modify PyTorch training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning.

> **Note**
>
> To find which PyTorch versions are supported by the library, see the section called "Supported Frameworks and AWS Regions".

> **Tip**
>
> For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker AI model parallelism library v1 examples.

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

Topics

Automated splitting with PyTorch

The following training script changes are required to run a PyTorch training script with SageMaker's model parallelism library:

1. Import and initialize the library with `smdistributed.modelparallel.torch.init()`.
2. Wrap the model with `smdistributed.modelparallel.torch.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

> **Note**
>
> For FP16 training, you need to use the smdistributed.modelparallel.torch.model_creation() context manager to wrap the model. For more information, see FP16 Training with Model Parallelism.

3. Wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`.

> **Note**
>
> For FP16 training, you need to set up static or dynamic loss scaling. For more information, see FP16 Training with Model Parallelism.

4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smdistributed.modelparallel.torch.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
8. Replace `torch.Tensor.backward` and `torch.autograd.backward` with `DistributedModel.backward`.
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.

10. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using [StepOutput API](#).
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's model parallelism library API, refer to the [API documentation](#).

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
```

```
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Manual splitting with PyTorch

Use [smp.partition](https://sagemaker.readthedocs.io/en/stable/api/training/smd_model_parallel.html) context managers to place modules in specific devices. Any module not placed in any `smp.partition` contexts is placed in the `default_partition`. The `default_partition` needs to be provided if `auto_partition` is set to `False`. The modules that are created within a specific `smp.partition` context are placed on the corresponding partition.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        with smp.partition(0):
            # define child modules on device 0
        with smp.partition(1):
            # define child modules on device 1

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
```

```
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
```

```
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Considerations

When you configure a PyTorch training script using SageMaker's model parallelism library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library’s communication basic data types to do this.
- All `torch.Tensor` arguments to the forward methods of the `nn.Modules` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.
- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.
- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.
- Since the library places `nn.Modules` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.
- You don’t need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don’t move the model to CPU and use it, as it won’t have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallelism library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.
- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, AllReduce of gradients is also guaranteed to finish.
- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that AllReduce does not hang waiting for a rank which is not participating in the step.
- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```
dataloader = torch.utils.data.DataLoader(
            data,
            batch_size=batch_size,
            num_workers=0,
            pin_memory=True,
            drop_last=True,
            shuffle=shuffle,
        )
```

- The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

  For example, if you define a `DataLoader` as follows:

```
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

  You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
```

```
@smp.step
def train_step(model, data, target):
    ...
    return output, loss
```

- The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

  For example, you may define the `train` function as follows. This function adds `data` and `target` to the current device using `.to()` API before using those input tensors to call `train_step`.

```
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current
 process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()
```

  The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does *not* need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

Unsupported framework features

The following PyTorch features are unsupported by SageMaker's model parallelism library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.
- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.
- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.
- `apex` : `FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from `apex` are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn` APIs instead.

Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a SageMaker TensorFlow estimator, a SageMaker PyTorch estimator, or a SageMaker generic Estimator to use the modified training script and model parallelism configuration.

Topics

Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the `distribution` parameter, which you can use to specify configuration parameters for using distributed training frameworks. The

SageMaker model parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the `distribution` parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled":True,              # Required
    "parameters": {
        "partitions": 2,         # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,         # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled" : True,            # Required
    "processes_per_host" : 8,    # Required
    # "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Using the SageMaker PyTorch estimator

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled":True,
    "parameters": {                        # Required
        "pipeline_parallel_degree": 2,     # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
    }
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8,              # Required
    # "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

To enable the library, you need to pass configuration dictionaries to the "smdistributed" and "mpi" keys through the distribution argument of the SageMaker estimator constructors.

Configuration parameters for SageMaker model parallelism

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.

> **Note**
>
> Using "modelparallel" and "dataparallel" in one training job is not supported.

  - "enabled" – Required. To enable model parallelism, set "enabled": True.
  - "parameters" – Required. Specify a set of parameters for SageMaker model parallelism.
    - For a complete list of common parameters, see Parameters for smdistributed in the *SageMaker Python SDK documentation*.

      For TensorFlow, see TensorFlow-specific Parameters.

      For PyTorch, see PyTorch-specific Parameters.
    - "pipeline_parallel_degree" (or "partitions" in smdistributed-modelparallel<v1.6.0) – Required. Among the parameters for smdistributed, this parameter is required to specify how many model partitions you want to split into.

> **Important**
>
> There is a breaking change in the parameter name. The "pipeline_parallel_degree" parameter replaces the "partitions" since smdistributed-modelparallel v1.6.0. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the *SageMaker Python SDK documentation*.

- For the "mpi" key, pass a dictionary that contains the following:
  - "enabled" – Required. Set True to launch the distributed training job with MPI.
  - "processes_per_host" – Required. Specify the number of processes MPI should launch on each host. In SageMaker AI, a host is a single Amazon EC2 ML instance. The SageMaker Python

SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker AI schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see Automated splitting with PyTorch.

> **Important**
>
> `process_per_host` *must* not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

- `"custom_mpi_options"` (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

> **Note**
>
> You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:
>
> ```
> The following MCA parameter has been listed multiple times on the command
>  line:
> MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed
>  once
> on a command line to ensure there is no ambiguity as to its value.
> Please correct the situation and try again.
> ```

> **Tip**
>
> If you launch a training job using an EFA-enabled instance type, such as `ml.p4d.24xlarge` and `ml.p3dn.24xlarge`, use the following flag for best performance:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the `estimator.fit()` function.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

- We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker AI model parallelism library v2 examples.
- You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see set up your AWS credentials and Region for development.

Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library

To extend a pre-built container and use SageMaker's model parallelism library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker model parallelism library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (`cuxyz`). For a complete list of DLC images, see Available Deep Learning Containers Images in the *AWS Deep Learning Containers GitHub repository*.

> **Tip**
>
> We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker model parallelism library.

For example, your Dockerfile should contain a `FROM` statement similar to the following:

```
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
```

```
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker AI container to determine our user
 code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the `entry_point` for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

Tip

You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (`image_uri`) to define a SageMaker estimator for training. For more information, see Extend a Pre-built Container.

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker `PyTorch` estimator object as follows. This example assumes that you have already defined `smp_options` and `mpi_options`.

```
smd_mp_estimator = Estimator(
    entry_point="your_training_script.py",
    role=sagemaker.get_execution_role(),
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='your_aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

> **Note**
>
> This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

   ```
   FROM <cuda-cudnn-base-image>
   ```

   > **Tip**
   >
   > The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (`cuxyz`) folder, and choose the Dockerfile ending with `.gpu` or `.sagemaker.gpu`.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

> **Important**
>
> Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create your own Docker container with the SageMaker AI distributed data parallel library to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

```
ARG SMD_MODEL_PARALLEL_URL=https://sagemaker-distributed-model-parallel.s3.us-
west-2.amazonaws.com/pytorch-1.10.0/build-artifacts/2022-02-21-19-26/
smdistributed_modelparallel-1.7.0-cp38-cp38-linux_x86_64.whl
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/
pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-
linux_x86_64.whl
```

4. Install dependencies that the SageMaker model parallel library requires.

   a. Install the METIS library.

```
ARG METIS=metis-5.1.0

RUN rm /etc/apt/sources.list.d/* \
  && wget -nv http://glaros.dtc.umn.edu/gkhome/fetch/sw/metis/${METIS}.tar.gz \
  && gunzip -f ${METIS}.tar.gz \
  && tar -xvf ${METIS}.tar \
  && cd ${METIS} \
  && apt-get update \
  && make config shared=1 \
  && make install \
  && cd .. \
  && rm -rf ${METIS}.tar* \
  && rm -rf ${METIS} \
  && rm -rf /var/lib/apt/lists/* \
  && apt-get clean
```

b. Install the RAPIDS Memory Manager library. This requires CMake 3.14 or later.

```
ARG RMM_VERSION=0.15.0

RUN  wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz \
  && tar -xvf v${RMM_VERSION}.tar.gz \
  && cd rmm-${RMM_VERSION} \
  && INSTALL_PREFIX=/usr/local ./build.sh librmm \
  && cd .. \
  && rm -rf v${RMM_VERSION}.tar* \
  && rm -rf rmm-${RMM_VERSION}
```

5. Install the SageMaker model parallel library.

```
RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}
```

6. Install the SageMaker data parallel library.

```
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

7. Install the sagemaker-training toolkit. The toolkit contains the common functionality that's necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

```
RUN pip install sagemaker-training
```

8. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container and host it in Amazon ECR.

> **Tip**
>
> For more general information about creating a custom Dockerfile for training in SageMaker AI, see Use Your Own Training Algorithms.

Checkpointing and Fine-Tuning a Model with Model Parallelism

The SageMaker model parallelism library provides checkpointing APIs to save the model state and the optimizer state split by the various model parallelism strategies, and to load checkpoints for continuous training from where you want to restart training and fine-tune. The APIs also support options to save the model and optimizer states partially or fully.

Topics

- Checkpointing a distributed model
- Fine-tuning a distributed model

Checkpointing a distributed model

Choose one of the following topics depending on the framework between PyTorch and TensorFlow and the version of the SageMaker model parallelism library you use.

Topics

- Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)
- Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0)
- Checkpointing a distributed TensorFlow model

Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)

The SageMaker model parallelism library provides checkpoint APIs to save and load full or partial checkpoints of the distributed model state and its optimizer state.

> **Note**
>
> This checkpointing method is recommended if you use PyTorch and the SageMaker model parallelism library v1.10.0 or later.

Partial checkpointing

To save checkpoints of a model trained with model parallelism, use the `smdistributed.modelparallel.torch.save_checkpoint` API with the partial checkpointing option set to true (`partial=True`). This saves each model partition individually. In addition to the model and the optimizer state, you can also save any additional custom data through the `user_content` argument. The checkpointed model, optimizer, and user content are saved as separate files. The `save_checkpoint` API call creates checkpoint folders in the following structure.

```
- path
  - ${tag}_partial (folder for partial checkpoints)
    - model_rankinfo.pt
    - optimizer_rankinfo.pt
    - fp16_states_rankinfo.pt
    - user_content.pt
  - $tag (checkpoint file for full checkpoints)
  - user_content_$tag (user_content file for full checkpoints)
  - newest (a file that indicates the newest checkpoint)
```

To resume training from partial checkpoints, use the [`smdistributed.modelparallel.torch.resume_from_checkpoint`]() API with `partial=True`, and specify the checkpoint directory and the tag used while saving the partial checkpoints. Note that the actual loading of model weights happens after model partitioning, during the first run of the `smdistributed.modelparallel.torch.step`-decorated training step function.

When saving a partial checkpoint, the library also saves the model partition decision as files with `.pt` file extension. Conversely, when resuming from the partial checkpoint, the library loads the partition decision files together. Once the partition decision is loaded, you can't change the partition.

The following code snippet shows how to set the checkpoint APIs in a PyTorch training script.

```
import smdistributed.modelparallel.torch as smp

model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...     # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
```

```
    partial=True,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(
    path=checkpoint_path,
    partial=True
)
```

Full checkpointing

To save the final model artifact for inference purposes, use the `smdistributed.modelparallel.torch.save_checkpoint` API with `partial=False`, which combines the model partitions to create a single model artifact. Note that this does not combine the optimizer states.

To initialize training with particular weights, given a full model checkpoint, you can use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=False`. Note that this does not load optimizer states.

> **Note**
>
> With tensor parallelism, in general, the `state_dict` must be translated between the original model implementation and the `DistributedModel` implementation. Optionally, you can provide the `state_dict` translation function as an argument to the `smdistributed.modelparallel.torch.resume_from_checkpoint`. However, for the section called "Supported Models Out of the Box", the library takes care of this translation automatically.

The following code shows an example of how to use the checkpoint APIs for fully checkpointing a PyTorch model trained with model parallelism.

```
import smdistributed.modelparallel.torch as smp
```

```
model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...     # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
    partial=False,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(
    path=checkpoint_path,
    partial=False
)
```

Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0)

The SageMaker model parallelism library provides Python functions for saving partial or full checkpoints for training jobs with tensor parallelism. The following procedure shows how to use `smp.save()` and `smp.load()` to save and load a checkpoint when you use tensor parallelism.

> **Note**
>
> This checkpointing method is recommended if you use PyTorch, the section called “Tensor Parallelism”, and the SageMaker model parallelism library between v1.6.0 and v1.9.0.

1. Prepare a model object and wrap it with the library's wrapper function `smp.DistributedModel()`.

    ```
    model = MyModel(...)
    ```

```
model = smp.DistributedModel(model)
```

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process `model.parameters()` to assign unique IDs to individual model parameters.

   If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:

```
unique_params = []
unique_params_set = set()
for p in model.parameters():
  if p not in unique_params_set:
    unique_params.append(p)
    unique_params_set.add(p)
del unique_params_set

optimizer = MyOpt(unique_params, ...)
```

3. Wrap the optimizer using the library's wrapper function `smp.DistributedOptimizer()`.

```
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using [`smp.save()`](). Depending on how you want to save checkpoints, choose one of the following two options:

   - **Option 1:** Save a partial model on each `mp_rank` for a single `MP_GROUP`.

```
model_dict = model.local_state_dict() # save a partial model
opt_dict = optimizer.local_state_dict() # save a partial optimizer state
# Save the dictionaries at rdp_rank 0 as a checkpoint
if smp.rdp_rank() == 0:
    smp.save(
        {"model_state_dict": model_dict, "optimizer_state_dict": opt_dict},
        f"/checkpoint.pt",
        partial=True,
    )
```

     With tensor parallelism, the library saves checkpointed files named in the following format: `checkpoint.pt_{pp_rank}_{tp_rank}`.

> **Note**
>
> With tensor parallelism, make sure you set the if statement as `if smp.rdp_rank() == 0` instead of `if smp.dp_rank() == 0`. When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong *if* statement for checkpointing might result in a stalling training job. For more information about using `if smp.dp_rank() == 0` without tensor parallelism, see General Instruction for Saving and Loading in the *SageMaker Python SDK documentation*.

- **Option 2:** Save the full model.

```
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True) # save the full model
    if smp.rank() == 0:
        smp.save(
            {"model_state_dict": model_dict},
            "/checkpoint.pt",
            partial=False,
        )
```

> **Note**
>
> Consider the following for full checkpointing:
>
> - If you set `gather_to_rank0=True`, all ranks other than `0` return empty dictionaries.
> - For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
> - The full model only needs to be saved at `smp.rank() == 0`.

5. Load the checkpoints using `smp.load()`. Depending on how you checkpointed in the previous step, choose one of the following two options:

- **Option 1:** Load the partial checkpoints.

```
checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
```

```
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])
```

You can set `same_partition_load=True` in `model.load_state_dict()` for a faster load, if you know that the partition will not change.

- **Option 2:** Load the full checkpoints.

```
if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])
```

The `if smp.rdp_rank() == 0` condition is not required, but it can help avoid redundant loading among different `MP_GROUP`s. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.

Checkpointing a distributed TensorFlow model

To save a TensorFlow model while training with model parallelism, use the following functions provided by the SageMaker model parallelism library.

- [`smdistributed.modelparallel.tensorflow.DistributedModel.save_model`]
- [`smdistributed.modelparallel.tensorflow.CheckpointManager`]

Fine-tuning a distributed model

The fine-tuning needs to be configured in your training script. The following code snippet shows an example structure of a training script using the AutoModelForCausalLM class of Hugging Face Transformers with modifications for registering the `smdistributed.model.parallel.torch` modules and settings for fine-tuning.

> **Note**
>
> Fine-tuning a distributed transformer (a Transformer model wrapped by `smp.DistributedModel()`) with the smp.delayed_param_initialization function activated requires the fine-tuning job to be configured with an FSx for Lustre file system. In cases where you want to fine-tune a large-scale model with the delayed parameter initialization option, you should set up an FSx for Lustre file system.

```
import argparse
from transformers import AutoModelForCausalLM
import smdistributed.modelparallel
import smdistributed.modelparallel.torch as smp

def parse_args():

    parser = argparse.ArgumentParser()

    # set an arg group for model
    model_grp = parser.add_argument_group(
        title="model", description="arguments to describe model configuration"
    )

    ... # set up numerous args to parse from the configuration dictionary to the script
 for training

    # add arg for activating fine-tuning
    model_grp.add_argument(
        "--fine_tune",
        type=int,
        default=0,
        help="Fine-tune model from checkpoint or pretrained model",
    )

def main():
    """Main function to train GPT."""
    args = parse_args()

    ... # parse numerous args

    if args.fine_tune > 0 and args.delayed_param > 0 and smp.rank() == 0:
        pretrained_model = AutoModelForCausalLM.from_pretrained(
            args.model_name or args.model_dir
        )
        model_state_dict = pretrained_model.state_dict()
        path = os.path.join(args.model_dir, "fullmodel.pt")
        torch.save(model_state_dict, path)

    # create a Transformer model and wrap by smp.model_creation()
    # with options to configure model parallelism parameters offered by SageMaker AI
    with smp.model_creation(
        tensor_parallelism=smp.tp_size() > 1 or args.use_distributed_transformer > 0,
```

```
        zero_init=args.use_distributed_transformer == 0,
        dtype=dtype,
        distribute_embedding=args.sharded_data_parallel_degree > 1 and smp.tp_size() >
1,
        use_alibi=args.alibi > 0,
        attention_in_fp32=args.attention_in_fp32 > 0,
        fp32_residual_addition=args.residual_addition_in_fp32 > 0,
        query_key_layer_scaling=args.query_key_layer_scaling > 0 and args.bf16 < 1,
        fused_softmax=args.fused_softmax > 0,
        fused_dropout=args.fused_dropout > 0,
        fused_bias_gelu=args.fused_bias_gelu > 0,
        flash_attention=args.flash_attention > 0,
    ):
        if args.fine_tune > 0 and args.delayed_param == 0:
            model = AutoModelForCausalLM.from_pretrained(
                args.model_name or args.model_dir
            )
        else:
            model = AutoModelForCausalLM.from_config(model_config)

    # wrap the model by smp.DistributedModel() to apply SageMaker model parallelism
    model = smp.DistributedModel(
        model, trace_device="gpu", backward_passes_per_step=args.gradient_accumulation
    )

    # wrap the optimizer by smp.DistributedOptimizer() to apply SageMaker model
parallelism
    optimizer= ... # define an optimizer
    optimizer = smp.DistributedOptimizer(
        optimizer,
        static_loss_scale=None,
        dynamic_loss_scale=True,
        dynamic_loss_args={"scale_window": 1000, "min_scale": 1, "delayed_shift": 2},
    )

    # for fine-tuning, use smp.resume_from_checkpoint() to load a pre-trained model
    if args.fine_tune > 0 and args.delayed_param > 0:
        smp.resume_from_checkpoint(args.model_dir, tag="fullmodel.pt", partial=False)
```

For a complete example of training scripts and Jupyter notebooks, see the [GPT-2 examples for PyTorch]() in the *SageMaker AI Examples GitHub repository*.

Amazon SageMaker AI model parallelism library v1 examples

This page provides a list of blogs and Jupyter notebooks that present practical examples of implementing the SageMaker model parallelism (SMP) library v1 to run distributed training jobs on SageMaker AI.

Blogs and Case Studies

The following blogs discuss case studies about using SMP v1.

- New performance improvements in the Amazon SageMaker AI model parallelism library, *AWS Machine Learning Blog* (December 16, 2022)
- Train gigantic models with near-linear scaling using sharded data parallelism on Amazon SageMaker AI, *AWS Machine Learning Blog* (October 31, 2022)

Example notebooks

Example notebooks are provided in the SageMaker AI examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/model_parallel`.

> **Note**
>
> Clone and run the example notebooks in the following SageMaker AI ML IDEs.
>
> - SageMaker JupyterLab (available in Studio created after December 2023)
> - SageMaker Code Editor (available in Studio created after December 2023)
> - Studio Classic (available as an application in Studio created after December 2023)
> - SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/model_parallel
```

SMP v1 example notebooks for PyTorch

- Train GPT-2 with near-linear scaling using the sharded data parallelism technique in the SageMaker model parallelism library

- Fine-tune GPT-2 with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library
- Train GPT-NeoX-20B with near-linear scaling using the sharded data parallelism technique in the SageMaker model parallelism library
- Train GPT-J 6B using the sharded data parallelism and tensor parallelism techniques in the SageMaker model parallelism library
- Train FLAN-T5 with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library
- Train Falcon with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library

SMP v1 example notebooks for TensorFlow

- CNN with TensorFlow 2.3.1 and the SageMaker model parallelism library
- HuggingFace with TensorFlow Distributed model parallelism library Training on SageMaker AI

SageMaker Distributed Model Parallelism Best Practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.

Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

> **Tip**
>
> If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

Using large GPU instance types

- In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using `ml.p4d` or `ml.p3dn` instances for training large DL models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.

Sharding optimizer state

- The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

  When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a compute cluster with 16 GPUs (for example, two P4d or P4de instances) might not always fit on a node with 8 GPUs (for example, a single P4d or P4de instance). This is because the combined memory of 8 GPUs is lower than the combined memory of 16 GPUs, and the required memory per GPU for sharding over 8 GPUs is also higher than the memory per GPU for sharding over the 16-GPU scenario. As a result, the increased memory requirement might not fit into the smaller cluster.

  For more information, see [Optimizer State Sharding](#).

Activation checkpointing

- Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the `strategy` argument of the `smp.set_activation_checkpointing` function groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

  For more information, see [Activation Checkpointing](#).

Tensor parallelism

- The degree of tensor parallelism should be a power of two (2, 4, 8, ..., 2^n), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism.

Pipeline parallelism across nodes

- You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.
- Pipeline parallelism comes with the following three knobs: `microbatches`, `active_microbatches`, and `prescaled_batch`.
  - When you use tensor parallelism with pipeline parallelism, we recommend activating `prescaled_batch` so that the batch size per model parallel group can be increased for efficient pipelining. With `prescaled_batch` activated, the batch size set in the training script becomes `tp_size` times the batch size set for each rank without `prescaled_batch`.
  - Increasing the number of `microbatches` helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.
  - The number of `active_microbatches` is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing `active_microbatches` takes up more GPU memory.
- If both GPU and GPU memory are underutilized, increase `active_microbatches` for better parallelization during pipelining.
- For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism.
- To find descriptions of the aforementioned parameters, see Parameters for `smdistributed` in the *SageMaker Python SDK documentation*.

Offloading activations to CPU

- Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the microbatches parameter.
- When offloading activations, you might be able to increase `active_microbatches` and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

  For more information, see [Activation Offloading](#).

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.

The number of model parameters	Instance type	Pipeline parallelism	Tensor parallelism	Optimizer state sharding	Activation checkpointing	Prescaled batch	Batch size
10 billion	16 `ml.p4d.24xlarge`	1	4	True	Each transformer layer	True	`batch_size=40`
30 billion	16 `ml.p4d.24xlarge`	1	8	True	Each transformer layer	True	`batch_size=32`
60 billion	32 `ml.p4d.24xlarge`	2	8	True	Each transformer layer	True	`batch_size=56` , `microbatches=4` , `active_microbatches=2`

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn't fit, try increasing the degree of tensor parallelism.

Modifying Your Training Script

- Before you use the SageMaker model parallel library's features in your training script, review The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls.
- To launch a training job faster, use the SageMaker AI local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

Monitoring and Logging a Training Job Using the SageMaker AI Console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker AI console.

1. In the left navigation pane, choose **Training**.
2. Choose **Training jobs**.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the **Monitor** section to see the automated visualization.
5. To see training job logs, choose **View logs** in the **Monitor** section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of **algo-n-1234567890**. The **algo-1** log stream tracks training logs from the main (0th) node.

For more information, see Amazon CloudWatch Metrics for Monitoring and Analyzing Training Jobs.

Permissions

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add `AmazonFSxFullAccess`.
- To use Amazon S3 as a data channel, add `AmazonS3FullAccess`.
- To use Docker, build your own container, and push it to Amazon ECR, add `AmazonEC2ContainerRegistryFullAccess`.
- To have a full access to use the entire suite of SageMaker AI features, add `AmazonSageMakerFullAccess`.

The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker AI's model parallelism library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow training script and Modify a PyTorch Training Script, respectively.

Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it

is not, you can set `drop_remainder=True` in the `tf.Dataset.batch()` call (in TensorFlow), or set `drop_last=True` in `DataLoader` (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

Returning Tensors from `smp.DistributedModel`

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The `@smp.step` Decorator

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see [`smp.step`] in the API documentation.

Delaying Parameter Initialization

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers `smp.delay_param_initialization` context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of a `smp.step`-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```
with smp.delay_param_initialization(enabled=True):
    model = MyModel()
```

Tensor Parallelism for PyTorch

- If you are using a seed for deterministic results, set the seed based on `smp.dp_rank()` (for example, `torch.manual_seed(42 + smp.dp_rank())`). If you do not do this, different partitions of an `nn.Parameter` are initialized in the same way, impacting convergence.
- SageMaker's model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, `smp` throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable `SMP_NCCL_THROTTLE_LIMIT`. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set `SMP_NCCL_THROTTLE_LIMIT=-1`.
- The following identity, which holds when the degree of tensor parallelism is 1, does not hold when the degree of tensor parallelism is greater than 1: `smp.mp_size() * smp.dp_size() == smp.size()`. This is because the tensor parallel group is part of both the model parallelism group and the data parallelism group. If your code has existing references to `mp_rank`, `mp_size`, `MP_GROUP`, and so on, and if you want to work with only the pipeline parallel group, you might need to replace the references with `smp.pp_size()`. The following identities are always true:
  - `smp.mp_size() * smp.rdp_size() == smp.size()`
  - `smp.pp_size() * smp.dp_size() == smp.size()`
  - `smp.pp_size() * smp.tp_size() * smp.rdp_size() == smp.size()`

- Since the `smp.DistributedModel` wrapper modifies the model parameters when tensor parallelism is enabled, the optimizer should be created after calling `smp.DistributedModel`, with the distributed parameters. For example, the following does not work:

```
## WRONG
model = MyModel()
optimizer = SomeOptimizer(model.parameters())
model = smp.DistributedModel(model)  # optimizer now has outdated parameters!
```

  Instead, the optimizer should be created with the parameters of the `smp.DistributedModel` as follows:

```
## CORRECT
model = smp.DistributedModel(MyModel())
optimizer = SomeOptimizer(model.optimizers())
```

- When a module is replaced with its distributed counterpart through tensor parallelism, the distributed module does not inherit its weights from the original module, and initializes new weights. This means that, for instance, if the weights need to be initialized in a particular call (for example, through a `load_state_dict` call), this needs to happen after the `smp.DistributedModel` call, once the module distribution takes place.
- When accessing the parameters of distributed modules directly, note that the weight does not have the same shape as the original module. For instance,

```
with smp.tensor_parallelism():
    linear = nn.Linear(60, 60)

# will pass
assert tuple(linear.weight.shape) == (60, 60)

distributed_linear = smp.DistributedModel(linear)

# will fail. the number of input channels will have been divided by smp.tp_size()
assert tuple(distributed_linear.module.weight.shape) == (60, 60)
```

- Using `torch.utils.data.distributed.DistributedSampler` is strongly recommended for tensor parallelism. This ensures that every data parallel rank receives the same number of data samples, which prevents hangs that might result from different `dp_ranks` taking a different number of steps.

- If you use the `join` API of PyTorch's `DistributedDataParallel` class to handle cases in which different data parallel ranks have different numbers of batches, you still need to make sure that ranks that are in the same `TP_GROUP` have the same number of batches; otherwise the communication collectives used in distributed execution of modules may hang. Ranks that are in different `TP_GROUP`s can have different numbers of batches, as long as `join` API is used.
- If you want to checkpoint your model and use tensor parallelism, consider the following:
  - To avoid stalling and race conditions while saving and loading models when you use tensor parallelism, make sure you call appropriate functions from the following model and optimizer states inside a reduced-data parallelism rank.
  - If you are transitioning an existing pipeline parallel script and enabling tensor parallel for the script, ensure that you modify any `if smp.dp_rank() == 0` block used for saving and loading with `if smp.rdp_rank() == 0` blocks. Otherwise, it might cause your training job to stall.

  For more information about checkpointing a model with tensor parallelism, see the section called "Checkpointing a distributed model".

Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

Topics

Considerations for Using SageMaker Debugger with the SageMaker Model Parallelism Library

SageMaker Debugger is not available for the SageMaker model parallelism library. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/
metadata.json.sagemaker-uploading
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework `estimator` as shown in the following example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name,
 checkpoint_in_bucket)

estimator = TensorFlow(
    ...

    distribution={"smdistributed": {"modelparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker AI:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker AI limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker AI, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use `checkpoint_s3_uri` with the SageMaker `estimator` call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```
import os

def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile"""
```

```
    import time, subprocess
    cmd = ["aws", "s3", "sync", "--quiet", source, destination]
    print(f"Syncing files from {source} to {destination}")
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print("Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
 s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/
checkpoints'):
    """ sample function to sync checkpoints from local path to s3 """

    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please
 check")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(local_path, s3_uri)
    return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
 s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/
checkpoints'):
    """ sample function to sync checkpoints from s3 to local path """

    import boto3
    #try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
```

```
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(s3_uri, local_path)
    return
```

Usage of helper functions:

```
#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

# save checkpoints on every node using local_rank
if smp.local_rank() == 0:
    base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))
    curr_host = os.environ['SM_CURRENT_HOST']
    full_s3_uri = f'{base_s3_uri}/checkpoints/{curr_host}/{iteration}'
    sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri)
```

Convergence Using Model Parallel and TensorFlow

When you use SageMaker AI multi-node training with TensorFlow and the model parallelism library, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Stalling or Crashing Distributed Training Jobs

If your training job has stalling, crashing, or not responding issues, read the following troubleshooting items to identify what's the cause of the issue. If you need any further support, reach out to the SageMaker distributed training team through AWS Support.

- If you see **a distributed training job stalling at the NCCL initialization step**, consider the following:
  - If you are using one of the EFA-enabled instances (`ml.p4d` or `ml.p3dn` instances) with a custom VPC and its subnet, ensure that the security group used has inbound and outbound connections for all ports to and from the same SG. You also generally need outbound connections to any IP as a separate rule (for internet access). To find instructions on how to add inbound and outbound rules for EFA communication, refer to SageMaker AI distributed training job stalling during initialization.
- If you see a **distributed training job stalling when checkpointing** the full model, this might be because the `state_dict()` call on the model or optimizer was not made on all ranks with `rdp_rank()==0` (when using tensor parallelism) or `dp_rank()==0` (when using only pipeline parallelism). These ranks need to communicate to construct the checkpoint to be saved. Similar stalling issues can also happen when checkpointing partial optimizer if `shard_optimizer_state` is enabled.

  For more information about checkpointing a model with model parallelism, see General Instruction for Saving and Loading and Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0).
- If the training job crashes with a **CUDA Out of Memory error**, this means that the distributed training configuration needs to be adjusted to fit the model on the GPU cluster. For more information and best practices, see Setting Up the Right Configuration for a Given Model.
- If the training job crashes with an **uncorrectable ECC error**, this means that one of the GPUs in the cluster has gone bad. If you need technical support, share the job ARN with the AWS team and restart your training job from a checkpoint if possible.
- In rare cases, a job configuration that worked previously but is close to the limits of GPU memory might fail later with a different cluster due to a **CUDA Out of Memory error**. This could be because some GPU has lower available memory than usual due to ECC errors.
- **Network timeout crash** might happen when running a multinode job which doesn’t use all GPUs in the node. To get around this, use all GPUs on the node by ensuring that the `processes_per_host` parameter is set to the number of GPUs in each instance. For

example, this is `processes_per_host=8` for `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge` instances.

- If you find that your training job takes a long time during the data downloading stage, make sure the Amazon S3 path you provided to `checkpoint_s3_uri` for the SageMaker `Estimator` class is unique for the current training job. If this path is reused across multiple training jobs running simultaneously, all those checkpoints are uploaded and downloaded to the same Amazon S3 path and might significantly increase checkpoint loading time.
- Use FSx for Lustre when you deal with large data and models.
  - If your dataset is large and fetching it takes a long time, we recommend keeping your dataset in FSx for Lustre.
  - When training models are beyond 10 billion parameters, we recommend using FSx for Lustre for checkpointing.
  - After you create a file system, make sure to wait for the status to become **available** before starting a training job using it.

Receiving NCCL Error for a PyTorch Training Job

If you encountered the following error, it might be due to a process running out of GPU memory.

```
NCCL error in: ../torch/lib/c10d/ProcessGroupNCCL.cpp:825, unhandled system error, NCCL
 version 2.7.8
ncclSystemError: System call (socket, malloc, munmap, etc) failed.
```

You can resolve this by reducing the batch size or `active_microbatches`. If auto partitioning is not resulting in a well-balanced partitioning, you might have to consider manual partitioning. For more information, see Pipeline parallelism across nodes.

Receiving `RecursionError` for a PyTorch Training Job

The library does not support calling `super.forward()` inside a module's forward call. If you use `super.forward()`, you might receive the following error message.

```
RecursionError: maximum recursion depth exceeded
```

To fix the error, instead of calling `super.forward()`, you should call `super()._orig_forward()`.

Distributed computing with SageMaker AI best practices

This best practices page presents various flavors of distributed computing for machine learning (ML) jobs in general. The term *distributed computing* in this page encompasses distributed training for machine learning tasks and parallel computing for data processing, data generation, feature engineering, and reinforcement learning. In this page, we discuss about common challenges in distributed computing, and available options in SageMaker Training and SageMaker Processing. For additional reading materials about distributed computing, see What Is Distributed Computing?.

You can configure ML tasks to run in a distributed manner across multiple nodes (instances), accelerators (NVIDIA GPUs, AWS Trainium chips), and vCPU cores. By running distributed computation, you can achieve a variety of goals such as computing operations faster, handling large datasets, or training large ML models.

The following list covers common challenges that you might face when you run an ML training job at scale.

- You need to make decisions on how to distribute computation depending on ML tasks, software libraries you want to use, and compute resources.
- Not all ML tasks are straightforward to distribute. Also, not all ML libraries support distributed computation.
- Distributed computation might not always result in a linear increase in compute efficiency. In particular, you need to identify if data I/O and inter-GPU communication have bottlenecks or cause overhead.
- Distributed computation might disturb numerical processes and change model accuracy. Specifically to data-parallel neural network training, when you change the global batch size while scaling up to a larger compute cluster, you also need to adjust the learning rate accordingly.

SageMaker AI provides distributed training solutions to ease such challenges for various use cases. Choose one of the following options that best fits your use case.

Topics

- Option 4: Launch multiple jobs in parallel or sequentially

Option 1: Use a SageMaker AI built-in algorithm that supports distributed training

SageMaker AI provides built-in algorithms that you can use out of the box through the SageMaker AI console or the SageMaker Python SDK. Using the built-in algorithms, you don't need to spend time for code customization, understanding science behind the models, or running Docker on provisioned Amazon EC2 instances.

A subset of the SageMaker AI built-in algorithms support distributed training. To check if the algorithm of your choice supports distributed training, see the **Parallelizable** column in the Common Information About Built-in Algorithms table. Some of the algorithms support multi-instance distributed training, while the rest of the parallelizable algorithms support parallelization across multiple GPUs in a single instance, as indicated in the **Parallelizable** column.

Option 2: Run a custom ML code in the SageMaker AI managed training or processing environment

SageMaker AI jobs can instantiate distributed training environment for specific use cases and frameworks. This environment acts as a ready-to-use whiteboard, where you can bring and run your own ML code.

If your ML code uses a deep learning framework

You can launch distributed training jobs using the Deep Learning Containers (DLC) for SageMaker Training, which you can orchestrate either through the dedicated Python modules in the SageMaker AI Python SDK, or through the SageMaker APIs with AWS CLI, AWS SDK for Python (Boto3). SageMaker AI provides training containers for machine learning frameworks, including PyTorch, TensorFlow, Hugging Face Transformers, and Apache MXNet. You have two options to write deep learning code for distributed training.

- **The SageMaker AI distributed training libraries**

  The SageMaker AI distributed training libraries propose AWS-managed code for neural network data parallelism and model parallelism. SageMaker AI distributed training also comes with launcher clients built into the SageMaker Python SDK, and you don't need to author parallel launch code. To learn more, see SageMaker AI's data parallelism library and SageMaker AI's model parallelism library.

- **Open-source distributed training libraries**

  Open source frameworks have their own distribution mechanisms such as DistributedDataParallelism (DDP) in PyTorch or `tf.distribute` modules in TensorFlow. You can choose to run these distributed training frameworks in the SageMaker AI-managed framework containers. For example, the sample code for training MaskRCNN in SageMaker AI shows how to use both PyTorch DDP in the SageMaker AI PyTorch framework container and Horovod in the SageMaker TensorFlow framework container.

SageMaker AI ML containers also come with MPI preinstalled, so you can parallelize your entry point script using mpi4py. Using the MPI integrated training containers is a great option when you launch a third-party distributed training launcher or write ad-hoc parallel code in the SageMaker AI managed training environment.

Notes for data-parallel neural network training on GPUs

- **Scale to multi-GPU and multi-machine parallelism when appropriate**

  We often run neural network training jobs on multiple-CPU or multiple-GPU instances. Each GPU-based instance usually contains multiple GPU devices. Consequently, distributed GPU computing can happen either within a single GPU instance with multiple GPUs (single-node multi-GPU training), or across multiple GPU instances with multiple GPU cores in each (multi-node multi-GPU training). Single-instance training is easier to write code and debug, and the intra-node GPU-to-GPU throughput is usually faster than the inter-node GPU-to-GPU throughput. Therefore, it is a good idea to scale data parallelism vertically first (use one GPU instance with multiple GPUs) and expand to multiple GPU instances if needed. This might not apply to cases where the CPU budget is high (for example, a massive workload for data pre-processing) and when the CPU-to-GPU ratio of a multi-GPU instance is too low. In all cases, you need to experiment with different combinations of instance types based on your own ML training needs and workload.
- **Monitor the quality of convergence**

  When training a neural network with data parallelism, increasing the number of GPUs while keeping the mini-batch size per GPU constant leads to increasing the size of global mini-batch for the mini-batch stochastic gradient descent (MSGD) process. The size of mini-batches for MSGD is known to impact the descent noise and convergence. For properly scaling while preserving accuracy, you need to adjust other hyperparameters such as the learning rate [Goyal et al. (2017)].

- **Monitor I/O bottlenecks**

  As you increase the number of GPUs, the throughput for reading and writing storage should also increase. Make sure that your data source and pipeline don't become bottlenecks.

- **Modify your training script as needed**

  Training scripts written for single-GPU training must be modified for multi-node multi-GPU training. In most data parallelism libraries, script modification is required to do the following.

  - Assign batches of training data to each GPU.
  - Use an optimizer that can deal with gradient computation and parameter updates across multiple GPUs.
  - Assign responsibility of checkpointing to a specific host and GPU.

If your ML code involves tabular data processing

PySpark is a Python frontend of Apache Spark, which is an open-source distributed computing framework. PySpark has been widely adopted for distributed tabular data processing for large-scale production workloads. If you want to run tabular data processing code, consider using the SageMaker Processing PySpark containers and running parallel jobs. You can also run data processing jobs in parallel using SageMaker Training and SageMaker Processing APIs in Amazon SageMaker Studio Classic, which is integrated with Amazon EMR and AWS Glue.

Option 3: Write your own custom distributed training code

When you submit a training or processing job to SageMaker AI, SageMaker Training and SageMaker AI Processing APIs launch Amazon EC2 compute instances. You can customize training and processing environment in the instances by running your own Docker container or installing additional libraries in the AWS managed containers. For more information about Docker with SageMaker Training, see Adapting your own Docker container to work with SageMaker AI and Create a container with your own algorithms and models. For more information about Docker with SageMaker AI Processing, see Use Your Own Processing Code.

Every SageMaker training job environment contains a configuration file at `/opt/ml/input/config/resourceconfig.json`, and every SageMaker Processing job environment contains a similar configuration file at `/opt/ml/config/resourceconfig.json`. Your code can read this file to find `hostnames` and establish inter-node communications. To learn more, including the schema of the JSON file, see Distributed Training Configuration and How Amazon SageMaker

Processing Configures Your Processing Container. You can also install and use third-party distributed computing libraries such as Ray or DeepSpeed in SageMaker AI.

You can also use SageMaker Training and SageMaker Processing to run custom distributed computations that do not require inter-worker communication. In the computing literature, those tasks are often described as *embarrassingly parallel* or *share-nothing*. Examples include parallel processing of data files, training models in parallel on different configurations, or running batch inference on a collection of records. You can trivially parallelize such share-nothing use cases with Amazon SageMaker AI. When you launch a SageMaker Training or SageMaker Processing job on a cluster with multiple nodes, SageMaker AI by default replicates and launches your training code (in Python or Docker) on all the nodes. Tasks requiring random spread of input data across such multiple nodes can be facilitated by setting `S3DataDistributionType=ShardedByS3Key` in the data input configuration of the SageMaker AI `TrainingInput` API.

Option 4: Launch multiple jobs in parallel or sequentially

You can also distribute an ML compute workflow into smaller parallel or sequential compute tasks, each represented by its own SageMaker Training or SageMaker Processing job. Splitting a task into multiple jobs can be beneficial for the following situations or tasks:

- When you have specific data channels and metadata entries (such as hyperparameters, model configuration, or instance types) for each sub-tasks.
- When you implement retry steps at a sub-task level.
- When you vary the configuration of the sub-tasks over the course of the workload, such as when training on increasing batch sizes.
- When you need to run an ML task that takes longer than the maximum training time allowed for a single training job (28 days maximum).
- When different steps of a compute workflow require different instance types.

For the specific case of hyperparameter search, use SageMaker AI Automated Model Tuning. SageMaker AI Automated Model Tuning is a serverless parameter search orchestrator that launches multiple training jobs on your behalf, according to a search logic that can be random, Bayesian, or HyperBand.

Additionally, to orchestrate multiple training jobs, you can also consider workflow orchestration tools, such as SageMaker Pipelines, AWS Step Functions, and Apache Airflow supported by Amazon Managed Workflows for Apache Airflow (MWAA) and SageMaker AI Workflows.

Amazon SageMaker Training Compiler

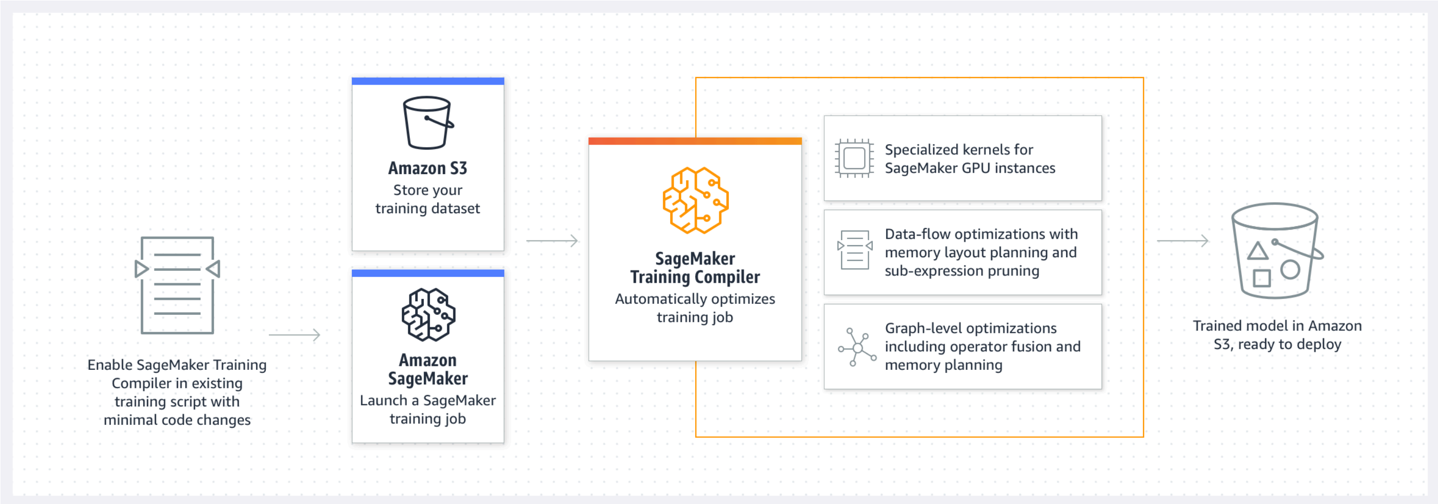
> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

Use Amazon SageMaker Training Compiler to train deep learning (DL) models faster on scalable GPU instances managed by SageMaker AI.

What Is SageMaker Training Compiler?

State-of-the-art deep learning (DL) models consist of complex multi-layered neural networks with billions of parameters that can take thousands of GPU hours to train. Optimizing such models on training infrastructure requires extensive knowledge of DL and systems engineering; this is challenging even for narrow use cases. Although there are open-source implementations of compilers that optimize the DL training process, they can lack the flexibility to integrate DL frameworks with some hardware such as GPU instances.

SageMaker Training Compiler is a capability of SageMaker AI that makes these hard-to-implement optimizations to reduce training time on GPU instances. The compiler optimizes DL models to accelerate training by more efficiently using SageMaker AI machine learning (ML) GPU instances. SageMaker Training Compiler is available at no additional charge within SageMaker AI and can help reduce total billable time as it accelerates training.



SageMaker Training Compiler is integrated into the AWS Deep Learning Containers (DLCs). Using the SageMaker Training Compiler–enabled AWS DLCs, you can compile and optimize training jobs on GPU instances with minimal changes to your code. Bring your deep learning models to SageMaker AI and enable SageMaker Training Compiler to accelerate the speed of your training job on SageMaker AI ML instances for accelerated computing.

How It Works

SageMaker Training Compiler converts DL models from their high-level language representation to hardware-optimized instructions. Specifically, SageMaker Training Compiler applies graph-level optimizations, dataflow-level optimizations, and backend optimizations to produce an optimized model that efficiently uses hardware resources. As a result, you can train your models faster than when you train them without compilation.

It is a two-step process to activate SageMaker Training Compiler for your training job:

1. Bring your own DL script and, if needed, adapt to compile and train with SageMaker Training Compiler. To learn more, see Bring Your Own Deep Learning Model.
2. Create a SageMaker AI estimator object with the compiler configuration parameter using the SageMaker Python SDK.
   a. Turn on SageMaker Training Compiler by adding `compiler_config=TrainingCompilerConfig()` to the SageMaker AI estimator class.
   b. Adjust hyperparameters (`batch_size` and `learning_rate`) to maximize the benefit that SageMaker Training Compiler provides.

Compilation through SageMaker Training Compiler changes the memory footprint of the model. Most commonly, this manifests as a reduction in memory utilization and a consequent increase in the largest batch size that can fit on the GPU. In some cases, the compiler intelligently promotes caching which leads to a decrease in the largest batch size that can fit on the GPU. Note that if you want to change the batch size, you must adjust the learning rate appropriately.

For a reference for `batch_size` tested for popular models, see Tested Models.

When you adjust the batch size, you also have to adjust the `learning_rate` appropriately. For best practices for adjusting the learning rate along with the change in batch size, see the section called “Best Practices and Considerations”.

c. By running the `estimator.fit()` class method, SageMaker AI compiles your model and starts the training job.

For instructions on how to launch a training job, see Enable SageMaker Training Compiler.

SageMaker Training Compiler does not alter the final trained model, while allowing you to accelerate the training job by more efficiently using the GPU memory and fitting a larger batch size per iteration. The final trained model from the compiler-accelerated training job is identical to the one from the ordinary training job.

> **Tip**
>
> SageMaker Training Compiler only compiles DL models for training on supported GPU instances managed by SageMaker AI. To compile your model for inference and deploy it to run anywhere in the cloud and at the edge, use SageMaker Neo compiler.

Supported Frameworks, AWS Regions, Instance Types, and Tested Models

> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

Before using SageMaker Training Compiler, check if your framework of choice is supported, the instance types are available in your AWS account, and your AWS account is in one of the supported AWS Regions.

> **Note**
>
> SageMaker Training Compiler is available in the SageMaker Python SDK v2.70.0 or later.

Supported Frameworks

SageMaker Training Compiler supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

Topics

- PyTorch
- TensorFlow

PyTorch

For more information, see Available Images in the *AWS Deep Learning Containers GitHub repository*.

AWS Regions

The SageMaker Training Compiler Containers are available in the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

Supported Instance Types

SageMaker Training Compiler is tested on and supports the following ML instance types.

- P4 instances
- P3 instances
- G4dn instances
- G5 instances

For specs of the instance types, see the **Accelerated Computing** section in the [Amazon EC2 Instance Types page](). For information about instance pricing, see [Amazon SageMaker Pricing]().

If you encountered an error message similar to the following, follow the instructions at [Request a service quota increase for SageMaker AI resources]().

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
for training job usage' is 0 Instances, with current utilization of 0 Instances
and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

Tested Models

The following table includes a list of the models that have been tested with SageMaker Training Compiler. For reference, the largest batch size that is able to fit into memory is also included alongside other training parameters. SageMaker Training Compiler can change the memory footprint of the model training process; as a result, a larger batch size can often be used during the training process, further decreasing total training time. In some cases, SageMaker Training Compiler intelligently promotes caching which leads to a decrease in the largest batch size that can fit on the GPU. You must retune your model hyperparameters and find an optimal batch size for your case. To save time, use the following reference tables to look up a batch size that can be a good starting point for your use case.

> **Note**
>
> The batch sizes are local batch size that fit into each individual GPU in the respective instance type. You should also adjust the learning rate when changing the batch size.

PyTorch 1.13.1

Natural language processing (NLP) models

Bring Your Own Deep Learning Model

> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

This guide walks you through how to adapt your training script for a compiler-accelerated training job. The preparation of your training script depends on the following:

- Training settings such as single-core or distributed training.
- Frameworks and libraries that you use to create the training script.

Choose one of the following topics depending on the framework you use.

Topics

- PyTorch
- TensorFlow

> **Note**
>
> After you finish preparing your training script, you can run a SageMaker training job using the SageMaker AI framework estimator classes. For more information, see the previous topic at Enable SageMaker Training Compiler.

PyTorch

Bring your own PyTorch model to SageMaker AI, and run the training job with SageMaker Training Compiler.

Topics

- PyTorch Models with Hugging Face Transformers

PyTorch Models with Hugging Face Transformers

PyTorch models with Hugging Face Transformers are based on PyTorch's torch.nn.Module API. Hugging Face Transformers also provides Trainer and pretrained model classes for PyTorch to help reduce the effort for configuring natural language processing (NLP) models. After preparing your training script, you can launch a training job using the SageMaker AI `PyTorch` or `HuggingFace` estimator with the SageMaker Training Compiler configuration when you'll proceed to the next topic at Enable SageMaker Training Compiler.

> **Tip**
>
> When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can trigger recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the *Hugging Face Transformers documentation*.

Topics

- Large Language Models Using the Hugging Face Transformers Trainer Class
- Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API)

Large Language Models Using the Hugging Face Transformers `Trainer` Class

If you use the transformers library's Trainer class, you don't need to make any additional changes to your training script. SageMaker Training Compiler automatically compiles your Trainer model if you enable it through the estimator class. The following code shows the basic form of a PyTorch training script with Hugging Face Trainer API.

```
from transformers import Trainer, TrainingArguments

training_args=TrainingArguments(**kwargs)
```

```
trainer=Trainer(args=training_args, **kwargs)
```

Topics

- For single GPU training
- For distributed training
- Best Practices to Use SageMaker Training Compiler with Trainer

For single GPU training

You don't need to change your code when you use the `transformers.Trainer` class.

For distributed training

PyTorch v1.11.0 and later

To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker AI distributed runtime for PyTorch (`pytorchxla`) to the `main()` function of your training script.

```
def _mp_fn(index):
    main()
```

This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

For Transformers v4.17 and before with PyTorch v1.10.2 and before

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job, and you don't need to make any modification in your training script. Instead, SageMaker Training Compiler requires you to pass a SageMaker AI distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker AI Hugging Face estimator.

Best Practices to Use SageMaker Training Compiler with `Trainer`

- Make sure that you use SyncFree optimizers by setting the `optim` argument to `adamw_torch_xla` while setting up transformers.TrainingArgument. See also Optimizer in the *Hugging Face Transformers documentation*.

- Ensure that the throughput of the data processing pipeline is higher than the training throughput. You can tweak the `dataloader_num_workers` and `preprocessing_num_workers` arguments of the transformers.TrainingArgument class to achieve this. Typically, these need to be greater than or equal to the number of GPUs but less than the number of CPUs.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler”.

Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API)

If you have a training script that uses PyTorch directly, you need to make additional changes to your PyTorch training script to implement PyTorch/XLA. Follow the instructions to modify your script to properly set up the PyTorch/XLA primatives.

Topics

- For single GPU training
- For distributed training
- Best Practices to Use SageMaker Training Compiler with PyTorch/XLA

For single GPU training

1. Import the optimization libraries.

```
import torch_xla
import torch_xla.core.xla_model as xm
```

2. Change the target device to be XLA instead of `torch.device("cuda")`

```
device=xm.xla_device()
```

3. If you're using PyTorch's Automatic Mixed Precision (AMP), do the following:

   a. Replace `torch.cuda.amp` with the following:

   ```
   import torch_xla.amp
   ```

   b. Replace `torch.optim.SGD` and `torch.optim.Adam` with the following:

```
import torch_xla.amp.syncfree.Adam as adam
import torch_xla.amp.syncfree.SGD as SGD
```

c. Replace `torch.cuda.amp.GradScaler` with the following:

```
import torch_xla.amp.GradScaler as grad_scaler
```

4. If you're not using AMP, replace `optimizer.step()` with the following:

```
xm.optimizer_step(optimizer)
```

5. If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's `ParallelLoader` class:

```
import torch_xla.distributed.parallel_loader as pl
parallel_loader=pl.ParallelLoader(dataloader, [device]).per_device_loader(device)
```

6. Add `mark_step` at the end of the training loop when you're not using `parallel_loader`:

```
xm.mark_step()
```

7. To checkpoint your training, use the PyTorch/XLA's model checkpoint method:

```
xm.save(model.state_dict(), path_to_save)
```

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler”.

For distributed training

In addition to the changes listed in the previous For single GPU training section, add the following changes to properly distribute workload across GPUs.

1. If you're using AMP, add `all_reduce` after `scaler.scale(loss).backward()`:

```
gradients=xm._fetch_gradients(optimizer)
xm.all_reduce('sum', gradients, scale=1.0/xm.xrt_world_size())
```

2. If you need to set variables for `local_ranks` and `world_size`, use similar code to the following:

```
local_rank=xm.get_local_ordinal()
world_size=xm.xrt_world_size()
```

3. For any `world_size` (`num_gpus_per_node*num_nodes`) greater than `1`, you must define a train sampler which should look similar to the following:

```
import torch_xla.core.xla_model as xm

if xm.xrt_world_size() > 1:
    train_sampler=torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=xm.xrt_world_size(),
        rank=xm.get_ordinal(),
        shuffle=True
    )

train_loader=torch.utils.data.DataLoader(
    train_dataset,
    batch_size=args.batch_size,
    sampler=train_sampler,
    drop_last=args.drop_last,
    shuffle=False if train_sampler else True,
    num_workers=args.num_workers
)
```

4. Make the following changes to make sure you use the `parallel_loader` provided by the `torch_xla distributed` module.

```
import torch_xla.distributed.parallel_loader as pl
train_device_loader=pl.MpDeviceLoader(train_loader, device)
```

The `train_device_loader` functions like a regular PyTorch loader as follows:

```
for step, (data, target) in enumerate(train_device_loader):
    optimizer.zero_grad()
    output=model(data)
    loss=torch.nn.NLLLoss(output, target)
    loss.backward()
```

With all of these changes, you should be able to launch distributed training with any PyTorch model without the Transformer Trainer API. Note that these instructions can be used for both single-node multi-GPU and multi-node multi-GPU.

5. **For PyTorch v1.11.0 and later**

   To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker AI distributed runtime for PyTorch (`pytorchxla`) to the `main()` function of your training script.

   ```
   def _mp_fn(index):
       main()
   ```

   This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

   For Transformers v4.17 and before with PyTorch v1.10.2 and before

   SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job and requires you to pass a SageMaker AI distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker AI Hugging Face estimator.

After you have completed adapting your training script, proceed to the section called "Run PyTorch Training Jobs with Training Compiler".

Best Practices to Use SageMaker Training Compiler with PyTorch/XLA

If you want to leverage the SageMaker Training Compiler on your native PyTorch training script, you may want to first get familiar with PyTorch on XLA devices. The following sections list some best practices to enable XLA for PyTorch.

> **Note**
>
> This section for best practices assumes that you use the following PyTorch/XLA modules:
>
> ```
> import torch_xla.core.xla_model as xm
> ```

```
import torch_xla.distributed.parallel_loader as pl
```

Understand the lazy mode in PyTorch/XLA

One significant difference between PyTorch/XLA and native PyTorch is that the PyTorch/XLA system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch/XLA system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.MpDeviceLoader/pl.ParallelLoader`, or when you explicitly request the value of a tensor such as by calling `loss.item()` or `print(loss)`.

Minimize the number of *compilation-and-executions* using `pl.MpDeviceLoader/pl.ParallelLoader` and `xm.step_closure`

For best performance, you should keep in mind the possible ways to initiate *compilation-and-executions* as described in Understand the lazy mode in PyTorch/XLA and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by `pl.MpDeviceLoader/pl.ParallelLoader`. The `MpDeviceLoader` is optimized for XLA and should always be used if possible for best performance. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using `xm.add_step_closure()` to avoid unnecessary compilation-and-executions.

Use AMP and `syncfree` optimizers

Training in Automatic Mixed Precision (AMP) mode significantly accelerates your training speed by leveraging the Tensor cores of NVIDIA GPUs. SageMaker Training Compiler provides `syncfree` optimizers that are optimized for XLA to improve AMP performance. Currently, the following three `syncfree` optimizers are available and should be used if possible for best performance.

```
torch_xla.amp.syncfree.SGD
torch_xla.amp.syncfree.Adam
torch_xla.amp.syncfree.AdamW
```

These `syncfree` optimizers should be paired with `torch_xla.amp.GradScaler` for gradient scaling/unscaling.

> **Tip**
>
> Starting PyTorch 1.13.1, SageMaker Training Compiler improves performance by letting PyTorch/XLA to automatically override the optimizers (such as SGD, Adam, AdamW) in `torch.optim` or `transformers.optimization` with the syncfree versions of them in `torch_xla.amp.syncfree` (such as `torch_xla.amp.syncfree.SGD`, `torch_xla.amp.syncfree.Adam`, `torch_xla.amp.syncfree.AdamW`). You don't need to change those code lines where you define optimizers in your training script.

TensorFlow

Bring your own TensorFlow model to SageMaker AI, and run the training job with SageMaker Training Compiler.

TensorFlow Models

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API.

> **Tip**
>
> For preprocessing your input dataset, ensure that you use a static input shape. Dynamic input shape can initiate recompilation of the model and might increase total training time.

Using Keras (Recommended)

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (tf.keras.Model).

For single GPU training

There's no additional change you need to make in the training script.

Without Keras

SageMaker Training Compiler does not support eager execution in TensorFlow. Accordingly, you should wrap your model and training loops with the TensorFlow function decorator (`@tf.function`) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the `@tf.function` decorator in front of every function that you use for constructing a TensorFlow model.

TensorFlow Models with Hugging Face Transformers

TensorFlow models with Hugging Face Transformers are based on TensorFlow's tf.keras.Model API. Hugging Face Transformers also provides pretrained model classes for TensorFlow to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker AI `HuggingFace` estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Run TensorFlow Training Jobs with SageMaker Training Compiler.

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API, such as the TensorFlow transformer models.

> **Tip**
>
> When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the *Hugging Face Transformers documentation*.

Topics

- Using Keras
- Without Keras

Using Keras

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (tf.keras.Model). As noted in the Quick tour page in the *Hugging Face Transformers documentation*, you can use the models as regular TensorFlow Keras models.

For single GPU training

There's no additional change you need to make in the training script.

For distributed training

SageMaker Training Compiler acceleration works transparently for multi-GPU workloads when the model is constructed and trained using Keras APIs within the scope of `tf.distribute.Strategy.scope()` call.

1. Choose the right distributed training strategy.

   a. For single-node multi-GPU, use `tf.distribute.MirroredStrategy` to set the strategy.

   ```
   strategy = tf.distribute.MirroredStrategy()
   ```

   b. For multi-node multi-GPU, add the following code to properly set the TensorFlow distributed training configuration before creating the strategy.

   ```
   def set_sm_dist_config():
       DEFAULT_PORT = '8890'
       DEFAULT_CONFIG_FILE = '/opt/ml/input/config/resourceconfig.json'
       with open(DEFAULT_CONFIG_FILE) as f:
           config = json.loads(f.read())
           current_host = config['current_host']
       tf_config = {
           'cluster': {
               'worker': []
           },
           'task': {'type': 'worker', 'index': -1}
       }
       for i, host in enumerate(config['hosts']):
           tf_config['cluster']['worker'].append("%s:%s" % (host, DEFAULT_PORT))
           if current_host == host:
               tf_config['task']['index'] = i
       os.environ['TF_CONFIG'] = json.dumps(tf_config)
   ```

```
set_sm_dist_config()
```

Use `tf.distribute.MultiWorkerMirroredStrategy` to set the strategy.

```
strategy = tf.distribute.MultiWorkerMirroredStrategy()
```

2. Using the strategy of your choice, wrap the model.

```
with strategy.scope():
    # create a model and do fit
```

Without Keras

If you want to bring custom models with custom training loops using TensorFlow without Keras, you should wrap the model and the training loop with the TensorFlow function decorator (`@tf.function`) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the `@tf.function` decorator in front of every function that you use for constructing a TensorFlow model.

For distributed training

In addition to the changes needed for Using Keras for distributed training, you need to ensure that functions to be run on each GPU are annotated with `@tf.function`, while cross-GPU communication functions are not annotated. An example training code should look like the following:

```
@tf.function()
def compiled_step(inputs, outputs):
    with tf.GradientTape() as tape:
        pred=model(inputs, training=True)
        total_loss=loss_object(outputs, pred)/args.batch_size
    gradients=tape.gradient(total_loss, model.trainable_variables)
```

```
    return total_loss, pred, gradients

def train_step(inputs, outputs):
    total_loss, pred, gradients=compiled_step(inputs, outputs)
    if args.weight_decay > 0.:
        gradients=[g+v*args.weight_decay for g,v in zip(gradients,
 model.trainable_variables)]

    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    train_loss.update_state(total_loss)
    train_accuracy.update_state(outputs, pred)

@tf.function()
def train_step_dist(inputs, outputs):
    strategy.run(train_step, args= (inputs, outputs))
```

Note that this instruction can be used for both single-node multi-GPU and multi-node multi-GPU.

Enable SageMaker Training Compiler

Important

Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

SageMaker Training Compiler is built into the SageMaker Python SDK and AWS Deep Learning Containers so that you don't need to change your workflows to enable Training Compiler. Choose one of the following topics that matches with your use case.

Topics

- Run PyTorch Training Jobs with SageMaker Training Compiler
- Run TensorFlow Training Jobs with SageMaker Training Compiler

Run PyTorch Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker AI interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio Classic, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics

- Using the SageMaker Python SDK
- Using the SageMaker AI CreateTrainingJob API Operation

Using the SageMaker Python SDK

SageMaker Training Compiler for PyTorch is available through the SageMaker AI `PyTorch` and `HuggingFace` framework estimator classes. To turn on SageMaker Training Compiler, add the `compiler_config` parameter to the SageMaker AI estimators. Import the `TrainingCompilerConfig` class and pass an instance of it to the `compiler_config` parameter. The following code examples show the structure of SageMaker AI estimator classes with SageMaker Training Compiler turned on.

> **Tip**
>
> To get started with prebuilt models provided by PyTorch or Transformers, try using the batch sizes provided in the reference table at Tested Models.

> **Note**
>
> The native PyTorch support is available in the SageMaker Python SDK v2.121.0 and later. Make sure that you update the SageMaker Python SDK accordingly.

> **Note**
>
> Starting PyTorch v1.12.0, SageMaker Training Compiler containers for PyTorch are available. Note that the SageMaker Training Compiler containers for PyTorch are not prepackaged with Hugging Face Transformers. If you need to install the library in the container, make sure that you add the `requirements.txt` file under the source directory when submitting a training job.

For PyTorch v1.11.0 and before, use the previous versions of the SageMaker Training Compiler containers for Hugging Face and PyTorch.

For a complete list of framework versions and corresponding container information, see the section called "Supported Frameworks".

For information that fits your use case, see one of the following options.

For single GPU training

PyTorch v1.12.0 and later

To compile and train a PyTorch model, configure a SageMaker AI PyTorch estimator with SageMaker Training Compiler as shown in the following code example.

Note

This native PyTorch support is available in the SageMaker AI Python SDK v2.120.0 and later. Make sure that you update the SageMaker AI Python SDK.

```
from sagemaker.pytorch import PyTorch, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_estimator=PyTorch(
    entry_point='train.py',
```

```
    source_dir='path-to-requirements-file', # Optional. Add this if need to install
 additional packages.
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='1.13.1',
    py_version='py3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_estimator.fit()
```

Hugging Face Transformers with PyTorch v1.11.0 and before

To compile and train a transformer model with PyTorch, configure a SageMaker AI Hugging Face estimator with SageMaker Training Compiler as shown in the following code example.

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.21.1',
    pytorch_version='1.11.0',
```

```
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

To prepare your training script, see the following pages.

- For single GPU training of a PyTorch model using Hugging Face Transformers' Trainer API
- For single GPU training of a PyTorch model without Hugging Face Transformers' Trainer API

To find end-to-end examples, see the following notebooks:

- Compile and Train a Hugging Face Transformers Trainer Model for Question and Answering with the SQuAD dataset
- Compile and Train a Hugging Face Transformer BERT Model with the SST Dataset using SageMaker Training Compiler
- Compile and Train a Binary Classification Trainer Model with the SST2 Dataset for Single-Node Single-GPU Training

For distributed training

PyTorch v1.12

For PyTorch v1.12, you can run distributed training with SageMaker Training Compiler by adding the `pytorch_xla` option specified to the `distribution` parameter of the SageMaker AI PyTorch estimator class.

> **Note**
>
> This native PyTorch support is available in the SageMaker AI Python SDK v2.121.0 and later. Make sure that you update the SageMaker AI Python SDK.

```
from sagemaker.pytorch import PyTorch, TrainingCompilerConfig
```

```
# choose an instance type, specify the number of instances you want to use,
# and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/
batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_estimator=PyTorch(
    entry_point='your_training_script.py',
    source_dir='path-to-requirements-file', # Optional. Add this if need to install
 additional packages.
    instance_count=instance_count,
    instance_type=instance_type,
    framework_version='1.13.1',
    py_version='py3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    distribution ={'pytorchxla' : { 'enabled': True }},
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_estimator.fit()
```

Tip

To prepare your training script, see PyTorch

Transformers v4.21 with PyTorch v1.11

For PyTorch v1.11 and later, SageMaker Training Compiler is available for distributed training with the `pytorch_xla` option specified to the `distribution` parameter.

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use,
# and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/
batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='your_training_script.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.21.1',
    pytorch_version='1.11.0',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
```

```
    distribution ={'pytorchxla' : { 'enabled': True }},
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

> **Tip**
>
> To prepare your training script, see the following pages.
>
> - For distributed training of a PyTorch model using Hugging Face Transformers' Trainer API
> - For distributed training of a PyTorch model without Hugging Face Transformers' Trainer API

Transformers v4.17 with PyTorch v1.10.2 and before

For the supported version of PyTorch v1.10.2 and before, SageMaker Training Compiler requires an alternate mechanism for launching a distributed training job. To run distributed training, SageMaker Training Compiler requires you to pass a SageMaker AI distributed training launcher script to the `entry_point` argument, and pass your training script to the `hyperparameters` argument. The following code example shows how to configure a SageMaker AI Hugging Face estimator applying the required changes.

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use,
# and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26
```

```
# update learning rate
learning_rate=learning_rate_native/
batch_size_native*batch_size*num_gpus*instance_count

training_script="your_training_script.py"

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate,
    "training_script": training_script     # Specify the file name of your training
 script.
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='distributed_training_launcher.py',    # Specify the distributed
 training launcher script.
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.17.0',
    pytorch_version='1.10.2',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

The launcher script should look like the following. It wraps your training script and configures the distributed training environment depending on the size of the training instance of your choice.

```
# distributed_training_launcher.py

#!/bin/python

import subprocess
import sys

if __name__ == "__main__":
    arguments_command = " ".join([arg for arg in sys.argv[1:]])
    """
```

```
    The following line takes care of setting up an inter-node communication
    as well as managing intra-node workers for each GPU.
    """
    subprocess.check_call("python -m torch_xla.distributed.sm_dist " +
arguments_command, shell=True)
```

Tip

To prepare your training script, see the following pages.

- For distributed training of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training of a PyTorch model without Hugging Face Transformers' Trainer API

Tip

To find end-to-end examples, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

Note

When using the SageMaker AI Hugging Face estimator, you must specify the `transformers_version`, `pytorch_version`, `hyperparameters`, and `compiler_config` parameters to enable SageMaker Training Compiler. You cannot use `image_uri` to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks.

- `entry_point` (str) – Required. Specify the file name of your training script.

> **Note**
>
> To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, specify the file name of a launcher script to this parameter. The launcher script should be prepared to wrap your training script and configure the distributed training environment. For more information, see the following example notebooks:
>
> - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
> - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- `source_dir` (str) – Optional. Add this if need to install additional packages. To install packages, you need to prapare a `requirements.txt` file under this directory.
- `instance_count` (int) – Required. Specify the number of instances.
- `instance_type` (str) – Required. Specify the instance type.
- `transformers_version` (str) – Required only when using the SageMaker AI Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks.
- `framework_version` or `pytorch_version` (str) – Required. Specify the PyTorch version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks.

> **Note**
>
> When using the SageMaker AI Hugging Face estimator, you must specify both `transformers_version` and `pytorch_version`.

- `hyperparameters` (dict) – Optional. Specify hyperparameters for the training job, such as `n_gpus`, `batch_size`, and `learning_rate`. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called “Tested Models” and SageMaker Training Compiler Example Notebooks and Blogs.

> **Note**
>
> To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, you need to add an additional parameter, `"training_script"`, to specify your training script, as shown in the preceding code example.

- `compiler_config` (TrainingCompilerConfig object) – Required to activate SageMaker Training Compiler. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the `TrainingCompilerConfig` class.
  - `enabled` (bool) – Optional. Specify `True` or `False` to turn on or turn off SageMaker Training Compiler. The default value is `True`.
  - `debug` (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to `True`. However, the additional logging might add overhead and slow down the compiled training job. The default value is `False`.
- `distribution` (dict) – Optional. To run a distributed training job with SageMaker Training Compiler, add `distribution = { 'pytorchxla' : { 'enabled': True }}`.

> **Warning**
>
> If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called "Considerations". To turn the Debugger functionalities off, add the following two arguments to the estimator:
>
> ```
> disable_profiler=True,
> debugger_hook_config=False
> ```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With `TrainingCompilerConfig(debug=False)`

```
Found configuration for Training Compiler
```

```
Configuring SM Training Compiler...
```

- With `TrainingCompilerConfig(debug=True)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
Training Compiler set to debug mode
```

Using the SageMaker AI `CreateTrainingJob` API Operation

SageMaker Training Compiler configuration options must be specified through the `AlgorithmSpecification` and `HyperParameters` field in the request syntax for the [`CreateTrainingJob` API operation](#).

```
"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false",
    "sagemaker_pytorch_xla_multi_worker_enabled": "false"    // set to "true" for
 distributed training
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see [Supported Frameworks](#).

Run TensorFlow Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker AI interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio Classic, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics

Using the SageMaker Python SDK

To turn on SageMaker Training Compiler, add the `compiler_config` parameter to the SageMaker AI TensorFlow or Hugging Face estimator. Import the `TrainingCompilerConfig` class and pass an instance of it to the `compiler_config` parameter. The following code examples show the structure of the SageMaker AI estimator classes with SageMaker Training Compiler turned on.

> **Tip**
>
> To get started with prebuilt models provided by the TensorFlow and Transformers libraries, try using the batch sizes provided in the reference table at Tested Models.

> **Note**
>
> SageMaker Training Compiler for TensorFlow is available through the SageMaker AI TensorFlow and Hugging Face framework estimators.

For information that fits your use case, see one of the following options.

For single GPU training

TensorFlow

```
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
```

```
}

tensorflow_estimator=TensorFlow(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='2.9.1',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_estimator.fit()
```

To prepare your training script, see the following pages.

- For single GPU training of a model constructed using TensorFlow Keras (`tf.keras.*`).
- For single GPU training of a model constructed using TensorFlow modules (`tf.*` excluding the TensorFlow Keras modules).

Hugging Face Estimator with TensorFlow

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
```

```
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.21.1',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_huggingface_estimator.fit()
```

To prepare your training script, see the following pages.

- For single GPU training of a TensorFlow Keras model with Hugging Face Transformers
- For single GPU training of a TensorFlow model with Hugging Face Transformers

For distributed training

Hugging Face Estimator with TensorFlow

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use,
# and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/
batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
```

```
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.21.1',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_huggingface_estimator.fit()
```

Tip

To prepare your training script, see the following pages.

- For distributed training of a TensorFlow Keras model with Hugging Face Transformers
- For distributed training of a TensorFlow model with Hugging Face Transformers

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

Note

When using the SageMaker AI Hugging Face estimator, you must specify the `transformers_version`, `tensorflow_version`, `hyperparameters`, and `compiler_config` parameters to enable SageMaker Training Compiler. You cannot use `image_uri` to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks.

- `entry_point` (str) – Required. Specify the file name of your training script.

- `instance_count` (int) – Required. Specify the number of instances.
- `instance_type` (str) – Required. Specify the instance type.
- `transformers_version` (str) – Required only when using the SageMaker AI Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks.
- `framework_version` or `tensorflow_version` (str) – Required. Specify the TensorFlow version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks.

> **Note**
>
> When using the SageMaker AI TensorFlow estimator, you must specify `framework_version`.
> When using the SageMaker AI Hugging Face estimator, you must specify both `transformers_version` and `tensorflow_version`.

- `hyperparameters` (dict) – Optional. Specify hyperparameters for the training job, such as `n_gpus`, `batch_size`, and `learning_rate`. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called "Tested Models" and SageMaker Training Compiler Example Notebooks and Blogs.
- `compiler_config` (TrainingCompilerConfig object) – Required. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the `TrainingCompilerConfig` class.
  - `enabled` (bool) – Optional. Specify `True` or `False` to turn on or turn off SageMaker Training Compiler. The default value is `True`.
  - `debug` (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to `True`. However, the additional logging might add overhead and slow down the compiled training job. The default value is `False`.

> **Warning**
>
> If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information,

see the section called "Considerations". To turn the Debugger functionalities off, add the following two arguments to the estimator:

```
disable_profiler=True,
debugger_hook_config=False
```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With `TrainingCompilerConfig(debug=False)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
```

- With `TrainingCompilerConfig(debug=True)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
Training Compiler set to debug mode
```

Using the SageMaker AI Python SDK and Extending SageMaker AI Framework Deep Learning Containers

AWS Deep Learning Containers (DLC) for TensorFlow use adapted versions of TensorFlow that include changes on top of the open-source TensorFlow framework. The SageMaker AI Framework Deep Learning Containers are optimized for the underlying AWS infrastructure and Amazon SageMaker AI. With the advantage of using the DLCs, SageMaker Training Compiler integration adds more performance improvements over the native TensorFlow. Furthermore, you can create a custom training container by extending the DLC image.

> **Note**
>
> This Docker customization feature is currently available only for TensorFlow.

To extend and customize the SageMaker AI TensorFlow DLCs for your use-case, use the following instructions.

Create a Dockerfile

Use the following Dockerfile template to extend the SageMaker AI TensorFlow DLC. You must use the SageMaker AI TensorFlow DLC image as the base image of your Docker container. To find the SageMaker AI TensorFlow DLC image URIs, see Supported Frameworks.

```
# SageMaker AI TensorFlow Deep Learning Container image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/tensorflow-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"

# This environment variable is used by the SageMaker AI container
# to determine user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# Add more code lines to customize for your use-case
...
```

For more information, see Step 2: Create and upload the Dockerfile and Python training scripts.

Consider the following pitfalls when extending SageMaker AI Framework DLCs:

- Do not explicitly uninstall or change the version of TensorFlow packages in SageMaker AI containers. Doing so causes the AWS optimized TensorFlow packages to be overwritten by open-source TensorFlow packages, which might result in performance degradation.
- Watch out for packages that have a particular TensorFlow version or flavor as a dependency. These packages might implicitly uninstall the AWS optimized TensorFlow and install open-source TensorFlow packages.

For example, there's a known issue that the tensorflow/models and tensorflow/text libraries always attempt to reinstall open source TensorFlow. If you need to install these libraries to choose a specific version for your use case, we recommend that you look into the SageMaker AI TensorFlow DLC Dockerfiles for v2.9 or later. The paths to the Dockerfiles are typically in the following format: `tensorflow/training/docker/<tensorflow-version>/py3/<cuda-version>/Dockerfile.gpu`. In the Dockerfiles, you should find the code lines to reinstall AWS managed TensorFlow binary (specified to the TF_URL environment variable) and other dependencies in order. The reinstallation section should look like the following example:

```
# tf-models does not respect existing installations of TensorFlow
```

```
# and always installs open source TensorFlow

RUN pip3 install --no-cache-dir -U \
    tf-models-official==x.y.z

RUN pip3 uninstall -y tensorflow tensorflow-gpu \
  ; pip3 install --no-cache-dir -U \
    ${TF_URL} \
    tensorflow-io==x.y.z \
    tensorflow-datasets==x.y.z
```

Build and push to ECR

To build and push your Docker container to Amazon ECR, follow the instructions in the following links:

- Step 3: Build the container
- Step 4: Test the container
- Step 5: Push the container to Amazon ECR

Run using the SageMaker Python SDK Estimator

Use the SageMaker AI TensorFlow framework estimator as usual. You must specify `image_uri` to use the new container you hosted in Amazon ECR.

```
import sagemaker, boto3
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'

byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(
    account_id, region, uri_suffix, ecr_repository + tag
)

byoc_image_uri
```

```
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/tf-custom-container-test:latest

estimator = TensorFlow(
    image_uri=image_uri,
    role=get_execution_role(),
    base_job_name='tf-custom-container-test-job',
    instance_count=1,
    instance_type='ml.p3.8xlarge'
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

# Start training
estimator.fit()
```

Enable SageMaker Training Compiler Using the SageMaker AI `CreateTrainingJob` API Operation

SageMaker Training Compiler configuration options must be specified through the `AlgorithmSpecification` and `HyperParameters` field in the request syntax for the [`CreateTrainingJob` API operation](#).

```
"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false"
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see [Supported Frameworks](#).

SageMaker Training Compiler Example Notebooks and Blogs

> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler

through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

The following blogs, case studies, and notebooks provide examples of how to implement SageMaker Training Compiler.

Example notebooks are provided in the SageMaker AI examples GitHub repository, and you can also browse them on the SageMaker AI examples website.

Blogs and Case Studies

The following blogs discuss case studies about using SageMaker Training Compiler.

- New – Introducing SageMaker Training Compiler
- Hugging Face Transformers BERT fine-tuning using Amazon SageMaker Training Compiler
- Speed up Hugging Face Training Jobs on AWS by Up to 50% with SageMaker Training Compiler

Examples Notebooks

SageMaker Training Compiler Best Practices and Considerations

Important

Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

Review the following best practices and considerations when using SageMaker Training Compiler.

Best Practices

Use the following guidelines to achieve the best results when you run training jobs with SageMaker Training Compiler.

General Best Practices

- Make sure that you use one of the Supported Instance Types and Tested Models.
- When you create a tokenizer for an NLP model using the Hugging Face Transformers library in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the *Hugging Face Transformers documentation*.
- Measure GPU memory utilization to make sure that you use the maximum batch size that can fit into the GPU memory. Amazon SageMaker Training Compiler reduces the memory footprint of your model during training, which typically allows you to fit a larger `batch_size` in the GPU memory. Using a larger `batch_size` results in a better GPU utilization and reduces the total training time.

  When you adjust the batch size, you also have to adjust the `learning_rate` appropriately. For example, if you increased the batch size by a factor of `k`, you need to adjust `learning_rate` linearly (simple multiplication by `k`) or multiply by the square root of `k`. This is to achieve the same or similar convergence behavior in the reduced training time. For reference of `batch_size` tested for popular models, see Tested Models.
- To debug the compiler-accelerated training job, enable the `debug` flag in the `compiler_config` parameter. This enables SageMaker AI to put the debugging logs into SageMaker training job logs.

  ```
  huggingface_estimator=HuggingFace(
      ...
      compiler_config=TrainingCompilerConfig(debug=True)
  )
  ```

  Note that if you enable full debugging of the training job with the compiler, this might add some overhead.

Best Practices for PyTorch

- If you bring a PyTorch model and want to checkpoint it, make sure you use PyTorch/XLA's model save function to properly checkpoint your model. For more information about the function, see `torch_xla.core.xla_model.save` in the *PyTorch on XLA Devices documentation*.

  To learn how to add the modifications to your PyTorch script, see Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API).

  For more information about the actual application of using the model save function, see Checkpoint Writing and Loading in the *Hugging Face on PyTorch/XLA TPUs: Faster and cheaper training blog*.
- To achieve the most optimal training time for distributed training, consider the following.
  - Use instances with multiple GPUs instead of using single-gpu instances. For example, a single `ml.p3dn.24xlarge` instance has faster training time compared to 8 x `ml.p3.2xlarge` instances.
  - Use instances with EFA support such as `ml.p3dn.24xlarge` and `ml.p4d.24xlarge`. These instance types have accelerated networking speed and reduce training time.
  - Tune the `preprocessing_num_workers` parameter for datasets, so that model training is not delayed by slow preprocessing.

Considerations

Consider the following when using SageMaker Training Compiler.

Performance degradation due to logging, checkpointing, and profiling

- Avoid logging, checkpointing, and profiling model tensors that lead to explicit evaluations. To understand what an explicit evaluation is, consider the following code compiling example.

  ```
  a = b+c
  e = a+d
  ```

  A compiler interprets the code as follows and reduces the memory footprint for the variable a:

  ```
  e = b+c+d
  ```

Now consider the following case in which the code is changed to add a print function for the variable a.

```
a = b+c
e = a+d
print(a)
```

The compiler makes an explicit evaluation of the variable a as follows.

```
e = b+c+d
a = b+c    # Explicit evaluation
print(a)
```

In PyTorch, for example, avoid using torch.tensor.items(), which might introduce explicit evaluations. In deep learning, such explicit evaluations can cause overhead because they break fused operations in a compilation graph of a model and lead to recomputation of the tensors.

If you still want to periodically evaluate the model during training while using SageMaker Training Compiler, we recommend logging and checkpointing at a lower frequency to reduce overhead due to explicit evaluations. For example, log every 10 epochs instead of every epoch.

- Graph compilation runs during the first few steps of training. As a result, the first few steps are expected to be exceptionally slow. However, this is a one-time compilation cost and can be amortized by training for a longer duration because compilation makes future steps much faster. The initial compilation overhead depends on the size of the model, the size of the input tensors, and the distribution of input tensor shapes.

Incorrect use of the PyTorch/XLA APIs when using PyTorch directly

PyTorch/XLA defines a set of APIs to replace some of the existing PyTorch training APIs. Failing to use them properly leads PyTorch training to fail.

- One of the most typical errors when compiling a PyTorch model is due to a wrong device type for operators and tensors. To properly compile a PyTorch model, make sure you use XLA devices (`xm.xla_device()`) instead of using CUDA or mixing CUDA devices and XLA devices.
- `mark_step()` is a barrier just for XLA. Failing to set it correctly causes a training job to stall.
- PyTorch/XLA provides additional distributed training APIs. Failing to program the APIs properly causes gradients to be collected incorrectly, which causes a training convergence failure.

To properly set up your PyTorch script and avoid the aforementioned incorrect API uses, see Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API).

SageMaker Training Compiler FAQ

Important

Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

Use the following FAQ items to find answers to commonly asked questions about SageMaker Training Compiler.

Q. How do I know SageMaker Training Compiler is working?

If you successfully launched your training job with SageMaker Training Compiler, you receive the following log messages:

- With `TrainingCompilerConfig(debug=False)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
```

- With `TrainingCompilerConfig(debug=True)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
Training Compiler set to debug mode
```

Q. Which models does SageMaker Training Compiler accelerate?

SageMaker Training Compiler supports the most popular deep learning models from the Hugging Face transformers library. With most of the operators that the compiler supports, these models can be trained faster with SageMaker Training Compiler. Compilable models include but are not limited to the following: bert-base-cased, bert-base-chinese, bert-base-uncased, distilbert-base-uncased, distilbert-base-uncased-finetuned-sst-2-english, gpt2, roberta-base, roberta-large, t5-base, and xlm-roberta-base. The compiler works with most DL operators and data structures and can accelerate many other DL models beyond those that have been tested.

Q. What happens if I enable SageMaker Training Compiler with a model that isn't tested?

For an untested model, you might need to first modify the training script to be compatible with SageMaker Training Compiler. For more information, see Bring Your Own Deep Learning Model and follow the instructions on how to prepare your training script.

Once you have updated your training script, you can start the training job. The compiler proceeds to compile the model. However, training speed may not increase and might even decrease relative to the baseline with an untested model. You might need to retune training parameters such as batch_size and learning_rate to achieve any speedup benefits.

If compilation of the untested model fails, the compiler returns an error. See SageMaker Training Compiler Troubleshooting for detailed information about the failure types and error messages.

Q. Will I always get a faster training job with SageMaker Training Compiler?

No, not necessarily. First, SageMaker Training Compiler adds some compilation overhead before the ongoing training process can be accelerated. The optimized training job must run sufficiently long to amortize and make up for this incremental compilation overhead at the beginning of the training job.

Additionally, as with any model training process, training with suboptimal parameters can increase training time. SageMaker Training Compiler can change the characteristics of the training job by, for example, changing the memory footprint of the job. Because of these differences, you might need to retune your training job parameters to speed up training. A reference table specifying the best performing parameters for training jobs with different instance types and models can be found at Tested Models.

Finally, some code in a training script might add additional overhead or disrupt the compiled computation graph and slow training. If working with a customized or untested model, see the instructions at Best Practices to Use SageMaker Training Compiler with PyTorch/XLA.

Q. Can I always use a larger batch size with SageMaker Training Compiler?

Batch size increases in most, but not all, cases. The optimizations made by SageMaker Training Compiler can change the characteristics of your training job, such as the memory footprint. Typically, a Training Compiler job occupies less memory than an uncompiled training job with the native framework, which allows for a larger batch size during training. A larger batch size, and a corresponding adjustment to the learning rate, increases training throughput and can decrease total training time.

However, there could be cases where SageMaker Training Compiler might actually increase memory footprint based on its optimization scheme. The compiler uses an analytical cost model to predict the execution schedule with the lowest cost of execution for any compute-intensive operator. This model could find an optimal schedule that increases memory use. In this case, you won't be able to increase batch sizes, but your sample throughput is still higher.

Q. Does SageMaker Training Compiler work with other SageMaker training features, such as the SageMaker AI distributed training libraries and SageMaker Debugger?

SageMaker Training Compiler is currently not compatible with SageMaker AI's distributed training libraries.

SageMaker Training Compiler is compatible with SageMaker Debugger, but Debugger might degrade computational performance by adding overhead.

Q. Does SageMaker Training Compiler support custom containers (bring your own container)?

SageMaker Training Compiler is provided through AWS Deep Learning Containers, and you can extend a subset of the containers to customize for your use-case. Containers that are extended from AWS DLCs are supported by SageMaker Training Compiler. For more information, see Supported Frameworks and Using the SageMaker AI Python SDK and Extending SageMaker AI Framework Deep Learning Containers. If you need further support, reach out to the SageMaker AI team through AWS Support or AWS Developer Forums for Amazon SageMaker AI.

SageMaker Training Compiler Troubleshooting

> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer

receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

If you run into an error, you can use the following list to try to troubleshoot your training job. If you need further support, reach out to the SageMaker AI team through AWS Support or AWS Developer Forums for Amazon SageMaker AI.

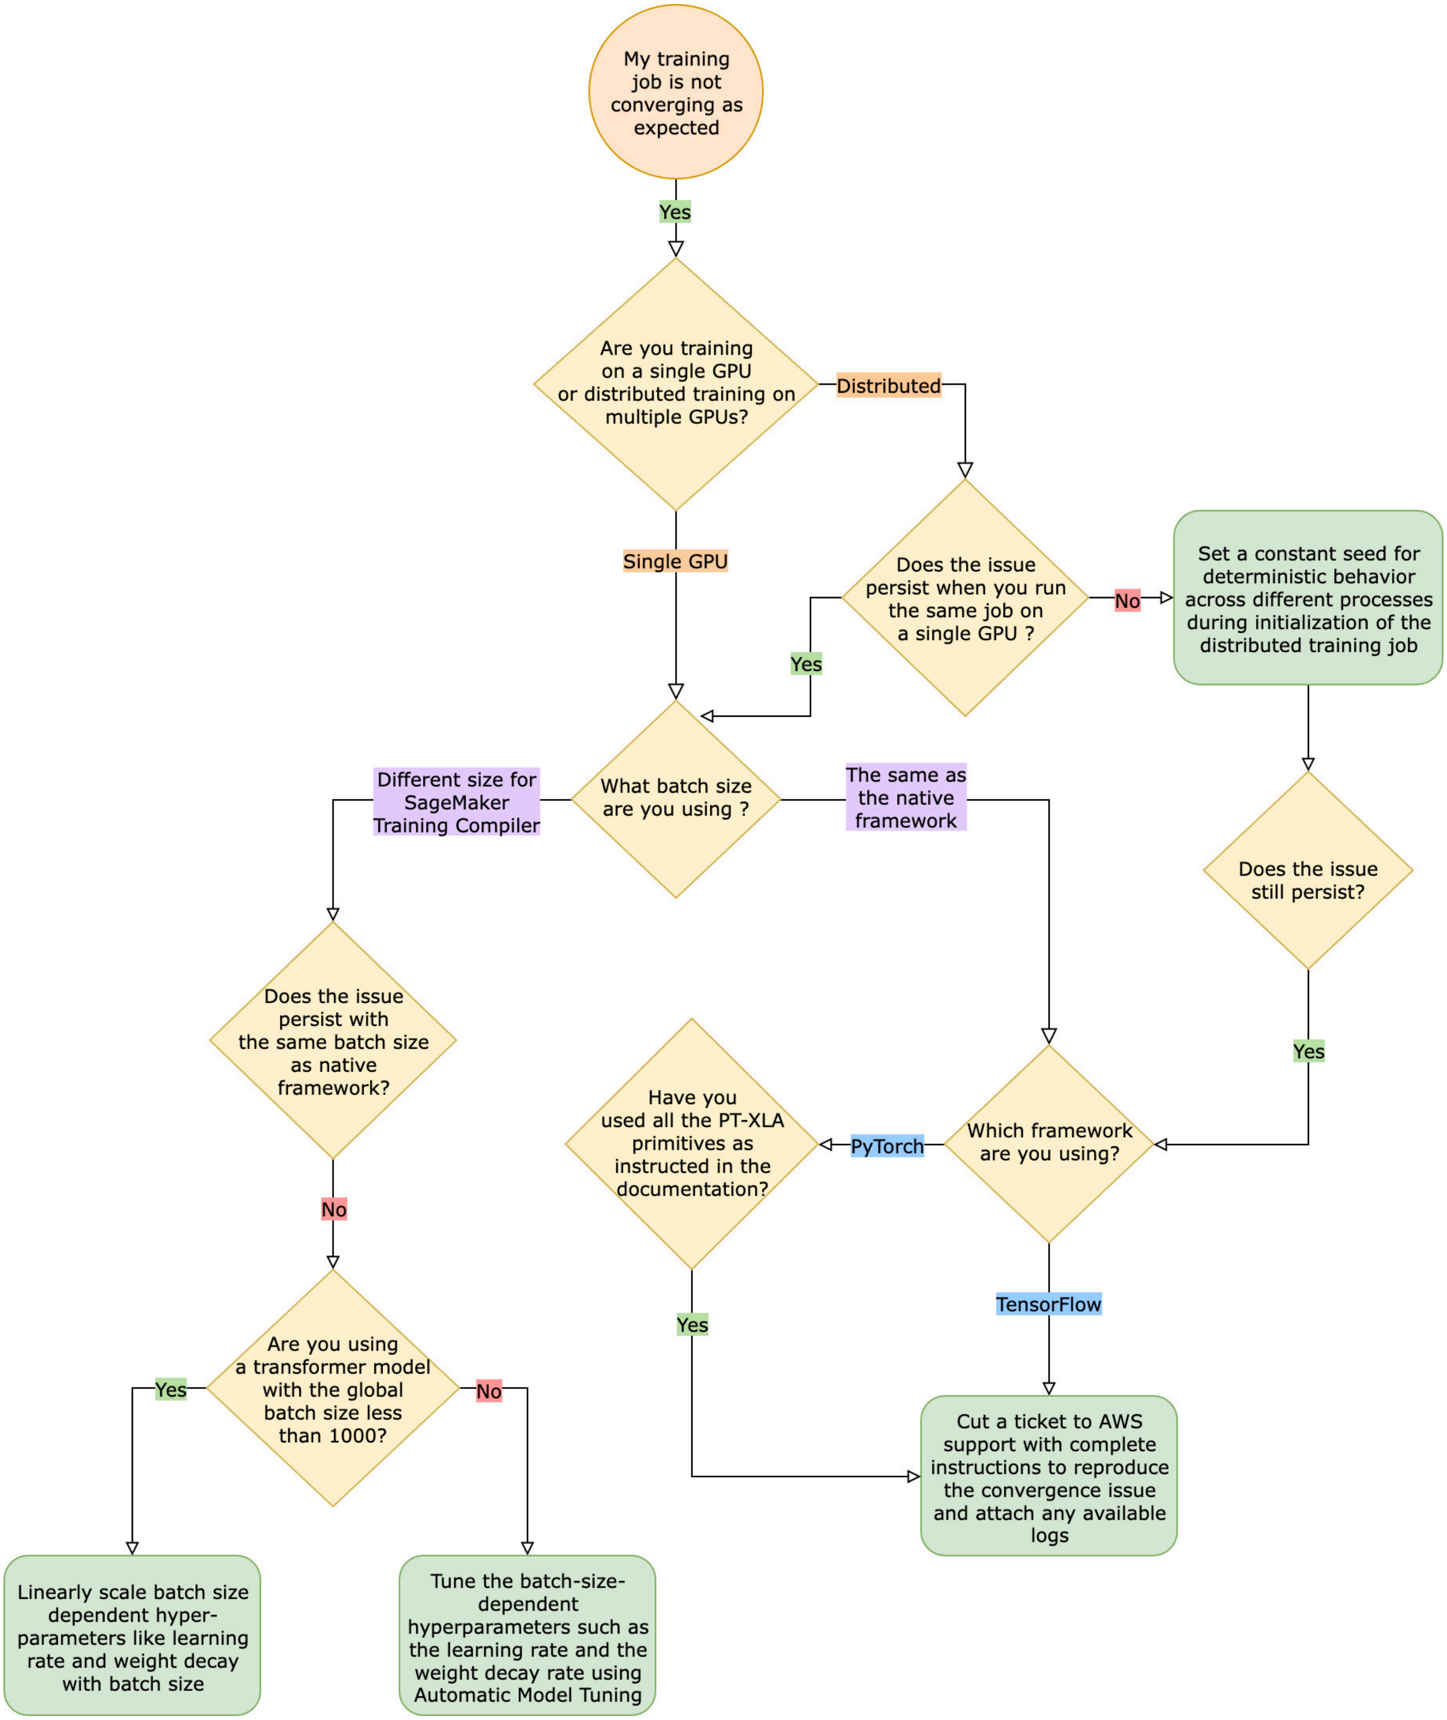
Training job is not converging as expected when compared to the native framework training job

Convergence issues range from “the model is not learning when SageMaker Training Compiler is turned on” to “the model is learning but slower than the native framework”. In this troubleshooting guide, we assume your convergence is fine without SageMaker Training Compiler (in the native framework) and consider this the baseline.

When faced with such convergence issues, the first step is to identify if the issue is limited to distributed training or stems from single-GPU training. Distributed training with SageMaker Training Compiler is an extension of single-GPU training with additional steps.

1. Set up a cluster with multiple instances or GPUs.
2. Distribute input data to all workers.
3. Synchronize the model updates from all workers.

Therefore, any convergence issue in single-GPU training propagates to distributed training with multiple workers.



My training job is not converging as expected
Yes
Are you training on a single GPU or distributed training on multiple GPUs?
Distributed
Single GPU
Does the issue persist when you run the same job on a single GPU ?
No
Yes
Set a constant seed for deterministic behavior across different processes during initialization of the distributed training job
What batch size are you using ?
Different size for SageMaker Training Compiler
The same as the native framework
Does the issue still persist?
Yes
Does the issue persist with the same batch size as native framework?
Have you used all the PT-XLA primitives as instructed in the documentation?
PyTorch
Which framework are you using?
No
TensorFlow
Yes
Are you using a transformer model with the global batch size less than 1000?
Yes
No
Cut a ticket to AWS support with complete instructions to reproduce the convergence issue and attach any available logs
Linearly scale batch size dependent hyper-parameters like learning rate and weight decay with batch size
Tune the batch-size-dependent hyperparameters such as the learning rate and the weight decay rate using Automatic Model Tuning

Convergence issues occurring in single-GPU training

If your convergence issue stems from single-GPU training, this is likely due to improper settings for hyperparameters or the `torch_xla` APIs.

Check the hyperparameters

Training with SageMaker Training Compiler leads to change in the memory footprint of a model. The compiler intelligently arbitrates between re-use and re-compute leading to a corresponding increase or decrease in memory consumption. To leverage this, it is essential to re-tune the batch size and associated hyperparameters when migrating a training job to SageMaker Training Compiler. However, incorrect hyperparameter settings often cause oscillation in training loss and possibly a slower convergence as a result. In rare cases, aggressive hyperparameters might result in the model not learning (the training loss metric doesn't decrease or returns `NaN`). To identify if the convergence issue is due to the hyperparameters, do a side-by-side test of two training jobs with and without SageMaker Training Compiler while keeping all the hyperparameters the same.

Check if the `torch_xla` APIs are properly set up for single-GPU training

If the convergence issue persists with the baseline hyperparameters, you need to check if there's any improper usage of the `torch_xla` APIs, specifically the ones for updating the model. Fundamentally, `torch_xla` continues to accumulate instructions (deferring execution) in the form of graph until it is explicitly instructed to run the accumulated graph. The `torch_xla.core.xla_model.mark_step()` function facilitates the execution of the accumulated graph. The graph execution should be synchronized using this function ***after each model update*** and ***before printing and logging any variables***. If it lacks the synchronization step, the model might use stale values from memory during prints, logs, and the subsequent forward passes, instead of using the most recent values that have to be synchronized after every iteration and model update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from the use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient un-scaling, gradient clipping, and then scaling
3. Model update
4. Synchronizing the graph execution with `mark_step()`

To find the right APIs for the operations mentioned in the list, see the guide for migrating your training script to SageMaker Training Compiler.

Consider using Automatic Model Tuning

If the convergence issue arises when re-tuning the batch size and associated hyperparameters such as the learning rate while using SageMaker Training Compiler, consider using Automatic Model Tuning to tune your hyperparameters. You can refer to the example notebook on tuning hyperparameters with SageMaker Training Compiler.

Convergence issues occurring in distributed training

If your convergence issue persists in distributed training, this is likely due to improper settings for weight initialization or the `torch_xla` APIs.

Check weight initialization across the workers

If the convergence issue arises when running a distributed training job with multiple workers, ensure there is a uniform deterministic behavior across all workers by setting a constant seed where applicable. Beware of techniques such as weight initialization, which involves randomization. Each worker might end up training a different model in the absence of a constant seed.

Check if the `torch_xla` APIs are properly set up for distributed training

If the issue still persists, this is likely due to improper use of the `torch_xla` APIs for distributed training. Make sure that you add the following in your estimator to set up a cluster for distributed training with SageMaker Training Compiler.

```
distribution={'torchxla': {'enabled': True}}
```

This should be accompanied by a function `_mp_fn(index)` in your training script, which is invoked once per worker. Without the `mp_fn(index)` function, you might end up letting each of the workers train the model independently without sharing model updates.

Next, make sure that you use the `torch_xla.distributed.parallel_loader.MpDeviceLoader` API along with the distributed data sampler, as guided in the documentation about migrating your training script to SageMaker Training Compiler, as in the following example.

```
torch.utils.data.distributed.DistributedSampler()
```

This ensures that the input data is properly distributed across all workers.

Finally, to synchronize model updates from all workers, use `torch_xla.core.xla_model._fetch_gradients` to gather gradients from all workers and `torch_xla.core.xla_model.all_reduce` to combine all the gathered gradients into a single update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient synchronization across all workers
3. Gradient un-scaling, gradient clipping, and then gradient scaling
4. Model update
5. Synchronizing the graph execution with `mark_step()`

Note that this checklist has an additional item for synchronizing all workers, compared to the checklist for single-GPU training.

Training job fails due to missing PyTorch/XLA configuration

If a training job fails with the `Missing XLA configuration` error message, it might be due to a misconfiguration in the number of GPUs per instance that you use.

XLA requires additional environment variables to compile the training job. The most common missing environment variable is `GPU_NUM_DEVICES`. For the compiler to work properly, you must set this environment variable equal to the number of GPUs per instance.

There are three approaches to set the `GPU_NUM_DEVICES` environment variable:

- **Approach 1** – Use the `environment` argument of the SageMaker AI estimator class. For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

```
# Using the SageMaker Python SDK's HuggingFace estimator

hf_estimator=HuggingFace(
    ...
    instance_type="ml.p3.8xlarge",
```

```
    hyperparameters={...},
    environment={
        ...
        "GPU_NUM_DEVICES": "4" # corresponds to number of GPUs on the specified
 instance
    },
)
```

- **Approach 2 –** Use the `hyperparameters` argument of the SageMaker AI estimator class and parse it in your training script.

  1. To specify the number of GPUs, add a key-value pair to the `hyperparameters` argument.

     For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

     ```
     # Using the SageMaker Python SDK's HuggingFace estimator

     hf_estimator=HuggingFace(
         ...
         entry_point = "train.py"
         instance_type= "ml.p3.8xlarge",
         hyperparameters = {
             ...
             "n_gpus": 4 # corresponds to number of GPUs on specified instance
         }
     )
     hf_estimator.fit()
     ```

  2. In your training script, parse the `n_gpus` hyperparameter and specify it as an input for the `GPU_NUM_DEVICES` environment variable.

     ```
     # train.py
     import os, argparse

     if __name__ == "__main__":
         parser = argparse.ArgumentParser()
         ...
         # Data, model, and output directories
         parser.add_argument("--output_data_dir", type=str,
      default=os.environ["SM_OUTPUT_DATA_DIR"])
         parser.add_argument("--model_dir", type=str,
      default=os.environ["SM_MODEL_DIR"])
         parser.add_argument("--training_dir", type=str,
      default=os.environ["SM_CHANNEL_TRAIN"])
     ```

```
    parser.add_argument("--test_dir", type=str, 
default=os.environ["SM_CHANNEL_TEST"])
    parser.add_argument("--n_gpus", type=str, default=os.environ["SM_NUM_GPUS"])

    args, _ = parser.parse_known_args()

    os.environ["GPU_NUM_DEVICES"] = args.n_gpus
```

- **Approach 3 –** Hard-code the `GPU_NUM_DEVICES` environment variable in your training script. For example, add the following to your script if you use an instance that has four GPUs.

```
# train.py

import os
os.environ["GPU_NUM_DEVICES"] = 4
```

> **Tip**
>
> To find the number of GPU devices on machine learning instances that you want to use, see [Accelerated Computing](#) in the *Amazon EC2 Instance Types page*.

SageMaker Training Compiler doesn't reduce the total training time

If the total training time does not decrease with SageMaker Training Compiler, we highly recommend you to go over the [SageMaker Training Compiler Best Practices and Considerations](#) page to check your training configuration, padding strategy for the input tensor shape, and hyperparameters.

Amazon SageMaker Training Compiler Release Notes

> **Important**
>
> Amazon Web Services (AWS) announces that there will be no new releases or versions of SageMaker Training Compiler. You can continue to utilize SageMaker Training Compiler through the existing AWS Deep Learning Containers (DLCs) for SageMaker Training. It is important to note that while the existing DLCs remain accessible, they will no longer

receive patches or updates from AWS, in accordance with the AWS Deep Learning Containers Framework Support Policy.

See the following release notes to track the latest updates for Amazon SageMaker Training Compiler.

SageMaker Training Compiler Release Notes: February 13, 2023

Currency Updates

- Added support for PyTorch v1.13.1

Bug Fixes

- Fixed a race condition issue on GPU which was causing NAN loss in some models like vision transformer (ViT) models.

Other Changes

- SageMaker Training Compiler improves performance by letting PyTorch/XLA to automatically override the optimizers (such as SGD, Adam, AdamW) in `torch.optim` or `transformers.optimization` with the syncfree versions of them in `torch_xla.amp.syncfree` (such as `torch_xla.amp.syncfree.SGD`, `torch_xla.amp.syncfree.Adam`, `torch_xla.amp.syncfree.AdamW`). You don't need to change those code lines where you define optimizers in your training script.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- PyTorch v1.13.1

```
763104351884.dkr.ecr.us-west-2.amazonaws.com/pytorch-trcomp-training:1.13.1-gpu-py39-cu117-ubuntu20.04-sagemaker
```

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: January 9, 2023

Breaking Changes

- `tf.keras.optimizers.Optimizer` points to a new optimizer in TensorFlow 2.11.0 and later. The old optimizers are moved to `tf.keras.optimizers.legacy`. You might encounter job failure due to the breaking change when you do the following.
  - Load checkpoints from an old optimizer. We recommend you to switch to use the legacy optimizers.
  - Use TensorFlow v1. We recommend you to migrate to TensorFlow v2, or switch to the legacy optimizers if you need to continue using TensorFlow v1.

  For more detailed list of breaking changes from the optimizer changes, see the official TensorFlow v2.11.0 release notes in the TensorFlow GitHub repository.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow v2.11.0

  ```
  763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.11.0-gpu-py39-cu112-ubuntu20.04-sagemaker
  ```

  To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: December 8, 2022

Bug Fixes

- Fixed the seed for PyTorch training jobs starting PyTorch v1.12 to ensure that there is no discrepancy in model initialization across different processes. See also PyTorch Reproducibility.

- Fixed the issue causing PyTorch distributed training jobs on G4dn and G5 instances to not default to communication through PCIe.

Known Issues

- Improper use of PyTorch/XLA APIs in Hugging Face's vision transformers might lead to convergence issues.

Other Changes

- When using the Hugging Face Transformers `Trainer` class, make sure that you use SyncFree optimizers by setting the `optim` argument to `adamw_torch_xla`. For more information, see Large Language Models Using the Hugging Face Transformers `Trainer` Class. See also Optimizer in the *Hugging Face Transformers documentation*.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- PyTorch v1.12.0

  ```
  763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-trcomp-training:1.12.0-gpu-py38-cu113-ubuntu20.04-sagemaker
  ```

  To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: October 4, 2022

Currency Updates

- Added support for TensorFlow v2.10.0.

Other Changes

- Added Hugging Face NLP models using the Transformers library to TensorFlow framework tests. To find the tested Transformer models, see the section called “Tested Models”.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow v2.10.0

```
763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.10.0-gpu-py39-cu112-ubuntu20.04-sagemaker
```

  To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: September 1, 2022

Currency Updates

- Added support for Hugging Face Transformers v4.21.1 with PyTorch v1.11.0.

Improvements

- Implemented a new distributed training launcher mechanism to activate SageMaker Training Compiler for Hugging Face Transformer models with PyTorch. To learn more, see Run PyTorch Training Jobs with SageMaker Training Compiler for Distributed Training.
- Integrated with EFA to improve the collective communication in distributed training.
- Added support for G5 instances for PyTorch training jobs. For more information, see the section called “Supported Frameworks, AWS Regions, Instance Types, and Tested Models”.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- HuggingFace v4.21.1 with PyTorch v1.11.0

```
763104351884.dkr.ecr.us-west-2.amazonaws.com/huggingface-pytorch-trcomp-
training:1.11.0-transformers4.21.1-gpu-py38-cu113-ubuntu20.04
```

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: June 14, 2022

New Features

- Added support for TensorFlow v2.9.1. SageMaker Training Compiler fully supports compiling TensorFlow modules (`tf.*`) and TensorFlow Keras modules (`tf.keras.*`).
- Added support for custom containers created by extending AWS Deep Learning Containers for TensorFlow. For more information, see Enable SageMaker Training Compiler Using the SageMaker Python SDK and Extending SageMaker AI Framework Deep Learning Containers.
- Added support for G5 instances for TensorFlow training jobs.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow 2.9.1

```
763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.9.1-gpu-py39-cu112-
ubuntu20.04-sagemaker
```

To find a complete list of the pre-built containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

SageMaker Training Compiler Release Notes: April 26, 2022

Improvements

- Added support for all of the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

SageMaker Training Compiler Release Notes: April 12, 2022

Currency Updates

- Added support for Hugging Face Transformers v4.17.0 with TensorFlow v2.6.3 and PyTorch v1.10.2.

SageMaker Training Compiler Release Notes: February 21, 2022

Improvements

- Completed benchmark test and confirmed training speed-ups on the `ml.g4dn` instance types. To find a complete list of tested `ml` instances, see Supported Instance Types.

SageMaker Training Compiler Release Notes: December 01, 2021

New Features

- Launched Amazon SageMaker Training Compiler at AWS re:Invent 2021.

Migration to AWS Deep Learning Containers

- Amazon SageMaker Training Compiler passed benchmark testing and is migrated to AWS Deep Learning Containers. To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models.

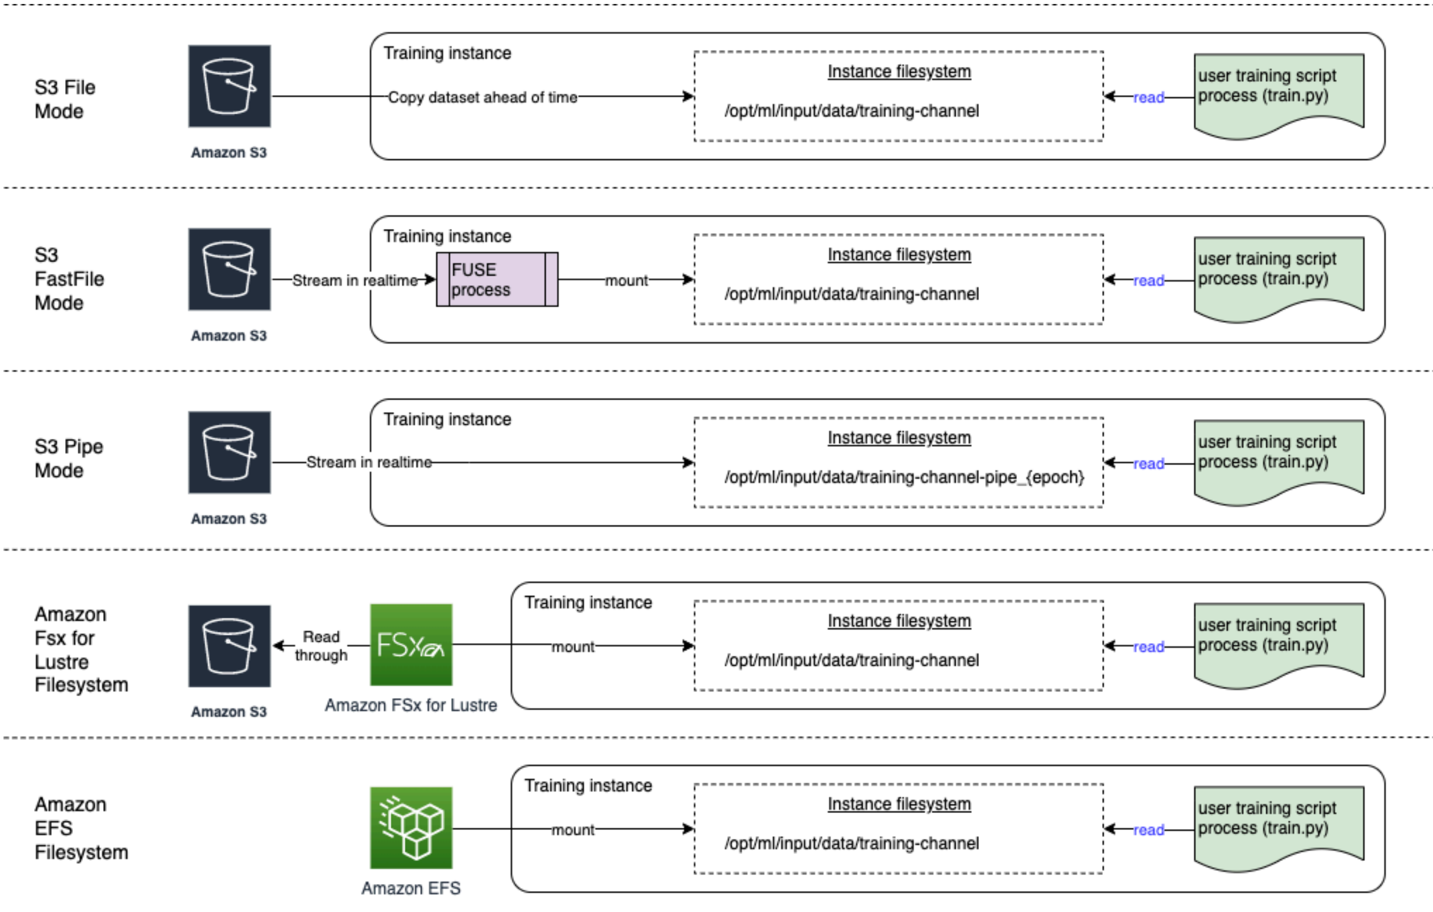
Setting up training jobs to access datasets

When creating a training job, you specify the location of training datasets in a data storage of your choice and the data input mode for the job. Amazon SageMaker AI supports Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre. You can choose one of the input modes to stream the dataset in real time or download the whole dataset at the start of the training job.

> **Note**
>
> Your dataset must reside in the same AWS Region as the training job.

SageMaker AI input modes and AWS cloud storage options

This section provides an overview of the file input modes supported by SageMaker for data stored in Amazon EFS and Amazon FSx for Lustre.



- *File mode* presents a file system view of the dataset to the training container. This is the default input mode if you don't explicitly specify one of the other two options. If you use file mode, SageMaker AI downloads the training data from the storage location to a local directory in the Docker container. Training starts after the full dataset has been downloaded. In file mode, the training instance must have enough storage space to fit the entire dataset. File mode download speed depends on the size of dataset, the average size of files, and the number of files. You can configure the dataset for file mode by providing either an Amazon S3 prefix, manifest file, or augmented manifest file. You should use an S3 prefix when all your dataset files are located within a common S3 prefix. File mode is compatible with [SageMaker AI local mode](#) (starting a SageMaker training container interactively in seconds). For distributed training, you can shard the dataset across multiple instances with the `ShardedByS3Key` option.

- *Fast file mode* provides file system access to an Amazon S3 data source while leveraging the performance advantage of pipe mode. At the start of training, fast file mode identifies the data files but does not download them. Training can start without waiting for the entire dataset to download. This means that the training startup takes less time when there are fewer files in the Amazon S3 prefix provided.

  In contrast to pipe mode, fast file mode works with random access to the data. However, it works best when data is read sequentially. Fast file mode doesn't support augmented manifest files.

  Fast file mode exposes S3 objects using a POSIX-compliant file system interface, as if the files are available on the local disk of your training instance. It streams S3 content on demand as your training script consumes data. This means that your dataset no longer needs to fit into the training instance storage space as a whole, and you don't need to wait for the dataset to be downloaded to the training instance before training starts. Fast file currently supports S3 prefixes only (it does not support manifest and augmented manifest). Fast file mode is compatible with SageMaker AI local mode.

  > **Note**
  >
  > Using Fast File mode might lead to increased CloudTrail costs due to additional logging of:
  >
  > - Amazon S3 data events (if enabled in CloudTrail).
  > - AWS KMS decryption events when accessing Amazon S3 objects encrypted with AWS KMS keys.
  > - Management events related to AWS KMS operations.
  >
  > Review your CloudTrail configuration and monitoring costs if you have CloudTrail logging enabled for these event types.

- *Pipe mode* streams data directly from an Amazon S3 data source. Streaming can provide faster start times and better throughput than file mode.

  When you stream the data directly, you can reduce the size of the Amazon EBS volumes used by the training instance. Pipe mode needs only enough disk space to store the final model artifacts.

  It is another streaming mode that is largely replaced by the newer and simpler-to-use fast file mode. In pipe mode, data is pre-fetched from Amazon S3 at high concurrency and throughput, and streamed into a named pipe, which also known as a First-In-First-Out (FIFO) pipe for its behavior. Each pipe may only be read by a single process. A SageMaker AI specific extension to TensorFlow conveniently integrates Pipe mode into the native TensorFlow data loader for streaming text, TFRecords, or RecordIO file formats. Pipe mode also supports managed sharding and shuffling of data.

- *Amazon S3 Express One Zone* is a high-performance, single Availability Zone storage class that can deliver consistent, single-digit millisecond data access for the most latency-sensitive applications including SageMaker model training. Amazon S3 Express One Zone allows customers to collocate their object storage and compute resources in a single AWS Availability Zone, optimizing both compute performance and costs with increased data processing speed. To further increase access speed and support hundreds of thousands of requests per second, data is stored in a new bucket type, an Amazon S3 directory bucket.

  SageMaker AI model training supports high-performance Amazon S3 Express One Zone directory buckets as a data input location for file mode, fast file mode, and pipe mode. To use Amazon S3 Express One Zone, input the location of the Amazon S3 Express One Zone directory bucket instead of an Amazon S3 bucket. Provide the ARN for the IAM role with the required access control and permissions policy. Refer to AmazonSageMakerFullAccesspolicy for details. You can only encrypt your SageMaker AI output data in directory buckets with server-side encryption with Amazon S3 managed keys (SSE-S3). Server-side encryption with AWS KMS keys (SSE-KMS) is not currently supported for storing SageMaker AI output data in directory buckets. For more information, see Amazon S3 Express One Zone.

- Amazon FSx for Lustre – FSx for Lustre can scale to hundreds of gigabytes of throughput and millions of IOPS with low-latency file retrieval. When starting a training job, SageMaker AI mounts the FSx for Lustre file system to the training instance file system, then starts your training script. Mounting itself is a relatively fast operation that doesn't depend on the size of the dataset stored in FSx for Lustre.

  To access FSx for Lustre, your training job must connect to an Amazon Virtual Private Cloud (VPC), which requires DevOps setup and involvement. To avoid data transfer costs, the file system uses a single Availability Zone, and you need to specify a VPC subnet which maps to this Availability Zone ID when running the training job.

- Amazon EFS – To use Amazon EFS as a data source, the data must already reside in Amazon EFS prior to training. SageMaker AI mounts the specified Amazon EFS file system to the training instance, then starts your training script. Your training job must connect to a VPC to access Amazon EFS.

> **Tip**
>
> To learn more about how to specify your VPC configuration to SageMaker AI estimators, see Use File Systems as Training Inputs in the *SageMaker AI Python SDK documentation*.

Configure data input mode using the SageMaker Python SDK

SageMaker Python SDK provides the generic Estimator class and its variations for ML frameworks for launching training jobs. You can specify one of the data input modes while configuring the SageMaker AI `Estimator` class or the `Estimator.fit` method. The following code templates show the two ways to specify input modes.

To specify the input mode using the Estimator class

```
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://amzn-s3-demo-bucket/checkpoint-destination/',
    output_path='s3://amzn-s3-demo-bucket/output-path/',
    base_job_name='job-name',
    input_mode='File'  # Available options: File | Pipe | FastFile
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(s3_data="s3://amzn-s3-demo-bucket/my-data/train")
)
```

For more information, see the sagemaker.estimator.Estimator class in the *SageMaker Python SDK documentation*.

To specify the input mode through the `estimator.fit()` method

```
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
```

```
    checkpoint_s3_uri='s3://amzn-s3-demo-bucket/checkpoint-destination/',
    output_path='s3://amzn-s3-demo-bucket/output-path/',
    base_job_name='job-name',
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(
        s3_data="s3://amzn-s3-demo-bucket/my-data/train",
        input_mode='File'  # Available options: File | Pipe | FastFile
    )
)
```

For more information, see the sagemaker.estimator.Estimator.fit class method and the sagemaker.inputs.TrainingInput class in the *SageMaker Python SDK documentation*.

Tip

To learn more about how to configure Amazon FSx for Lustre or Amazon EFS with your VPC configuration using the SageMaker Python SDK estimators, see Use File Systems as Training Inputs in the *SageMaker AI Python SDK documentation*.

Tip

The data input mode integrations with Amazon S3, Amazon EFS, and FSx for Lustre are recommended ways to optimally configure data source for the best practices. You can strategically improve data loading performance using the SageMaker AI managed storage options and input modes, but it's not strictly constrained. You can write your own data reading logic directly in your training container. For example, you can set to read from a different data source, write your own S3 data loader class, or use third-party frameworks' data loading functions within your training script. However, you must make sure that you specify the right paths that SageMaker AI can recognize.

> **Tip**
>
> If you use a custom training container, make sure you install the [SageMaker training toolkit] that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see [Create a container with your own algorithms and models].

For more information about how to set the data input modes using the low-level SageMaker APIs, see [How Amazon SageMaker AI Provides Training Information], the `CreateTrainingJob` API, and the `TrainingInputMode` in `AlgorithmSpecification`.

Configure data input channel to use Amazon FSx for Lustre

Learn how to use Amazon FSx for Lustre as your data source for higher throughput and faster training by reducing the time for data loading.

> **Note**
>
> When you use EFA-enabled instances such as P4d and P3dn, make sure that you set appropriate inbound and output rules in the security group. Specially, opening up these ports is necessary for SageMaker AI to access the Amazon FSx file system in the training job. To learn more, see [File System Access Control with Amazon VPC].

Sync Amazon S3 and Amazon FSx for Lustre

To link your Amazon S3 to Amazon FSx for Lustre and upload your training datasets, do the following.

1. Prepare your dataset and upload to an Amazon S3 bucket. For example, assume that the Amazon S3 paths for a train dataset and a test dataset are in the following format.

```
s3://amzn-s3-demo-bucket/data/train
s3://amzn-s3-demo-bucket/data/test
```

2. To create an FSx for Lustre file system linked with the Amazon S3 bucket with the training data, follow the steps at [Linking your file system to an Amazon S3 bucket] in the *Amazon FSx for*

Lustre User Guide. Make sure that you add an endpoint to your VPC allowing Amazon S3 access. For more information, see the section called "Create an Amazon S3 VPC Endpoint". When you specify **Data repository path**, provide the Amazon S3 bucket URI of the folder that contains your datasets. For example, based on the example S3 paths in step 1, the data repository path should be the following.

```
s3://amzn-s3-demo-bucket/data
```

3. After the FSx for Lustre file system is created, check the configuration information by running the following commands.

```
aws fsx describe-file-systems && \
aws fsx describe-data-repository-association
```

These commands return `FileSystemId`, `MountName`, `FileSystemPath`, and `DataRepositoryPath`. For example, the outputs should look like the following.

```
# Output of aws fsx describe-file-systems
"FileSystemId": "fs-0123456789abcdef0"
"MountName": "1234abcd"

# Output of aws fsx describe-data-repository-association
"FileSystemPath": "/ns1",
"DataRepositoryPath": "s3://amzn-s3-demo-bucket/data/"
```

After the sync between Amazon S3 and Amazon FSx has completed, your datasets are saved in Amazon FSx in the following directories.

```
/ns1/train  # synced with s3://amzn-s3-demo-bucket/data/train
/ns1/test   # synced with s3://amzn-s3-demo-bucket/data/test
```

Set the Amazon FSx file system path as the data input channel for SageMaker training

The following procedures walk you through the process of setting the Amazon FSx file system as the data source for SageMaker training jobs.

Using the SageMaker Python SDK

To properly set the Amazon FSx file system as the data source, configure the SageMaker AI estimator classes and `FileSystemInput` using the following instruction.

1. Configure a FileSystemInput class object.

```
from sagemaker.inputs import FileSystemInput

train_fs = FileSystemInput(
    file_system_id="fs-0123456789abcdef0",
    file_system_type="FSxLustre",
    directory_path="/1234abcd/ns1/",
    file_system_access_mode="ro",
)
```

> **Tip**
>
> When you specify `directory_path`, make sure that you provide the Amazon FSx file system path starting with `MountName`.

2. Configure a SageMaker AI estimator with the VPC configuration used for the Amazon FSx file system.

```
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    role="your-iam-role-with-access-to-your-fsx",
    subnets=["subnet-id"],  # Should be the same as the subnet used for Amazon FSx
    security_group_ids="security-group-id"
)
```

Make sure that the IAM role for the SageMaker training job has the permissions to access and read from Amazon FSx.

3. Launch the training job by running the estimator.fit method with the Amazon FSx file system.

```
estimator.fit(train_fs)
```

To find more code examples, see [Use File Systems as Training Inputs](#) in the *SageMaker Python SDK documentation*.

Using the SageMaker AI CreateTrainingJob API

As part of the [CreateTrainingJob](#) request JSON, configure `InputDataConfig` as follows.

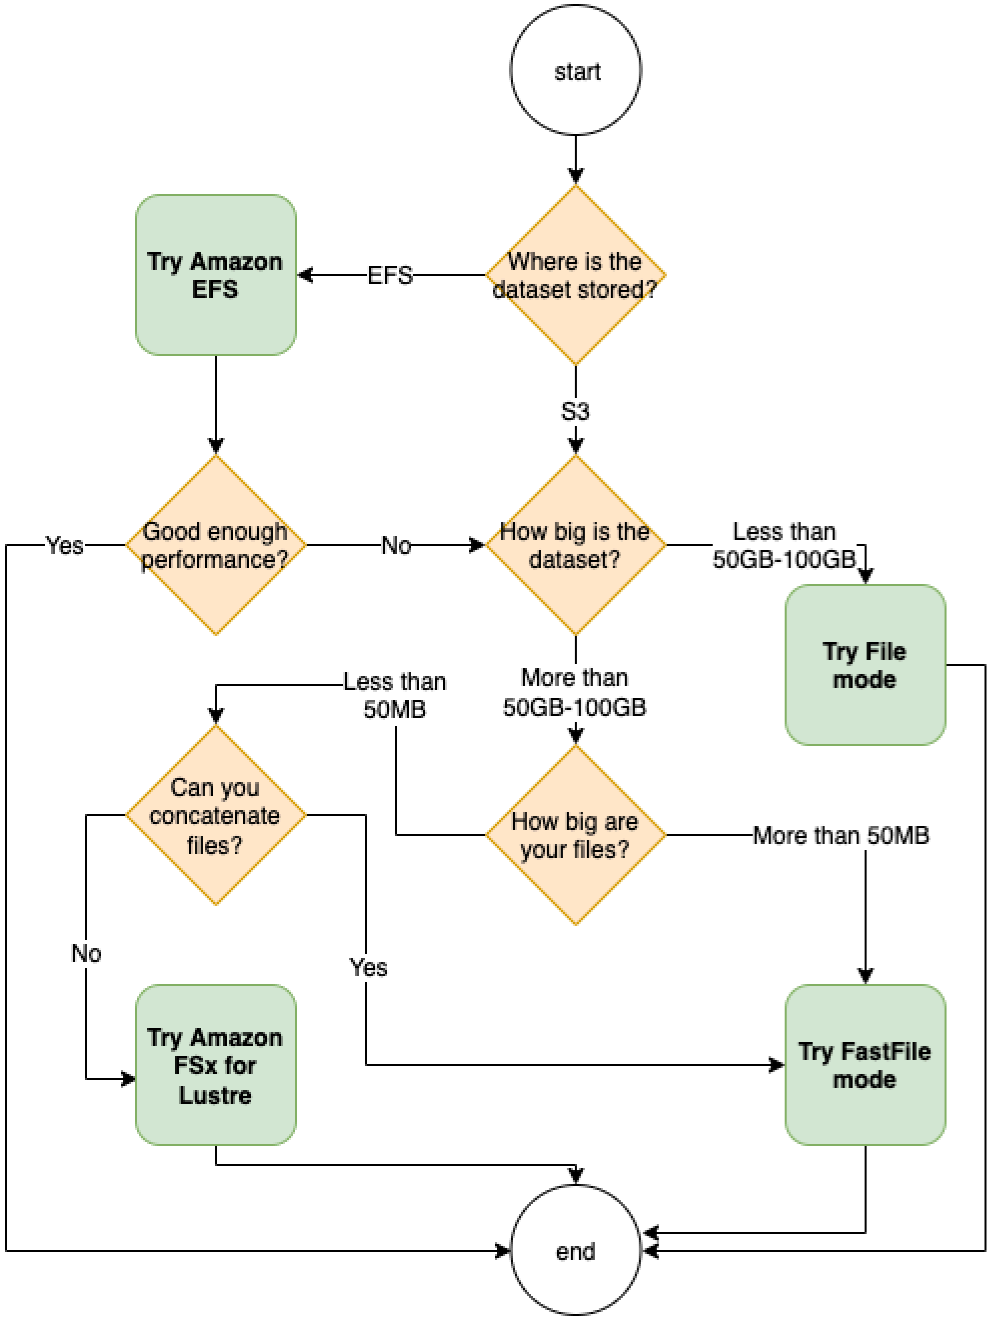
```
"InputDataConfig": [
    {
        "ChannelName": "string",
        "DataSource": {
            "FileSystemDataSource": {
                "DirectoryPath": "/1234abcd/ns1/",
                "FileSystemAccessMode": "ro",
                "FileSystemId": "fs-0123456789abcdef0",
                "FileSystemType": "FSxLustre"
            }
        }
    }
],
```

Tip

When you specify `DirectoryPath`, make sure that you provide the Amazon FSx file system path starting with `MountName`.

Choosing an input mode and a storage unit

The best data source for your training job depends on workload characteristics such as the size of the dataset, the file format, the average size of files, the training duration, a sequential or random data loader read pattern, and how fast your model can consume the training data. The following best practices provide guidelines to get started with the most suitable input mode and data storage service for your use case.



When to use Amazon EFS

If your dataset is stored in Amazon Elastic File System, you might have a preprocessing or annotations application that uses Amazon EFS for storage. You can run a training job configured with a data channel that points to the Amazon EFS file system. For more information, see Speed up training on Amazon SageMaker AI using Amazon FSx for Lustre and Amazon EFS file systems. If you cannot achieve better performance, check your optimization options following the Amazon Elastic File System performance guide or consider using different input modes or data storage.

Use file mode for small datasets

If the dataset is stored in Amazon Simple Storage Service and its overall volume is relatively small (for example, less than 50-100 GB), try using file mode. The overhead of downloading a 50 GB dataset can vary based on the total number of files. For example, it takes about 5 minutes if a dataset is chunked into 100 MB shards. Whether this startup overhead is acceptable primarily depends on the overall duration of your training job, because a longer training phase means a proportionally smaller download phase.

Serializing many small files

If your dataset size is small (less than 50-100 GB), but is made up of many small files (less than 50 MB per file), the file mode download overhead grows, because each file needs to be downloaded individually from Amazon Simple Storage Service to the training instance volume. To reduce this overhead and data traversal time in general, consider serializing groups of such small files into fewer larger file containers (such as 150 MB per file) by using file formats, such as TFRecord for TensorFlow, WebDataset for PyTorch, and RecordIO for MXNet.

When to use fast file mode

For larger datasets with larger files (more than 50 MB per file), the first option is to try fast file mode, which is more straightforward to use than FSx for Lustre because it doesn't require creating a file system, or connecting to a VPC. Fast file mode is ideal for large file containers (more than 150 MB), and might also do well with files more than 50 MB. Because fast file mode provides a POSIX interface, it supports random reads (reading non-sequential byte-ranges). However, this is not the ideal use case, and your throughput might be lower than with the sequential reads. However, if you have a relatively large and computationally intensive ML model, fast file mode might still be able to saturate the effective bandwidth of the training pipeline and not result in an IO bottleneck. You'll need to experiment and see. To switch from file mode to fast file mode (and back), just add (or remove) the `input_mode='FastFile'` parameter while defining your input channel using the SageMaker Python SDK:

```
sagemaker.inputs.TrainingInput(S3_INPUT_FOLDER,  input_mode = 'FastFile')
```

When to use Amazon FSx for Lustre

If your dataset is too large for file mode, has many small files that you can't serialize easily, or uses a random read access pattern, FSx for Lustre is a good option to consider. Its file system scales to hundreds of gigabytes per second (GB/s) of throughput and millions of IOPS, which is ideal when you have many small files. However, note that there might be the cold start issue due to lazy loading and the overhead of setting up and initializing the FSx for Lustre file system.

> **Tip**
>
> To learn more, see Choose the best data source for your Amazon SageMaker training job. This AWS machine learning blog further discusses case studies and performance benchmark of data sources and input modes.

Use attribute-based access control (ABAC) for multi-tenancy training

In a multi-tenant environment, it is crucial to ensure that each tenant's data is isolated and accessible only to authorized entities. SageMaker AI supports the use of attribute-based access control (ABAC) to achieve this isolation for training jobs. Instead of creating multiple IAM roles for each tenant, you can use the same IAM role for all tenants by configuring a session chaining configuration that uses AWS Security Token Service (AWS STS) session tags to request temporary, limited-privilege credentials for your training job to access specific tenants. For more information about session tags, see Passing session tags in AWS STS.

When creating a training job, your session chaining configuration uses AWS STS to request temporary security credentials. This request generates a session, which is tagged. Each SageMaker training job can only access a specific tenant using a single role shared by all training jobs. By implementing ABAC with session chaining, you can ensure that each training job has access only to the tenant specified by the session tag, effectively isolating and securing each tenant. The following section guides you through the steps to set up and use ABAC for multi-tenant training job isolation using the SageMaker Python SDK.

Prerequisites

To get started with ABAC for multi-tenant training job isolation, you must have the following:

- Tenants with consistent naming across locations. For example, if an input data Amazon S3 URI for a tenant is `s3://your-input-s3-bucket/example-tenant`, the Amazon FSx directory for that same tenant should be `/fsx-train/train/example-tenant` and the output data Amazon S3 URI should be `s3://your-output-s3-bucket/example-tenant`.
- A SageMaker AI job creation role. You can create a SageMaker AI job creation role using Amazon SageMaker AI Role Manager. For information, see Using the role manager.

- A SageMaker AI execution role that has `sts:AssumeRole`, and `sts:TagSession` permissions in its trust policy. For more information on SageMaker AI execution roles, see SageMaker AI Roles.

  The execution role should also have a policy that allows tenants in any attribute-based multi-tenancy architecture to read from the prefix attached to a principal tag. The following is an example policy that limits the SageMaker AI execution role to have access to the value associated with the `tenant-id` key. For more information on naming tag keys, see Rules for tagging in IAM and STS.

                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::<your-input-s3-bucket>/${aws:PrincipalTag/tenant-id}/*"
            ],
            "Effect": "Allow"
        },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::<your-output-s3-bucket>/
${aws:PrincipalTag/tenant-id}/*"
        },
        {
            "Action": "s3:ListBucket",
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

Create a training job with session tag chaining enabled

The following procedure shows you how to create a training job with session tag chaining using the SageMaker Python SDK for ABAC-enabled multi-tenancy training.

> **Note**
>
> In addition to multi-tenancy data storage, you can also use the ABAC workflow to pass session tags to your execution role for Amazon VPC, AWS Key Management Service, and any other services you allow SageMaker AI to call

Enable session tag chaining for ABAC

1. Import `boto3` and the SageMaker Python SDK. ABAC-enabled training job isolation is only available in version [2.217](https://github.com/aws/sagemaker-python-sdk/releases/tag/v2.217.0) or later of the SageMaker AI Python SDK.

```
import boto3
import sagemaker

from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput
```

2. Set up an AWS STS and SageMaker AI client to use the tenant-labeled session tags. You can change the tag value to specify a different tenant.

```
# Start an AWS STS client
sts_client = boto3.client('sts')

# Define your tenants using tags
# The session tag key must match the principal tag key in your execution role
 policy
tags = []
tag = {}
tag['Key'] = "tenant-id"
tag['Value'] = "example-tenant"
tags.append(tag)

# Have AWS STS assume your ABAC-enabled job creation role
response = sts_client.assume_role(
    RoleArn="arn:aws:iam::<account-id>:role/<your-training-job-creation-role>",
    RoleSessionName="SessionName",
    Tags=tags)
credentials = response['Credentials']

# Create a client with your job creation role (which was assumed with tags)
sagemaker_client = boto3.client(
```

```
    'sagemaker',
    aws_access_key_id=credentials['AccessKeyId'],
    aws_secret_access_key=credentials['SecretAccessKey'],
    aws_session_token=credentials['SessionToken']
)
sagemaker_session = sagemaker.Session(sagemaker_client=sagemaker_client)
```

When appending the tags "`tenant-id=example-tenant`" to the job creation role, these tags are extracted by the execution role to use the following policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::<your-input-s3-bucket>/example-tenant/*"
            ],
            "Effect": "Allow"
        },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::<your-output-s3-bucket>/example-tenant/*"
        },
        {
            "Action": "s3:ListBucket",
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

3. Define an estimator to create a training job using the SageMaker Python SDK. Set `enable_session_tag_chaining` to `True` to allow your SageMaker AI training execution role to retrieve the tags from your job creation role.

```
# Specify your training input
trainingInput = TrainingInput(
```

```
    s3_data='s3://<your-input-bucket>/example-tenant',
    distribution='ShardedByS3Key',
    s3_data_type='S3Prefix'
)

# Specify your training job execution role
execution_role_arn = "arn:aws:iam::<account-id>:role/<your-training-job-execution-
role>"

# Define your esimator with session tag chaining enabled
estimator = Estimator(
    image_uri="<your-training-image-uri>",
    role=execution_role_arn,
    instance_count=1,
    instance_type='ml.m4.xlarge',
    volume_size=20,
    max_run=3600,
    sagemaker_session=sagemaker_session,
    output_path="s3://<your-output-bucket>/example-tenant",
    enable_session_tag_chaining=True
)

estimator.fit(inputs=trainingInput, job_name="abac-demo")
```

SageMaker AI can only read tags provided in the training job request and does not add any tags to resources on your behalf.

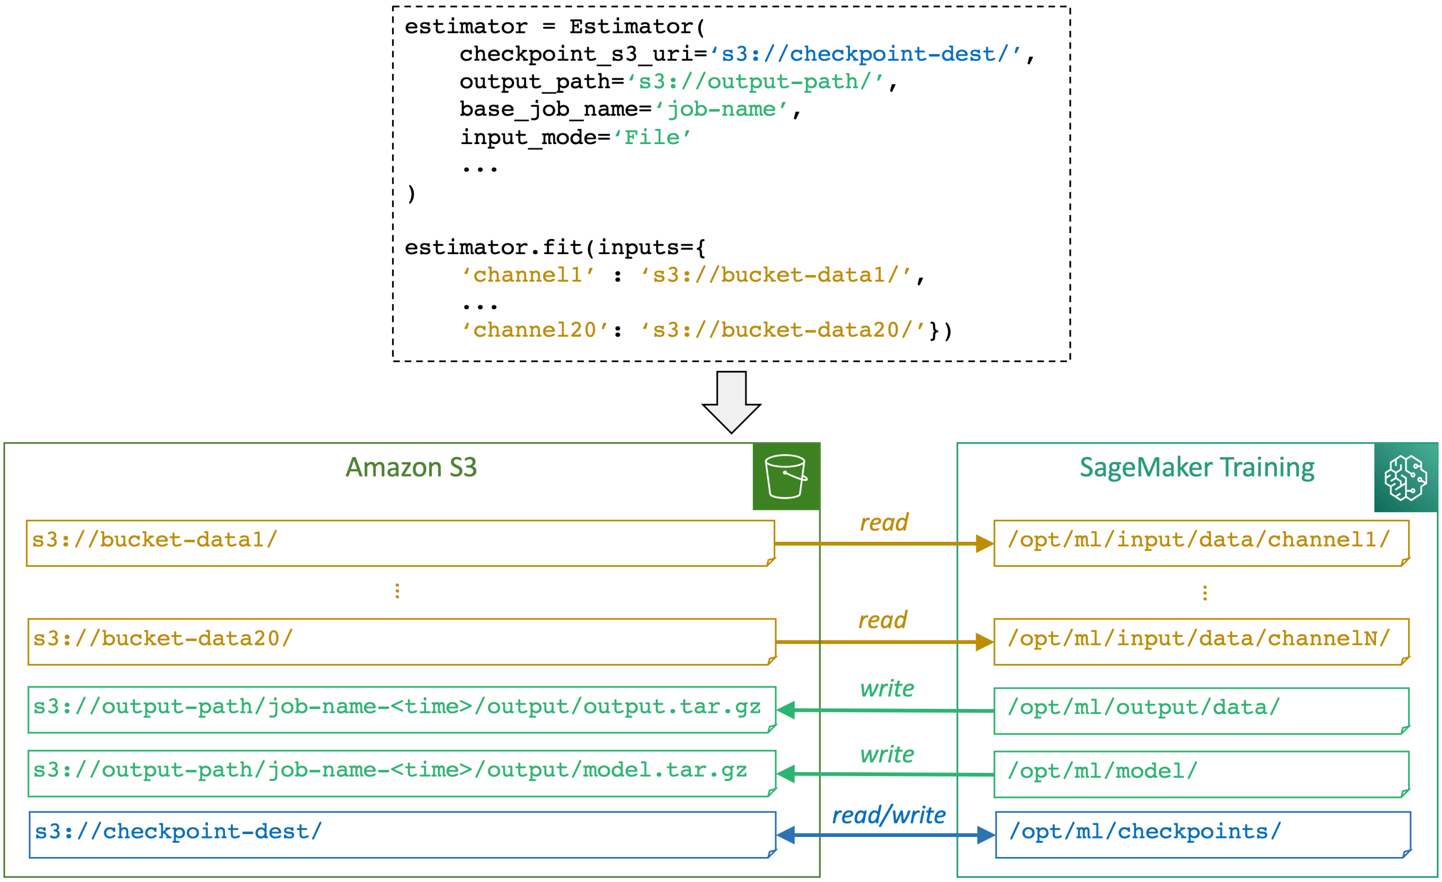
ABAC for SageMaker training is compatible with SageMaker AI managed warm pools. To use ABAC with warm pools, matching training jobs must have identical session tags. For more information, see the section called "Matching training jobs".

Mapping of training storage paths managed by Amazon SageMaker AI

This page provides a high-level summary of how the SageMaker training platform manages storage paths for training datasets, model artifacts, checkpoints, and outputs between AWS cloud storage and training jobs in SageMaker AI. Throughout this guide, you learn to identify the default paths set by the SageMaker AI platform and how the data channels can be streamlined with your data sources in Amazon Simple Storage Service (Amazon S3), FSx for Lustre, and Amazon EFS. For more information about various data channel input modes and storage options, see [Setting up training jobs to access datasets](#).

Overview of how SageMaker AI maps storage paths

The following diagram shows an example of how SageMaker AI maps input and output paths when you run a training job using the SageMaker Python SDK [Estimator](#) class.



SageMaker AI maps storage paths between a storage (such as Amazon S3, Amazon FSx, and Amazon EFS) and the SageMaker training container based on the paths and input mode specified through a SageMaker AI estimator object. More information about how SageMaker AI reads from or writes to the paths and the purpose of the paths, see [the section called "SageMaker AI environment variables and the default paths for training storage locations"](#).

You can use `OutputDataConfig` in the [CreateTrainingJob](#) API to save the results of model training to an S3 bucket. Use the [ModelArtifacts](#) API to find the S3 bucket that contains your model artifacts. See the [abalone_build_train_deploy](#) notebook for an example of output paths and how they are used in API calls.

For more information and examples of how SageMaker AI manages data source, input modes, and local paths in SageMaker training instances, see Access Training Data.

Topics

Uncompressed model output

SageMaker AI stores your model in `/opt/ml/model` and your data in `/opt/ml/output/data`. After the model and data are written to those locations, they're uploaded to your Amazon S3 bucket as compressed files by default.

You can save time on large data file compression by uploading model and data outputs to your S3 bucket as uncompressed files. To do this, create a training job in uncompressed upload mode by using either the AWS Command Line Interface (AWS CLI) or the SageMaker Python SDK.

The following code example shows how to create a training job in uncompressed upload mode when using the AWS CLI. To enable uncompressed upload mode, set `CompressionType` field in the `OutputDataConfig` API to **NONE**.

```
{
   "TrainingJobName": "uncompressed_model_upload",
   ...
   "OutputDataConfig": {
      "S3OutputPath": "s3://amzn-s3-demo-bucket/uncompressed_upload/output",
      "CompressionType": "NONE"
   },
   ...
}
```

The following code example shows you how to create a training job in uncompressed upload mode using the SageMaker Python SDK.

```
import sagemaker
from sagemaker.estimator import Estimator

estimator = Estimator(
```

```
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    disable_output_compression=True
)
```

Managing storage paths for different types of instance local storage

Consider the following when setting up storage paths for training jobs in SageMaker AI.

- If you want to store training artifacts for distributed training in the `/opt/ml/output/data` directory, you must properly append subdirectories or use unique file names for the artifacts through your model definition or training script. If the subdirectories and file names are not properly configured, all of the distributed training workers might write outputs to the same file name in the same output path in Amazon S3.
- If you use a custom training container, make sure you install the [SageMaker Training Toolkit](https://github.com/aws/sagemaker-training-toolkit) that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see [Create a container with your own algorithms and models]().
- When using an ML instance with [NVMe SSD volumes](), SageMaker AI doesn't provision Amazon EBS gp2 storage. Available storage is fixed to the NVMe-type instance's storage capacity. SageMaker AI configures storage paths for training datasets, checkpoints, model artifacts, and outputs to use the entire capacity of the instance storage. For example, ML instance families with the NVMe-type instance storage include `ml.p4d`, `ml.g4dn`, and `ml.g5`. When using an ML instance with the EBS-only storage option and without instance storage, you must define the size of EBS volume through the `volume_size` parameter in the SageMaker AI estimator class (or `VolumeSizeInGB` if you are using the `ResourceConfig` API). For example, ML instance families that use EBS volumes include `ml.c5` and `ml.p2`. To look up instance types and their instance storage types and volumes, see [Amazon EC2 Instance Types]().
- The default paths for SageMaker training jobs are mounted to Amazon EBS volumes or NVMe SSD volumes of the ML instance. When you adapt your training script to SageMaker AI, make sure that you use the default paths listed in the previous topic about [the section called "SageMaker AI environment variables and the default paths for training storage locations"](). We recommend that you use the `/tmp` directory as a scratch space for temporarily storing any large

objects during training. This means that you must not use directories that are mounted to small disk space allocated for system, such as `/user` and `/home`, to avoid out-of-space errors.

To learn more, see the AWS machine learning blog Choose the best data source for your Amazon SageMaker training job that further discusses case studies and performance benchmarks of data sources and input modes.

SageMaker AI environment variables and the default paths for training storage locations

The following table summarizes the input and output paths for training datasets, checkpoints, model artifacts, and outputs, managed by the SageMaker training platform.

Local path in SageMaker training instance	SageMaker AI environment variable	Purpose	Read from S3 during start	Read from S3 during Spot-restart	Writes to S3 during training	Writes to S3 when job is terminated
`/opt/ml/input/data/` *`channel_name`* [1]	SM_CHANNEL_*CHANNEL_NAME*	Reading training data from the input channels specified through the SageMaker AI Python SDK Estimator class or the CreateTrainingJob API operation. For more information about how to specify it in your training script using the SageMaker Python SDK, see Prepare a Training script.	Yes	Yes	No	No

Local path in SageMaker training instance	SageMaker AI environment variable	Purpose	Read from S3 during start	Read from S3 during Spot-restart	Writes to S3 during training	Writes to S3 when job is terminated
`/opt/ml/output/data` [2]	SM_OUTPUT_DIR	Saving outputs such as loss, accuracy, intermediate layers, weights, gradients, bias, and TensorBoard-compatible outputs. You can also save any arbitrary output you'd like using this path. Note that this is a different path from the one for storing the final model artifact `/opt/ml/model/` .	No	No	No	Yes
`/opt/ml/model` [3]	SM_MODEL_DIR	Storing the final model artifact. This is also the path from where the model artifact is deployed for [Real-time inference](#) in SageMaker AI Hosting.	No	No	No	Yes

Local path in SageMaker training instance	SageMaker AI environment variable	Purpose	Read from S3 during start	Read from S3 during Spot-restart	Writes to S3 during training	Writes to S3 when job is terminated
/opt/ml/checkpoints [4]	-	Saving model checkpoints (the state of model) to resume training from a certain point, and recover from unexpected or Managed Spot Training interruptions.	Yes	Yes	Yes	No
/opt/ml/code	SAGEMAKER_SUBMIT_DIRECTORY	Copying training scripts, additional libraries, and dependencies.	Yes	Yes	No	No
/tmp	-	Reading or writing to /tmp as a scratch space.	No	No	No	No

[1] channel_name is the place to specify user-defined channel names for training data inputs. Each training job can contain several data input channels. You can specify up to 20 training input channels per training job. Note that the data downloading time from the data channels is counted to the billable time. For more information about data input paths, see How Amazon SageMaker AI Provides Training Information. Also, there are three types of data input modes that SageMaker AI supports: file, FastFile, and pipe mode. To learn more about the data input modes for training in SageMaker AI, see Access Training Data.

[2] SageMaker AI compresses and writes training artifacts to TAR files (tar.gz). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker AI Processes Training Output.

[3] SageMaker AI compresses and writes the final model artifact to a TAR file (`tar.gz`). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker AI Processes Training Output.

[4] Sync with Amazon S3 during training. Write as is without compressing to TAR files. For more information, see Use Checkpoints in Amazon SageMaker AI.

Running training jobs on a heterogeneous cluster

Using the heterogeneous cluster feature of SageMaker Training, you can run a training job with multiple types of ML instances for a better resource scaling and utilization for different ML training tasks and purposes. For example, if your training job on a cluster with GPU instances suffers low GPU utilization and CPU bottleneck problems due to CPU-intensive tasks, using a heterogeneous cluster can help offload CPU-intensive tasks by adding more cost-efficient CPU instance groups, resolve such bottleneck problems, and achieve a better GPU utilization.

> **Note**
>
> This feature is available in the SageMaker Python SDK v2.98.0 and later.

> **Note**
>
> This feature is available through the SageMaker AI PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later.

See also the blog Improve price performance of your model training using Amazon SageMaker AI heterogeneous clusters.

- Run distributed training on a heterogeneous cluster in Amazon SageMaker AI
- Modify your training script to assign instance groups

Configure a training job with a heterogeneous cluster in Amazon SageMaker AI

This section provides instructions on how to run a training job using a heterogeneous cluster that consists of multiple instance types.

Note the following before you start.

- All instance groups share the same Docker image and training script. Therefore, your training script should be modified to detect which instance group it belongs to and fork execution accordingly.
- The heterogeneous cluster feature is not compatable with SageMaker AI local mode.
- The Amazon CloudWatch log streams of a heterogeneous cluster training job are not grouped by instance groups. You need to figure out from the logs which nodes are in which group.

Topics

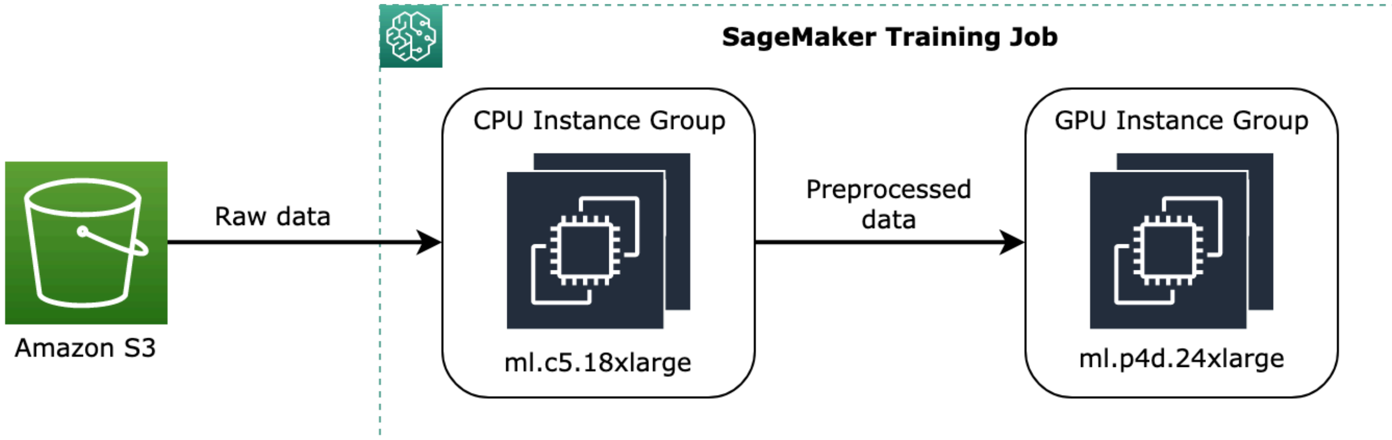
Option 1: Using the SageMaker Python SDK

Follow instructions on how to configure instance groups for a heterogeneous cluster using the SageMaker Python SDK.

1. To configure instance groups of a heterogeneous cluster for a training job, use the `sagemaker.instance_group.InstanceGroup` class. You can specify a custom name for each instance group, the instance type, and the number of instances for each instance group. For more information, see sagemaker.instance_group.InstanceGroup in the *SageMaker AI Python SDK documentation*.

> **Note**
>
> For more information about available instance types and the maximum number of instance groups that you can configure in a heterogeneous cluster, see the InstanceGroup API reference.

The following code example shows how to set up two instance groups that consists of two `ml.c5.18xlarge` CPU-only instances named `instance_group_1` and one `ml.p3dn.24xlarge` GPU instance named `instance_group_2`, as shown in the following diagram.



The preceding diagram shows a conceptual example of how pre-training processes, such as data preprocessing, can be assigned to the CPU instance group and stream the preprocessed data to the GPU instance group.

```
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 2
)
instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 1
)
```

2. Using the instance group objects, set up training input channels and assign instance groups to the channels through the `instance_group_names` argument of the [sagemaker.inputs.TrainingInput](https://sagemaker.readthedocs.io/en/stable/api/utility/inputs.html#sagemaker.inputs.TrainingInput) class. The `instance_group_names` argument accepts a list of strings of instance group names.

   The following example shows how to set two training input channels and assign the instance groups created in the example of the previous step. You can also specify Amazon S3 bucket paths to the `s3_data` argument for the instance groups to process data for your usage purposes.

```
from sagemaker.inputs import TrainingInput

training_input_channel_1 = TrainingInput(
    s3_data_type='S3Prefix', # Available Options: S3Prefix | ManifestFile |
 AugmentedManifestFile
    s3_data='s3://your-training-data-storage/folder1',
    distribution='FullyReplicated', # Available Options: FullyReplicated |
 ShardedByS3Key
    input_mode='File', # Available Options: File | Pipe | FastFile
    instance_groups=["instance_group_1"]
)

training_input_channel_2 = TrainingInput(
    s3_data_type='S3Prefix',
    s3_data='s3://your-training-data-storage/folder2',
    distribution='FullyReplicated',
    input_mode='File',
    instance_groups=["instance_group_2"]
)
```

For more information about the arguments of `TrainingInput`, see the following links.

- The sagemaker.inputs.TrainingInput class in the *SageMaker Python SDK documentation*
- The S3DataSource API in the *SageMaker AI API Reference*

3. Configure a SageMaker AI estimator with the `instance_groups` argument as shown in the following code example. The `instance_groups` argument accepts a list of `InstanceGroup` objects.

> **Note**
>
> The heterogeneous cluster feature is available through the SageMaker AI PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later. To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker AI Framework Containers in the AWS Deep Learning Container GitHub repository.

PyTorch

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z',    # 1.10.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=[instance_group_1, instance_group_2]
)
```

TensorFlow

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z', # 2.6.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=[instance_group_1, instance_group_2]
)
```

Note

The `instance_type` and `instance_count` argument pair and the `instance_groups` argument of the SageMaker AI estimator class are mutually exclusive. For homogeneous cluster training, use the `instance_type` and `instance_count` argument pair. For heterogeneous cluster training, use `instance_groups`.

Note

To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker AI Framework Containers in the AWS Deep Learning Container GitHub repository.

4. Configure the `estimator.fit` method with the training input channels configured with the instance groups and start the training job.

```
estimator.fit(
    inputs={
        'training': training_input_channel_1,
        'dummy-input-channel': training_input_channel_2
    }
)
```

Option 2: Using the low-level SageMaker APIs

If you use the AWS Command Line Interface or AWS SDK for Python (Boto3) and want to use low-level SageMaker APIs for submitting a training job request with a heterogeneous cluster, see the following API references.

- CreateTrainingJob
- ResourceConfig
- InstanceGroup
- S3DataSource

Run distributed training on a heterogeneous cluster in Amazon SageMaker AI

Through the `distribution` argument of the SageMaker AI estimator class, you can assign a specific instance group to run distributed training. For example, assume that you have the following two instance groups and want to run multi-GPU training on one of them.

```
from sagemaker.instance_group import InstanceGroup
```

```
instance_group_1 = InstanceGroup("instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup("instance_group_2", "ml.p3dn.24xlarge", 2)
```

You can set the distributed training configuration for one of the instance groups. For example, the following code examples show how to assign `training_group_2` with two `ml.p3dn.24xlarge` instances to the distributed training configuration.

> **Note**
>
> Currently, only one instance group of a heterogeneous cluster can be specified to the distribution configuration.

With MPI

PyTorch

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "mpi": {
            "enabled": True, "processes_per_host": 8
        },
        "instance_groups": [instance_group_2]
    }
)
```

TensorFlow

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "mpi": {
            "enabled": True, "processes_per_host": 8
```

```
        },
        "instance_groups": [instance_group_2]
    }
)
```

With the SageMaker AI data parallel library

PyTorch

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

TensorFlow

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

> **Note**
>
> When using the SageMaker AI data parallel library, make sure the instance group consists of the supported instance types by the library.

For more information about the SageMaker AI data parallel library, see SageMaker AI Data Parallel Training.

With the SageMaker AI model parallel library

PyTorch

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled":True,
                "parameters": {
                    ...   # SageMaker AI model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

TensorFlow

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled":True,
```

```
                "parameters": {
                    ...   # SageMaker AI model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

For more information about the SageMaker AI model parallel library, see SageMaker AI Model Parallel Training.

Modify your training script to assign instance groups

With the heterogeneous cluster configuration in the previous sections, you have prepared the SageMaker training environment and instances for your training job. To further assign the instance groups to certain training and data processing tasks, the next step is to modify your training script. By default, the training job simply makes training script replicas for all nodes regardless the size of the instance, and this might lead to performance loss.

For example, if you mix CPU instances and GPU instances in a heterogeneous cluster while passing a deep neural network training script to the `entry_point` argument of the SageMaker AI estimator, the `entry_point` script is replicated to each instance. This means that, without proper task assignments, CPU instances also run the entire script and start the training job that's designed for distributed training on GPU instances. Therefore, you must make changes in specific processing functions that you want to offload and run on the CPU instances. You can use the SageMaker AI environment variables to retrieve the information of the heterogeneous cluster and let specific processes to run accordingly.

When your training job starts, your training script reads SageMaker training environment information that includes heterogeneous cluster configuration. The configuration contains information such as the current instance groups, the current hosts in each group, and in which group the current host resides.

You can query instance group information during the initialization phase of a SageMaker AI training job in the following ways.

(Recommended) Reading instance group information with the SageMaker training toolkit

Use the environment Python module that the SageMaker training toolkit library provides. The toolkit library is preinstalled in the SageMaker framework containers for TensorFlow and PyTorch, so you don't need an additional installation step when using the prebuilt containers. This is the recommended way to retrieve the SageMaker AI environment variables with fewer code changes in your training script.

```
from sagemaker_training import environment

env = environment.Environment()
```

Environment variables related to general SageMaker training and heterogeneous clusters:

- `env.is_hetero` – Returns a Boolean result whether a heterogeneous cluster is configured or not.
- `env.current_host` – Returns the current host.
- `env.current_instance_type` – Returns the type of instance of the current host.
- `env.current_instance_group` – Returns the name of the current instance group.
- `env.current_instance_group_hosts` – Returns a list of hosts in current instance group.
- `env.instance_groups` – Returns a list of instance group names used for training.
- `env.instance_groups_dict` – Returns the entire heterogeneous cluster configuration of the training job.
- `env.distribution_instance_groups` – Returns a list of instance groups assigned to the `distribution` parameter of the SageMaker AI estimator class.
- `env.distribution_hosts` – Returns a list of hosts belonging to the instance groups assigned to the `distribution` parameter of the SageMaker AI estimator class.

For example, consider the following example of a heterogeneous cluster that consists of two instance groups.

```
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 2)
```

The output of `env.instance_groups_dict` of the example heterogeneous cluster should be similar to the following.

```
{
    "instance_group_1": {
        "hosts": [
            "algo-2"
        ],
        "instance_group_name": "instance_group_1",
        "instance_type": "ml.c5.18xlarge"
    },
    "instance_group_2": {
        "hosts": [
            "algo-3",
            "algo-1"
        ],
        "instance_group_name": "instance_group_2",
        "instance_type": "ml.p3dn.24xlarge"
    }
}
```

(Optional) Reading instance group information from the resource configuration JSON file

If you prefer to retrieve the environment variables in JSON format, you can directly use the resource configuration JSON file. The JSON file in a SageMaker training instance is located at `/opt/ml/input/config/resourceconfig.json` by default.

```
file_path = '/opt/ml/input/config/resourceconfig.json'
config = read_file_as_json(file_path)
print(json.dumps(config, indent=4, sort_keys=True))
```

Use Incremental Training in Amazon SageMaker AI

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.

- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don't need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see Train a Model with Amazon SageMaker.

You can train incrementally using the SageMaker AI console or the Amazon SageMaker Python SDK.

> **Important**
>
> Only three built-in algorithms currently support incremental training: Object Detection - MXNet, Image Classification - MXNet, and Semantic Segmentation Algorithm.

Topics

- Perform Incremental Training (Console)
- Perform Incremental Training (API)

Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code.
- The URL of the S3 bucket where you've stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker AI console, choose **Inference**, choose **Models**, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

To perform incremental training (console)

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Built-in algorithms and pretrained models in Amazon SageMaker.
6. (Optional) For **Resource configuration**, either leave the default values or increase the resource consumption to reduce computation time.

   a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.

   b. For **Instance count**, use the default, 1.

   c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.

   a. For **Channel name**, either leave the default (**`train`**) or enter a more meaningful name for the training dataset, such as **`expanded-training-dataset`**.

   b. For **InputMode**, choose **File**. For incremental training, you need to use file input mode.

   c. For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.

   d. If the expanded dataset is uncompressed, set the **Compression type** to **None**. If the expanded dataset is compressed using Gzip, set it to **Gzip**.

   e. (Optional) If you are using File input mode, leave **Content type** empty. For Pipe input mode, specify the appropriate MIME type. *Content type* is the multipurpose internet mail extension (MIME) type of the data.

f. For **Record wrapper**, if the dataset is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO formatted file, choose **None**.

g. For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose **Manifest**.

h. For **S3 location**, provide the URL to the path where you stored the expanded dataset.

i. Choose **Done**.

8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.

a. For **Input data configuration**, choose **Add channel**.

b. For **Channel name**, enter **`model`** to identify this channel as the source of the model artifacts.

c. For **InputMode**, choose **File**. Model artifacts are stored as files.

d. For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.

e. For **Compression type**, choose **None** because we are using a model for the channel.

f. Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.

g. Set **Record wrapper** to **None** because model artifacts are not stored in RecordIO format.

h. For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose **Manifest**.

i. For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name `model.tar.gz`. To find the URL for the model artifacts, in the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container** .

j. Choose **Done**.

9. For **Output data configuration**, provide the following information:

a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

b. (Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see KMS-Managed Encryption Keys.

10. (Optional) For **Tags**, add one or more tags to the training job. A *tag* is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **`Project`** as a key and a value referring to a project that is related to the training job, such as **`Home value forecasts`**.
11. Choose **Create training job**. SageMaker AI creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see Deploy the model to Amazon EC2.

Perform Incremental Training (API)

This example shows how to use SageMaker AI APIs to train a model using the SageMaker AI image classification algorithm and the Caltech 256 Image Dataset, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the incremental training sample notebook for more details on using incremental training.

Note

In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the `data_channels` variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)

sess = sagemaker.Session()

bucket=sess.default_bucket()
print(bucket)
```

```
prefix = 'ic-incr-training'
```

Get the training image for the image classification algorithm:

```
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification',
 repo_version="latest")
#Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split("/")[-1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}/{}/train/'.format(bucket, prefix)
s3validation = 's3://{}/{}/validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet
```

Define the training hyperparameters:

```
# Define hyperparameters for the estimator
hyperparams = { "num_layers": "18",
                "resize": "32",
                "num_training_samples": "50000",
```

```
                 "num_classes": "10",
                 "image_shape": "3,28,28",
                 "mini_batch_size": "128",
                 "epochs": "3",
                 "learning_rate": "0.1",
                 "lr_scheduler_step": "2,3",
                 "lr_scheduler_factor": "0.1",
                 "augmentation_type": "crop_color",
                 "optimizer": "sgd",
                 "momentum": "0.9",
                 "weight_decay": "0.0001",
                 "beta_1": "0.9",
                 "beta_2": "0.999",
                 "gamma": "0.9",
                 "eps": "1e-8",
                 "top_k": "5",
                 "checkpoint_frequency": "1",
                 "use_pretrained_model": "0",
                 "model_prefix": "" }
```

Create an estimator object and train the first model using the training and validation datasets:

```
# Fit the base estimator
s3_output_location = 's3://{}/{}/output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
                                   role,
                                   instance_count=1,
                                   instance_type='ml.p2.xlarge',
                                   volume_size=50,
                                   max_run=360000,
                                   input_mode='File',
                                   output_path=s3_output_location,
                                   sagemaker_session=sess,
                                   hyperparameters=hyperparams)

train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
                                        content_type='application/x-recordio',
 s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
 distribution='FullyReplicated',
                                             content_type='application/x-recordio',
 s3_data_type='S3Prefix')
```

```
data_channels = {'train': train_data, 'validation': validation_data}

ic.fit(inputs=data_channels, logs=True)
```

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (`ic.model_data`, in this example) for the `model_uri` input argument:

```
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
                                        role,
                                        instance_count=1,
                                        instance_type='ml.p2.xlarge',
                                        volume_size=50,
                                        max_run=360000,
                                        input_mode='File',
                                        output_path=s3_output_location,
                                        sagemaker_session=sess,
                                        hyperparameters=hyperparams,
                                        model_uri=ic.model_data) # This parameter will
 ingest the previous job's model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the `S3 output path` that you provided in `Output_path`. To deploy the model to get predictions, see [Deploy the model to Amazon EC2](#).

Managed Spot Training in Amazon SageMaker AI

Amazon SageMaker AI makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker AI manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker AI waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker AI automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model tuning, see [Automatic model tuning with SageMaker AI](#).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker AI copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker AI copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Checkpoints in Amazon SageMaker AI.

> **Note**
>
> Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker AI built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a `MaxWaitTimeInSeconds` of 3600 seconds (60 minutes).

To use managed spot training, create a training job. Set `EnableManagedSpotTraining` to `True` and specify the `MaxWaitTimeInSeconds`. `MaxWaitTimeInSeconds` must be larger than `MaxRuntimeInSeconds`. For more information about creating a training job, see DescribeTrainingJob.

You can calculate the savings from using managed spot training using the formula `(1 - (BillableTimeInSeconds / TrainingTimeInSeconds)) * 100`. For example, if `BillableTimeInSeconds` is 100 and `TrainingTimeInSeconds` is 500, this means that your training job ran for 500 seconds, but you were billed for only 100 seconds. Your savings is (1 - (100 / 500)) * 100 = 80%.

To learn how to run training jobs on Amazon SageMaker AI spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:

- Managed Spot Training with TensorFlow
- Managed Spot Training with PyTorch
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet
- Amazon SageMaker AI Managed Spot Training Examples GitHub repository

Managed Spot Training Lifecycle

You can monitor a training job using `TrainingJobStatus` and `SecondaryStatus` returned by [DescribeTrainingJob](). The list below shows how `TrainingJobStatus` and `SecondaryStatus` values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. `InProgress`: `Starting`↠ `Downloading` ↠ `Training` ↠ `Uploading`
- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. `InProgress`: `Starting` ↠ `Downloading` ↠ `Training` ↠ `Interrupted` ↠ `Starting` ↠ `Downloading` ↠ `Training` ↠ `Uploading`
- **Spot instances interrupted twice and `MaxWaitTimeInSeconds` exceeded.**
  1. `InProgress`: `Starting` ↠ `Downloading` ↠ `Training` ↠ `Interrupted` ↠ `Starting` ↠ `Downloading` ↠ `Training` ↠ `Interrupted` ↠ `Downloading` ↠ `Training`
  2. `Stopping`: `Stopping`
  3. `Stopped`: `MaxWaitTimeExceeded`
- **Spot instances were never launched.**
  1. `InProgress`: `Starting`
  2. `Stopping`: `Stopping`
  3. `Stopped`: `MaxWaitTimeExceeded`

SageMaker AI Managed Warm Pools

SageMaker AI managed warm pools let you retain and reuse provisioned infrastructure after the completion of a training job to reduce latency for repetitive workloads, such as iterative experimentation or running many jobs consecutively. Subsequent training jobs that match specified parameters run on the retained warm pool infrastructure, which speeds up start times by reducing the time spent provisioning resources.

> **Important**
>
> SageMaker AI managed warm pools are a billable resource. For more information, see [Billing]().

Topics

How it works

To use SageMaker AI managed warm pools and reduce latency between similar consecutive training jobs, create a training job that specifies a `KeepAlivePeriodInSeconds` value in its `ResourceConfig`. This value represents the duration of time in seconds to retain configured resources in a warm pool for subsequent training jobs. If you need to run several training jobs using similar configurations, you can further reduce latency and billable time by using a dedicated persistent cache directory to store and re-use your information in a different job.

Topics

Warm pool lifecycle

1. Create an initial training job with a `KeepAlivePeriodInSeconds` value greater than 0. When you run this first training job, this “cold-starts” a cluster with typical startup times.
2. When the first training job completes, the provisioned resources are kept alive in a warm pool for the period specified in the `KeepAlivePeriodInSeconds` value. As long as the cluster is healthy and the warm pool is within the specified `KeepAlivePeriodInSeconds`, then the warm pool status is `Available`.
3. The warm pool stays `Available` until it either identifies a matching training job for reuse or it exceeds the specified `KeepAlivePeriodInSeconds` and is terminated. The maximum length

of time allowed for the KeepAlivePeriodInSeconds is 3600 seconds (60 minutes). If the warm pool status is Terminated, then this is the end of the warm pool lifecycle.

4. If the warm pool identifies a second training job with matching specifications such as instance count or instance type, then the warm pool moves from the first training job to the second training job for reuse. The status of the first training job warm pool becomes Reused. This is the end of the warm pool lifecycle for the first training job.
5. The status of the second training job that reused the warm pool becomes InUse. After the second training job completes, the warm pool is Available for the KeepAlivePeriodInSeconds duration specified in the second training job. A warm pool can continue moving to subsequent matching training jobs for a maximum of 28 days.
6. If the warm pool is no longer available to reuse, the warm pool status is Terminated. Warm pools are no longer available if they are terminated by a user, for a patch update, or for exceeding the specified KeepAlivePeriodInSeconds.

For more information on warm pool status options, see WarmPoolStatus in the *Amazon SageMaker API Reference*.

Warm pool creation

If an initial training job successfully completes and has a KeepAlivePeriodInSeconds value greater than 0, this creates a warm pool. If you stop a training job after a cluster is already launched, a warm pool is still retained. If the training job fails due to an algorithm or client error, a warm pool is still retained. If the training job fails for any other reason that might compromise the health of the cluster, then the warm pool is not created.

To verify successful warm pool creation, check the warm pool status of your training job. If a warm pool successfully provisions, the warm pool status is Available. If a warm pool fails to provision, the warm pool status is Terminated.

Matching training jobs

For a warm pool to persist, it must find a matching training job within the time specified in the KeepAlivePeriodInSeconds value. The next training job is a match if the following values are identical:

- RoleArn
- ResourceConfig values:

  - `InstanceCount`
  - `InstanceType`
  - `VolumeKmsKeyId`
  - `VolumeSizeInGB`
- `VpcConfig` values:
  - `SecurityGroupIds`
  - `Subnets`
- `EnableInterContainerTrafficEncryption`
- `EnableNetworkIsolation`
- If you passed session tags for your training job with `EnableSessionTagChaining` set to `True` in the training job's `SessionChainingConfig`, then a matching training job must also set `EnableSessionTagChaining` to `True` and have identical session keys. For more information, see Use attribute-based access control (ABAC) for multi-tenancy training.

All of these values must be the same for a warm pool to move to a subsequent training job for reuse.

Maximum warm pool duration

The maximum `KeepAlivePeriodInSeconds` for a single training job is 3600 seconds (60 minutes) and the maximum length of time that a warm pool cluster can continue running consecutive training jobs is 28 days.

Each subsequent training job must also specify a `KeepAlivePeriodInSeconds` value. When the warm pool moves to the next training job, it inherits the new `KeepAlivePeriodInSeconds` value specified in that training job's `ResourceConfig`. In this way, you can keep a warm pool moving from training job to training job for a maximum of 28 days.

If no `KeepAlivePeriodInSeconds` is specified, then the warm pool spins down after the training job completes.

Using persistent cache

When you create a warm pool, SageMaker AI mounts a special directory on the volume that will persist throughout the lifecycle of the warm pool. This directory can also be used to store information that you want to re-use in another job.

Using persistent cache can reduce latency and billable time over using warm pools alone for jobs that require the following:

- multiple interactions with similar configurations
- incremental training jobs
- hyperparameter optimization

For example, you can avoid downloading the same Python dependencies on repeated runs by setting up a pip cache directory inside the persistent cache directory. You are fully responsible for managing the contents of this directory. The following are examples of types of information that you can put in your persistent cache to help reduce your latency and billable time.

- Dependencies managed by pip.
- Dependencies managed by conda.
- Checkpoint information.
- Any additional information generated during training.

The location of the persistent cache is `/opt/ml/sagemaker/warmpoolcache`. The environment variable `SAGEMAKER_MANAGED_WARMPOOL_CACHE_DIRECTORY` points to the location of the persistent cache directory.

The following code example shows you how to set up a warm pool and use persistent cache to store your pip dependencies for use in a subsequent job. The subsequent job must run within the time frame given by the parameter `keep_alive_period_in_seconds`.

```
import sagemakerfrom sagemaker import get_execution_rolefrom sagemaker.tensorflow
 import TensorFlow
# Creates a SageMaker session and gets execution role
session = sagemaker.Session()
role = get_execution_role()
# Creates an example estimator
estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='2.2',
```

```
    py_version='py37',
    job_name='my-training-job-1',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
"batch-size": 512,
        "epochs": 1,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
    },
    keep_alive_period_in_seconds=1800,
    environment={"PIP_CACHE_DIR": "/opt/ml/sagemaker/warmpoolcache/pip"}
)
```

In the previous code example, using the environment parameter exports the environment variable `PIP_CACHE_DIRECTORY` to point to the directory `/opt/ml/sagemaker/warmpoolcache/pip`. Exporting this environment variable will change where pip stores its cache to the new location. Any directory, including nested directories, that you create inside the persistent cache directory will be available for re-use during a subsequent training run. In the previous code example, a directory called `pip` is changed to be the default location to cache any dependencies installed using pip.

The persistent cache location may also be accessed from within your Python training script using the environment variable as shown in the following code example.

```
import os
import shutil
if __name__ == '__main__':
    PERSISTED_DIR = os.environ["SAGEMAKER_MANAGED_WARMPOOL_CACHE_DIRECTORY"]

    # create a file to be persisted
    open(os.path.join(PERSISTED_DIR, "test.txt"), 'a').close()
    # create a directory to be persisted
    os.mkdir(os.path.join(PERSISTED_DIR, "test_dir"))

    # Move a file to be persisted
    shutil.move("path/of/your/file.txt", PERSISTED_DIR)
```

Billing

SageMaker AI managed warm pools are a billable resource. Retrieve the warm pool status for your training job to check the billable time for your warm pools. You can check the warm pool status either through the Using the Amazon SageMaker AI console or directly through the DescribeTrainingJob API command. For more information, see WarmPoolStatus in the *Amazon SageMaker API Reference*.

> **Note**
>
> After the time specified by the parameter `KeepAlivePeriodInSeconds` has ended, both the warm pool and persistent cache will shut down, and the contents will be deleted.

Considerations

Consider the following items when using SageMaker AI managed warm pools.

- SageMaker AI managed warm pools cannot be used with heterogeneous cluster training.
- SageMaker AI managed warm pools cannot be used with spot instances.
- SageMaker AI managed warm pools are limited to a `KeepAlivePeriodInSeconds` value of 3600 seconds (60 minutes).
- If a warm pool continues to successfully match training jobs within the specified `KeepAlivePeriodInSeconds` value, the cluster can only continue running for a maximum of 28 days.

Request a warm pool quota increase

To get started, you must first request a service limit increase for SageMaker AI managed warm pools. The default resource limit for warm pools is 0.

If a training job is created with `KeepAlivePeriodInSeconds` specified, but you did not request a warm pool limit increase, then a warm pool is not retained after the completion of the training job. A warm pool is only created if your warm pool limit has sufficient resources. After a warm pool is created, the resources are released when they move to a matching training job or if the `KeepAlivePeriodInSeconds` expires (if the warm pool status is `Reused` or `Terminated`).

Request a warm pool quota increase using the AWS Service Quotas console.

Note

All warm pool instance usage counts toward your SageMaker training resource limit. Increasing your warm pool resource limit does not increase your instance limit, but allocates a subset of your resource limit to warm pool training.

1. Open the AWS Service Quotas console.
2. On the left-hand navigation panel, choose **AWS services**.
3. Search for and choose **Amazon SageMaker AI**.
4. Search for the keyword **`warm pool`** to see all available warm pool service quotas.
5. Find the instance type for which you want to increase your warm pool quota, select the warm pool service quota for that instance type, and choose **Request quota increase**.
6. Enter your requested instance limit number under **Change quota value**. The new value must be greater than the current **Applied quota value**.
7. Choose **Request**.

There is a limit on the number of instances that you can retain for each account, which is determined by instance type. You can check your resource limits in the AWS Service Quotas console or directly using the list-service-quotas AWS CLI command. For more information on AWS Service Quotas, see Requesting a quota increase in the *Service Quotas User Guide*.

You can also use AWS Support Center to request a warm pool quota increase. For a list of available instance types according to Region, see Amazon SageMaker Pricing and choose **Training** in the **On-Demand Pricing** table.

Use SageMaker AI managed warm pools

You can use SageMaker AI managed warm pools through the SageMaker Python SDK, the Amazon SageMaker AI console, or through the low-level APIs. Administrators can optionally use the `sagemaker:KeepAlivePeriod` condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups.

- IAM condition key

Using the SageMaker AI Python SDK

Create, update, or terminate warm pools using the SageMaker Python SDK.

> **Note**
>
> This feature is available in the SageMaker AI Python SDK v2.110.0 and later.

Topics

- Create a warm pool
- Update a warm pool
- Terminate a warm pool

Create a warm pool

To create a warm pool, use the SageMaker Python SDK to create an estimator with a `keep_alive_period_in_seconds` value greater than 0 and call `fit()`. When the training job completes, a warm pool is retained. For more information on training scripts and estimators, see Train a Model with the SageMaker Python SDK. If your script does not create a warm pool, see Warm pool creation for possible explanations.

```
import sagemaker
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow

# Creates a SageMaker AI session and gets execution role
session = sagemaker.Session()
role = get_execution_role()

# Creates an example estimator
estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    source_dir='code',
```

```
    role=role,
    model_dir='model_dir',
    framework_version='2.2',
    py_version='py37',
    job_name='my-training-job-1',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
        "batch-size": 512,
        "epochs": 1,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
    },
    keep_alive_period_in_seconds=1800,
)

# Starts a SageMaker training job and waits until completion
estimator.fit('s3://my_bucket/my_training_data/')
```

Next, create a second matching training job. In this example, we create `my-training-job-2`, which has all of the necessary attributes to match with `my-training-job-1`, but has a different hyperparameter for experimentation. The second training job reuses the warm pool and starts up faster than the first training job. The following code example uses a Tensorflow estimator. The warm pool feature can be used with any training algorithm that runs on Amazon SageMaker AI. For more information on which attributes need to match, see Matching training jobs.

```
# Creates an example estimator
estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='py37',
    py_version='pyxy',
    job_name='my-training-job-2',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
```

```
        "batch-size": 512,
        "epochs": 2,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
    },
    keep_alive_period_in_seconds=1800,
)

# Starts a SageMaker training job and waits until completion
estimator.fit('s3://my_bucket/my_training_data/')
```

Check the warm pool status of both training jobs to confirm that the warm pool is `Reused` for `my-training-job-1` and `InUse` for `my-training-job-2`.

Note

Training job names have date/time suffixes. The example training job names `my-training-job-1` and `my-training-job-2` should be replaced with actual training job names. You can use the `estimator.latest_training_job.job_name` command to fetch the actual training job name.

```
session.describe_training_job('my-training-job-1')
session.describe_training_job('my-training-job-2')
```

The result of `describe_training_job` provides all details about a given training job. Find the `WarmPoolStatus` attribute to check information about a training job's warm pool. Your output should look similar to the following example:

```
# Warm pool status for training-job-1
...
'WarmPoolStatus': {'Status': 'Reused',
  'ResourceRetainedBillableTimeInSeconds': 1000,
  'ReusedByName': my-training-job-2}
...

# Warm pool status for training-job-2
...
'WarmPoolStatus': {'Status': 'InUse'}
```

```
...
```

Update a warm pool

When the training job is complete and the warm pool status is `Available`, then you can update the `KeepAlivePeriodInSeconds` value.

```
session.update_training_job(job_name,
 resource_config={"KeepAlivePeriodInSeconds":3600})
```

Terminate a warm pool

To manually terminate a warm pool, set the `KeepAlivePeriodInSeconds` value to 0.

```
session.update_training_job(job_name, resource_config={"KeepAlivePeriodInSeconds":0})
```

The warm pool automatically terminates when it exceeds the designated `KeepAlivePeriodInSeconds` value or if there is a patch update for the cluster.

Using the Amazon SageMaker AI console

Through the console, you can create a warm pool, release a warm pool, or check the warm pool status and billable time of specific training jobs. You can also see which matching training job reused a warm pool.

1. Open the Amazon SageMaker AI console and choose **Training jobs** from the navigation pane. If applicable, the warm pool status of each training job is visible in the **Warm pool status** column and the time left for an active warm pool is visible in the **Time left** column.
2. To create a training job that uses a warm pool from the console, choose **Create training job**. Then, be sure to specify a value for the **Keep alive period** field when configuring your training job resources. This value must be an integer between 1 and 3600, which represents duration of time in seconds.
3. To release a warm pool from the console, select a specific training job and choose **Release cluster** from the **Actions** dropdown menu.
4. To see more information about a warm pool, choose a training job name. In the job details page, scroll down to the **Warm pool status** section to find the warm pool status, the time left if the warm pool status is `Available`, the warm pool billable seconds, and the name of the training job that reused the warm pool if the warm pool status is `Reused`.

Using the low-level SageMaker APIs

Use SageMaker AI managed warm pools with either the SageMaker API or the AWS CLI.

SageMaker AI API

Set up SageMaker AI managed warm pools using the SageMaker API with the following commands:

- CreateTrainingJob
- UpdateTrainingJob
- ListTrainingJobs
- DescribeTrainingJob

AWS CLI

Set up SageMaker AI managed warm pools using the AWS CLI with the following commands:

- create-training-job
- update-training-job
- list-training-jobs
- describe-training-job

IAM condition key

Administrators can optionally use the `sagemaker:KeepAlivePeriod` condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups. SageMaker AI managed warm pools are limited to a `KeepAlivePeriodInSeconds` value of 3600 seconds (60 minutes), but administrators can lower this limit if needed.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceKeepAlivePeriodLimit",
```

```
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob"
            ],
            "Resource": "*",
            "Condition": {
                "NumericLessThanIfExists": {
                    "sagemaker:KeepAlivePeriod": "1800"
                }
            }
        }
    ]
}
```

For more information, see Condition keys for Amazon SageMaker AI in the *Service Authorization Reference*.

Amazon CloudWatch Metrics for Monitoring and Analyzing Training Jobs

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker AI monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the `DescribeTrainingJob` operation.

> **Note**
>
> Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

Tip

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio Classic and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

Topics

Define Training Metrics

SageMaker AI automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker AI sends system resource utilization metrics listed in SageMaker AI Jobs and Endpoint Metrics. If you want SageMaker AI to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker AI training job request.

You can specify the metrics that you want to track using the SageMaker AI console, the SageMaker AI Python SDK, or the low-level SageMaker AI API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318;  Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
    {
        "Name": "train:error",
        "Regex": "Train_error=(.*?);"
    },
    {
        "Name": "validation:error",
        "Regex": "Valid_error=(.*?);"
    }
]
```

In the regex for the `train:error` metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=", and the expression `(.*?);` captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, `.` means any character, `*` means zero or more, and `?` means capture only until the first instance of the `;` character.

Define Metrics Using the SageMaker AI Python SDK

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following example:

```
import sagemaker
from sagemaker.estimator import Estimator

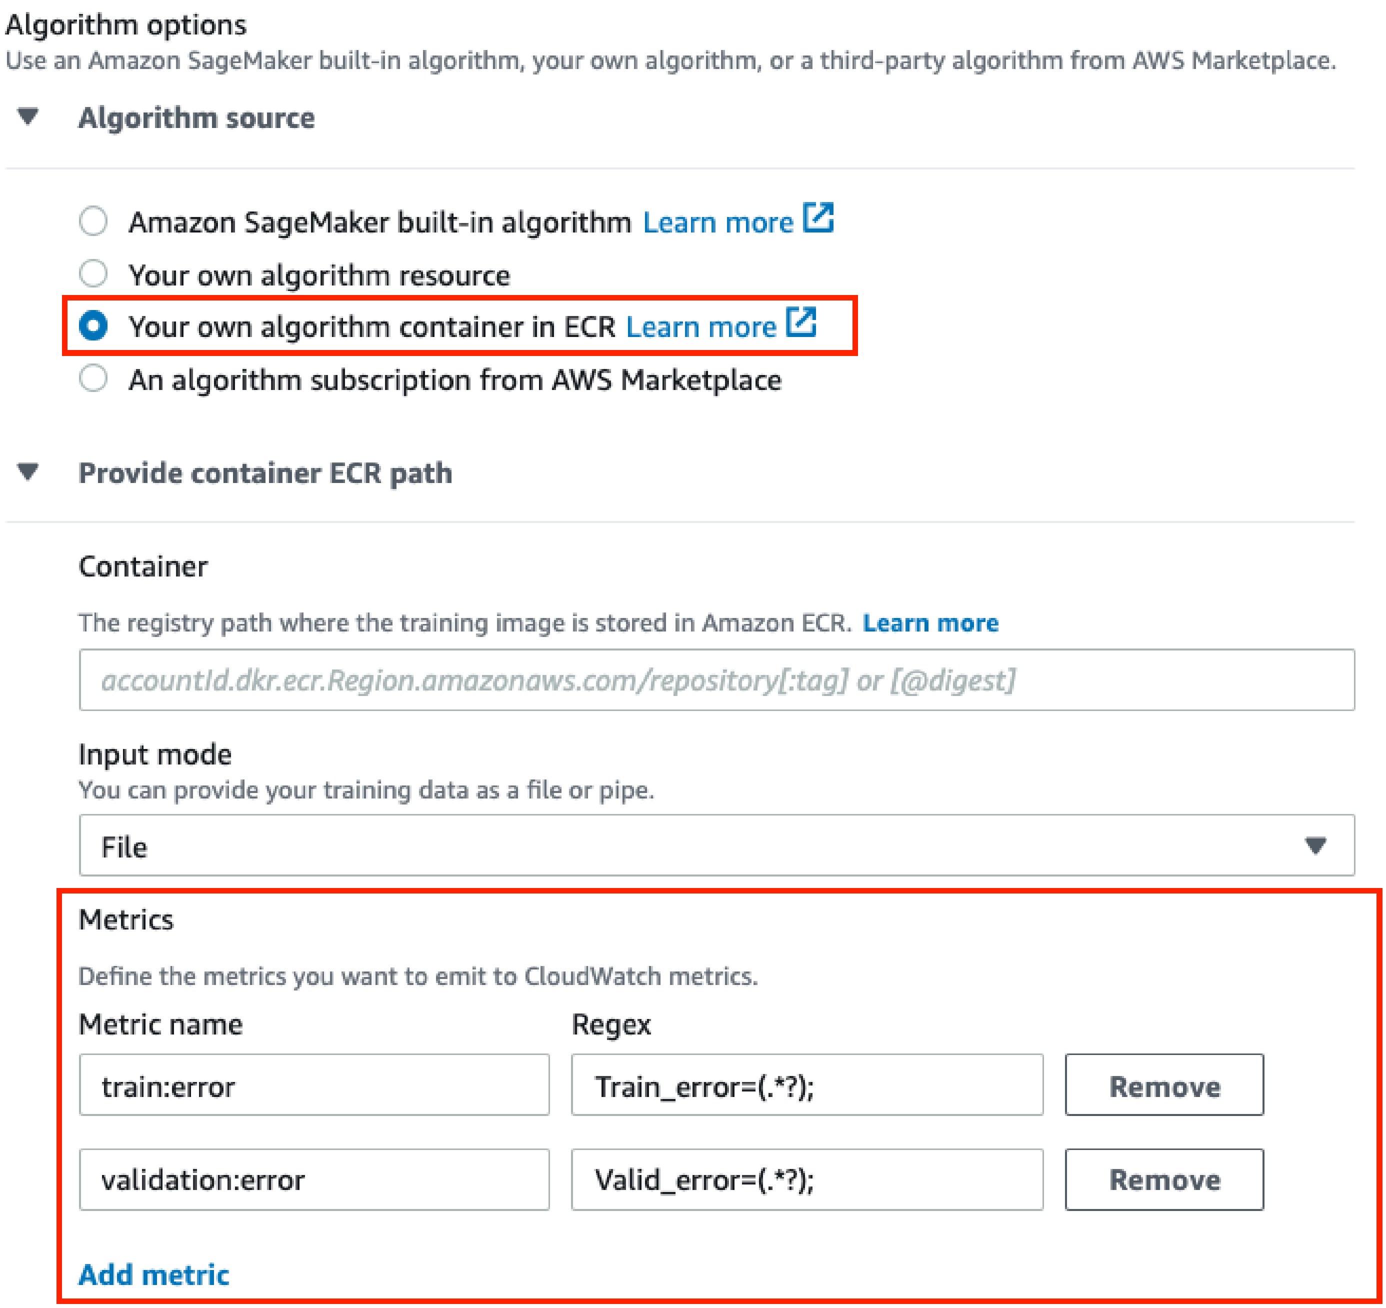
estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
```

```
    instance_type='ml.c4.xlarge',
    metric_definitions=[
       {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
       {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)
```

For more information about training by using Amazon SageMaker Python SDK estimators, see Sagemaker Python SDK on GitHub.

Define Metrics Using the SageMaker AI Console

If you choose the **Your own algorithm container in ECR** option as your algorithm source in the SageMaker AI console when you create a training job, add the metric definitions in the **Metrics** section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.



Define Metrics Using the Low-level SageMaker AI API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the `MetricDefinitions` field of the [`AlgorithmSpecification`](#) input parameter that you pass to the [`CreateTrainingJob`](#) operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following example:

```
"AlgorithmSpecification": {
    "TrainingImage": your-own-image-uri,
    "TrainingInputMode": "File",
    "MetricDefinitions" : [
        {
            "Name": "train:error",
            "Regex": "Train_error=(.*?);"
        },
        {
            "Name": "validation:error",
            "Regex": "Valid_error=(.*?);"
        }
    ]
}
```

For more information about defining and running a training job by using the low-level SageMaker AI API, see `CreateTrainingJob`.

View training job metrics

You can view the metrics emitted from your Amazon SageMaker training jobs in either the Amazon CloudWatch or SageMaker AI console.

Monitor training job metrics (CloudWatch console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

To monitor training job metrics (CloudWatch console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
2. Choose **Metrics**, then choose **/aws/sagemaker/TrainingJobs**.
3. Choose **TrainingJobName**.
4. On the **All metrics** tab, choose the names of the training metrics that you want to monitor.
5. On the **Graphed metrics** tab, configure the graph options. For more information about using CloudWatch graphs, see Graph Metrics in the *Amazon CloudWatch User Guide*.

Monitor training job metrics (SageMaker AI console)

You can monitor the metrics that a training job emits in real time by using the SageMaker AI console.

To monitor training job metrics (SageMaker AI console)

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker.
2. Choose **Training jobs**, then choose the training job whose metrics you want to see.
3. Choose **TrainingJobName**.
4. In the **Monitor** section, you can review the graphs of instance utilization and algorithm metrics.

Monitor

Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

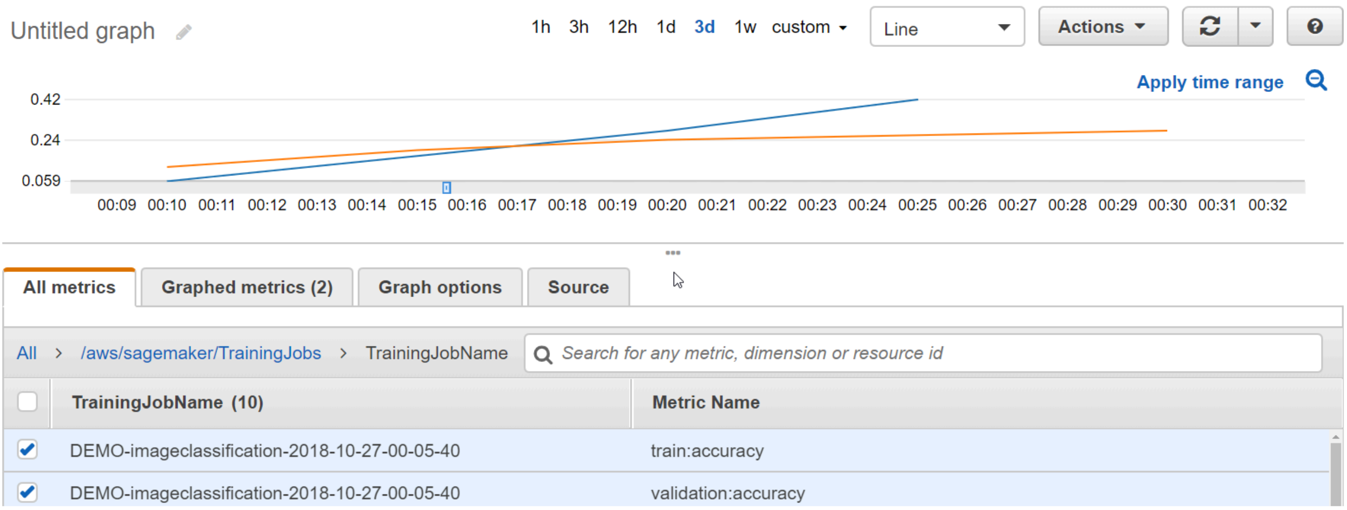
Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the **Image-classification-full-training** example in the **Example notebooks** section of your SageMaker AI notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Create an Amazon SageMaker Notebook Instance for the tutorial. If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

1. Open the SageMaker AI console at https://console.aws.amazon.com/sagemaker.
2. Choose **Notebooks**, and then choose **Notebook instances**.
3. Choose the notebook instance that you want to use, and then choose **Open**.
4. On the dashboard for your notebook instance, choose **SageMaker AI Examples**.
5. Expand the **Introduction to Amazon Algorithms** section, and then choose **Use** next to **Image-classification-fulltraining.ipynb**.
6. Choose **Create copy**. SageMaker AI creates an editable copy of the **Image-classification-fulltraining.ipynb** notebook in your notebook instance.
7. Run all of the cells in the notebook up to the **Inference** section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
9. Choose **Metrics**, then choose **/aws/sagemaker/TrainingJobs**.

10. Choose **TrainingJobName**.
11. On the **All metrics** tab, choose the **train:accuracy** and **validation:accuracy** metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.



Augmented Manifest Files for Training Jobs

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3), and you must configure your training job to use the dataset stored there. You specify the location and format of this dataset for one or more `Channel`. Augmented manifests can only support Pipe input mode. See the section, **InputMode** in `Channel` to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a `S3Uri`. Amazon SageMaker AI interprets this URI based on the specified `S3DataType` in `S3DataSource`. The `AugmentedManifestFile` option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.

During training, SageMaker AI parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the `AttributeNames` parameter of the `CreateTrainingJob` API. The `AttributeNames` parameter is an ordered list of attribute names that SageMaker AI looks for in the JSON object to use as training input.

For example, if you list `["line", "book"]` for `AttributeNames`, the input data must include the attribute names of `line` and `book` in the specified order. For this example, the following augmented manifest file content is valid:

```
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker AI ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the `AttributeNames` parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed `AttributeNames` can be a subset of all of the attributes in the JSON line. SageMaker AI ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in `AttributeNames`, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix `-ref` to it.

If an attribute name contains the suffix `-ref`, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if `AttributeNames` contains `["image-ref", "is-a-cat"]`, the following example shows a valid augmented manifest file:

```
{"image-ref": "s3://amzn-s3-demo-bucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://amzn-s3-demo-bucket/sample02/image2.jpg", "is-a-cat": 0}
```

In case of the first JSON line of this manifest file, SageMaker AI retrieves the `image1.jpg` file from `s3://amzn-s3-demo-bucket/sample01/` and the string representation of the `is-a-cat` attribute `"1"` for image classification.

> **Tip**
>
> To create an augmented manifest file, use Amazon SageMaker Ground Truth and create a labeling job. For more information about the output from a labeling job, see Labeling job output data.

Augmented Manifest File Format for Pipe Mode Training

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see `Input Mode`.

Attribute names with a `"-ref"` suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying `RecordIO` for `RecordWrapperType` solves this issue. If the algorithm is not compatible with `RecordIO` format, specify `None` for `RecordWrapperType` and make sure that your data is parsed correctly for your algorithm.

Using the `["image-ref", "is-a-cat"]` example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://amzn-s3-demo-bucket/foo/
image1.jpg)recordio_formatted("1")recordio_formatted(s3://amzn-s3-demo-
bucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding `is-a-cat` attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as `S3DataDistributionType`. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

Use an Augmented Manifest File

The following sections show you how to use augmented manifest files in your Amazon SageMaker training jobs, either with the SageMaker AI console or programmatically using the SageMaker Python SDK.

Use an Augmented Manifest File (Console)

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

To use an augmented manifest file in a training job (console)

1. Open the Amazon SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Built-in algorithms and pretrained models in Amazon SageMaker. If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For **Resource configuration**, either accept the default values or, to reduce computation time, increase the resource consumption.

    a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.

    b. For **Instance count**, use the default, 1.

c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.

7. Provide information about the input data for the training dataset.

   a. For **Channel name**, either accept the default (**`train`**) or enter a more meaningful name, such as **`training-augmented-manifest-file`**.

   b. For **InputMode**, choose **Pipe**.

   c. For **S3 data distribution type**, choose **FullyReplicated**. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as Neural Topic Model (NTM) Algorithm, choose `ShardedByS3Key`.

   d. If the data specified in the augmented manifest file is uncompressed, set the **Compression type** to **None**. If the data is compressed using gzip, set it to **Gzip**.

   e. (Optional) For **Content type**, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.

   f. For **Record wrapper**, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO-formatted file, choose **None**.

   g. For **S3 data type**, choose **AugmentedManifestFile**.

   h. For **S3 location**, provide the path to the bucket where you stored the augmented manifest file.

   i. For **AugmentedManifestFile attribute names**, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.

   j. (Optional) To add more attribute names, choose **Add row** and specify another attribute name for each attribute.

   k. (Optional) To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.

   l. Choose **Done**.

8. For **Output data configuration**, provide the following information:

   a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

    b. (Optional) You can use your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. For **Encryption key**, provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).

9. (Optional) For **Tags**, add one or more tags to the training job. A *tag* is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **`Project`** as a key and a value that refers to a project that is related to the training job, such as **`Home value forecasts`**.
10. Choose **Create training job**. SageMaker AI creates and runs the training job.

After the training job has finished, SageMaker AI stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see [Deploy the model to Amazon EC2](#).

Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker AI high-level Python library:

```
import sagemaker

# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(
    training_image,
    role,
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode = 'Pipe',
    output_path=s3_output_location,
    sagemaker_session=session
)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and
 attribute names.
train_data = sagemaker.inputs.TrainingInput(
    your_augmented_manifest_file,
    distribution='FullyReplicated',
    content_type='application/x-recordio',
```

```
    s3_data_type='AugmentedManifestFile',
    attribute_names=['source-ref', 'annotations'],
    input_mode='Pipe',
    record_wrapping='RecordIO'
)

data_channels = {'train': train_data}

# Train a model.
model.fit(inputs=data_channels, logs=True)
```

After the training job has finished, SageMaker AI stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see Deploy the model to Amazon EC2.

Checkpoints in Amazon SageMaker AI

Use checkpoints in Amazon SageMaker AI to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with S3 Express One Zone for increased access speeds.
- Use checkpoints with SageMaker AI managed spot training to save on training costs.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers (the default is `/opt/ml/checkpoints`). SageMaker AI provides the functionality to copy the checkpoints from the local path to Amazon S3 and automatically syncs the checkpoints in that directory with S3. Existing checkpoints in S3 are written to the SageMaker AI container at the start of the job, enabling jobs to resume from a checkpoint. Checkpoints added to the S3 folder after the job has started are not copied to the training container. SageMaker AI also writes new checkpoints from the container to

S3 during training. If a checkpoint is deleted in the SageMaker AI container, it will also be deleted in the S3 folder.

You can use checkpoints in Amazon SageMaker AI with the Amazon S3 Express One Zone storage class (S3 Express One Zone) for faster access to checkpoints. When you enable checkpointing and specify the S3 URI for your checkpoint storage destination, you can provide an S3 URI for a folder in either an S3 general purpose bucket or an S3 directory bucket. S3 directory buckets that are integrated with SageMaker AI can only be encrypted with server-side encryption with Amazon S3 managed keys (SSE-S3). Server-side encryption with AWS KMS keys (SSE-KMS) is not currently supported. For more information on S3 Express One Zone and S3 directory buckets, see [What is S3 Express One Zone](#).

If you are using checkpoints with SageMaker AI managed spot training, SageMaker AI manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker AI managed spot training, you can significantly reduce the billable time for training ML models. For more information, see [Managed Spot Training in Amazon SageMaker AI](#).

Topics

Checkpoints for frameworks and algorithms in SageMaker AI

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker AI.

SageMaker AI frameworks and algorithms that support checkpointing

SageMaker AI supports checkpointing for AWS Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker AI saves the checkpoints to the default local path `'/opt/ml/checkpoints'` and copies them to Amazon S3.

- Deep Learning Containers: TensorFlow, PyTorch, MXNet, and HuggingFace

> **Note**
>
> If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker AI in the *HuggingFace documentation*.

- Built-in algorithms: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)

> **Note**
>
> If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in *the XGBoost Python SDK documentation*.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker AI does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`'/opt/ml/checkpoints'`) and load from the local path in your training script. SageMaker AI estimators can sync up with the local path and save the checkpoints to Amazon S3.

Considerations for checkpointing

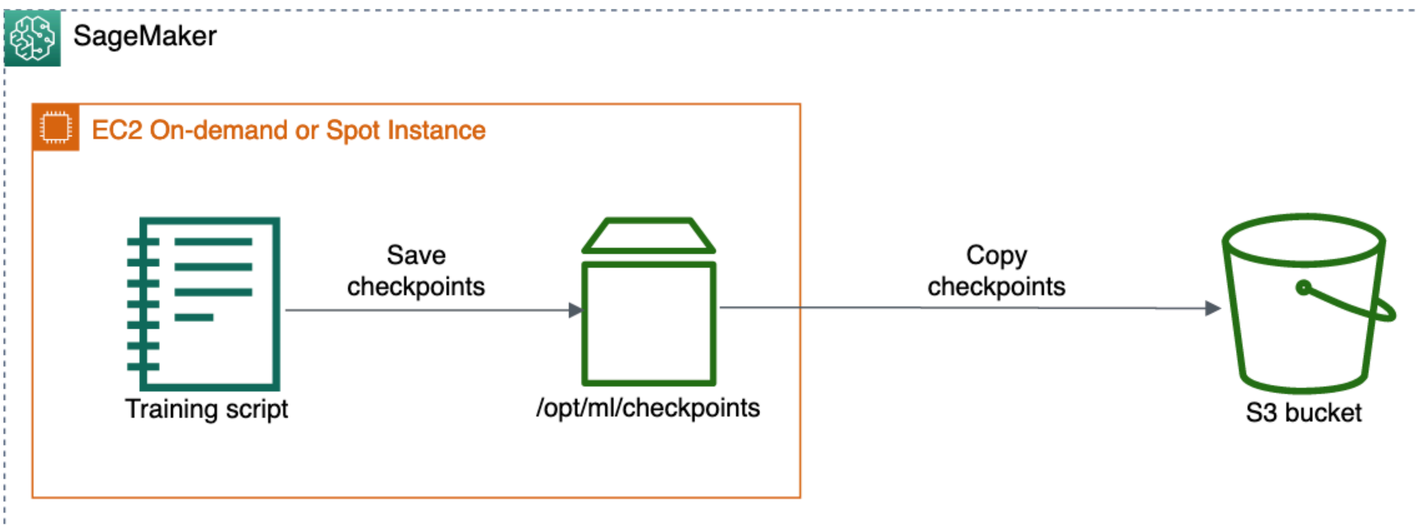
Consider the following when using checkpoints in SageMaker AI.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker AI checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.

- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker AI checkpoints with SageMaker Debugger and SageMaker AI distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Distributed training supported by Amazon SageMaker Debugger
  - Troubleshooting for distributed training in Amazon SageMaker AI
  - Model Parallel Troubleshooting

Enable checkpointing

After you enable checkpointing, SageMaker AI saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket. You can use either S3 general purpose or S3 directory buckets for your checkpoint S3 bucket.



The following example shows how to configure checkpoint paths when you construct a SageMaker AI estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker AI estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker AI, see Docker Registry Paths and Example Code. You can also replace `estimator` and `Estimator` with other SageMaker AI frameworks' estimator parent classes and estimator classes, such as `TensorFlow`, `PyTorch`, `MXNet`, `HuggingFace` and `XGBoost`.

```
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name,
 checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...
    image_uri="<ecr_path>/<algorithm-name>:<tag>" # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,

    # Parameters required to enable checkpointing
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path
)
```

The following two parameters specify paths for checkpointing:

- `checkpoint_local_path` – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to `'/opt/ml/checkpoints'`. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to `'/opt/ml/checkpoints'`.

  > **Note**
  >
  > We recommend specifying the local paths as `'/opt/ml/checkpoints'` to be consistent with the default SageMaker AI checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the `checkpoint_local_path` parameter of the SageMaker AI estimators.

- `checkpoint_s3_uri` – The URI to an S3 bucket where the checkpoints are stored in real time. You can specify either an S3 general purpose or S3 directory bucket to store your checkpoints.

For more information on S3 directory buckets, see [Directory buckets](#) in the *Amazon Simple Storage Service User Guide*.

To find a complete list of SageMaker AI estimator parameters, see the [Estimator API](#) in the [*Amazon SageMaker Python SDK*](#) *documentation*.

Browse checkpoint files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

To find the checkpoint files programmatically

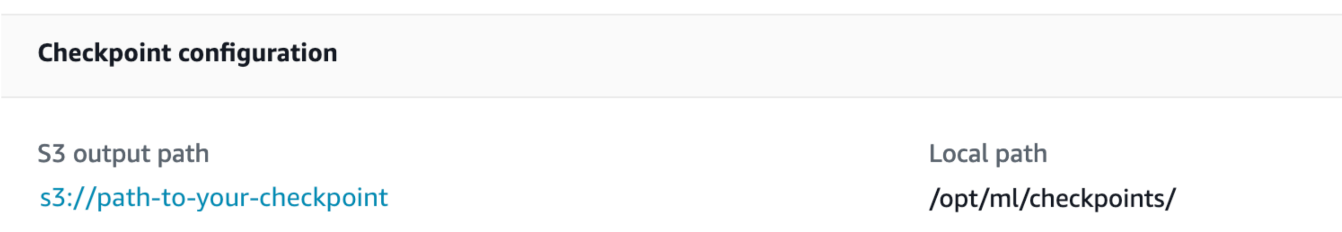
To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the S3 console, use the following procedure.

To find the checkpoint files from the S3 console

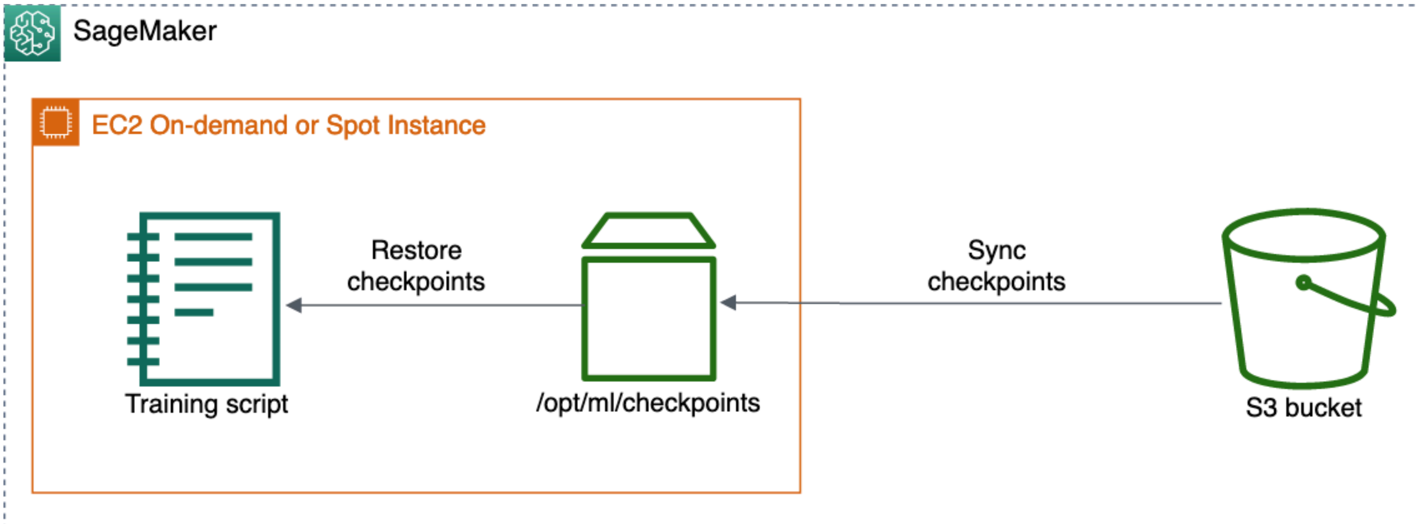
1. Sign in to the AWS Management Console and open the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Training jobs**.
3. Choose the link to the training job with checkpointing enabled to open **Job settings**.
4. On the **Job settings** page of the training job, locate the **Checkpoint configuration** section.



5. Use the link to the S3 bucket to access the checkpoint files.

Resume training from a checkpoint

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the Enable checkpointing section. Once the training has resumed, the checkpoints from this S3 bucket are restored to `checkpoint_local_path` in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker AI session.



Cluster repairs for GPU errors

If you are running a training job that fails on a GPU, SageMaker AI will run a GPU health check to see whether the failure is related to a GPU issue. SageMaker AI takes the following actions based on the health check results:

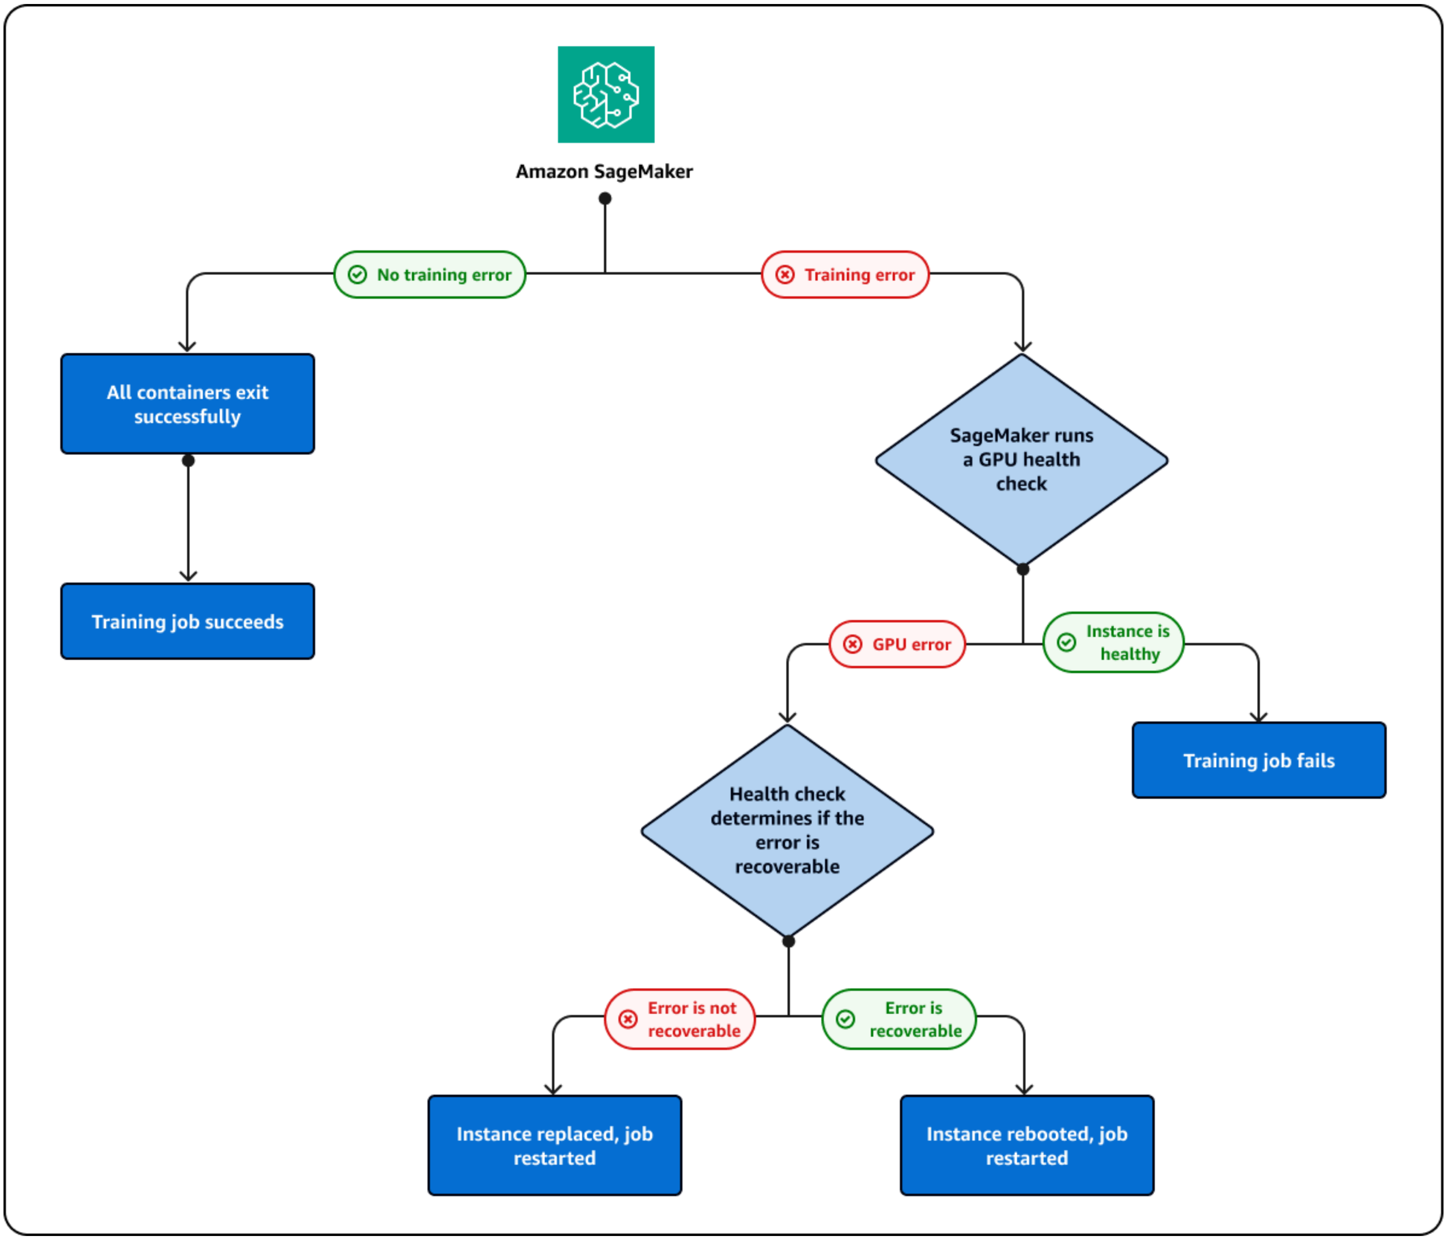
- If the error is recoverable, and can be fixed by rebooting the instance or resetting the GPU, SageMaker AI will reboot the instance.
- If the error is not recoverable, and caused by a GPU that needs to be replaced, SageMaker AI will replace the instance.

The instance is either replaced or rebooted as part of a SageMaker AI cluster repair process. During this process, you will see the following message in your training job status:

```
Repairing training cluster due to hardware failure
```

SageMaker AI will attempt to repair the cluster up to `10` times. If the cluster repair is successful, SageMaker AI will automatically restart the training job from the previous checkpoint. If the cluster repair fails, the training job will also fail. You are not billed for the cluster repair process. Cluster repairs will not initiate unless your training job fails. If a GPU issue is detected for a warmpool cluster, the cluster will enter into repair mode to either reboot or replace the faulty instance. After repair, the cluster can still be used as a warmpool cluster.

The previously described cluster and instance repair process is depicted in the following diagram:



Customizing Amazon Nova models on Amazon SageMaker AI

You can customize Amazon Nova models through recipes and train them on SageMaker AI. These recipes support techniques such as supervised fine-tuning (SFT) and Direct Preference Optimization (DPO), with both full-rank and low-rank adaptation (LoRA) options.

The end-to-end customization workflow involves stages like model training, model evaluation, and deployment for inference. This model customization approach on SageMaker AI provides greater flexibility and control to fine-tune its supported Amazon Nova models, optimize hyperparameters with precision, and implement techniques such as LoRA parameter-efficient fine-tuning (PEFT), full-rank SFT, DPO, Continued Pre-Training (CPT), Proximal Policy Optimization (PPO), etc.

SageMaker AI offers two environments for customizing Amazon Nova models.

- **Amazon SageMaker training jobs** provides a fully managed environment for customizing Nova models where you don't need to create or maintain any clusters. The service automatically handles all infrastructure provisioning, scaling, and resource management, allowing you to focus solely on configuring your training parameters and submitting your job. You can customize Nova models on SageMaker training jobs with techniques like Parameter Efficient Fine-tuning (PEFT), Full rank fine tuning as well as Direct Preference Optimization (DPO). For more information, see the section called “On SageMaker training jobs”.
- **Amazon SageMaker HyperPod** offers a specialized environment to train Nova models by requiring you to create and manage SageMaker HyperPod EKS clusters with restricted instance groups (RIGs). This environment gives you flexibility in configuring your training environment with specialized GPU instances and integrated Amazon FSx for Lustre storage, making it particularly well-suited for advanced distributed training scenarios and ongoing model development. For more information, see the section called “On SageMaker HyperPod”.

In this chapter

- Amazon Bedrock inference
- Limitations
- Amazon Nova customization FAQs

General prerequisites

The customization process involves several key stages including model training, evaluation, and deployment for inference, each requiring specific resources and configurations. Before beginning your Amazon Nova model customization on SageMaker AI, ensure you have the following general prerequisites.

- An AWS account. If you don't have an AWS account, follow these instructions to sign up for one.
- Installing the AWS CLI and Setting up the configuration.
- Access to the base Amazon Nova model customization recipes.
- Familiarity of YAML configuration files.
- Familiarity of how to run a Jupyter notebook in your environment.
- Familiarity of how to create AWS resources like Amazon S3 buckets and IAM roles with appropriate permissions.
- Familiarity of how to train a model with Amazon SageMaker AI.
- Familiarity of Amazon SageMaker HyperPod with EKS orchestration.
- Familiarity of Amazon SageMaker HyperPod CLI.
- Familiarity of Amazon Nova foundational models.
- Familiarity of available Amazon Nova models and algorithms for customization.
- Familiarity of Amazon Bedrock inference.

Amazon Nova recipes

You can get an Amazon Nova recipe from the SageMaker HyperPod recipes repository. A Nova recipe is a YAML configuration file that provides details to SageMaker AI on how to run your model customization job. It provides the base model name, sets training hyperparameters, defines optimization settings, and includes any additional options required to fine-tune or train the model successfully.

You can also access Nova recipes through Amazon SageMaker Studio and Amazon SageMaker Unified Studio by navigating to the JumpStart model hub, selecting AWS, and browsing Amazon Nova models to find their associated recipes. Both Amazon SageMaker Studio and Amazon SageMaker Unified Studio provide sample notebooks for each recipe, which include all the necessary steps to modify the recipes and run customization jobs using SageMaker AI training jobs or Amazon SageMaker HyperPod environments.

To access the recipes pages in Amazon SageMaker Studio, the execution role must have the following permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::*model-customization-recipes*"
            ]
        }
    ]
}
```

To execute the sample notebooks on SageMaker training jobs and SageMaker HyperPod, use one of the following SageMaker distribution image versions: `2.7.1+`, `2.8.0+`, `3.2.1+`, `3.3.0+`. This applies to both Amazon SageMaker Studio and Amazon SageMaker Unified Studio.

Topics

- Getting Amazon Nova recipes
- Available models and algorithms
- Amazon Nova recipes reference

Getting Amazon Nova recipes

To get a base Amazon Nova recipe, clone the SageMaker HyperPod recipes repository by running the following command.

```
git clone https://github.com/aws/sagemaker-hyperpod-recipes.git
```

The base recipes are available at `recipes_collection/recipes/`.

```
cd recipes_collection/recipes/
```

The Amazon Nova customization recipes are in the following folders.

Recipe type	Folder
SFT (Full-rank and PEFT), PPO, DPO (Full-rank and PEFT)	fine-tuning/nova
Evaluation	evaluation/nova
CPT	training/nova

Available models and algorithms

The following table summarizes the availability of customization for Amazon Nova models and supported algorithms using SageMaker AI.

Model name	Model ID	Fine-tuning	Notes
Amazon Nova Micro	amazon.nova-micro-v1:0:128k	Yes	For both SFT and DPO, this model accepts text as input and produces text as output only.
Amazon Nova Lite	amazon.nova-lite-v1:0:300k	Yes	• SFT - Accepts either text and/or image or text and/or video as the input and produces

Model name	Model ID	Fine-tuning	Notes
			text as output. A single job can't combine text, image, and video in the same run. • DPO - Accepts text and image as the input and produces text as output.
Amazon Nova Pro	amazon.nova-pro-v1:0:300k	Yes	• SFT - Accepts either text and/or image or text and/or video as the input and produces text as output. A single job can't combine text, image, and video in the same run. • DPO - Accepts text and image as the input and produces text as output.

Amazon Nova customization on SageMaker training jobs

Amazon SageMaker training jobs is an environment that enables you to train machine learning models at scale. It automatically provisions and scales compute resources, loads training data from sources like Amazon S3, executes your training code, and stores the resulting model artifacts.

The purpose of training is to customize the base Amazon Nova model using your proprietary data. The training process typically involves steps to prepare your data, choose a recipe, modify configuration parameters in YAML files, and submit a training job. The training process will output trained model checkpoint in a service-managed Amazon S3 bucket. You can use this checkpoint location for evaluation jobs. Nova customization on SageMaker training jobs stores model artifacts in a service-managed Amazon S3 bucket. Artifacts in the service-managed bucket are encrypted with SageMaker-managed KMS keys. Service-managed Amazon S3 buckets don't currently support data encryption using customer-managed KMS keys.

Topics

Amazon Nova distillation

This quick start guide helps you get started with Amazon Nova model distillation using supervised fine-tuning (SFT) on SageMaker AI.

Topics

Concepts

Model distillation is a method that transfers knowledge from large, advanced models to smaller, efficient ones. With Amazon Nova models, a larger "teacher" model (like Amazon Nova Pro or Amazon Nova Premier) passes its capabilities to a smaller "student" model (like Amazon Nova Lite or Amazon Nova Micro). This creates a customized model that maintains high performance while using fewer resources.

Key components

The distillation process primarily involves two types of models:

Teacher models serve as the knowledge source and include:

- Amazon Nova Pro (amazon.nova-pro-v1:0)
- Amazon Nova Premier (amazon.nova-premier-v1:0)

Student models receive and implement the knowledge:

- Amazon Nova Lite (amazon.nova-lite-v1:0:300k)
- Amazon Nova Micro (amazon.nova-micro-v1:0:128k)
- Amazon Nova Pro (amazon.nova-pro-v1:0:300k) - Available only when using Amazon Nova Premier as teacher

Use cases

Mode distillation is particularly beneficial when:

- Your application has strict latency, cost, and accuracy requirements.
- You need a custom model for specific tasks but lack sufficient high-quality labeled training data.
- You want to match the performance of advanced models while maintaining the efficiency of smaller models.

Prerequisites

- AWS account with access to Amazon Nova models and appropriate service quotas (min. 6 P5 and 1 R5 instances).
- IAM role with permissions for SageMaker training jobs.
- Amazon S3 bucket to store training data and outputs.

Setting up data augmentation

The data augmentation phase uses SageMaker training jobs to generate high-quality training data using the teacher model. This section details the setup process and requirements.

IAM role

To create IAM roles and attach policies, see Creating roles and attaching policies (console). If you use AWS CLI, follow instructions in create-role and attach-role-policy. For more information, see How to use SageMaker AI execution roles from the *SageMaker AI Developer Guide*.

The following are example commands for your reference.

Create a SageMaker AI execution role

The role is created with a trust relationship allowing SageMaker AI, Amazon Bedrock, to assume this role. This enables these services to act on your behalf when executing batch inference jobs.

```
aws iam create-role \
 --role-name NovaCustomizationRole \
 --assume-role-policy-document '{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
 "Principal": {
 "Service": ["sagemaker.amazonaws.com",
            "bedrock.amazonaws.com"]
 },
 "Action": "sts:AssumeRole"
 }
 ]
}'
```

Attach necessary policies

```
# Attach AmazonSageMakerFullAccess
 aws iam attach-role-policy \
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess

# Attach AmazonBedrockFullAccess
 aws iam attach-role-policy \
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/AmazonBedrockFullAccess

 # Attach S3 access policy
 aws iam attach-role-policy \
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess

# Attach AmazonEC2FullAccess
 aws iam attach-role-policy \
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/AmazonEC2FullAccess

# Attach AmazonEC2ContainerRegistryFullAccess
 aws iam attach-role-policy \
```

```
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryFullAccess

# Attach AmazonEC2ContainerRegistryFullAccess
 aws iam attach-role-policy \
 --role-name NovaCustomizationRole \
 --policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess
```

Attach the following inline policy to customer execution role needed for Distillation Container.

- AWS KMS permissions: Allows the role to interact with AWS Key Management Service, necessary for accessing encrypted resources or managing encryption keys.
- `IAM:PassRole`: This permission is often required when one service needs to pass this role to another service, a common pattern in AWS service integrations.

```
aws iam put-role-policy \
 --role-name NovaCustomizationRole \
 --policy-name Distillation-Additional-Permissions\
 --policy-document '{
 "Version": "2012-10-17",
 "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "*"
        }
    ]
}
```

Amazon VPC configuration

To create Amazon VPC configuration for SageMaker AI training jobs using the AWS Management Console, follow instructions in Configure Your private VPC for SageMaker training (console).

Create a new Amazon VPC

```
Name: Distillation-VPC
IPv4 CIDR: 10.0.0.0/16 (or your preferred range)
Availability Zones: 2
Public Subnets: 2
Private Subnets: 2
NAT Gateways: 1 (in one AZ)
```

Create a security group

```
Name: Distillation-SG
Description: Security group for data distillation jobs
Inbound Rules: Allow all traffic from self
Outbound Rules: Allow all traffic (0.0.0.0/0)
```

Create VPC endpoints for the following services

```
com.amazonaws.[region].s3
com.amazonaws.[region].sagemaker.api
com.amazonaws.[region].sagemaker.runtime
com.amazonaws.[region].bedrock.api
com.amazonaws.[region].bedrock.runtime
com.amazonaws.[region].sts
com.amazonaws.[region].logs
com.amazonaws.[region].ecr.api
com.amazonaws.[region].ecr.dkr
```

For each endpoint:

- Select your Distillation-VPC
- Choose the private subnets
- Select the Distillation-SG security group

AWS KMS keys

When working with Amazon Bedrock batch inference, a AWS KMS key is required for data security and compliance. Amazon Bedrock batch inference jobs require input and output Amazon S3 buckets to be encrypted with AWS KMS keys to ensure data protection at rest.

Create a KMS key using AWS CLI with this command:

```
# Create KMS key
aws kms create-key \
--description "KMS key for Amazon Bedrock batch inference Amazon S3 bucket" \
--region us-east-1
```

The command will output the key information including the ARN. Example output:

```
{
    "KeyMetadata": {
        "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
        "Arn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
}
```

> **Note**
>
> Save the KMS key ARN from the output as you'll need it for the Amazon S3 bucket creation in the next section.

Amazon S3 bucket

You need two types of Amazon S3 storage. Customer-managed Amazon S3 bucket stores your input data and output `manifest.json` files. You create and manage this bucket and can use a single bucket for both input and output. This bucket must be configured with KMS encryption since it will store sensitive output data and will be used by Amazon Bedrock batch inference jobs - Amazon Bedrock requires KMS-encrypted buckets for processing batch inference tasks.

Service-managed Amazon S3 bucket stores model weights. A service-managed Amazon S3 bucket is created automatically during your first training job. It has restricted access controls with specific paths accessible via manifest files only.

To create a bucket in a specific AWS Region, use the create-bucket CLI command.

Example command to create an Amazon S3 bucket with AWS KMS encryption. Replace `{kms_key_arn}` with your AWS KMS key ARN. You'll need to create a AWS KMS key first if you haven't already done so.

```
aws s3api create-bucket \
--bucket {my_bucket_name} \
--region {aws_region} \
--create-bucket-configuration LocationConstraint={aws_region} \
--server-side-encryption-configuration '{
    "Rules": [
        {
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "aws:kms",
                "KMSMasterKeyID": "{kms_key_arn}"
            },
            "BucketKeyEnabled": true
        }
    ]
}'
```

Starting a SageMaker training job

Before you start a training job, prepare your data.

Data format requirement - Your input dataset must be in JSONL format with each line containing a sample in converse format for more information follow Preparing data for distilling understanding models.

Dataset constraints

- Minimum prompts: 100
- Maximum file size: 2GB
- Maximum line length: 180KB
- File format: JSONL only

To upload input data, run the following command.

```
aws s3 cp /path/to/input-data/ s3://customer-input-data-bucket/ —recursive
```

Data augmentation recipe

You can get the distillation recipe from the [SageMaker HyperPod recipes](#) repository. The distillation recipe is under the directory: `recipes-collection/recipes/fine-tuning/nova`. The data augmentation process is controlled by a YAML configuration file. Below is a detailed explanation of each parameter. All are required fields.

Paramete	Description
name	A descriptive name for your training job. This helps identify your job in the AWS Management Console.
distillat ion_data	Enables data distillation job, do not modify this field.
maxNumb OfPrompt	The Maximum number of prompts in the dataset.
maxRespo seLength	The Maximum response length per prompt (tokens).
maxInputF ileSizeIn GB	The Maximum size of the input file (in GB).
maxLineLe ngthInKB	The Maximum size of a single line in the input file (in KB).
maxStude tModelFin eTuningCc ntextLeng thInToken s	The Maximum context window size (tokens) for student model. The is value must not exceed student model capacity. You can set this value to 32k or 64k based on student model capacity.
teacherMc delId	When you set Teacher Model Id, select from two:

Parameter	Description
	• For Amazon Titan Premier: "us.amazon.nova-premier-v1:0" for IAD region. Note: This is only available in IAD region. • For Amazon Nova Pro: "us.amazon.nova-pro-v1:0" for IAD region and "eu.amazon.nova-pro-v1:0" for ARN region.
temperature	Controls response randomness (0.7 recommended for balance).
top_p	Cumulative probability threshold for token sampling (0.9 is recommended).
customer_bucket	Amazon S3 bucket for input/output data.
kms_key	AWS KMS key to encrypt output in S3, This needed by Bedrock batch inference to store output returned by inference job.

Limitation

For Teacher Model as Nova Premier - Only supported in IAD region (`us-east-1`) due to Amazon Bedrock batch inference is not available in ARN (`eu-north-1`) region.

Best Practices

Data preparation

- Include 100 high-quality labeled examples to guide the teacher model
- Remove poor quality labels before submission
- Follow text understanding prompting best practices
- Test prompts with the teacher model before starting distillation

Model selection

- Use Nova Pro as teacher for general use cases
- Consider Nova Premier for specialized domain knowledge
- Choose student model based on latency and cost requirements

Performance optimization

- Start with recommended temperature (0.7) and top_p (0.9)
- Validate augmented data quality before fine-tuning
- Follow the guidelines in Selecting hyperparameters to adjust the hyperparameters

Starting a job with PySDK

The following sample notebook demonstrates how to run a SageMaker training job for distillation. For more information, see Use a SageMaker AI estimator to run a training job.

```
import os
import sagemaker,boto3
from sagemaker.pytorch import PyTorch
from sagemaker.inputs import TrainingInput

sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()

# SETUP
job_name = <Your_job_name> # Must be unique for every run

input_s3_uri = <S3 URI to your input dataset> # Must end in .jsonl file
output_s3_uri = <S3 URI to your output bucket> + job_name

image_uri = "708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-distillation-repo:SM-TJ-
DISTILL-LATEST" # Do not change
instance_type = "ml.r5.4xlarge" # Recommedation is to use cpu instances
instance_count = 1 # Must be 1, do not change
role_arn = <IAM role to execute the job with>
recipe_path = <Local path to your recipe>

# Execution

estimator = PyTorch(
    output_path=output_s3_uri,
```

```
    base_job_name=job_name,
    role=role_arn,
    instance_count=instance_count,
    instance_type=instance_type,
    training_recipe=recipe_path,
    max_run=432000,
    sagemaker_session=sagemaker_session,
    image_uri=image_uri,
    subnets= ['subnet-xxxxxxxxxxxxxxxxx','subnet-xxxxxxxxxxxxxxxxx'], # Add subnet
 groups created in previous steps
    security_group_ids= ['sg-xxxxxxxxxxxxxxxxx'], # Add security group created in
 previous steps
    disable_profiler=True,
    debugger_hook_config=False
)

trainingInput = TrainingInput(
    s3_data=input_s3_uri,
    distribution='FullyReplicated',
    s3_data_type='Converse'
)

# The keys must be "train".
estimator.fit(inputs={"train": trainingInput})
```

CloudWatch logs

Logs are available in Amazon CloudWatch under the `/aws/sagemaker/TrainingJobs` log group in your AWS account. You will see one log file per host used for your training job.

Successful training

For a successful training job, you will see the log message "Training is complete" at the end of the log.

The output bucket contains the following files:

- `distillation_data/manifest.json`: Contains the location of augmented data. You can use this dataset to start an Amazon Nova fine-tuning job. Only SFT training is supported with this dataset.

  ```
  {
    "distillation_data": "s3://customer_escrow_bucket/job_id/distillation_data/"
  ```

```
}
```

- `distillation_data/sample_training_data.jsonl`: This JSONL file contains 50 samples of augmented data for preview to help you determine data quality.
- `distillation_data/training_config.json`: This file contains recommended hyperparameters for Amazon Nova fine-tuning jobs. The following is an example file:

```
{
    "epochCount": 5,
    "learningRate": 1e-05,
    "batchSize": 1,
    "learningRateWarmupSteps": 1
}
```

Validating augmented data quality

Before proceeding to fine-tuning, it's crucial to validate the quality of the augmented data:

1. Review the `sample_training_data.jsonl` file in your output bucket. This file contains 50 random samples from the augmented dataset.
2. Manually inspect these samples for relevance, coherence, and alignment with your use case.
3. If the quality doesn't meet your expectations, you may need to adjust your input data or distillation parameters and rerun the data augmentation process.

After data augmentation completes, the second phase involves fine-tuning the student model using Amazon SageMaker HyperPod. For more information, see ???.

In SFT training recipe you can pass the dataset path returned form previous job.

```
data_s3_path: "s3://[escrow-bucket]/[job-name]/distillation_data/training_data.jsonl"
```

Also override the training config recommended generated from previous step.

Limitations

- Only supports SFT Nova fine-tuning technique on this augmented data.
- Only supports SFT Nova fine-tuning technique on Amazon SageMaker HyperPod.
- No support for multi-modal distillation.

- No support for custom teacher models.

Fine-tuning Amazon Nova models using SageMaker training jobs

Fine-tuning Amazon Nova models with SageMaker training jobs offers a powerful way to customize foundation models for your specific use cases.

Topics

Prerequisites

Before you start a training job, note the following.

- Amazon S3 buckets to store your input data and output of training jobs. You can either use one bucket for both or separate buckets for each type of the data. Make sure your buckets are in the same AWS Region where you create all the other resources for training. For more information, see Creating a general purpose bucket.
- An IAM role with permissions to run a training job. Make sure you attach an IAM policy with `AmazonSageMakerFullAccess`. For more information, see How to use SageMaker execution roles.
- Base Amazon Nova recipes, see ???.

Data preparation

Preparing high-quality, properly formatted data is a critical first step in the fine-tuning process for large language models. Whether you're using supervised fine-tuning (SFT) or Direct Preference Optimization (DPO), with either full-rank or low-rank adaptation (LoRA) approaches, your data must adhere to specific format requirements to ensure successful model training. This section outlines the necessary data formats, validation methods, and best practices to help you prepare your datasets effectively for fine-tuning Amazon Nova models.

Data format requirements

SFT

SFT data format requirements - For both full-rank SFT and LoRA SFT, data should follow the Converse format. For examples and constraints of this format, see [Preparing data for fine-tuning Understanding models](#).

SFT data validation - To validate your dataset format before submission, we recommend using the following validation script from the [Amazon Bedrock samples repository](#). This validation tool will help ensure your `jsonl` files adhere to the required format specifications and identify any potential issues before submitting your fine-tuning job.

DPO

DPO data format requirements - For both DPO in full-rank and DPO with LoRA, data should follow the Converse format. The dataset also needs to be in the similar format as SFT except the last turn needs to have preference pairs.

DPO dataset other constraints - Other constraints on datasets are the same for SFT. For more information, see [Dataset constraints](#). A single JSONL file for training and a single JSONL file for validation is expected. Validation set is optional.

DPO dataset recommendations - A minimum of 1,000 preference pairs for effective training. High-quality preference data will result in more efficient results.

Examples

Sample DPO data format

```
// N-1 turns same as SFT format
{
    "role": "assistant",
    "candidates": [
        {
            "content": [
                {
                    "text": "..."
                } // content list can contain multiple 'text' objects
            ],
            "preferenceLabel": "preferred"
        },
```

```
        {
            "content": [
                {
                    "text": "..."
                } // content list can contain multiple 'text' objects
            ],
            "preferenceLabel": "non-preferred"
        }
    ]
}
```

Sample DPO data format (multi-turn)

```
{
    "system": [
        {
            "text": "..."
        }
    ],
    "messages":[
        {
            "role": "user",
            "content": [
                {
                    "text": "..."
                }
            ]
        },
        {
            "role": "assistant",
            "content": [
                {
                    "text": "..."
                }
            ]
        },
        {
            "role": "user",
            "content": [
                {
                    "text": "..."
                }
            ]
```

```
        },
        {
            "role": "assistant",
            "candidates": [
                {
                    "content": [
                        {

                    ],
                    "preferenceLabel": "non-preferred"
                }
            ]
        }
    ],
}
```

Dataset limits

Training jobs default to a 1-day time limit, though the estimates in the tables below assume a 5-day training duration for illustration purposes. As a best practice, we recommend increasing your training time limit to 28 days maximum to accommodate longer training workloads. To request a limit increase, see Requesting a quota increase.

SFT dataset limits

Context length	Model	Method	Datasets	Description
32k context length jobs	Amazon Nova Micro	Full rank and LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5

Context length	Model	Method	Datasets	Description
				epochs, you can only have up to 100k records.
	Amazon Nova Lite	Full rank	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 100k records.
			Image and video	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 50k records.
		LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 100k records.
			Image and video	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 90k records.
	Amazon Nova Pro	Full rank	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 40k records.

Context length	Model	Method	Datasets	Description
			Image and video	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 30k records.
		LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 40k records.
			Image and video	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 35k records.
64k context length jobs	Amazon Nova Micro	Full rank and LoRA	Text only	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can only have up to 50k records.
	Amazon Nova Lite	Full rank	Text only	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 50k records.
			Image and video	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 30k records.

Context length	Model	Method	Datasets	Description
		LoRA	-	LoRA is not supported at 64k for Nova Lite.
	Amazon Nova Pro	Full rank and LoRA	Text only	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 17k records.
			Image and video	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 15k records.

DPO dataset limits

Context length	Model	Method	Datasets	Description
16k context length jobs	Amazon Nova Micro	Full rank	Text only	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can only have up to 120k records.
		LoRA	Text only	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can only have up to 125k records.
	Amazon Nova Lite	Full rank	Text only	If you use a dataset where all records have 16k context length,

Context length	Model	Method	Datasets	Description
				and for example, run for 5 epochs, you can have up to 130k records.
			Image	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can complete 20k samples within 2 days
		LoRA	Text only	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can have up to 140k records.
			Image	if you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can complete 20k samples within 2 days.
	Amazon Nova Pro	Full rank	Text only	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can have up to 45k records.
			Image	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can complete 20k samples within 4 days

Context length	Model	Method	Datasets	Description
		LoRA	Text only	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can have up to 55k records.
			Image	If you use a dataset where all records have 16k context length, and for example, run for 5 epochs, you can complete 20k samples within 4 days
32k context length jobs	Amazon Nova Micro	Full rank	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can only have up to 45k records.
		LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can only have up to 50k records.
	Amazon Nova Lite	Full rank	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 55k records.
			Image	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 35k records.

Context length	Model	Method	Datasets	Description
		LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 60k records.
			Image	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 35k records.
	Amazon Nova Pro	Full rank	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 20k records.
			Image	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 16k records.
		LoRA	Text only	If you use a dataset where all records have 32k context length, and for example, run for 5 epochs, you can have up to 22k records.
			Image	If you use a dataset where all records have 64k context length, and for example, run for 5 epochs, you can have up to 18k records.

By reducing the number of epochs or the context length of your records, you could provide more records.

Full-rank SFT and LoRA PEFT configurations

This section covers guidance on recipe configurations for both full-rank supervised fine-tuning (SFT) and low-rank adaptation parameter-efficient fine-tuning (LoRA PEFT) approaches. These recipe files serve as the blueprint for your model customization jobs, allowing you to specify training parameters, hyperparameters, and other critical settings that determine how your model learns from your data. To adjust the hyperparameters, follow the guidelines in Selecting hyperparameters.

Fine-tuning configurations (Full-rank SFT and LoRA PEFT)

The only difference between full-rank SFT and LoRA PEFT in terms of recipe is the LoRA PEFT configuration, which is set to 'null' for full rank and set to appropriate values if using LoRA PEFT-based fine-tuning. Example recipes are available in the SageMaker HyperPod recipes GitHub repository. The following tables show detailed configurations that you might find helpful.

About **"run" configuration**.

	Key	Definition	Micro	Lite	Pro
Run configuration	model_type	Specifies the Nova model variant to use. Do not modify this field.	"amazon.nova-micro-v1:0:128k"	"amazon.nova-lite-v1:0:300k"	"amazon.nova-pro-v1:0:300k"
	model_name_or_path	The path to the base model.	"nova-micro/prod"	"nova-lite/prod"	"nova-pro/prod"
	replicas	The number of compute instances to use for	2, 4 or 8	4, 8 or 16	6, 12 or 24

	Key	Definition	Micro	Lite	Pro
		distributed training.			

About **“training_config” configuration**.

	Root key	Child keys	Definition	Min	Max
		max_length	The maximum sequence length in tokens. This determines the context window size for training. Tunable to nearest 1024 multiple, max value: 65536 (for Lite Lora 32768).	1024	65536, except Lite LoRA which supports 32768.
		global_batch_size	Total samples per step, allowed values are 16, 32, 64. Max value: 32 for Nova Pro, 64 for Nova Lite and Micro.	16	32 for Nova Pro, 64 for Nova Lite and Micro.

	Root key	Child keys	Definition	Min	Max
Trainer configuration	trainer	max_epochs	The number of complete passes through your training dataset. For most customization tasks, 1-5 epochs are typically sufficient. Recommended to keep up to 5.	1	-
Model configuration	model	hidden_dropout	Probability of dropping hidden state outputs. Increase (0.0-0.2) to reduce overfitting on smaller datasets. The bounds are between 0 - 1.	0	1

	Root key	Child keys	Definition	Min	Max
	model	attention _dropout	Probability of dropping attention weights. Can help with generaliz ation. The bounds are between 0 - 1.	0	1
	model	ffn_dropout	Probability of dropping feed-forw ard network outputs. The bounds are between 0 - 1.	0	1
Optimizer configura tion	model.optim	lr	Learning rate, controls step size during optimization. The limits are between 0 and 1. Typically set between 1e-6 and 1e-4. for good performance.	0	1

	Root key	Child keys	Definition	Min	Max
	model.optim	name	Optimizer algorithm. Currently, only `distributed_fused_adam` is supported.	-	-
	model.optim	adam_w_mode	Enable AdamW mode (true/false).	-	-
	model.optim	eps	Epsilon for numerical stability.		
	model.optim	weight_decay	L2 regularization strength, must be between 0.0 and 1.0.	0	1
	model.optim	betas	Adam optimizer betas, must be between 0.0 and 1.0.	0	1

	Root key	Child keys	Definition	Min	Max
	model.optim	sched_warmup_steps	Number of steps to gradually increase learning rate. This improves training stability. Between 1 and 20.	1	20
	model.optim	sched_constant_steps	Steps at constant learning rate.	1.00E-10	1.00E-06
	model.optim	sched.min_lr	Minimum learning rate at the end of decay. The limits are between 0 and 1, but must be less than learning rate.	0	1

	Root key	Child keys	Definition	Min	Max
LoRA PEFT configuration	model.peft	peft_scheme	Use "lora" or "null". "lora" uses LoRA PEFT method for parameter-efficient fine-tuning. "null" kicks off a full rank fine tuning.	-	-
	model.peft	lora_tuning.loraplus_lr_ratio	LoRA+ learning rate scaling factor, must be between 0.0 and 100.0.	0	100
	model.peft	lora_tuning.alpha	Scaling factor for LoRA weights. Allowed values are 32, 64, 96, 128, 160 and 192.	32	192

	Root key	Child keys	Definition	Min	Max
	model.peft	lora_tuning.adapter_dropout	Regularization for LoRA parameters.Must be between 0.0 and 1.0.	0	1

Fine-tuning specific configurations (DPO)

The only difference between Direct Preference Optimization (DPO) as compared to LoRA PEFT and FullRank SFT is in terms of dpo_cfg configuration and allowed values. Refer to the table below the example for allowed specifically for DPO. Example recipes are available in the [SageMaker HyperPod recipes](#) GitHub repository. The following table shows detailed configurations that you might find helpful.

	Root key	Child keys	Definition	Min	Max
		max_length	The maximum sequence length in tokens. This determines the context window size for training. Tunable to nearest 1024 multiple, max value: 32,768.	1024	32768
		global_batch_size	Global batch size, allowed	16	256

	Root key	Child keys	Definition	Min	Max
			values are {16, 32, 64, 128, 256}.		
Trainer configuration	trainer	max_epochs	The number of complete passes through your training dataset. For most customization tasks, 1-5 epochs are typically sufficient. Max epochs is 5.	1	5
Model configuration	model	hidden_dropout	Probability of dropping hidden state outputs. Increase (0.0-0.2) to reduce overfitting on smaller datasets. The bounds are between 0 - 1.	0	1

	Root key	Child keys	Definition	Min	Max
	model	attention _dropout	Probability of dropping attention weights. Can help with generaliz ation. The bounds are between 0 - 1.	0	1
	model	ffn_dropout	Probability of dropping feed-forw ard network outputs. The bounds are between 0 - 1.	0	1
Optimizer configura tion	model.optim	lr	Learning rate, controls step size during optimization. The limits are between 0 and 1. Typically set between 1e-6 and 1e-4. for good performance.	0	1

	Root key	Child keys	Definition	Min	Max
	model.optim	name	Optimizer algorithm. Currently, only `distributed_fused_adam` is supported.	-	-
	model.optim	adam_w_mode	Enable AdamW mode (true/false).	-	-
	model.optim	eps	Epsilon for numerical stability.	1.00E-10	1.00E-06
	model.optim	weight_decay	L2 regularization strength, must be between 0.0 and 1.0.	0	1
	model.optim	betas	Adam optimizer betas, must be between 0.0 and 1.0.	0	1

	Root key	Child keys	Definition	Min	Max
	model.optim	sched_warmup_steps	Number of steps to gradually increase learning rate. This improves training stability. Between 1 and 20.	1	20
	model.optim	sched_constant_steps	Steps at constant learning rate.		
	model.optim	sched.min_lr	Minimum learning rate at the end of decay. The limits are between 0 and 1, but must be less than learning rate.	0	1

	Root key	Child keys	Definition	Min	Max
LoRA PEFT configuration	model.peft	peft_scheme	Use "lora" or "null". "lora" uses LoRA PEFT method for parameter-efficient fine-tuning. "null" kicks off a full rank fine tuning.	-	-
	model.peft	lora_tuning.loraplus_lr_ratio	LoRA+ learning rate scaling factor, must be between 0.0 and 100.0.	0	100
	model.peft	lora_tuning.alpha	Scaling factor for LoRA weights. Allowed values are 32, 64, 96, 128, 160 and 192.	32	192

	Root key	Child keys	Definition	Min	Max
	model.peft	lora_tuning.adapter_dropout	Regularization for LoRA parameters. Must be between 0.0 and 1.0.	0	1
DPO configuration	model-dpo_cfg	beta	Strength of preference enforcement.	0.001	0.1

Running customized Nova model on SageMaker training jobs

This section demonstrates how to run a customized Nova model on SageMaker training jobs through a Jupyter notebook environment. You'll find a complete example that walks through the process of configuring and launching a training job, along with reference tables for selecting the appropriate container image URIs and instance configurations. This approach gives you programmatic control over your fine-tuning workflows while leveraging SageMaker's managed infrastructure for model customization. For more information, see [Use a SageMaker AI estimator to run a training job](#).

Reference tables

Before running the sample notebook, refer to the following tables for selecting the appropriate container image URIs and instance configurations.

Selecting image URI

Recipe	Image URI
SFT image URI	`708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:SM-TJ-SFT-latest`
DPO image URI	`708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:SM-TJ-DPO-latest`

Selecting instance type and count

Model	Job type	Instance type	Recommended instance count	Allowed instance count
Amazon Nova Micro	Fine-tuning (SFT, LoRA)	g5.12xlarge	1	1
Amazon Nova Micro	Fine-tuning (SFT, DPO)	p5.48xlarge	2	2,4,8
Amazon Nova Lite	Fine-tuning (SFT, DPO)	p5.48xlarge	4	4,8,16
Amazon Nova Pro	Fine-tuning (SFT, DPO)	p5.48xlarge	6	6,12,24

Sample notebook

The following sample notebook demonstrates how to run a training job. For additional getting started notebooks on how to customize Nova models using SageMaker AI training jobs, see [Use a SageMaker AI estimator to run a training job](#).

```
# 1. Install dependencies

!pip install sagemaker

# 2. Import dependencies and initialize sagemaker session

import sagemaker,boto3

sm = boto3.client('sagemaker', region_name='us-east-1')
sagemaker_session = sagemaker.session.Session(boto_session=boto3.session.Session(),
 sagemaker_client=sm)

# 3. Configure your job
# Define the core configuration for launching a SageMaker Training Job. This includes
 input/output S3 URIs, container image, hardware setup, and other runtime parameters.
 Update the placeholders below before submitting the job.
```

```
job_name = "<Your Job Name>"

input_s3_uri = "<S3 path to input data>"
validation_s3_uri = "<S3 path to validation data>" # optional, leave blank if no
 validation data

output_s3_uri = "<S3 path to output location>"

image_uri = "<Image URI from documentation>" # you can choose the image for SFT/DPO
instance_type = "ml.p5.48xlarge" # do not change
instance_count = <Integer number of hosts> # change hosts as needed. Refer to
 documentation for allowed values based on model type.
role_arn = "<IAM Role you want to use to run the job>"
recipe_path = "<Local path to the recipe file>"

# 4. Launch SageMaker Training Job
# This block sets up and runs the SageMaker training job using the PyTorch estimator.
 It configures the training image, hardware, input channels, and TensorBoard
 integration. Validation data is included if provided.

from sagemaker.debugger import TensorBoardOutputConfig
from sagemaker.pytorch import PyTorch
from sagemaker.inputs import TrainingInput

tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path=output_s3_uri,
)

estimator = PyTorch(
    output_path=output_s3_uri,
    base_job_name=job_name,
    role=role_arn,
    instance_count=instance_count,
    instance_type=instance_type,
    training_recipe=recipe_path,
    sagemaker_session=sagemaker_session,
    image_uri=image_uri,
    tensorboard_output_config=tensorboard_output_config, # Add the setting for using
 TensorBoard.
    disable_profiler=True,
    debugger_hook_config=False
)

trainingInput = TrainingInput(
```

```
    s3_data=input_s3_uri,
    distribution='FullyReplicated',
    s3_data_type='Converse'
)

if (validation_s3_uri):
    validationInput = TrainingInput(
        s3_data=validation_s3_uri,
        distribution='FullyReplicated',
        s3_data_type='Converse'
    )

    estimator.fit(inputs={"train": trainingInput, "validation": validationInput}) #
 inputs must be called "train" and "validation", do not change
else:
    estimator.fit(inputs={"train": trainingInput})

# 5. Monitor your training job
# To monitor your training job, you can either:
#   * Go to your AWS console -> Amazon Sagemaker AI -> Training -> Training Jobs
#   * run the following command

# sm.describe_training_job(TrainingJobName="<complete training job name>")
```

Hyperparameter optimization guidance

Fine-tuning your Nova LLM model effectively requires careful selection of hyperparameters. While this section explains the basic recipe structure and components, optimizing hyperparameters for your specific use case often requires additional guidance. For comprehensive recommendations on hyperparameter selection, best practices, and optimization strategies, see Selecting hyperparameters. This resource provides detailed guidance on selecting appropriate learning rates, batch sizes, training epochs, and other critical parameters based on your dataset characteristics and training objectives. We recommend consulting this guide when fine-tuning your recipe configuration to achieve optimal model performance.

For details about minimum, maximum, and default values for epochs, learning rate, and learning warmup steps, see Hyperparameters for Understanding models.

Common recipe modifications

Here are some common recipe adjustments based on specific use cases:

- **For smaller datasets (< 1,000 examples)**

```
training_config:
    max_epochs: 2  # More passes through a smaller dataset
model:
    hidden_dropout: 0.1  # Increase regularization
    weight_decay: 0.01   # Increase regularization
```

- **For efficiency with limited compute**

```
peft:
    peft_scheme: "lora"

Evaluating your SageMaker AI-trained model

The purpose of the evaluation process is to assess trained-model performance against benchmarks or custom dataset. The evaluation process typically involves steps to create evaluation recipe pointing to the trained model, specify evaluation datasets and metrics, submit a separate job for the evaluation, and evaluate against standard benchmarks or custom data. The evaluation process will output performance metrics stored in your Amazon S3 bucket.

> **Note**
>
> The evaluation process described in this topic is an offline process. The model is tested against fixed benchmarks with predefined answers, rather than being assessed in real-time or through live user interactions. For real-time evaluation, you can test the model after it has been deployed to Amazon Bedrock by calling Amazon Bedrock Runtime APIs.

Topics

Prerequisites

Before you start a evaluation training job, note the following.

- A SageMaker AI-trained Amazon Nova model which you want to evaluate its performance.
- Base Amazon Nova recipe for evaluation. For more information, see ???.

Available benchmark tasks

A sample code package is available that demonstrates how to calculate benchmark metrics using the SageMaker model evaluation feature for Amazon Nova. To access the code packages, see sample-Nova-lighteval-custom-task.

Here is a list of available industry standard benchmarks supported. You can specify the following benchmarks in the `eval_task` parameter.

Available benchmarks for model evaluation

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
mmlu	Text	Multi-task Language Understanding – Tests knowledge	accuracy	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
		across 57 subjects.			
mmlu_pro	Text	MMLU – Professional Subset – Focuses on professional domains such as law, medicine, accounting, and engineering.	accuracy	zs_cot	No
bbh	Text	Advanced Reasoning Tasks – A collection of challenging problems that test higher-level cognitive and problem-solving skills.	accuracy	fs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
gpqa	Text	General Physics Question Answering – Assesses comprehension of physics concepts and related problem-solving abilities.	accuracy	zs_cot	No
math	Text	Mathematical Problem Solving – Measures mathematical reasoning across topics including algebra, calculus, and word problems.	exact_match	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
strong_reject	Text	Quality-Control Task – Tests the model's ability to detect and reject inappropriate, harmful, or incorrect content.	deflection	zs	Yes
ifeval	Text	Instruction-Following Evaluation – Gauges how accurately a model follows given instructions and completes tasks to specification.	accuracy	zs	No

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
gen_qa	Text	Custom Dataset Evaluation – Lets you supply your own dataset for benchmarking, comparing model outputs to reference answers with metrics such as ROUGE and BLEU.	all	gen_qa	No

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
mmmu	Multi-Modal	Massive Multidiscipline Multimodal Understanding (MMMU) – College-level benchmark comprising multiple-choice and open-ended questions from 30 disciplines.	accuracy	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask available
llm_judge	Text	LLM-as-a-Judge Preference Comparison – Uses a Nova Judge model to determine preference between paired responses (B compared with A) for your prompts, calculating the probability of B being preferred over A.	all	judge	No

Evaluation specific configurations

Below is a breakdown of the key components in the recipe and guidance on how to modify them for your use cases.

Understanding and modifying your recipes

General run configuration

```
run:
  name: eval_job_name
  model_type: amazon.nova-micro-v1:0:128k
  model_name_or_path: nova-micro/prod
  replicas: 1
```

```
  data_s3_path: ""
```

- `name`: A descriptive name for your evaluation job.
- `model_type`: Specifies the Nova model variant to use. Do not manually modify this field. Options include:
  - amazon.nova-micro-v1:0:128k
  - amazon.nova-lite-v1:0:300k
  - amazon.nova-pro-v1:0:300k
- `model_name_or_path`: The path to the base model or s3 path for post trained checkpoint. Options include:
  - nova-micro/prod
  - nova-lite/prod
  - nova-pro/prod
  - S3 path for post trained checkpoint path (`s3:customer-escrow-111122223333-smtj-<unique_id>/<training_run_name>`)

> **Note**
>
> **Evaluate post-trained model**
> To evaluate a post-trained model after a Nova SFT training job, follow these steps after running a successful training job. At the end of the training logs, you will see the log message "Training is complete". You will also find a `manifest.json` file in your output bucket containing the location of your checkpoint. This file will be located within an `output.tar.gz` file at your output S3 location. To proceed with evaluation, use this checkpoint by setting it as the value for `run.model_name_or_path` in your recipe configuration.

- `replica`: The number of compute instances to use for distributed training. Set to 1 as multi-node is not supported.
- `data_s3_path`: The input dataset Amazon S3 path. This field is required but should always left empty.

Evaluation configuration

```
evaluation:
```

```
task: mmlu
strategy: zs_cot
subtask: abstract_algebra
metric: accuracy
```

- `task`: Specifies the evaluation benchmark or task to use. Supported task includes:
  - `mmlu`
  - `mmlu_pro`
  - `bbh`
  - `gpqa`
  - `math`
  - `strong_reject`
  - `gen_qa`
  - `ifeval`
  - `mmmu`
  - `llm_judge`
- `strategy`: Defines the evaluation approach.
  - `zs_cot`: Zero-shot Chain of Thought - an approach to prompt large language models that encourages step-by-step reasoning without requiring explicit examples.
  - `fs_cot`: Few-shot Chain of Thought - an approach that provides a few examples of step-by-step reasoning before asking the model to solve a new problem.
  - `zs`: Zero-shot - an approach to solve a problem without any prior training examples.
  - `gen_qa`: Strategy specific for bring your own dataset.
  - `judge`: Strategy specific for Nova LLM as Judge.
- `subtask`: Optional. Specific components of the evaluation task. For a complete list of available subtasks, see ???.
  - Check supported subtasks in Available benchmarks tasks.
  - Should remove this field if there are no subtasks benchmarks.
- `metric`: The evaluation metric to use.
  - `accuracy`: Percentage of correct answers.
  - `exact_match`: For math benchmark, returns the rate at which the input predicted strings exactly match their references.

- `deflection`: For strong reject benchmark, returns relative deflection to base model and difference significance metrics.
- `all`:

  For `gen_qa`, bring your own dataset benchmark, return following metrics:

  - `rouge1`: Measures overlap of unigrams (single words) between generated and reference text.
  - `rouge2`: Measures overlap of bigrams (two consecutive words) between generated and reference text.
  - `rougeL`: Measures longest common subsequence between texts, allowing for gaps in the matching.
  - `exact_match`: Binary score (0 or 1) indicating if the generated text matches the reference text exactly, character by character.
  - `quasi_exact_match`: Similar to exact match but more lenient, typically ignoring case, punctuation, and white space differences.
  - `f1_score`: Harmonic mean of precision and recall, measuring word overlap between predicted and reference answers.
  - `f1_score_quasi`: Similar to f1_score but with more lenient matching, using normalized text comparison that ignores minor differences.
  - `bleu`: Measures precision of n-gram matches between generated and reference text, commonly used in translation evaluation.

  For `llm_judge`, bring your own dataset benchmark, return following metrics:

  - `a_scores`: Number of wins for `response_A` across forward and backward evaluation passes.
  - `a_scores_stderr`: Standard error of `response_A_scores` across pairwise judgements.
  - `b_scores`: Measures Number of wins for `response_B` across forward and backward evaluation passes.
  - `a_scores_stderr`: Standard error of `response_B_scores` across pairwise judgements.
  - `ties`: Number of judgements where `response_A` and `response_B` are evaluated as equal.
  - `ties_stderr`: Standard error of `ties` across pairwise judgements.
  - `inference_error`: Count of judgements that could not be properly evaluated.

- `score`: Aggregate score based on wins from both forward and backward passes for `response_B`.
- `score_stderr`: Aggregate score based on wins from both forward and backward passes for `response_B`.
- `inference_error_stderr`: Standard error of the aggregate score across pairwise judgements.
- `winrate`: The probability that `response_B` will be preferred over `response_A` calculated using Bradley-Terry probability.
- `lower_rate`: Lower bound (2.5th percentile) of the estimated win rate from bootstrap sampling.
- `upper_rate`: Upper bound (97.5th percentile) of the estimated win rate from bootstrap sampling.

Inference configuration (optional)

```
inference:
  max_new_tokens: 2048
  top_k: -1
  top_p: 1.0
  temperature: 0
```

- `max_new_tokens`: Maximum number of tokens to generate. Must be an integer. (Unavailable for LLM Judge)
- `top_k`: Number of the highest probability tokens to consider. Must be an integer.
- `top_p`: Cumulative probability threshold for token sampling. Must be a float between 1.0 to 0.0.
- `temperature`: Randomness in token selection (higher = more random), keep 0 to make the result deterministic. Float type, minimal value is 0.

Evaluation recipe examples

Amazon Nova provides four different types of evaluation recipes. All recipes are available in Amazon SageMaker HyperPod recipes GitHub repository.

General text benchmark recipes

These recipes enable you to evaluate the fundamental capabilities of Amazon Nova models across a comprehensive suite of text-only benchmarks.

Recipe format: `xxx_ general_text_benchmark_eval.yaml`.

General multi-modal benchmark recipes

These recipes enable you to evaluate the fundamental capabilities of Amazon Nova models across a comprehensive suite of multi-modality benchmarks.

Recipe format: `xxx_general_multi_modal_benchmark_eval.yaml`.

Multi-modal benchmark requirements

- Model support - Only support nova-lite and nova-pro base model and its post-trained variants.

Bring your own dataset benchmark recipes

These recipes enable you to bring your own dataset for benchmarking and compare model outputs to reference answers using different types of metrics.

Recipe format: `xxx_ bring_your_own_dataset_eval.yaml`.

Bring your own dataset requirements

File format:

- Single `gen_qa.jsonl` file containing evaluation examples. The file name should be exact `gen_qa.jsonl`.
- Your must upload your dataset to an S3 location where SageMaker training jobs can access.
- The file must follow the required schema format for general Q&Q dataset.

Schema format - Each line in the `.jsonl` file must be a JSON object with the following fields.

- Required fields.

  `query`: String containing the question or instruction that needs an answer.

  `response`: String containing the expected model output.

- Optional fields.

  `system`: String containing the system prompt that sets the behavior, role, or personality of the AI model before it processes the query.

Example entry

```
{
"system":"You are an English major with top marks in class who likes to give minimal
 word responses: ",
   "query":"What is the symbol that ends the sentence as a question",
   "response":"?"
}{
"system":"You are a pattern analysis specialist who provides succinct answers: ",
   "query":"What is the next number in this series? 1, 2, 4, 8, 16, ?",
   "response":"32"
}{
"system":"You have great attention to detail and follow instructions accurately: ",
   "query":"Repeat only the last two words of the following: I ate a hamburger today
 and it was kind of dry",
   "response":"of dry"
}
```

To use your custom dataset, modify your evaluation recipe with the following required fields, don't change any of the content:

```
evaluation:
  task: gen_qa
  strategy: gen_qa
  metric: all
```

Limitations

- Only one `.jsonl` file is allowed per evaluation.
- File must strictly follow the defined schema.

Nova LLM as a Judge benchmark recipes

Nova LLM Judge is a model evaluation feature that enables you to compare the quality of responses from one model against a baseline model's responses using a custom dataset. It accepts a dataset containing prompts, baseline responses, and challenger responses, then uses a Nova Judge model to provide a win rate metric based on [Bradley-Terry](https://en.wikipedia.org/wiki/Bradley%E2%80%93Terry_model) probability through pairwise comparisons. Recipe format: `xxx_llm_judge _eval.yaml`.

Nova LLM dataset requirements

File format:

- Single `llm_judge.jsonl` file containing evaluation examples. The file name should be exact `llm_judge.jsonl`.
- Your must upload your dataset to an S3 location where SageMaker training jobs can access.
- The file must follow the required schema format for the `llm_judge` dataset.
- The input dataset should ensure all records are under 12 k context length.

Schema format - Each line in the `.jsonl` file must be a JSON object with the following fields.

- Required fields.

  `prompt`: String containing the prompt for the generated response.

  `response_A`: String containing the baseline response.

  `response_B`: String containing the alternative response be compared with baseline response.

Example entry

```
{
"prompt": "What is the most effective way to combat climate change?",
"response_A": "The most effective way to combat climate change is through a combination
 of transitioning to renewable energy sources and implementing strict carbon pricing
 policies. This creates economic incentives for businesses to reduce emissions while
 promoting clean energy adoption.",
"response_B": "We should focus on renewable energy. Solar and wind power are good.
 People should drive electric cars. Companies need to pollute less."
}
{
"prompt": "Explain how a computer's CPU works",
"response_A": "CPU is like brain of computer. It does math and makes computer work
 fast. Has lots of tiny parts inside.",
```

```
"response_B": "A CPU (Central Processing Unit) functions through a fetch-execute
 cycle, where instructions are retrieved from memory, decoded, and executed through its
 arithmetic logic unit (ALU). It coordinates with cache memory and registers to process
 data efficiently using binary operations."
}
{
"prompt": "How does photosynthesis work?",
"response_A": "Plants do photosynthesis to make food. They use sunlight and water. It
 happens in leaves.",
"response_B": "Photosynthesis is a complex biochemical process where plants convert
 light energy into chemical energy. They utilize chlorophyll to absorb sunlight,
 combining CO2 and water to produce glucose and oxygen through a series of chemical
 reactions in chloroplasts."
}
```

To use your custom dataset, modify your evaluation recipe with the following required fields, don't change any of the content:

```
evaluation:
  task: llm_judge
  strategy: judge
  metric: all
```

Limitations

- Only one `.jsonl` file is allowed per evaluation.
- The file must strictly follow the defined schema.
- Nova Judge models are the same across micro / lite / pro specifications.
- Custom judge models are not currently supported.

Running evaluation training jobs

Start a training job using the following sample Jupyter notebook. For more information, see Use a SageMaker AI estimator to run a training job.

Reference tables

Before running the notebook, refer to the following reference tables to select image URI and instance configurations.

Selecting image URI

Recipe	Image URI
Evaluation image URI	`708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-evaluation-repo:SM-TJ-Eval-latest`

Selecting instance type and count

Model	Job type	Instance type	Recommended instance count	Allowed instance count
Amazon Nova Micro	Evaluation (SFT/DPO)	g5.12xlarge	1	1
Amazon Nova Lite	Evaluation (SFT/DPO)	g5.12xlarge	1	1
Amazon Nova Pro	Evaluation (SFT/DPO)	p5.48xlarge	1	1

Sample notebook

The following sample notebook demonstrates how to run an evaluation training job.

```
# install python SDK
!pip install sagemaker

import os
import sagemaker,boto3
from sagemaker.inputs import TrainingInput
from sagemaker.pytorch import PyTorch

sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()

# Download recipe from https://github.com/aws/sagemaker-hyperpod-recipes/tree/main/
recipes_collection/recipes/evaluation/nova to local
# Assume the file name be `recipe.yaml`

# Populate parameters
```

```
# input_s3_uri = "s3://<path>/input/" # (Optional) Only used for multi-modal dataset or
 bring your own dataset s3 location
output_s3_uri= "s3://<path>/output/" # Output data s3 location, a zip containing
 metrics json and tensorboard metrics files will be stored to this location
instance_type = "instace_type"  # ml.g5.16xlarge as example
job_name = "your job name"
recipe_path = "recipe path" # ./recipe.yaml as example
image_uri = "708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-evaluation-repo:SM-TJ-
Eval-latest" # Do not change

# (Optional) To bring your own dataset and LLM judge for evaluation
# evalInput = TrainingInput(
# s3_data=input_s3_uri,
# distribution='FullyReplicated',
# s3_data_type='S3Prefix'
#)

estimator = PyTorch(
    output_path=output_s3_uri,
    base_job_name=job_name,
    role=role,
    instance_type=instance_type,
    training_recipe=recipe_path,
    sagemaker_session=sagemaker_session,
    image_uri = image_uri
)
estimator.fit()

# If input dataset exist, pass in inputs
# estimator.fit(inputs={"train": evalInput})
```

Assessing and analyzing evaluation results

After your evaluation job completes successfully, you can assess and analyze the results using the following steps.

To assess and analyze the results, following these steps.

1. Understand the output location structure. Results are stored in your specified Amazon S3 output location as a compressed file:

    ```
    s3://your-bucket/output/benchmark-name/
    ### job_name/
    ```

```
    ### output/
        ### output.tar.gz
```

2. Download the `output.tar.gz` file from your bucket. Extract the contents to reveal.

```
run_name/
### eval_results/
|   ### results_[timestamp].json
#   ### inference_output.jsonl (only present for gen_qa)
|   ### details/
|         ### model/
|              ### <execution-date-time>/
|                    ###details_<task_name>_#_<datetime>.parquet
### tensorboard_results/
    ### eval/
        ### events.out.tfevents.[timestamp]
```

- `results_[timestamp].json` - Output metrics JSON file
- `details_<task_name>_#_<datetime>.parquet` - Inference output file (except for `strong_reject`)
- `events.out.tfevents.[timestamp]` - TensorBoard output file
- `inference_output.jsonl` - Cleaned inference output file (only for `gen_qa` tasks)

3. View results in TensorBoard. To visualize your evaluation metrics:

   1. Upload the extracted folder to an S3 bucket
   2. Navigate to SageMaker TensorBoard
   3. Select your "S3 folders"
   4. Add the S3 folder path
   5. Wait for synchronization to complete

4. Analyze inference outputs. All evaluation tasks, except `llm_judge` and `strong_reject`, will have the following fields for analysis in the inference output.

- `full_prompt` - the full user prompt sent to the model used for the evaluation task.
- `gold` - the field that contains the correct answer(s) as specified by the dataset.
- `metrics` - the field that contains the metrics evaluated on the individual inference. Values that require aggregation would not have a value on the individual inference outputs.
- `predictions` - the field that contains a list of the model's output for the given prompt.

By looking at these fields, you can determine the cause for metric differences and understand the behavior of the customized models.

For `llm_judge`, the inference output file contains the following fields under the metrics field per pair of evaluations.

- `forward_output` - Judge's raw preferences when evaluating in order (response_A, response_B).
- `backward_output` - Judge's raw preferences when evaluating in reverse order (response_B, response_A).
- `Pairwise metrics` - Metrics that are calculated per pair of forward and backward evaluation including `a_scores`, `b_scores`, `ties`, `inference-score` and `score`.

> **Note**
>
> Aggregate metrics like `winrate` are only available in the summary results files, not per individual judgement.

For `gen_qa`, the `inference_output.jsonl` file contains the following fields for each JSON object:

- prompt - The final prompt submitted to the model
- inference - The raw inference output from the model

Evaluation best practices and troubleshooting

Best practices

The following lists some best practices for the evaluation process.

- Keep your output paths organized by model and benchmark type.
- Maintain consistent naming conventions for easy tracking.
- Save extracted results in a secure location.
- Monitor TensorBoard sync status for successful data loading.

Troubleshooting

You can use CloudWatch log group `/aws/sagemaker/TrainingJobs` for training job error logs.

CUDA Out of Memory Error

Issue:

When running model evaluation, you receive the following error:

```
torch.cuda.OutOfMemoryError: CUDA out of memory. Tried to allocate X MiB.
GPU 0 has a total capacity of Y GiB of which Z MiB is free.
```

Cause:

This error occurs when you attempt to load a model that requires more GPU memory than what's available on your current instance type.

Solution:

Choose an instance type with more GPU memory. For example, if you use G5.12xlarge (96 GiB GPU memory), upgrade to G5.48xlarge (192 GiB GPU memory)

Prevention:

Before running model evaluation, do the following.

- Estimate your model's memory requirements
- Ensure your selected instance type has sufficient GPU memory
- Consider the memory overhead needed for model loading and inference

Available subtasks

The following lists available subtasks for model evaluation across multiple domains including MMLU (Massive Multitask Language Understanding), BBH (Big Bench Hard), mathematics, and MMMU (Massive Multi-discipline Multimodal Understanding). These subtasks allow you to assess your model's performance on specific capabilities and knowledge areas.

Amazon Nova customization on Amazon SageMaker HyperPod

You can customize Amazon Nova models using Amazon Nova recipes and train them on Amazon SageMaker HyperPod. A recipe is a YAML configuration file that provides details to SageMaker AI on how to run your model customization job.

Amazon SageMaker HyperPod offers high-performance computing with optimized GPU instances and Amazon FSx for Lustre storage, robust monitoring through integration with tools like TensorBoard, flexible checkpoint management for iterative improvement, seamless deployment to Amazon Bedrock for inference, and efficient scalable multi-node distributed training-all working together to provide organizations with a secure, performant, and flexible environment to tailor Nova models to their specific business requirements.

Amazon Nova customization on Amazon SageMaker HyperPod stores model artifacts including model checkpoints in a service-managed Amazon S3 bucket. Artifacts in the service-managed bucket are encrypted with SageMaker-managed AWS KMS keys. Service-managed Amazon S3 buckets don't currently support data encryption using customer-managed KMS keys. You can use this checkpoint location for evaluation jobs or Amazon Bedrock inference.

Standard pricing can apply for compute instances, Amazon S3 storage, and FSx for Lustre. For pricing details, see SageMaker HyperPod pricing, Amazon S3 pricing, and FSx for Lustre pricing.

Compute requirements

The following tables summarize the computational requirements for SageMaker HyperPod training.

Pre-training

Model	Sequence length	Nodes	Instance	Accelerator
Amazon Nova Micro	8,192	8	ml.p5.48xlarge	GPU H100
Amazon Nova Lite	8,192	16	ml.p5.48xlarge	GPU H100
Amazon Nova Pro	8,192	24	ml.p5.48xlarge	GPU H100

Direct preference optimization (DPO)

Model	Sequence length	Number of nodes	Instance	Accelerator
Direct Preference Optimization (Full)	32,768	2, 4, or 6	ml.p5.48xlarge	GPU H100
Direct Preference Optimization (LoRA)	32,768	2, 4, or 6	ml.p5.48xlarge	GPU H100

Fine-tuning

Model	Sequence length	Number of nodes	Instance	Accelerator
Supervised Fine-Tuning (LoRA)	65,536	2	ml.p5.48xlarge	GPU H100
Supervised Fine-Tuning (Full)	65,536	2	ml.p5.48xlarge	GPU H100

Model	Sequence length	Number of nodes	Instance	Accelerator
Supervised Fine-Tuning (LoRA)	32,768	4	ml.p5.48xlarge	GPU H100
Supervised Fine-Tuning (Full)	65,536	4	ml.p5.48xlarge	GPU H100

Topics

- [Creating a HyperPod EKS cluster with restricted instance group (RIG)]()

Creating a HyperPod EKS cluster with restricted instance group (RIG)

This topic covers the steps to create a Amazon SageMaker HyperPod EKS cluster with a restricted instance group (RIG). A RIG configuration in SageMaker HyperPod EKS clusters provides a specialized environment for training Amazon Nova models. RIG has the following restrictions:

- RIG workloads run in an internet-free VPC, all ingress and egress are strictly regulated.
- RIG has restrictions on the observability of Kubernetes functions such as Kubectl exec and logs to ensure a secured environment for Nova model training.
- RIG only allows Nova customization images, and jobs running with other images will be denied.

You can create RIGs when setting up instance groups in your HyperPod EKS cluster. While you can control the size and scaling of these resources, you cannot directly access the worker nodes. This architecture ensures Nova components (model weights, checkpoints, training data, and code) are only accessible through regulated channels and a service-managed account system.

Nova model customization on SageMaker HyperPod relies on a service-managed FSx for Lustre file system to achieve optimal performance. When creating a RIG, you must specify the volume size and throughput for the FSx for Lustre file system, which will be mounted to all worker nodes in the instance group. FSx for Lustre is used to store intermediate checkpoints and internal model states during distributed training. Follow the guidance provided in the recipe to choose an appropriate volume size and throughput to ensure sufficient capacity and performance. FSx for Lustre usage costs will apply to your AWS account.

Important notes for RIG in HyperPod EKS clusters

- RIG supports only the use of the execution role for permissions. Ensure that the execution role includes the necessary IAM permissions, such as access to Amazon S3.

- When using service-managed Amazon FSx for Lustre and Amazon S3, ensure that your FSx for Lustre file system is appropriately sized for your workload. The training data manifest is uploaded to Amazon S3, which must be accessible by the execution role.
- RIG must be created or updated on a new SageMaker HyperPod EKS cluster-specifically, one created on or after July 16, 2025. Clusters created before this date might contain incompatible software versions or configurations that are not supported by RIG.

Create a HyperPod EKS cluster with RIG (Console)

Follow these instructions to create a HyperPod EKS cluster with a RIG using the HyperPod console.

Create a HyperPod EKS cluster with RIG (CLI)

Follow these instructions to create a HyperPod EKS cluster with a RIG using the AWS CLI.

Continued pre-training (CPT)

Continued pre-training (CPT) is the process of further training a pre-trained foundation model on new data using the same unsupervised objectives (such as masked language modeling or causal language modeling). It preserves the previously learned general language capabilities while adapting to new domains or distributional shifts.

CPT does not involve architectural changes or fine-tuning for specific downstream tasks. Instead, it extends the model's language understanding capacity in a domain-aware manner.

You should use CPT in the following scenarios:

- You have large-scale, unlabeled data that's specific to a domain (for example medicine or finance).
- You want the model to retain general language capabilities while improving on domain-specific content.
- You want to improve zero-shot and few-shot performance in specialized areas without performing extensive, task-specific fine-tuning.

Data format requirements

We recommend adhering to the following dataset characteristics when performing CPT:

- **Diversity**: Your data should cover a broad range of expressions within the target domain to avoid over-fitting.
- **Representation**: Your data should reflect the distribution that the model will face during inference.
- **Cleanliness**: Noise and redundancy in your data can degrade performance. Deduplication and text normalization improve model training.
- **Scale**: Larger datasets help, but beyond a certain threshold (such as running multiple epochs on limited data), over-fitting risks increase.

Training and validation datasets must be JSONL files following the Converse format, where each line contains a JSON object representing a conversation with the required fields and structure. Here is an example:

```
{"text": "AWS stands for Amazon Web Services"}
{"text": "Amazon SageMaker is a fully managed machine learning service"}
{"text": "Amazon Bedrock is a fully managed service for foundation models"}
```

Text entries should contain naturally flowing, high-quality content that represents your target domain.

Dataset validation

To validate your dataset before submitting your CPT job, check for the following conditions:

- Each line must contain a valid JSON object.
- Each object has a "text" field that contains string data.
- No fields other than "text" are present.
- The file is a `.jsonl` extension.

Training times

The amount of time spent training depends heavily on the size of the dataset, the number of instances use, and the model being trained. Training times are expected to scale linearly. The following table provides some example training times for various models.

Model Type	GBS	Number of Samples in Dataset	Number of P5 Instances	max_length value	Approximate training time in hours
Amazon Nova Micro	256	100,000	8	8,192	4
Amazon Nova Lite	256	100,000	16	8,192	4
Amazon Nova Pro	256	100,000	24	8,192	10

Training and validation datasets must be JSONL files following the [Amazon Bedrock Converse operation format](), where each line contains a JSON object representing a conversation with the required fields and structure.

The Amazon Nova parameters that are available for tuning with CPT include:

- **Run configuration**
  - `name`: A descriptive name for your training job. This helps identify your job in the AWS Management Console.
  - `model_type`: The Amazon Nova model variant to use. The available options are `amazon.nova-micro-v1:0:128k`, `amazon.nova-lite-v1:0:300k`, or `amazon.nova-pro-v1:0:300k`.
  - `model_name_or_path`: The path to the base model to use for your training. The available options are `nova-micro/prod`, `nova-lite/prod`, `nova-pro/prod`, or the S3 path for the post-training checkpoint (`s3://customer-escrow-bucket-unique_id/training_run_name`).
  - `replicas`: The number of compute instances to use for distributed training. Available values vary based on the model you choose. Amazon Nova Micro supports 2, 4, or 8 replicas. Amazon Nova Lite supports 4, 8, 16, or 32 replicas. Amazon Nova Pro supports 6, 12, or 24 replicas.
  - `data_s3_path`: The S3 location of the training dataset, which is a JSONL file. This file must reside in the same AWS account and Region as the cluster. All of the S3 locations provided must be in the same account and Region.

  - `validation_data_s3_path`: (Optional) The S3 location of the validation dataset, which is a JSONL file. This file must reside in the same account and region as the cluster. All of the S3 locations provided must be in the same account and Region.
  - `output_s3_path`: The S3 location where the manifest and TensorBoard logs are stored. All of the S3 locations provided must be in the same AWS account and AWS Region.
- **Training configuration**
  - `max_length`: The maximum sequence length in tokens. This determines the context window size for training. The maximum supported value are 8192 tokens for CPT.

    Longer sequences will improve training efficiencies at the cost of increased memory requirements. We recommend that you match the `max_length` parameter to your data distribution.
- **Trainer settings**
  - `global_batch_size`: The total number of training samples processed together in one forward or backward pass across all devices and workers.

    This value multiplies the per-device batch size and number of devices. It affects the stability of training and throughput. We recommend that you start with a batch size that fits comfortably within your memory and scale up from there. For domain-specific data, larger batches might over-smooth gradients.
  - `max_epochs`: The number of complete passes through your training dataset.

    In general, larger datasets require fewer epochs to converge, while smaller datasets require more epochs to converge. We recommend that you adjust the number of epochs based on the size of your data to prevent over-fitting.
- **Model settings**
  - `hidden_dropout`: The probability of dropping hidden state outputs. Increase this value by approximately 0.0-0.2 to reduce overfitting on smaller datasets. Valid values are between 0-1, inclusive.
  - `attention_dropout`: The probability of dropping attention weights. This parameter can help with generalization. Valid values are between 0-1, inclusive.
  - `ffn_dropout`: The probability of dropping feed-forward network outputs. Valid values are between 0-1, inclusive.
- **Optimizer configuration**

- `lr`: The learning rate, which controls the step size during optimization. We recommend values between 1e-6-1e-4 for good performance. Valid values are between 0-1, inclusive.
- `name`: The optimizer algorithm. Currently, only `distributed_fused_adam` is supported.
- `weight_decay`: The L2 regularization strength. Higher values (between 0.01-0.1) increase regularization.
- `warmup_steps`: The number of steps to gradually increase learning rate. This improves training stability. Valid values are between 1-20, inclusive.
- `min_lr`: The minimum learning rate at the end of decay. Valid values are between 0-1, inclusive, but must be less than learning rate.

CPT recipe

The following is a recipe for CPT.

```
## Run config
run:
  name: "my-cpt-run"             # A descriptive name for your training job
  model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification, do not
 change
  model_name_or_path: "nova-lite/prod"      # Base model path, do not change
  replicas: 4                     # Number of compute instances for training, allowed
 values are 4, 8, 16
  data_s3_path: [S3_PATH_TO_TRAIN_DATASET]
  validation_data_s3_path: (OPTIONAL)[S3_PATH_TO_VALIDATION_DATASET]
  output_s3_path: [S3_PATH_TO_STORE_MANIFEST]

## Training specific configs
training_config:
  max_length: 8192               # Maximum context window size (tokens).
  global_batch_size: 256           # Global batch size, allowed values are 32, 64, 128,
 256.

  trainer:
    max_epochs: 2                # Number of training epochs

  model:
    hidden_dropout: 0.0          # Dropout for hidden states, must be between 0.0 and
 1.0
    attention_dropout: 0.0       # Dropout for attention weights, must be between 0.0
 and 1.0
```

```
    ffn_dropout: 0.0             # Dropout for feed-forward networks, must be between
 0.0 and 1.0

    optim:
      lr: 1e-5                   # Learning rate
      name: distributed_fused_adam  # Optimizer algorithm, do not change
      adam_w_mode: true          # Enable AdamW mode
      eps: 1e-06                 # Epsilon for numerical stability
      weight_decay: 0.0          # L2 regularization strength, must be between 0.0 and
 1.0
      betas:                     # Adam optimizer betas, must be between 0.0 and 1.0
        - 0.9
        - 0.999
      sched:
        warmup_steps: 10     # Learning rate warmup steps
        constant_steps: 0    # Steps at constant learning rate
        min_lr: 1e-6         # Minimum learning rate, must be lower than lr
```

Limitations

CPT has the following limitations:

- Multimodal datasets aren't supported.
- Intermediate checkpoints aren't saved for evaluation and you can't resume from an intermediate checkpoint. Only the last checkpoint is saved.
- MLflow logging isn't supported.

Supervised fine-tuning (SFT)

The following sections outline the process of supervised fine-tuning (SFT), both full-rank SFT and parameter-efficient SFT.

Full-rank supervised fine-tuning (SFT)

Supervised fine-tuning (SFT) is the process of providing a collection of prompt-response pairs to a foundation model to improve the performance of a pre-trained foundation model on a specific task. The labeled examples are formatted as prompt-response pairs and phrased as instructions. This fine-tuning process modifies the weights of the model.

You should use SFT when you have domain-specific data that requires providing specific prompt-response pairs for optimal results.

Note that your training and validation input datasets must reside in customer-owned buckets, not in escrow, or service-managed S3 buckets.

Data requirements

For full-rank SFT and low-rank adapter (LoRA) SFT, the data should follow the [Amazon Bedrock Converse operation format](). For examples and constraints of this format, see [Preparing data for fine-tuning Understanding models]().

To validate your dataset format before submission, we recommend using [the validation script from the Amazon Bedrock samples repository](). This validation tool helps ensure that your JSONL files adhere to the required format specifications and identify any potential issues before you submit your fine-tuning job.

The Amazon Nova parameters that are available for tuning with SFT are as follows:

- **Run configuration**
  - `name`: A descriptive name for your training job. This helps identify your job in the AWS Management Console.
  - `model_type`: The Amazon Nova model variant to use. The available options are `amazon.nova-micro-v1:0:128k`, `amazon.nova-lite-v1:0:300k`, or `amazon.nova-pro-v1:0:300k`.
  - `model_name_or_path`: The path to the base model to use for your training. Select the model to use from `nova-micro/prod`, `nova-lite/prod`, `nova-pro/prod`, or the S3 path for the post-training checkpoint (`s3://<escrow bucket>/<job id>/outputs/checkpoints`).
  - `replicas`: The number of compute instances to use for distributed training. Available values vary based on the model chosen. Amazon Nova Micro supports 2, 4, or 8 replicas. Amazon Nova Lite supports 4, 8, 16, or 32 replicas. Amazon Nova Pro supports 6, 12, or 24 replicas.
  - `data_s3_path`: The S3 location of the training dataset, which is a JSONL file. This file must reside in the same AWS account and Region as the cluster. All of the S3 locations within the provided S3 path must be in the same account and Region.
  - `validation_data_s3_path`: (Optional) The S3 location of the validation dataset, which is a JSONL file. This file must reside in the same account and Region as the cluster. All of the S3 locations within the provided S3 path must be in the same account and Region.
  - `output_s3_path`: The S3 location where the manifest and TensorBoard logs are stored. All of the S3 locations within the provided S3 path must be in the same account and region.
- **Training configuration**

- max_length: The maximum sequence length in tokens. This determines the context window size for training. The maximum supported value are 65,536 tokens for SFT.

  Longer sequences will improve training efficiencies at the cost of increased memory requirements. We recommend that you match the max_length parameter to your data distribution.

- **Trainer settings**
  - max_epochs: The number of complete passes through your training dataset. The maximum value is 5.

    In general, larger datasets require fewer epochs to converge, while smaller datasets require more epochs to converge. We recommend that you adjust the number of epochs based on the size of your data.

- **Model settings**
  - hidden_dropout: The probability of dropping hidden state outputs. Increase this value by approximately 0.0-0.2 to reduce over-fitting on smaller datasets. Valid values are between 0-1, inclusive.
  - attention_dropout: The probability of dropping attention weights. This parameter can help with generalization. Valid values are between 0-1, inclusive.
  - ffn_dropout: The probability of dropping feed-forward network outputs. Valid values are between 0-1, inclusive.

- **Optimizer configuration**
  - lr: The learning rate, which controls the step size during optimization. Valid values are between 1e-6-1e-3, inclusive. We recommend values between 1e-6-1e-4 for good performance.
  - name: The optimizer algorithm. Currently, only distributed_fused_adam is supported.
  - weight_decay: The L2 regularization strength. Higher values (between 0.01-0.1) increase regularization.
  - warmup_steps: The number of steps to gradually increase learning rate. This improves training stability. Valid values are between 1-20, inclusive.
  - min_lr: The minimum learning rate at the end of decay. Valid values are between 0-1, inclusive, but must be less than learning rate.

Quick start with a full-rank SFT recipe

The following is a recipe for full-rank SFT that's intended for you to quickly start an SFT job on a HyperPod cluster. This recipe also assumes that you have connected to your HyperPod cluster using the correct AWS credentials.

```
run:
  name: "my-sft-micro-job" # gets appended with a unique ID for HP jobs
  model_type: "amazon.nova-micro-v1:0:128k"
  model_name_or_path: "nova-micro/prod"
  replicas: 2
  data_s3_path: s3:Replace with your S3 bucket name/input.jsonl
  validation_data_s3_path: [OPTIONAL] s3:your S3 bucket name/input.jsonl
  output_s3_path: [S3_PATH_TO_STORE_MANIFEST]

## training specific configs

            sched:
                warmup_steps: 10     # Learning rate warmup steps
                constant_steps: 0    # Steps at constant learning rate
                min_lr: 1e-6         # Minimum learning rate

        peft:
            peft_scheme: null        # Set to null for full-parameter fine-tuning
```

Limitations

Publishing metrics to Weights & Biases and MLFlow is not supported.

Intermediate checkpoints are not saved for evaluation and you can't resume from an intermediate checkpoint. Only the last checkpoint is saved.

To adjust the hyperparameters, follow the guidance in Selecting hyperparameters.

Parameter-efficient fine-tuning (PEFT)

Parameter-efficient fine-tuning (PEFT) involves retraining a small number of additional weights to adapt a foundation model to new tasks or domains. Specifically, low-rank adapter (LoRA) PEFT efficiently fine-tunes foundation models by introducing low-rank trainable weight matrices into specific model layers, reducing the number of trainable parameters while maintaining model quality.

A LoRA PEFT adapter augments the base foundation model by incorporating lightweight adapter layers that modify the model's weights during inference while keeping the original model parameters intact. This approach is also considered one of the most cost-effective fine-tuning techniques. For more information, see Fine-tune models with adapter inference components.

You should use LoRA PEFT in the following scenarios:

- You want to start with a fast training procedure.
- The base model's performance is already satisfactory. In this case, the goal of LoRA PEFT is to enhance its capabilities across multiple related tasks, such as text summarization or language translation. LoRA PEFT's regularization properties help prevent overfitting and mitigate the risks of the model "forgetting" the source domain. This ensures the model remains versatile and adaptable to various applications.

- You want to perform instruction fine-tuning scenarios with relatively small datasets. LoRA PEFT performs better with smaller, task-specific datasets than broader, larger datasets.
- You have large, labeled datasets that exceed the Amazon Bedrock customization data limits. In this case, you can use LoRA PEFT on SageMaker AI to generate better results.
- If you have already achieved promising results through Amazon Bedrock fine-tuning, LoRA PEFT in SageMaker AI can help further optimize the model hyperparameters.

The Amazon Nova parameters that are available for with LoRA PEFT include:

- **Run configuration**
  - `name`: A descriptive name for your training job. This helps identify your job in the AWS Management Console.
  - `model_type`: The Nova model variant to use. The available options are `amazon.nova-micro-v1:0:128k`, `amazon.nova-lite-v1:0:300k`, or `amazon.nova-pro-v1:0:300k`.
  - `model_name_or_path`: The path to the base model to use for your training. Select the model to use. The available options are `nova-micro/prod`, `nova-lite/prod`, `nova-pro/prod`, or the S3 path for the post-training checkpoint (`s3://<escrow bucket>/<job id>/outputs/checkpoints`).
  - `replicas`: The number of compute instances to use for distributed training. Available values vary based on the model you use. Amazon Nova Micro supports 2, 4, or 8 replicas. Amazon Nova Lite supports 4, 8, 16, or 32 replicas. Amazon Nova Pro supports 6, 12, or 24 replicas.
  - `output_s3_path`: The S3 location where the manifest and TensorBoard logs are stored. All of the S3 locations within the provided S3 path must be in the same account and region.
- **Training configuration**
  - `max_length`: The maximum sequence length in tokens. This determines the context window size for training. The maximum supported value are 65,536 tokens for LoRA PEFT.

    Longer sequences will improve training efficiencies at the cost of increased memory requirements. We recommend that you match the `max_length` parameter to your data distribution.
- **Trainer settings**
  - `max_epochs`: The number of complete passes through your training dataset. You can set either `max_steps` or `max_epochs`, but we do not recommend setting both. The maximum value is 5.

In general, larger datasets require fewer epochs to converge, while smaller datasets require more epochs to converge. We recommend that you adjust the number of epochs based on the size of your data.

- **Model settings**
  - `hidden_dropout`: The probability of dropping hidden state outputs. Increase this value by approximately 0.0-0.2 to reduce overfitting on smaller datasets. Valid values are between 0-1, inclusive.
  - `attention_dropout`: The probability of dropping attention weights. This parameter can help with generalization. Valid values are between 0-1, inclusive.
  - `ffn_dropout`: The probability of dropping feed-forward network outputs. Valid values are between 0-1, inclusive.
- **Optimizer configuration**
  - `lr`: The learning rate, which controls the step size during optimization. We recommend values between 1e-6-1e-4 for good performance. Valid values are between 0-1, inclusive.
  - `name`: The optimizer algorithm. Currently, only `distributed_fused_adam` is supported.
  - `weight_decay`: The L2 regularization strength. Higher values (between 0.01-0.1) increase regularization.
  - `warmup_steps`: The number of steps to gradually increase learning rate. This improves training stability. Valid values are between 1-20, inclusive.
  - `min_lr`: The minimum learning rate at the end of decay. Valid values are between 0-1, inclusive, but must be less than learning rate.
- **LoRA configuration parameters**
  - `peft_scheme`: Set to `lora` to enable low-rank adaptation.
  - `alpha`: The scaling factor for LoRA weights. This is typically set to same value as `adapter_dim`.
  - `adaptor_dropout`: The regularization parameter for LoRA.

PEFT recipe

The following is a recipe for LoRA PEFT.

```
## Run config
run:
    name: "my-lora-run"             # A descriptive name for your training job
```

```
    model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification
    model_name_or_path: "nova-lite/prod"      # Base model path
    replicas: 4                     # Number of compute instances for training
    output_s3_path: [S3_PATH_TO_STORE_MANIFEST]

## Training specific configs
training_config:
    max_length: 32768               # Maximum context window size (tokens)

    trainer:
        max_epochs: 2               # Number of training epochs

    model:
        hidden_dropout: 0.0          # Dropout for hidden states
        attention_dropout: 0.0       # Dropout for attention weights
        ffn_dropout: 0.0             # Dropout for feed-forward networks

        optim:
            lr: 1e-5                 # Learning rate
            name: distributed_fused_adam  # Optimizer algorithm
            adam_w_mode: true        # Enable AdamW mode
            eps: 1e-06               # Epsilon for numerical stability
            weight_decay: 0.0        # L2 regularization strength
            betas:                   # Adam optimizer betas
                - 0.9
                - 0.999
            sched:
                warmup_steps: 10     # Learning rate warmup steps
                constant_steps: 0    # Steps at constant learning rate
                min_lr: 1e-6         # Minimum learning rate

        peft:
            peft_scheme: "lora"      # Enable LoRA for parameter-efficient fine-tuning
            lora_tuning:
                loraplus_lr_ratio: 8.0  # LoRA+ learning rate scaling factor
                alpha: 32            # Scaling factor for LoRA weights
                adapter_dropout: 0.01  # Regularization for LoRA parameters
```

Limitations

PEFT has the following limitations:

- The training configuration provided earlier has the recommended values for each parameter.

- Intermediate checkpoints are not saved for evaluation and you can't resume from an intermediate checkpoint. Only the last checkpoint is saved.
- MLflow logging isn't supported.

Troubleshooting

Use the following information to help resolve issues that you might encounter:

- The input dataset for both training and validation should reside in customer-owned buckets, not in escrow, or service-managed S3 buckets.
- If you receive a Region not found error in the AWS CLI, resubmit the job with the region prepended to the start-job command. For example: `AWS_REGION=us-east-1 hyperpod start-job ...Job Parameters`.
- To adjust the hyperparameters, follow the guidance in Selecting hyperparameters.

Direct preference optimization (DPO)

Direct preference optimization (DPO) is an efficient fine-tuning method for foundation models that uses paired comparison data to align model outputs with human preferences. This approach enables direct optimization of model behavior based on human feedback about which responses are more desirable.

Both full-rank DPO and low-rank adapter (LoRA) DPO are available.

Data format requirements

For both full-rank and LoRA DPO, the training data format requirements are similar to SFT. However, for DPO, the final turn needs to have preference pairs. Here is an example of the DPO data format:

```
// N-1 turns same as SFT format
{
    "role": "assistant",
    "candidates": [
        {
            "content": [
                {
                    "text": "..."
                } // content list can contain multiple 'text' objects
```

```
            ],
            "preferenceLabel": "preferred"
        },
        {
            "content": [
                {
                    "text": "..."
                } // content list can contain multiple 'text' objects
            ],
            "preferenceLabel": "non-preferred"
        }
    ]
}
```

Here is another complete DPO text sample:

```
{
    "system": [
        {
            "text": "..."
        }
    ],
    "messages":[
        {
            "role": "user",
            "content": [
                {
                    "text": "..."
                }
            ]
        },
        {
            "role": "assistant",
            "content": [
                {
                    "text": "..."
                }
            ]
        },
        {
            "role": "user",
            "content": [
                {
```

```
                    "text": "..."
                }
            ]
        },
        {
            "role": "assistant",
            "candidates": [
                {
                    "content": [
                        {
                            "text": "..."
                        }
                    ],
                    "preferenceLabel": "preferred"
                },
                {
                    "content": [
                        {
                            "text": "..."
                        }
                    ],
                    "preferenceLabel": "non-preferred"
                }
            ]
        }
    ],
}
```

Here is a complete DPO image sample:

```
{
    "system": [
        {
            "text": "..."
        }
    ],
    "messages":[
        {
            "role": "user",
            "content": [
                {
                    "text": "..."
                },
```

```
                {
                    "text": "..."
                },
                {
                    "image": {
                        "format": "jpeg",
                        "source": {
                            "s3Location": {
                                "uri": "s3://your-bucket/your-path/your-image.jpg",
                                "bucketOwner": "your-aws-account-id"
                            }
                        }
                    }
                } // "content" can have multiple "text" and "image" objects.
                 // max image count is 10
            ]
        },
        {
            "role": "assistant",
            "content": [
                {
                    "text": "..."
                }
            ]
        },
        {
            "role": "user",
            "content": [
                {
                    "text": "..."
                },
                {
                    "text": "..."
                },
                {
                    "image": {
                        "format": "jpeg",
                        "source": {
                            "s3Location": {
                                "uri": "s3://your-bucket/your-path/your-image.jpg",
                                "bucketOwner": "your-aws-account-id"
                            }
                        }
                    }
```

```
                } // "content" can have multiple "text" and "image" objects.
                 // max image count is 10
            ]
        },
        {
            "role": "assistant",
            "candidates": [
                {
                    "content": [
                        {
                            "text": "..."
                        }
                    ],
                    "preferenceLabel": "preferred"
                },
                {
                    "content": [
                        {
                            "text": "..."
                        }
                    ],
                    "preferenceLabel": "non-preferred"
                }
            ]
        }
    ],
}
```

Other constraints on the input datasets apply. For more information, see Dataset constraints. We recommend that you include a minimum of 1,000 preference pairs for effective training. High-quality preference data leads to more efficient results.

We recommend using DPO in the following scenarios:

- Optimizing for subjective outputs that require alignment with specific human preferences.
- Adjusting the model's tone, style, or content characteristics to match desired response patterns.
- Making targeted improvements to an existing model based on user feedback and error analysis.
- Maintaining consistent output quality across different use cases.
- Implementing safety guardrails through preferred response patterns.
- Training with reward-free reinforcement learning.
- Using only preference data instead of graded or labeled data.

- Improving the model in nuanced alignment tasks, such as helpfulness, harmlessness, or honesty.

Full-rank DPO

The Amazon Nova parameters that are available for full-rank DPO are as follows:

- **Run configuration**
  - `name`: A descriptive name for your training job. This helps identify your job in the AWS Management Console.
  - `model_type`: The Nova model variant to use. The available options are `amazon.nova-micro-v1:0:128k`, `amazon.nova-lite-v1:0:300k`, or `amazon.nova-pro-v1:0:300k`.
  - `model_name_or_path`: The path to the base model. Select the model to use from `nova-micro/prod`, `nova-lite/prod`, `nova-pro/prod`, or the S3 path for the post-training checkpoint (`s3://<escrow bucket>/<job id>/outputs/checkpoints`).
  - `replicas`: The number of compute instances to use for distributed training. Available values vary based on the model chosen. Amazon Nova Micro supports 2, 4, or 8 replicas. Amazon Nova Lite supports 4, 8, 16, or 32 replicas. Amazon Nova Pro supports 6, 12, or 24 replicas.
  - `data_s3_path`: The S3 location of the training dataset, which is a JSONL file. This file must reside in the same account and Region as the cluster. All of the S3 locations provided must be in the same account and Region.
  - `validation_data_s3_path`: The S3 location of the validation dataset, which is a JSONL file. This file must reside in the same AWS account and Region as the cluster. All of the S3 locations provided must be in the same account and Region.
- **Training configuration**
  - `max_length`: The maximum sequence length in tokens. This determines the context window size for training. The maximum supported value are 32,768 tokens for DPO.

    Longer sequences will improve training efficiencies at the cost of increased memory requirements. We recommend that you match the `max_length` parameter to your data distribution.
- **Trainer settings**
  - `max_epochs`: The number of complete passes through your training dataset. The maximum value is 5.

In general, larger datasets require fewer epochs to converge, while smaller datasets require more epochs to converge. We recommend that you adjust the number of epochs based on the size of your data.

- **Model settings**
  - `hidden_dropout`: The probability of dropping hidden state outputs. Increase this value by approximately 0.0-0.2 to reduce overfitting on smaller datasets. Valid values are between 0-1, inclusive.
  - `attention_dropout`: The probability of dropping attention weights. This parameter can help with generalization. Valid values are between 0-1, inclusive.
  - `ffn_dropout`: The probability of dropping feed-forward network outputs. Valid values are between 0-1, inclusive.
- **Optimizer configuration**
  - `lr`: The learning rate, which controls the step size during optimization. We recommend values between 1e-6-1e-4 for good performance. Valid values are between 0-1, inclusive.
  - `name`: The optimizer algorithm. Currently, only `distributed_fused_adam` is supported.
  - `weight_decay`: The L2 regularization strength. Higher values (between 0.01-0.1) increase regularization.
  - `warmup_steps`: The number of steps to gradually increase learning rate. This improves training stability. Valid values are between 1-20, inclusive.
  - `min_lr`: The minimum learning rate at the end of decay. Valid values are between 0-1, inclusive, but must be less than learning rate.
- **DPO configuration**
  - `beta`: Determines how closely the model should fit the training data or the original model. Valid values are between 0.001-0.5, inclusive.

    Specify larger values (for example, 0.5) to preserve more of the reference model behavior while more slowly learning new preferences. Specify smaller values (for example, 0.01-0.05) to more quickly learn new preferences at the risk of diverging from the reference model behavior.

Full-rank DPO recipe

The following is a full-rank recipe for DPO

```
## Run config
```

```
run:
  name: "my-dpo-micro-job"             # A descriptive name for your training job
  model_type: "amazon.nova-micro-v1:0:128k"  # Model variant specification, do not
 change
  model_name_or_path: "nova-micro/prod"      # Base model path, do not change
  replicas: 2                      # Number of compute instances for training, allowed
 values are 2, 4, 8
  data_s3_path: s3:Replace with your S3 bucket name/input.jsonl
  validation_data_s3_path: [OPTIONAL] s3:your S3 bucket name/input.jsonl
  output_s3_path: [S3_PATH_TO_STORE_MANIFEST]

## Training specific configs
training_config:
  max_length: 32768                # Maximum context window size (tokens).
  global_batch_size: 64            # Global batch size, allowed values are 16, 32, 64.

  trainer:
    max_epochs: 2                  # Number of training epochs

  model:
    hidden_dropout: 0.0            # Dropout for hidden states, must be between 0.0 and
 1.0
    attention_dropout: 0.0         # Dropout for attention weights, must be between 0.0
 and 1.0
    ffn_dropout: 0.0               # Dropout for feed-forward networks, must be between
 0.0 and 1.0

    optim:
      lr: 1e-5                    # Learning rate
      name: distributed_fused_adam  # Optimizer algorithm, do not change
      adam_w_mode: true           # Enable AdamW mode
      eps: 1e-06                  # Epsilon for numerical stability
      weight_decay: 0.0           # L2 regularization strength, must be between 0.0 and
 1.0
      betas:                      # Adam optimizer betas, must be between 0.0 and 1.0
        - 0.9
        - 0.999
      sched:
        warmup_steps: 10      # Learning rate warmup steps
        constant_steps: 0     # Steps at constant learning rate
        min_lr: 1e-6          # Minimum learning rate, must be lower than lr

    dpo_cfg:
```

```
        beta: 0.1               # Strength of preference enforcement. Limits: [0.001,
 0.5]

    peft:
        peft_scheme: null        # Disable LoRA, trigger full rank fine tuning
```

Low-rank adapter DPO

The Amazon Nova parameters that are available for low-rank adapter DPO are as follows:

- **Run configuration**
  - `name`: A descriptive name for your training job. This helps identify your job in the AWS Management Console.
  - `model_type`: The Nova model variant to use. The available options are `amazon.nova-micro-v1:0:128k`, `amazon.nova-lite-v1:0:300k`, or `amazon.nova-pro-v1:0:300k`.
  - `model_name_or_path`: The path to the base model. Select the model to use from `nova-micro/prod`, `nova-lite/prod`, `nova-pro/prod`, or the S3 path for the post-training checkpoint (`s3://<escrow bucket>/<job id>/outputs/checkpoints`).
  - `replicas`: The number of compute instances to use for distributed training. Available values vary based on the model chosen. Amazon Nova Micro supports 2, 4, or 8 replicas. Amazon Nova Lite supports 4, 8, 16, or 32 replicas. Amazon Nova Pro supports 6, 12, or 24 replicas.
- **Training configuration**
  - `max_length`: The maximum sequence length in tokens. This determines the context window size for training. The maximum supported value are 32,768 tokens for DPO.

    Longer sequences will improve training efficiencies at the cost of increased memory requirements. We recommend that you match the `max_length` parameter to your data distribution.
- **Trainer settings**
  - `max_epochs`: The number of complete passes through your training dataset. The maximum value is 5.

    In general, larger datasets require fewer epochs to converge, while smaller datasets require more epochs to converge. We recommend that you adjust the number of epochs based on the size of your data.
- **Model settings**

  - `hidden_dropout`: The probability of dropping hidden state outputs. Increase this value by approximately 0.0-0.2 to reduce overfitting on smaller datasets. Valid values are between 0-1, inclusive.
  - `attention_dropout`: The probability of dropping attention weights. This parameter can help with generalization. Valid values are between 0-1, inclusive.
  - `ffn_dropout`: The probability of dropping feed-forward network outputs. Valid values are between 0-1, inclusive.
- **Optimizer configuration**
  - `lr`: The learning rate, which controls the step size during optimization. We recommend values between 1e-6-1e-4 for good performance. Valid values are between 0-1, inclusive.
  - `name`: The optimizer algorithm. Currently, only `distributed_fused_adam` is supported.
  - `weight_decay`: The L2 regularization strength. Higher values (between 0.01-0.1) increase regularization.
  - `warmup_steps`: The number of steps to gradually increase learning rate. This improves training stability. Valid values are between 1-20, inclusive.
  - `min_lr`: The minimum learning rate at the end of decay. Valid values are between 0-1, inclusive, but must be less than learning rate.
- **DPO configuration**
  - `beta`: Determines how closely the model should fit the training data or the original model. Valid values are between 0.001-0.5, inclusive.

    Specify larger values (for example, 0.5) to preserve more of the reference model behavior while more slowly learning new preferences. Specify smaller values (for example, 0.01-0.05) to more quickly learn new preferences at the risk of diverging from the reference model behavior.
- **LoRA configuration parameters**
  - `peft_scheme`: Set to `lora` to enable Low-Rank Adaptation, which generates a more efficient, smaller output model. These LoRA-specific properties are also available:
    - `alpha`: The scaling factor for LoRA weights. This is typically set to same value as `adapter_dim`.
    - `adapter_dropout`: The regularization parameter for the LoRA parameters.

LoRA DPO recipe

The following is a recipe for LoRA DPO.

```
## Run config
run:
    name: "my-lora-run"             # A descriptive name for your training job
    model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification, do not
 change
    model_name_or_path: "nova-lite/prod"      # Base model path, do not change
    replicas: 4                     # Number of compute instances for training. All
 supported values: {4, 8, 16}
    data_s3_path: s3:Replace with your S3 bucket name/input.jsonl
    validation_data_s3_path: [OPTIONAL] s3:your S3 bucket name/input.jsonl
    output_s3_path: [S3_PATH_TO_STORE_MANIFEST]

## Training specific configs
training_config:
    max_length: 16384               # Maximum context window size (tokens). Should be
 between [1024, 32768] and multiple of 1024.
                                    # Note: Image dataset for DPO has a limit on 20k
 samples and 16384 max_length
    global_batch_size: 64           # Total samples per step. Limits: {16, 32, 64, 128,

                adapter_dropout: 0.01  # Regularization for LoRA parameters. Limits:
[0.0, 1.0]
```

Limitations

DPO has the following limitations:

- Intermediate checkpoints are not saved for evaluation and you can't resume from an intermediate checkpoint. Only the last checkpoint is saved.
- MLflow logging is not supported.
- To adjust the hyperparameters, follow the guidance in Selecting hyperparameters.

Proximal policy optimization (PPO)

Proximal policy optimization (PPO) is the process of using several machine learning models to train and score a model. The following models are part of the PPO process:

- **Actor train or policy model**: A supervised fine-tuning (SFT) model that gets fine-tuned and updated every epoch. The updates are made by sampling prompts, generating completions, and updating weights using a clipped-surrogate objective. This limits the per-token log-profitability change so that each policy step is *proximal* to the previous one, preserving training stability.
- **Actor generation model**: A model that generates prompt completions or responses to be judged by the reward model and critic model. The weights of this model are updated from the actor train or policy model each epoch.
- **Reward model**: A model with frozen weights that's used to score the actor generation model.

- **Critic model**: A model with unfrozen weights that's used to score the actor generation model. This score is often viewed as an estimate of the total reward the actor receives when generating the remaining tokens.
- **Anchor model**: An SFT model with frozen weights that is used to calculate the KL divergence between the actor train model and the base model. The anchor model ensures that the updates to the actor model are not too drastic compared to the base model. Drastic changes can lead to instability or performance degradation.

The training data must be in JSONL format where each line contains a single JSON object that represents a training example. Here is an example:

```
{
    "turns": ["string", "string", ...], // Required
    "turns_to_mask": [integer, integer, ...], // Required
    "reward_category": "string", // Required
    "meta_data": {} // Optional
}
```

- `turns` is an array of conversation string arrays that represent the dialog sequence. This line contains system prompts, user messages, and bot responses. User messages typically end with "Bot: " to indicate where the model output begins. For example, `[["System prompt"], ["User: Question Bot:"], ["Bot response"]]`.
- `turns_to_mask` is an array of 0-based indices that identify which turns should not receive gradient updates. The masked turns are typically system prompts and user turns. For example, `[0, 1, 3]` masks the system prompt and user messages (the first and third messages).
- `reward_category` is a string that identifies what aspects of model performance to evaluate. It's used to select the appropriate reward model category during training. The reward category is available for the following reward categories: `default`, `math`, `coding`, `if`, `rag`, and `rai`.
- `meta_data` is an optional object that contains additional contextual or ground-truth information. This can include identifiers, source information, or conversation context. The structure is flexible based on your dataset needs.

Here is an example record:

```
{
    "turns": ["You are a helpful AI assistant.",
```

```
        "User: What is ML? Bot:",
        "Machine learning is...", "User: Examples? Bot:",
        "Email spam filtering is..."
    ],
    "turns_to_mask": [0, 1, 3],
    "reward_category": "default",
    "meta_data": {
        "messages": [{
                "role": "system",
                "content": "You are a helpful AI assistant."
            },
            {
                "role": "user",
                "content": "What is ML?"
            },
            {
                "role": "assistant",
                "content": "Machine learning is..."
            },
            {
                "role": "user",
                "content": "Examples?"
            },
            {
                "role": "assistant",
                "content": "Email spam filtering is..."
            }
        ]
    }
}
```

The reward modeling framework implements multi-dimensional optimization across distinct categorical objectives to facilitate robust model convergence. The reward category should be selected based on the task that the model must be optimized for.

We recommend the following guidelines for selecting the right framework for your tasks:

- `default`: A general purpose optimizer for standard conversational tasks and basic interactions. Used for general conversations and discussions, basic writing tasks, simple question answering, and non-specialized knowledge queries.

  Here is an example:

```
{
    "turns": ["Write a summary of climate change"],
    "turns_to_mask": [0],
    "reward_category": "default"
}
```

- `math`: A specialized optimizer for mathematical computations and numerical reasoning tasks. Used for mathematical problem-solving, arithmetic calculations, algebraic equations, geometric problems, and statistical analysis.

  Here is an example:

```
{
    "turns": ["Calculate the derivative of x²"],
    "turns_to_mask": [0],
    "reward_category": "math"
}
```

- `coding`: A dedicated category for programming and software development-related queries. Used for code implementation, debugging assistance, algorithm design, technical documentation, and system architecture questions.

  Here is an example:

```
{
    "turns": ["Write a function to check if a string is palindrome"],
    "turns_to_mask": [0],
    "reward_category": "coding"
}
```

- `if`: A category for tasks that require precise procedural execution and step-by-step guidance. Used for multi-step procedures, sequential instructions, complex task decomposition, and process documentation.

  Here is an example:

```
{
    "turns": ["Provide steps to deploy a web application"],
    "turns_to_mask": [0],
    "reward_category": "if"
```

```
}
```

- `rag`: A reward category for tasks that require answering queries based specifically on retrieved contextual information. Used when responses should be derived directly from provided reference materials, synthesizing factual content without going beyond the scope of retrieved information, ensuring answers are grounded in the supplied context rather than general knowledge.

  Here is an example:

```
{
            "turns": ["The Synthesis Report integrates findings from all six IPCC
 assessment cycles, revealing that global surface temperature has increased 1.1°C
 from 1850-1900 to 2011-2020, with human activities unequivocally identified as the
 cause of this warming. Alarmingly, current policies put the world on track for
 3.2°C warming by 2100. The document identifies 5 key climate system "tipping points"
 approaching and emphasizes that greenhouse gas emissions must decline 43% by 2030
 (compared to 2019 levels) to limit warming to 1.5°C. Climate-related risks will
 escalate with every increment of warming, with loss and damage disproportionately
 affecting vulnerable populations. Despite some progress, climate adaptation remains
 uneven with significant gaps, and financial flows continue to fall below levels
 needed for mitigation goals.",
            "What were the key findings of the latest IPCC climate report?"],
            "turns_to_mask": [0, 0],
            "reward_category": "rag"
            }
```

- `rai`: A reward category for tasks that require applying responsible AI principles such as fairness, transparency, and ethics. Used for evaluating potential biases in AI systems, ensuring privacy considerations, addressing ethical dilemmas, and promoting inclusive design principles.

  Here is an example:

```
{
            "turns": ["Identify potential bias concerns when developing a loan
 approval algorithm and suggest mitigation strategies"],
            "turns_to_mask": [0],
            "reward_category": "rai"
            }
```

Masking turns

In training datasets, the `turns_to_mask` parameter is crucial for controlling which conversation turns receive gradient updates during training. This array of indices determines which parts of the dialogue the model should learn to generate versus which parts should be treated as context only. Proper masking ensures the model learns appropriate response patterns while avoiding training on system prompts or user inputs that could degrade performance.

We recommend the following guidance for masking:

- **Always mask index 0** - System prompts should never receive gradient updates.
- **Always mask user turns** - Prevent the model from learning to generate user inputs.
- **Pattern consistency** - Use identical masking patterns for similar conversation structures, such as (0, 1, 3, 5) for multi-turn dialogues.
- **Selective training** - Mask early bot responses to focus training on improved final responses.
- **Chain-of-thought preservation** - Only mask system and user turns when training on reasoning sequences.
- **Quality filtering** - Mask low-quality assistant responses to prevent performance degradation.
- **Context optimization** - Ensure masked turns don't remove essential context needed for subsequent responses.

The key to effective masking is monitoring training metrics and validation performance to identify whether your masking strategy preserves necessary context while focusing gradient updates on the desired model outputs.

Enable KL-divergence loss

For enabling KL-divergence loss, the anchor server needs to be enabled to compute the divergence of the current policy from the original distribution. The KL loss type needs to be specified, and coefficients need to be a value other than zero. Higher coefficient values help the model not deviate much from the original policy which results in lesser changes to general performance. Lower coefficient values allow larger deviations from previous policy, leading to better performance of target metrics but impacting the general performance.

```
ppo_anchor:
  max_length: 8192
  trainer:
    num_nodes: ${recipes.run.cm_replicas}
  model:
    global_batch_size: 32
```

```
ppo_actor_train:
  model:
    ######## Use KL in actor loss ########
    kl_loss_type: low_var_kl
    kl_loss_coeff: 0.1

    ######## Use KL in reward model ######
    kl_reward_penalty_coeff: 0.1
```

Learning rate

The learning rate for the critic and policy models can be adjusted, with 3e-6 being the default balanced choice. Higher learning rates typically lead to training instabilities, which can be identified through KL divergence spikes and erratic policy behavior. Lower learning rates may cause convergence issues and slow learning, indicated by stagnant rewards and minimal policy updates. Regular monitoring of KL divergence, reward score, and value loss helps in determining whether to adjust the learning rate during training.

```
ppo_critic:
  model:
    optim:
      lr: 3e-6

ppo_actor_train:
  model:
    optim:
      lr: 3e-06
```

Global batch size

Global batch size significantly impacts PPO performance in Amazon Nova, with larger batches generally improving training stability and gradient estimation while enabling more efficient parallel processing. However, very large batch sizes can lead to diminishing returns and may be constrained by available memory, requiring careful balance with learning rate and other hyperparameters.

```
ppo_actor_train:
  model:
    global_batch_size: 160
```

The Amazon Nova parameters that are available for tuning with PPO include:

- **Run configuration**
  - `actor_train_replicas`: The number of compute instances to be used for the actor train model. Available values vary based on the model chosen. Amazon Nova Micro supports 1 or 2 replicas. Amazon Nova Lite supports 1, 2, or 4 replicas. Amazon Nova Pro supports 3, 6, or 12 replicas.
  - `rm_replicas`: The number of compute instances used for the reward model. We recommend that you use one replica for any model size.
  - `cm_replicas`: The number of compute instances used for the critic model. We recommend that you use one replica for any model size.
  - `actor_generation_replicas`: The number of compute instances used for the actor generation. Available values vary based on the model chosen. Amazon Nova Micro supports 1 replica. Amazon Nova Lite supports 1 or 2 replicas. Amazon Nova Pro supports 1 or 2 replicas.
  - `am_replicas`: The number of compute instances used for the anchor model. We recommend that you use one replica for any model size.
- **Actor train configuration (policy config)**
  - `max_steps`: The maximum number of steps to fine-tune or train the actor train model. Here, one step is defined as rollout, followed by training the actor train model with `global_batch_size` number of samples. One epoch is defined as `global_batch_size * trajectory_buffer_scale`.

    The value chosen here will vary based on your use case and dataset complexity. We recommend starting with 65 epochs or 520 steps, which is the number of epochs multiplied by the value of the `trajectory_buffer_scale`. However, some tasks require a longer PPO training time to achieve the same performance.

    For PPO, the training metrics, such as saturating reward model score and average action length from the ml-flow console, can help in identifying the optimal points for evaluation.
  - `actor_model_max_length`: The maximum length of the input data that is sent to the actor generation component to generate completions.
  - `reward_model_max_length`: The maximum length of the input data that is sent to the reward server to score completions.

- `trajectory_buffer_scale`: This buffer represents the number of rollouts generated using the old actor train (policy) model before updating the weights and generating the new rollouts. The supported values are 1, 2, 4, 8, and 16.

  If `trajectory_buffer_scale` is 1, then the training is on policy. That means the rollouts are generated with the most updated model weights, but throughput suffers. If it's 16, then the model is slightly off-policy but throughput is higher. We recommend starting with 8 for each model.
- `kl_reward_penalty_coeff`: This is the KL divergence term that ensures updates are not too drastic and the policy does not draft from the base or SFT model.
- `kl_loss_coeff`: This value controls how much the KL divergence penalty influences the overall training objective in PPO.
- `kl_loss_type`: This value specifies how to compute the divergence between current and reference policy distributions. The `kl_loss_types` available are `kl` (Standard KL divergence), `mse` (Mean squared error), `abs` (Absolute difference between log probabilities), and `low_var_kl` (low-variance KL approximation).
- `model.clip_ratio`: The actor clip ratio (ε) in PPO is a hyperparameter that limits how much the policy can change during each update.
- `model.optim.lr`: The learning rate used for surrogate model loss training in the actor model.
- `model.lam`: Part of the advantage estimation process. Higher λ gives more weight to longer-term rewards but with higher variance, while a lower λ focuses more on immediate rewards with lower variance but more bias.
- `model.ent_coeff`: Entropy loss in PPO encourages exploration by penalizing the policy when it becomes too deterministic (that is, always picking the same actions with high confidence).

- **Reward model configuration**
  - `global_batch_size`: The batch size for scoring the completions using the reward model. If `ppo_actor_train.model.global_batch_size` is greater than `ppo_reward.model.global_batch_size`, they are processed in multiple batches. Note that `ppo_actor_train.model.global_batch_size % ppo_reward.model.global_batch_size` must equal 0.
  - `max_length`: The maximum context length of the reward model. This should be same as `ppo_actor_train.model.max_length`.

- **Critic model configuration**
  - `global_batch_size`: The batch size of the critic model value. The critic model will provide value estimates for each token in the responses provided by the actor model. The batch size is used for both inference and training.

    Note that `ppo_actor_train.model.global_batch_size % ppo_critic.model.global_batch_size` must equal 0 and `ppo_actor_train.model.global_batch_size * ppo_actor_train.model.trajectory_buffer_size % ppo_critic.model.global_batch_size == 0`.
  - `max_length`: The maximum context length of the critic model. This should be same as `ppo_actor_train.model.max_length`.
  - `model.optim.lr`: The learning rate used for surrogate model loss training in the actor model.
- **Anchor model configuration**
  - `global_batch_size`: The batch size for generating the logp of the frozen SFT or anchor model. Note that `ppo_actor_train.model.global_batch_size % ppo_anchor.model.global_batch_size` must equal 0.
  - `max_length`: The maximum context length of the reward model. This should be same as `ppo_actor_train.model.max_length`.
- **Actor generation model configuration**
  - `actor_model_max_length`: The maximum context length of the actor model generation component. This should be the same as `ppo_actor_train.model.max_length`.

PPO recipe

The following is a recipe for PPO.

```
## Run config
run:
  name: ndry-ppo-pro
  model_type: amazon.nova-pro-v1:0:300k
  model_name_or_path: nova-pro/prod
  data_s3_path: s3://testing/train.jsonl # Your training data S3 path

  actor_train_replicas: 6 # Actor train model replicas
  rm_replicas: 1 # Reward model replicas
```

```
  cm_replicas: 1 # Critic model replicas
  actor_generation_replicas: 2 # Actor generation model replicas
  am_replicas: 1 # Anchor model replicas

## Training config for each PPO component
ppo_reward:
  max_length: 8192 # model architecture max length
  trainer:
    num_nodes: ${recipes.run.rm_replicas}
  model:
    global_batch_size: 16

ppo_critic:
  max_length: 8192
  trainer:
    num_nodes: ${recipes.run.cm_replicas}
  model:
    global_batch_size: 16
    optim:
      lr: 3e-6
      name: distributed_fused_adam
      adam_w_mode: true
      eps: 1e-06
      weight_decay: 0.0
      betas:
        - 0.9
        - 0.999

ppo_anchor:
  max_length: 8192

      eps: 1e-08
      weight_decay: 0.0
      betas:
        - 0.9
        - 0.999
```

Limitations

PPO has the following limitations:

- Intermediate checkpoints are not saved for evaluation and you can't resume from an intermediate checkpoint. Only the last checkpoint is saved.
- Multimodal datasets aren't supported.
- Training jobs aren't automatically stopped. You have to stop the job using the HyperPod CLI.
- MLflow logging isn't supported.
- Critic training metrics are not supported on TensorBoard.
- To adjust the hyperparameters, follow the guidance in Selecting hyperparameters.

Starting a training job using the HyperPod CLI

SageMaker HyperPod CLI is a command-line interface tool for managing Amazon SageMaker HyperPod clusters. You can use the HyperPod CLI to create, configure, and monitor HyperPod clusters for machine learning workloads. For more information, see the sagemaker-hyperpod-cli GitHub repository.

Prerequisites

- Install the HyperPod CLI. For Amazon Nova customization on Amazon SageMaker HyperPod, you must check out the `release_v2` branch to use the SageMaker HyperPod CLI.
- Verify that the Nova output bucket exists before submitting jobs. To verify, run `aws s3 ls s3://nova-111122223333/`.

  The bucket name is the value you specified for `recipes.run.output_s3_path` in the recipe. This output bucket will store a manifest file generated after training, which will contain S3 paths to the output artifacts stored in the service-managed Amazon S3 bucket. Additionally, it might optionally store TensorBoard files or evaluation results.
- Understanding Amazon FSx data sync requirements. Amazon FSx needs time to sync Amazon S3 training data before jobs can run.

Set up the HyperPod CLI for Amazon Nova customization

To set up the HyperPod CLI for Amazon Nova customization, follow these steps.

1. Clone the sagemaker-hyperpod-cli GitHub repository with branch `release_v2`.

   ```
   git clone --recurse-submodules https://github.com/aws/sagemaker-hyperpod-cli.git --
   branch release_v2
   ```

2. Navigate to the `sagemaker-hyperpod-cli` folder.

   ```
   cd sagemaker-hyperpod-cli
   ```

3. Check that you have all the prerequisites in Prerequisites.
4. To set up Helm, follow these steps.

   a. To download the Helm installation script, run:

```
curl -fsSL -o get_helm.sh https://raw.githubusercontent.com/helm/helm/main/
scripts/get-helm-3
```

b. To make the script executable, run:

```
chmod 700 get_helm.sh
```

This command changes permissions to make the script executable.

c. To run the Helm installation script, run:

```
./get_helm.sh
```

d. To remove the installation script, run:

```
rm -f ./get_helm.sh
```

5. To install HyperPod dependencies with restricted instance group (RIG) support, follow these steps.

> **Note**
>
> Before installing the dependencies, you must have a HyperPod EKS cluster with RIG. If you don't have one already, follow these instructions to create one.

a. To connect to your HyperPod EKS cluster, run:

```
aws eks update-kubeconfig --name <eks_cluster_name> --region us-east-1
```

b. To verify connection to your HyperPod EKS cluster, run:

```
kubectl config current-context
```

c. To pull updates for standard HyperPod dependencies, run:

```
helm dependencies update helm_chart/HyperPodHelmChart
```

d. To install standard HyperPod dependencies, run:

```
helm install dependencies helm_chart/HyperPodHelmChart --namespace kube-system
```

e. To navigate to Helm chart directory, run:

```
cd helm_chart
```

f. To install RIG specific HyperPod dependencies, run the following command.

> **Note**
>
> Before installing the dependencies, consider the following:
>
> - You should only run this command once per cluster after it's created.
> - You should ensure the yq utility is installed with version at least 4 (such as v4). There is a built-in check to confirm yq >=4 is available in the installation script.
> - You will need to confirm installation by entering `y` when prompted. Optionally, before confirmation, view the intended installation at `./rig-dependencies.yaml`.

```
chmod 700 ./install_rig_dependencies.sh && ./install_rig_dependencies.sh
```

g. To navigate back to the root of `codesagemaker-hyperpod-cli` repo, run:

```
cd ..
```

6. To proceed with installing the HyperPod CLI in `sagemaker-hyperpod-cli`, follow these steps.

   a. Install the CLI using pip:

   ```
   pip install -e .
   ```

   b. Verify the installation:

   ```
   hyperpod --help
   ```

Submit a job

You can use the HyperPod CLI to submit a training job.

To submit a job using a recipe, run the following command.

```
hyperpod start-job [--namespace <namespace>] --recipe {{fine-tuning | evaluation |
 training}}/nova/<Your_Recipe_Name> --override-parameters \
  '{
      "instance_type":"p5d.48xlarge",
      "container": <Docker Image>,
      "recipes.run.name": <custom-run-name>,
      "recipes.run.output_s3_path": "<customer-s3-path>"
  }'
```

- `--recipe`: The type of the job you are running using the recipe. Valid values are: `fine-tuning` | `evaluation` | `training`.

Job type	Value
SFT/PEFT/PPO/DPO jobs	`fine-tuning`
Evaluation jobs	`evaluation`
CPT jobs	`training`

- Recipe name: You can find the name in the repository under the directory:`/src/hyperpod_cli/sagemaker_hyperpod_recipes/recipe_collection/recipes/`.
- Example recipe: `--recipe evaluation/nova/nova_lite_g5_12xl_bring_your_own_dataset_eval`.
- Container: This field is required. To find your images for the job types, see the following table.

Technique	Container
DPO	708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:SM-HP-DPO-latest

Technique	Container
Evaluation jobs	708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-evaluation-repo:SM-HP-Eval-latest
CPT	708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:HP-CPT-latest
PPO	708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:SMHP-PPO-TRAIN-latest
SFT/PEFT	708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-fine-tune-repo:SM-HP-SFT-latest

- Custom run name: There are definition constraints on the `custom-run-time` input, for example, no capitals, no spaces, no underscores. For more information, see [Object Names and IDs](#).

[Optional] If you already have a training job and want to target a specific node for your next job, follow these steps.

1. To get all free nodes, run the following command.

```
kubectl get nodes –no-headers | awk '$2 != "NotReady" && $3 !=
 "SchedulingDisabled" {print $1}'
```

2. Add the following to the `src\hyperpod_cli\sagemaker_hyperpod_recipes\recipes_collection\cluster\k8s.yaml`file for label selector.

```
label_selector:
  required:
    kubernetes.io/hostname:
      - <node_name>
```

3. On the root directory, run the following command. This ensures SageMaker HyperPod is installed on the user's system, enabling them to use the "hyperpod" keyword for job submission and other functions. You should run this command from the root folder where the HyperPod CLI code is.

   ```
   pip install .
   ```

List jobs

To list jobs, run the following command.

```
hyperpod list-jobs [--namespace <namespace>] [--all-namespaces]
```

The command lists all jobs in the specified namespace or across all namespaces.

Get job details

To get the details of a job, run the following command.

```
hyperpod get-job --job-name <job-name> [--namespace <namespace>] [--verbose]
```

The command retrieves detailed information about a specific job.

List pods

To list pods, run the following command.

```
hyperpod list-pods --job-name <job-name> [--namespace <namespace>]
```

The command lists all pods associated with a specific job in the specified namespace.

Cancel jobs

To cancel a job, run the following command.

```
hyperpod cancel-job --job-name <job-name> [--namespace <namespace>]
```

This command cancels and deletes a running training job in the specified namespace.

Evaluating your trained model

An evaluation recipe is a YAML configuration file that defines how your Amazon Nova model evaluation job is executed. With this recipe, you can assess the performance of a base or trained model against common benchmarks or your own custom datasets. Metrics can be stored in Amazon S3 or TensorBoard. The evaluation provides quantitative metrics that help you assess model performance across various tasks to determine if further customization is needed.

Model evaluation is an offline process, where models are tested against fixed benchmarks with predefined answers. They are not assessed in real-time or against live user interactions. For real-time evaluations, you can evaluate the model after it is deployed to Amazon Bedrock by calling the Amazon Bedrock runtime APIs.

Topics

Available benchmark tasks

A sample code package is available that demonstrates how to calculate benchmark metrics using the SageMaker AI model evaluation feature for Amazon Nova. To access the code packages, see sample-Nova-lighteval-custom-task.

Here is a list of the supported, available industry standard benchmarks. You can specify the following benchmarks in the `eval_task` parameter:

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
mmlu	Text	Multi-task Language Understanding – Tests knowledge	accuracy	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
		across 57 subjects.			
mmlu_pro	Text	MMLU – Professional Subset – Focuses on professional domains such as law, medicine, accounting, and engineering.	accuracy	zs_cot	No
bbh	Text	Advanced Reasoning Tasks – A collection of challenging problems that test higher-level cognitive and problem-solving skills.	accuracy	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
gpqa	Text	General Physics Question Answering – Assesses comprehension of physics concepts and related problem-solving abilities.	accuracy	zs_cot	No
math	Text	Mathematical Problem Solving – Measures mathematical reasoning across topics including algebra, calculus, and word problems.	exact_match	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
strong_reject	Text	Quality-Control Task – Tests the model's ability to detect and reject inappropriate, harmful, or incorrect content.	deflection	zs	Yes
IFEval	Text	Instruction-Following Evaluation – Gauges how accurately a model follows given instructions and completes tasks to specification.	accuracy	zs	No

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
gen_qa	Text	Custom Dataset Evaluation – Lets you bring your own dataset for benchmarking, comparing model outputs to reference answers with metrics such as ROUGE and BLEU.	all	gen_qa	No

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
mmmu	Multi-modal	Massive Multidiscipline Multimodal Understanding (MMMU) – College-level benchmark comprising multiple-choice and open-ended questions from 30 disciplines.	accuracy	zs_cot	Yes

Benchmark	Modality	Description	Metrics	Strategy	Subtask Available
llm_judge	Text	LLM-as-a-Judge Preference Comparison – Uses a Nova Judge model to determine preference between paired responses (B compared with A) for your prompts, calculating the probability of B being preferred over A.	all	judge	No
humaneval	Text	HumanEval - A benchmark dataset designed to evaluate the code generation capabilities of large language models	pass@1	zs	No

The following mmlu subtasks are available:

```
MMLU_SUBTASKS = [
    "abstract_algebra",

```

Understanding the recipe parameters

Run configuration

The following is a general run configuration and an explanation of the parameters involved.

```
run:
  name: eval_job_name
  model_type: amazon.nova-micro-v1:0:128k
  model_name_or_path: nova-micro/prod
  replicas: 1
  data_s3_path: ""
  output_s3_path: s3://output_path
```

- `name`: (Required) A descriptive name for your evaluation job. This helps identify your job in the AWS console.
- `model_type`: (Required) Specifies the Amazon Nova model variant to use. Do not manually modify this field. Options include:
  - `amazon.nova-micro-v1:0:128k`
  - `amazon.nova-lite-v1:0:300k`
  - `amazon.nova-pro-v1:0:300k`

- `model_name_or_path`: (Required) The path to the base model or S3 path for the post-trained checkpoint. Options include:
  - `nova-micro/prod`
  - `nova-lite/prod`
  - `nova-pro/prod`
  - (S3 path for the post-trained checkpoint) `s3://<escrow bucket>/<job id>/outputs/checkpoints`
- `replicas`: (Required) The number of compute instances to use for distributed training. You must set this value to 1 because multi-node is not supported.
- `data_s3_path`: (Required) The S3 path to the input dataset. Leave this parameter empty unless you are using the *bring your own dataset* or *LLM as a judge* recipe.
- `output_s3_path`: (Required) The S3 path to store output evaluation artifacts. Note that the output S3 bucket must be created by the same account that is creating the job.

Evaluation configuration

The following is a model evaluation configuration and an explanation of the parameters involved.

```
evaluation:
  task: mmlu
  strategy: zs_cot
  subtask: mathematics
  metric: accuracy
```

- `task`: (Required) Specifies the evaluation benchmark or task to use.

  Supported task list:
  - mmlu
  - mmlu_pro
  - bbh
  - gpqa
  - math
  - strong_reject
  - gen_qa
  - ifeval

  - mmmu
  - llm_judge
  - humaneval
- `strategy`: (Required) Defines the evaluation approach:
  - zs_cot: Zero-shot Chain-of-Thought - An approach to prompt large language models that encourages step-by-step reasoning without requiring explicit examples.
  - zs: Zero-shot - An approach to solve a problem without any prior training examples.
  - gen_qa: A strategy specific for bring your own dataset recipes.
  - judge: A strategy specific for Amazon Nova LLM as Judge recipes.
- `subtask`: (Optional and Removable) Specifies a specific subtask for certain evaluation tasks. Remove this from your recipe if your task does not have any subtasks.
- `metric`: (Required) The evaluation metric to use.
  - accuracy: Percentage of correct answers
  - exact_match: (For `math` benchmark), returns the rate at which the input predicted strings exactly match their references.
  - deflection: (For `strong reject` benchmark), returns the relative deflection to the base model and the difference in significance metrics.
  - pass@1: (For `humaneval` benchmark) is a metric used to measures the percentage of cases where the model's highest confidence prediction matches the correct answer.
  - `all`: Returns the following metrics:
    - For `gen_qa` and bring your own dataset benchmark, return following metrics:
      - `rouge1`: Measures the overlap of unigrams (single words) between generated and reference text.
      - `rouge2`: Measures the overlap of bigrams (two consecutive words) between generated and reference text.
      - `rougeL`: Measures the longest common subsequence between texts, allowing for gaps in the matching.
      - `exact_match`: Binary score (0 or 1) indicating if the generated text matches the reference text exactly, character by character.
      - `quasi_exact_match`: Similar to exact match but more lenient, typically ignoring case, punctuation, and white space differences.

    - `f1_score`: Harmonic mean of precision and recall, measuring word overlap between predicted and reference answers.
    - `f1_score_quasi`: Similar to f1_score but with more lenient matching, using normalized text comparison that ignores minor differences.
    - `bleu`: Measures precision of n-gram matches between generated and reference text, commonly used in translation evaluation.
- For `llm_judge` and bring your own dataset benchmark, return following metrics:
    - `a_scores`: Number of wins for `response_A` across forward and backward evaluation passes.
    - `a_scores_stderr`: Standard error of `response_A scores` across pairwise judgements.
    - `b_scores`: Number of wins for `response_B` across forward and backward evaluation passes.
    - `b_scores_stderr`: Standard error of `response_B scores` across pairwise judgements.
    - `ties`: Number of judgements where `response_A` and `response_B` are evaluated as equal.
    - `ties_stderr`: Standard error of ties across pairwise judgements.
    - `inference_error`: Count of judgements that could not be properly evaluated.
    - `inference_error_stderr`: Standard error of inference errors across judgements.
    - `score`: Aggregate score based on wins from both forward and backward passes for `response_B`.
    - `score_stderr`: Standard error of the aggregate score across pairwise judgements.
    - `winrate`: the probability that response_B will be preferred over response_A calculated using Bradley-Terry probability.
    - `lower_rate`: Lower bound (2.5th percentile) of the estimated win rate from bootstrap sampling.

Inference configuration

The following is an inference configuration and an explanation of the parameters involved. All parameters are optional.

```
inference:
  max_new_tokens: 200
  top_k: -1
```

```
  top_p: 1.0
  temperature: 0
```

- max_new_tokens: The maximum number of tokens to generate. This must be an integer.
- top_k: The number of highest probability tokens to consider. This must be an integer.
- top_p: The cumulative probability threshold for token sampling. This must be a float between 0.0 and 1.0, inclusive.
- temperature: Randomness in token selection. Larger values introduce more randomness. Use 0 to make the results deterministic. This value must be a float with a minimum value of 0.

Note that for humaneval, we recommend the following inference configuration:

```
inference:
  top_k: 1
  max_new_tokens: 1600
  temperature: 0.0
```

Evaluation recipe examples

Amazon Nova provides four types of evaluation recipes, which are available in the HyperPod recipes GitHub repository.

General text benchmark recipes

These recipes enable you to evaluate the fundamental capabilities of Amazon Nova models across a comprehensive suite of text-only benchmarks. They are provided in the format xxx_general_text_benchmark_eval.yaml.

General multi-modal benchmark recipe

These recipes enable you to evaluate the fundamental capabilities of Amazon Nova models across a comprehensive suite of multi-modality benchmarks. They are provided in the format xxx_general_multi_modal_benchmark_eval.yaml.

Bring your own dataset benchmark recipe

These recipes enable you to bring your own dataset for benchmarking and compare model outputs to reference answers using different types of metrics. They are provided in the format xxx_bring_your_own_dataset_eval.yaml.

The following are the bring your own dataset requirements:

- File format requirements
  - You must include a single `gen_qa.jsonl` file containing evaluation examples.
  - Your dataset must be uploaded to an S3 location where SageMaker AI training job can access it.
  - The file must follow the required schema format for a general Q&A dataset.
- Schema format requirements - Each line in the JSONL file must be a JSON object with the following fields:
  - `query`: (Required) String containing the question or instruction that needs an answer
  - `response`: (Required) String containing the expected model output
  - `system`: (Optional) String containing the system prompt that sets the behavior, role, or personality of the AI model before it processes the query

Here is a bring your own data set example entry

```
{
   "system":"You are a english major with top marks in class who likes to give minimal
 word responses: ",
   "query":"What is the symbol that ends the sentence as a question",
   "response":"?"
}
{
   "system":"You are a pattern analysis specialist that provides succinct answers: ",
   "query":"What is the next number in this series? 1, 2, 4, 8, 16, ?",
   "response":"32"
}
{
   "system":"You have great attention to detail that follows instructions accurately:
 ",
   "query":"Repeat only the last two words of the following: I ate a hamburger today
 and it was kind of dry",
   "response":"of dry"
}
```

To use your custom dataset, modify your evaluation recipe with the following required fields, do not change any of the content:

```
evaluation:
  task: gen_qa
  strategy: gen_qa
  metric: all
```

The following limitations apply:

- Only one JSONL file is allowed per evaluation.
- The file must strictly follow the defined schema.
- Context length limit: For each sample in the dataset, the context length (including system + query prompts) should be less than 3.5k

Amazon Nova LLM as a Judge benchmark recipe

Amazon Nova LLM as a Judge is a model evaluation feature that enables customers to compare the quality of responses from one model to a baseline model response on a custom dataset. It takes in a dataset with prompts, baseline responses, and challenger responses, and uses a Nova Judge model to provide a winrate metric based on Bradley-Terry probability with pairwise comparisons.

The recipes are provided in the format `xxx_llm_judge_eval.yaml`.

The following are the LLM as a Judge requirements:

- File format requirements
  - Include a single `llm_judge.jsonl` file containing evaluation examples. The file name must be `llm_judge.jsonl`.
  - Your dataset must be uploaded to an S3 location that SageMaker AI HyperPod RIG can access.
  - The file must follow the required schema format for the `llm_judge.jsonl` dataset.
  - The input dataset should ensure all records are under 12k context length.
- Schema format requirements - Each line in the JSONL file must be a JSON object with the following fields:
  - `prompt`: (Required) A string containing the prompt for the generated response.
  - `response_A`: A string containing the baseline response.
  - `response_B`: A string containing the alternative response be compared with baseline response.

Here is an LLM as a judge example entry

```
{
"prompt": "What is the most effective way to combat climate change?",
"response_A": "The most effective way to combat climate change is through a combination
 of transitioning to renewable energy sources and implementing strict carbon pricing
 policies. This creates economic incentives for businesses to reduce emissions while
 promoting clean energy adoption.",
"response_B": "We should focus on renewable energy. Solar and wind power are good.
 People should drive electric cars. Companies need to pollute less."
}
{
"prompt": "Explain how a computer's CPU works",
"response_A": "CPU is like brain of computer. It does math and makes computer work
 fast. Has lots of tiny parts inside.",
"response_B": "A CPU (Central Processing Unit) functions through a fetch-execute
 cycle, where instructions are retrieved from memory, decoded, and executed through its
 arithmetic logic unit (ALU). It coordinates with cache memory and registers to process
 data efficiently using binary operations."
}
{
"prompt": "How does photosynthesis work?",
"response_A": "Plants do photosynthesis to make food. They use sunlight and water. It
 happens in leaves.",
"response_B": "Photosynthesis is a complex biochemical process where plants convert
 light energy into chemical energy. They utilize chlorophyll to absorb sunlight,
 combining CO2 and water to produce glucose and oxygen through a series of chemical
 reactions in chloroplasts."
}
```

To use your custom dataset, modify your evaluation recipe with the following required fields, don't change any of the content:

```
evaluation:
  task: llm_judge
  strategy: judge
  metric: all
```

The following limitations apply:

- Only one JSONL file is allowed per evaluation.
- The file must strictly follow the defined schema.

- Amazon Nova Judge models are the same across all model family specifications (that is, Lite, Micro, and Pro).
- Custom judge models are not supported at this time.
- Context length limit: For each sample in the dataset, the context length (including system + query prompts) should be less than 7k

Starting an evaluation job

The following provides a suggested evaluation instance type and model type configuration:

```
# Install Dependencies (Helm - https://helm.sh/docs/intro/install/)
curl -fsSL -o get_helm.sh https://raw.githubusercontent.com/helm/helm/main/scripts/get-
helm-3
chmod 700 get_helm.sh
./get_helm.sh
rm -f ./get_helm.sh

# Install the HyperPod CLI
git clone --recurse-submodules https://github.com/aws/sagemaker-hyperpod-cli.git
git checkout -b release_v2
cd sagemaker-hyperpod-cli
pip install .

# Verify the installation
hyperpod --help

# Connect to a HyperPod Cluster
hyperpod connect-cluster --cluster-name cluster-name

# Submit the Job using the recipe for eval
# Namespace by default should be kubeflow
hyperpod start-job [--namespace namespace] --recipe evaluation/nova/
nova_micro_p5_48xl_general_text_benchmark_eval --override-parameters \
'{
    "instance_type":"p5d.48xlarge",
    "container": "708977205387.dkr.ecr.us-east-1.amazonaws.com/nova-evaluation-repo:SM-
HP-Eval-latest",
    "recipes.run.name": custom-run-name,
    "recipes.run.model_type": model_type,
    "recipes.run.model_name_or_path" " model name or finetune checkpoint s3uri,
```

```
    "recipes.run.data_s3_path": s3 for input data only for genqa and llm_judge, must be
 full S3 path that include filename,
}'

# List jobs
hyperpod list-jobs [--namespace namespace] [--all-namespaces]

# Getting Job details
hyperpod get-job --job-name job-name [--namespace namespace] [--verbose]

# Listing Pods
hyperpod list-pods --job-name job-name --namespace namespace

# Cancel Job
hyperpod cancel-job --job-name job-name [--namespace namespace]
```

You should also be able to view the job status through Amazon EKS cluster console.

Accessing and analyzing evaluation results

After your evaluation job completes successfully, you can access and analyze the results using the information in this section. Based on the `output_s3_path` (such as `s3://output_path/`) defined in the recipe, the output structure is the following:

```
job_name/
### eval-result/
#    ### results_[timestamp].json
#    ### inference_output.jsonl (only present for gen_qa)
#    ### details/
#        ### model/
#            ### execution-date-time/
#                ###details_task_name_#_datetime.parquet
### tensorboard-results/
    ### eval/
        ### events.out.tfevents.[timestamp]
```

Metrics results are stored in the specified S3 output location `s3://output_path/job_name/eval-result/result-timestamp.json`.

Tensorboard results are stored in the S3 path `s3://output_path/job_name/eval-tensorboard-result/eval/event.out.tfevents.epoch+ip`.

All inference outputs, except for `llm_judge` and `strong_reject`, are stored in the S3 path: `s3://output_path/job_name/eval-result/details/model/taskname.parquet`.

For `gen_qa`, the `inference_output.jsonl` file contains the following fields for each JSON object:

- prompt - The final prompt submitted to the model
- inference - The raw inference output from the model

To visualize your evaluation metrics in Tensorboard, complete the following steps:

1. Navigate to SageMaker AI Tensorboard.
2. Select **S3 folders**.
3. Add your S3 folder path, for example `s3://output_path/job-name/eval-tensorboard-result/eval`.
4. Wait for synchronization to complete.

The time series, scalars, and text visualizations are available.

We recommend the following best practices:

- Keep your output paths organized by model and benchmark type.
- Maintain consistent naming conventions for easy tracking.
- Save extracted results in a secure location.
- Monitor TensorBoard sync status for successful data loading.

You can find HyperPod job error logs in the CloudWatch log group `/aws/sagemaker/Clusters/cluster-id`.

Iterative training

Iterative training enables the development of sophisticated training pipelines for Amazon Nova models by chaining multiple training techniques in sequence. This approach allows you to layer different customization methods to achieve precisely tailored models.

The process begins by training an Amazon Nova model using one of the standard techniques (such as SFT, PEFT, or DPO). After completion, you'll find a `manifest.json` file in your specified S3 output location. This file contains a `checkpoint_s3_bucket` value that indicates where the trained model is stored.

You can then use this checkpoint location as the `model_name_or_path` parameter in subsequent training runs, effectively building upon your previous customization work. This creates a chain of progressive improvements, with each training stage refining the model further based on your specific requirements.

Iterative training allows you to develop more sophisticated training pipelines to tune Amazon Nova models. By chaining training modules, you're able to layer training techniques to customize your models exactly to your needs.

You start by training Amazon Nova using one of the techniques described in ???. In the output S3 location defined during training, locate the `manifest.json` file. This file contains the value `checkpoint_s3_bucket` that indicates where the output model is defined. You can utilize this output location as the `model_name_or_path` value in future training runs.

Example

The following example steps through a workflow that defines supervised fine-tuning (SFT) > SFT > direct preference optimization (DPO) iterative training runs for an Amazon Nova Lite model. First, you must define the run recipe for the initial SFT training of the foundation model.

```
## Run config
run:
  name: "my-fullrank-run-sft"             # A descriptive name for your training job
  model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification, do not
 change
  model_name_or_path: "nova-lite/prod"      # Base model path, do not change
  replicas: 4                               # Number of compute instances for training,
 allowed values are 4, 8, 16
  data_s3_path: "s3://Path to training data"           # Your training data path
  output_s3_path: "s3://Path to output data location" # Output artifact path
```

This training job will produce a `manifest.json` file in the path defined at `output_s3_path` that resembles the following:

```
{"checkpoint_s3_bucket":"s3://<escrow bucket>/<job id>/outputs/
checkpoints"}
```

This checkpoint path can be used in the next iterative training step as the `model_name_or_path`. Doing so directs the training to use the previous checkpoint as the base model for the next training method instead of the base foundation model.

The following step in the example defines a SFT training run on a different set of data, which can be used to train a model across various sets of interactions.

```
## Run config
run:
  name: "my-fullrank-run-sft-2"             # A descriptive name for your training job
  model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification, do not
 change
  model_name_or_path: "s3://customer-escrow-bucket-unique_id/my-fullrank-run-sft-unique
 id/outputs/checkpoints"      # Model checkpoint after 1st SFT run
  replicas: 4                               # Number of compute instances for training,
 allowed values are 4, 8, 16
  data_s3_path: "s3://Path to training data #2"       # Customer data path
  output_s3_path: "s3://Path to output data location" # Output artifact path
```

Like the first training set, this will output a similar `manifest.json` file in the output location:

```
{"checkpoint_s3_bucket":"s3://<escrow bucket>/<job id>/outputs/
checkpoints"}
```

This can then be used as the final input to the last iterative training run using DPO:

```
## Run config
run:
  name: "my-fullrank-run-dpo"             # A descriptive name for your training job
  model_type: "amazon.nova-lite-v1:0:300k"  # Model variant specification, do not
 change
  model_name_or_path: "s3://customer-escrow-bucket-unique_id/my-fullrank-run-sft-2-
unique id/outputs/checkpoints"      # Model checkpoint after 2nd SFT run
  replicas: 4                               # Number of compute instances for training,
 allowed values are 4, 8, 16
  data_s3_path: "s3://Path to training data #2"       # Your training data path
  output_s3_path: "s3://Path to output data location" # Output artifact path
```

The output at any step of this iterative training pipeline can be used for either inference or evaluation as well to check the progress of the model along the way to ensure it is converging to the desired output.

Limitations

Iterative training can be run with any of the available training methods in any order, for as many iterations you need to achieve your desired outcome. When iteratively training, both the model and the technique (that is full-rank compared with LoRA PEFT) must stay consistent. For example, if you attempt to iteratively train with full-rank fine-tuning after a LoRA PEFT training, the training job will throw an error. Similarly, if you want to define a Amazon Nova Lite training job on top of a Amazon Nova Micro checkpoint, you will receive an error.

Amazon Bedrock inference

In this topic, you will learn how to deploy a trained Amazon Nova model to Amazon Bedrock for inference. The purpose of inference is to deploy trained model to Amazon Bedrock for production use. The deployment process typically involves the steps to use Amazon Bedrock APIs to create custom model, point to model artifacts in service-managed Amazon S3 bucket, wait for model to become `ACTIVE`, and configure provisioned throughput. The output of the process is a deployed model endpoint for application integration.

For detailed explanation, see Import a SageMaker AI-trained Amazon Nova model.

Limitations

Amazon Nova customization doesn't support the following capabilities on SageMaker AI.

- **Custom metrics for evaluation (RegEx or LLMAsJudge-based)**

  The current Amazon Nova evaluation recipe doesn't support incorporating your own regex-based or LLMAsJudge-based custom metrics. As a workaround, you can export the model to Amazon Bedrock and then make inference calls in order to evaluate the custom model with custom metrics.
- **SSH into the instance to find the metrics**

  Due to security controls in place, you can't SSH into the master node in the training algo-1 instance to find memory stats or NVIDIA stats and validate the training steps.
- **Support for SageMaker trainer SDK**

  SageMaker trainer is currently not available to start training jobs. You can start training jobs only via **estimator API** today.

- **Warm pools are not accessible to SageMaker training jobs**

  Due to security controls in place, the SageMaker warm pools can't be used to keep the instance in the warm pool till the time to live.
- **Custom model merging**

  Merging multiple models is not currently supported. This means that creating multiple LoRA adapters and perform a multi-merge operation with the base model is not available.
- **Supported observability tool**

  TensorBoard is the only supported observability tool to view metrics for SageMaker AI training jobs. MLFlow or WandB are not currently supported. For more information about using TensorBoard in SageMaker, see TensorBoard in SageMaker AI.

Amazon Nova customization FAQs

Q: How do I clean up my model artifacts?

A: To clean up your model artifacts from the service-managed Amazon S3 bucket, contact https://aws.amazon.com/premiumsupport/. This step is optional.

Deploy models for inference

With Amazon SageMaker AI, you can start getting predictions, or *inferences*, from your trained machine learning models. SageMaker AI provides a broad selection of ML infrastructure and model deployment options to help meet all your ML inference needs. With SageMaker AI Inference, you can scale your model deployment, manage models more effectively in production, and reduce operational burden. SageMaker AI provides you with various inference options, such as real-time endpoints for getting low latency inference, serverless endpoints for fully managed infrastructure and auto-scaling, and asynchronous endpoints for batches of requests. By leveraging the appropriate inference option for your use case, you can ensure efficient model deployment and inference.

Choosing a feature

There are several use cases for deploying ML models with SageMaker AI. This section describes those use cases, as well as the SageMaker AI feature we recommend for each use case.

Use cases

The following are the main uses cases for deploying ML models with SageMaker AI.

- **Use case 1: Deploy a machine learning model in a low-code or no-code environment.** For beginners or those new to SageMaker AI, you can deploy pre-trained models using Amazon SageMaker JumpStart through the Amazon SageMaker Studio interface, without the need for complex configurations.
- **Use case 2: Use code to deploy machine learning models with more flexibility and control.** Experienced ML practitioners can deploy their own models with customized settings for their application needs using the `ModelBuilder` class in the SageMaker AI Python SDK, which provides fine-grained control over various settings, such as instance types, network isolation, and resource allocation.
- **Use case 3: Deploy machine learning models at scale.** For advanced users and organizations who want to manage models at scale in production, use the AWS SDK for Python (Boto3) and AWS CloudFormation along with your desired Infrastructure as Code (IaC) and CI/CD tools to provision resources and automate resource management.

Recommended features

The following table describes key considerations and tradeoffs for SageMaker AI features corresponding with each use case.

	Use case 1	Use case 2	Use case 3
SageMaker AI feature	Use JumpStart in Studio to accelerate your foundational model deployment.	Deploy models using ModelBuilder from the SageMaker Python SDK.	Deploy and manage models at scale with AWS CloudFormation.
Description	Use the Studio UI to deploy pre-trained models from a catalog to pre-configured inference endpoints. This option is ideal for citizen data scientists, or for anyone who wants to deploy a model without configuring complex settings.	Use the `ModelBuilder` class from the Amazon SageMaker AI Python SDK to deploy your own model and configure deployment settings. This option is ideal for experienced data scientists, or for anyone who has their own model to deploy and requires fine-grained control.	Use AWS CloudFormation and Infrastructure as Code (IaC) for programmatic control and automation for deploying and managing SageMaker AI models. This option is ideal for advanced users who require consistent and repeatable deployments.
Optimized for	Fast and streamlined deployments of popular open source models	Deploying your own models	Ongoing management of models in production
Considerations	Lack of customization for container settings and specific application needs	No UI, requires that you're comfortable developing and maintaining Python code	Requires infrastructure management and organizational resources, and also requires familiarity with the AWS SDK for Python (Boto3) or with AWS CloudFormation templates.

	Use case 1	Use case 2	Use case 3
Recommended environment	A SageMaker AI domain	A Python development environment configured with your AWS credentials and the SageMaker Python SDK installed, or a SageMaker AI IDE such as SageMaker JupyterLab	The AWS CLI, a local development environment, and Infrastructure as Code (IaC) and CI/CD tools

Additional options

SageMaker AI provides different options for your inference use cases, giving you choice over the technical breadth and depth of your deployments:

- **Deploying a model to an endpoint.** When deploying your model, consider the following options:
  - Real-time inference. Real-time inference is ideal for inference workloads where you have interactive, low latency requirements.
  - Deploy models with Amazon SageMaker Serverless Inference. Use Serverless Inference to deploy models without configuring or managing any of the underlying infrastructure. This option is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts.
  - Asynchronous inference. Queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to one hour), and near real-time latency requirements.
- **Cost optimization.** To optimize your inference costs, consider the following options:
  - Model performance optimization with SageMaker Neo. Use SageMaker Neo to optimize and run your machine learning models with better performance and efficiency, helping you to minimize compute costs by automatically optimizing models to run in environments like AWS Inferentia chips.
  - Automatic scaling of Amazon SageMaker AI models. Use autoscaling to dynamically adjust the compute resources for your endpoints based on incoming traffic patterns, which helps you optimize costs by only paying for the resources you're using at a given time.

Model deployment options in Amazon SageMaker AI

After you train your machine learning model, you can deploy it using Amazon SageMaker AI to get predictions. Amazon SageMaker AI supports the following ways to deploy a model, depending on your use case:

- For persistent, real-time endpoints that make one prediction at a time, use SageMaker AI real-time hosting services. See Real-time inference.
- Workloads that have idle periods between traffic spikes and can tolerate cold starts, use Serverless Inference. See Deploy models with Amazon SageMaker Serverless Inference.
- Requests with large payload sizes up to 1GB, long processing times, and near real-time latency requirements, use Amazon SageMaker Asynchronous Inference. See Asynchronous inference.
- To get predictions for an entire dataset, use SageMaker AI batch transform. See Batch transform for inference with Amazon SageMaker AI.

SageMaker AI also provides features to manage resources and optimize inference performance when deploying machine learning models:

- To manage models on edge devices so that you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices, see Model deployment at the edge with SageMaker Edge Manager. This applies to edge devices like smart cameras, robots, personal computers, and mobile devices.
- To optimize Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx, see Model performance optimization with SageMaker Neo.

For more information about all deployment options, see Deploy models for inference.

Understand the options for deploying models and getting inferences in Amazon SageMaker AI

To help you get started with SageMaker AI Inference, see the following sections which explain your options for deploying your model in SageMaker AI and getting inferences. The Inference options in Amazon SageMaker AI section can help you determine which feature best fits your use case for inference.

You can refer to the Resources section for more troubleshooting and reference information, blogs and examples to help you get started, and common FAQs.

Topics

Before you begin

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. You don't need to train your model in SageMaker AI in order to deploy your model in SageMaker AI and get inferences. If you don't have your own model, you can also use SageMaker AI's built-in algorithms or pre-trained models.

If you are new to SageMaker AI and haven't picked out a model to deploy, work through the steps in the Get Started with Amazon SageMaker AI tutorial. Use the tutorial to get familiar with how SageMaker AI manages the data science process and how it handles model deployment. For more information about training a model, see Train Models.

For additional information, reference, and examples, see the Resources.

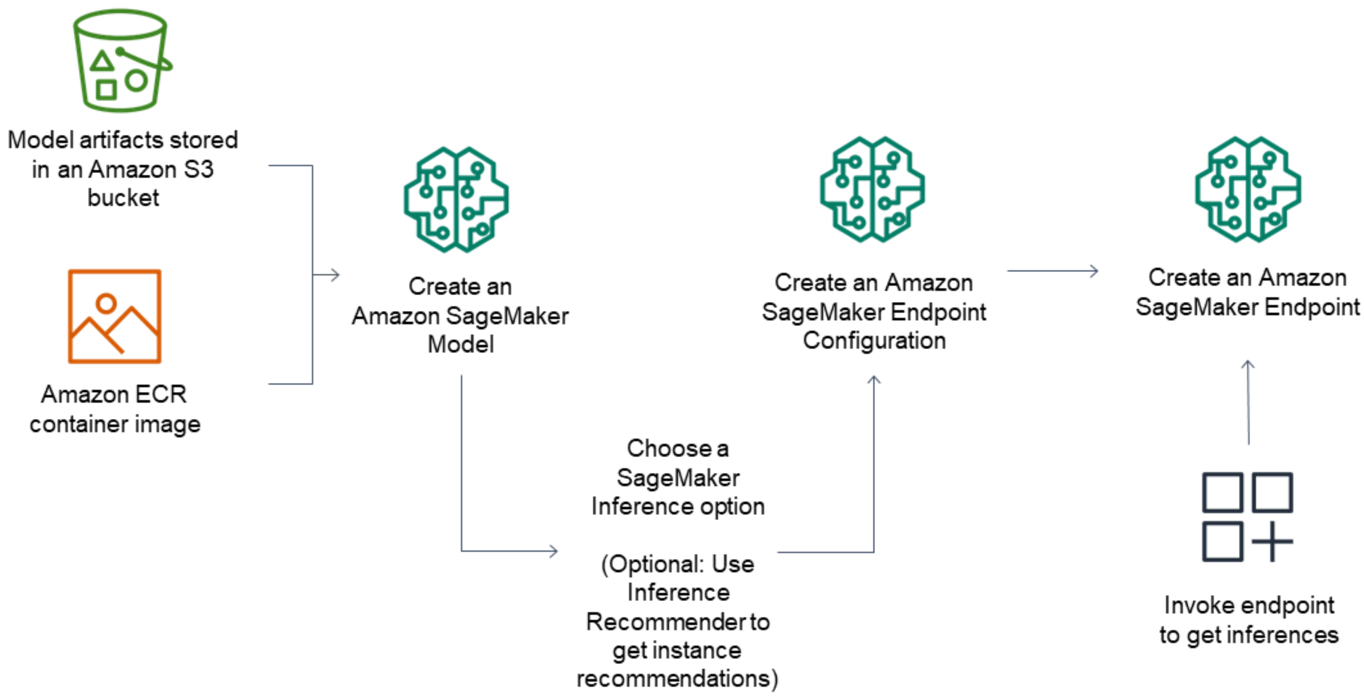
Steps for model deployment

For inference endpoints, the general workflow consists of the following:

- Create a model in SageMaker AI Inference by pointing to model artifacts stored in Amazon S3 and a container image.
- Select an inference option. For more information, see Inference options in Amazon SageMaker AI.
- Create a SageMaker AI Inference endpoint configuration by choosing the instance type and number of instances you need behind the endpoint. You can use Amazon SageMaker Inference Recommender to get recommendations for instance types. For Serverless Inference, you only need to provide the memory configuration you need based on your model size.

- Create a SageMaker AI Inference endpoint.
- Invoke your endpoint to receive an inference as a response.

The following diagram shows the preceding workflow.



You can perform these actions using the AWS console, the AWS SDKs, the SageMaker Python SDK, AWS CloudFormation or the AWS CLI.

For batch inference with batch transform, point to your model artifacts and input data and create a batch inference job. Instead of hosting an endpoint for inference, SageMaker AI outputs your inferences to an Amazon S3 location of your choice.

Inference options in Amazon SageMaker AI

SageMaker AI provides multiple inference options so that you can pick the option that best suits your workload:

- Real-Time Inference: *Real-time inference* is ideal for online inferences that have low latency or high throughput requirements. Use real-time inference for a persistent and fully managed endpoint (REST API) that can handle sustained traffic, backed by the instance type of your choice. Real-time inference can support payload sizes up to 25 MB and processing times of 60 seconds for regular responses and 8 min for streaming responses.

- Serverless Inference: *Serverless inference* is ideal when you have intermittent or unpredictable traffic patterns. SageMaker AI manages all of the underlying infrastructure, so there's no need to manage instances or scaling policies. You pay only for what you use and not for idle time. It can support payload sizes up to 4 MB and processing times up to 60 seconds.
- Batch Transform: *Batch transform* is suitable for offline processing when large amounts of data are available upfront and you don't need a persistent endpoint. You can also use batch transform for pre-processing datasets. It can support large datasets that are GBs in size and processing times of days.
- Asynchronous Inference: *Asynchronous inference* is ideal when you want to queue requests and have large payloads with long processing times. Asynchronous Inference can support payloads up to 1 GB and long processing times up to one hour. You can also scale down your endpoint to 0 when there are no requests to process.

Advanced endpoint options for inference with Amazon SageMaker AI

With real-time inference, you can further optimize for performance and cost with the following advanced inference options:

- Multi-model endpoints – Use this option if you have multiple models that use the same framework and can share a container. This option helps you optimize costs by improving endpoint utilization and reducing deployment overhead.
- Multi-container endpoints – Use this option if you have multiple models that use different frameworks and require their own containers. You get many of the benefits of Multi-Model Endpoints and can deploy a variety of frameworks and models.
- Serial Inference Pipelines – Use this option if you want to host models with pre-processing and post-processing logic behind an endpoint. Inference pipelines are fully managed by SageMaker AI and provide lower latency because all of the containers are hosted on the same Amazon EC2 instances.

Next steps for inference with Amazon SageMaker AI

After you have an endpoint and understand the general inference workflow, you can use the following features in SageMaker AI to improve your inference workflow.

Monitoring

To track your model over time through metrics such as model accuracy and drift, you can use Model Monitor. With Model Monitor, you can set alerts that notify you when there are deviations in your model's quality. To learn more, see the Model Monitor documentation.

To learn more about tools that can be used to monitor model deployments and events that change your endpoint, see Monitor Amazon SageMaker AI. For example, you can monitor your endpoint's health through metrics such as invocation errors and model latency using Amazon CloudWatch metrics. The SageMaker AI endpoint invocation metrics can provide you with valuable information about your endpoint's performance.

CI/CD for model deployment

To put together machine learning solutions in SageMaker AI, you can use SageMaker AI MLOps. You can use this feature to automate the steps in your machine learning workflow and practice CI/CD. You can use MLOps Project Templates to help with the setup and implementation of SageMaker AI MLOps projects. SageMaker AI also supports using your own third-party Git repo for creating a CI/CD system.

For your ML pipelines, use Model Registry to manage your model versions and the deployment and automation of your models.

Deployment guardrails

If you want to update your model while it's in production without impacting production, you can use deployment guardrails. Deployment guardrails are a set of model deployment options in SageMaker AI Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes give you granular control over the traffic shifting process, and built-in safeguards like auto-rollbacks help you catch issues early on.

To learn more about deployment guardrails, see the deployment guardrails documentation.

Inferentia

If you need to run large-scale machine learning and deep learning applications, you can use an `Inf1` instance with a real-time endpoint. This instance type is suitable for use cases such as image or speech recognition, natural language processing (NLP), personalization, forecasting, or fraud detection.

`Inf1` instances are built to support machine learning inference applications and feature the AWS Inferentia chips. `Inf1` instances provide higher throughput and lower cost per inference than GPU-based instances.

To deploy a model on `Inf1` instances, compile your model with SageMaker Neo and choose an `Inf1` instance for your deployment option. To learn more, see Optimize model performance using SageMaker Neo.

Optimize model performance

SageMaker AI provides features to manage resources and optimize inference performance when deploying machine learning models. You can use SageMaker AI's built-in algorithms and pre-built models, as well as prebuilt Docker images, which are developed for machine learning.

To train models and optimize them for deployment, see prebuilt Docker imagesOptimize model performance using SageMaker Neo. With SageMaker Neo, you can train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models. Then, you can optimize them and deploy on ARM, Intel, and Nvidia processors.

Autoscaling

If you have varying amounts of traffic to your endpoints, you might want to try autoscaling. For example, during peak hours, you might require more instances to process requests. However, during periods of low traffic, you might want to reduce your use of computing resources. To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatic scaling of Amazon SageMaker AI models.

If you have unpredictable traffic patterns or don't want to set up scaling policies, you can also use Serverless Inference for an endpoint. Then, SageMaker AI manages autoscaling for you. During periods of low traffic, SageMaker AI scales down your endpoint, and if traffic increases, then SageMaker AI scales your endpoint up. For more information, see the Deploy models with Amazon SageMaker Serverless Inference documentation.

Create a model in Amazon SageMaker AI with ModelBuilder

Preparing your model for deployment on a SageMaker AI endpoint requires multiple steps, including choosing a model image, setting up the endpoint configuration, coding your serialization and deserialization functions to transfer data to and from server and client, identifying model dependencies, and uploading them to Amazon S3. `ModelBuilder` can reduce the complexity of initial setup and deployment to help you create a deployable model in a single step.

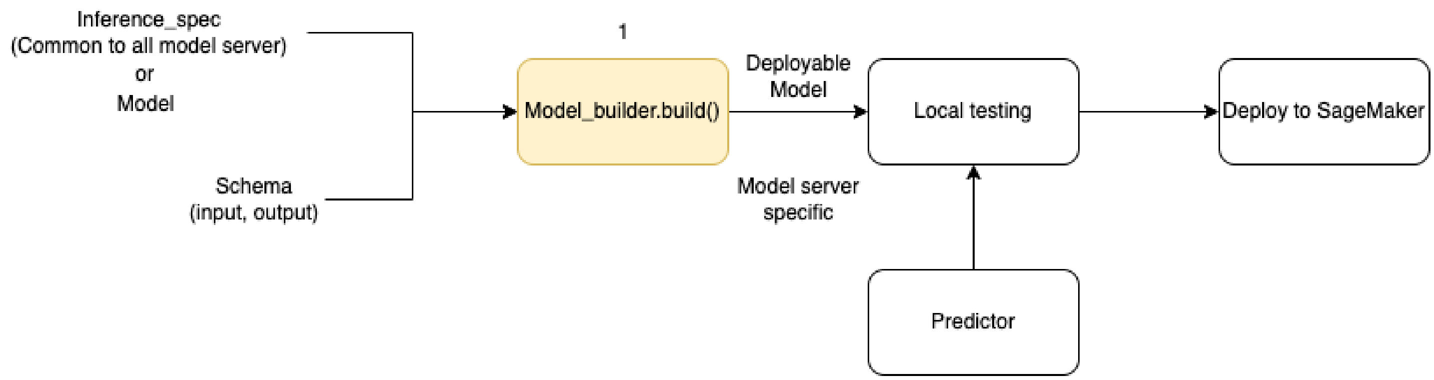
`ModelBuilder` performs the following tasks for you:

- Converts machine learning models trained using various frameworks like XGBoost or PyTorch into deployable models in one step.
- Performs automatic container selection based on the model framework so you don't have to manually specify your container. You can still bring your own container by passing your own URI to `ModelBuilder`.
- Handles the serialization of data on the client side before sending it to the server for inference and deserialization of the results returned by the server. Data is correctly formatted without manual processing.
- Enables automatic capture of dependencies and packages the model according to model server expectations. `ModelBuilder`'s automatic capture of dependencies is a best-effort approach to dynamically load dependencies. (We recommend that you test the automated capture locally and update the dependencies to meet your needs.)
- For large language model (LLM) use cases, optionally performs local parameter tuning of serving properties that can be deployed for better performance when hosting on a SageMaker AI endpoint.
- Supports most of the popular model servers and containers like TorchServe, Triton, DJLServing and TGI container.

Build your model with ModelBuilder

`ModelBuilder` is a Python class that takes a framework model, such as XGBoost or PyTorch, or a user-specified inference specification and converts it into a deployable model. `ModelBuilder` provides a build function that generates the artifacts for deployment. The model artifact generated is specific to the model server, which you can also specify as one of the inputs. For more details about the `ModelBuilder` class, see ModelBuilder.

The following diagram illustrates the overall model creation workflow when you use `ModelBuilder`. `ModelBuilder` accepts a model or inference specification along with your schema to create a deployable model that you can test locally before deployment.



`ModelBuilder` can handle any customization you want to apply. However, to deploy a framework model, the model builder expects at minimum a model, sample input and output, and the role. In the following code example, `ModelBuilder` is called with a framework model and an instance of `SchemaBuilder` with minimum arguments (to infer the corresponding functions for serializing and deserializing the endpoint input and output). No container is specified and no packaged dependencies are passed—SageMaker AI automatically infers these resources when you build your model.

```
from sagemaker.serve.builder.model_builder import ModelBuilder
from sagemaker.serve.builder.schema_builder import SchemaBuilder

model_builder = ModelBuilder(
    model=model,
    schema_builder=SchemaBuilder(input, output),
    role_arn="execution-role",
)
```

The following code sample invokes `ModelBuilder` with an inference specification (as an `InferenceSpec` instance) instead of a model, with additional customization. In this case, the call to model builder includes a path to store model artifacts and also turns on autocapture of all available dependencies. For additional details about `InferenceSpec`, see [Customize model loading and handling of requests](#).

```
model_builder = ModelBuilder(
    mode=Mode.LOCAL_CONTAINER,
    model_path=model-artifact-directory,
    inference_spec=your-inference-spec,
    schema_builder=SchemaBuilder(input, output),
    role_arn=execution-role,
    dependencies={"auto": True}
```

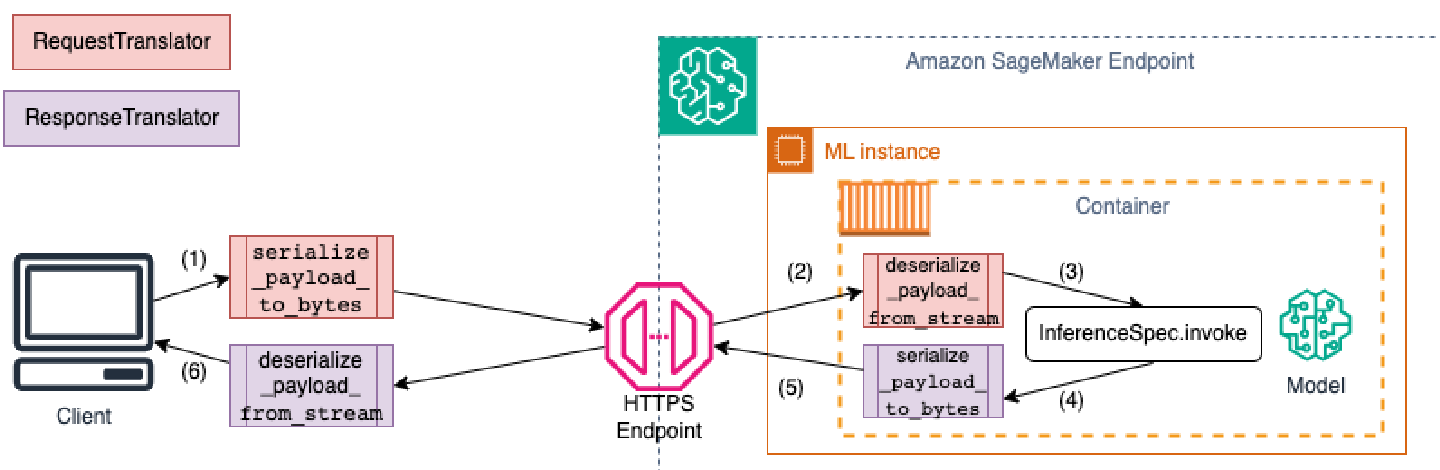
```
)
```

Define serialization and deserialization methods

When invoking a SageMaker AI endpoint, the data is sent through HTTP payloads with different MIME types. For example, an image sent to the endpoint for inference needs to be converted to bytes at the client side and sent through an HTTP payload to the endpoint. When the endpoint receives the payload, it needs to deserialize the byte string back to the data type that is expected by the model (also known as server-side deserialization). After the model finishes prediction, the results also need to be serialized to bytes that can be sent back through the HTTP payload to the user or the client. Once the client receives the response byte data, it needs to perform client-side deserialization to convert the bytes data back to the expected data format, such as JSON. At minimum, you need to convert data for the following tasks:

1. Inference request serialization (handled by the client)
2. Inference request deserialization (handled by the server or algorithm)
3. Invoking the model against the payload and send response payload back
4. Inference response serialization (handled by the server or algorithm)
5. Inference response deserialization (handled by the client)

The following diagram shows the serialization and deserialization processes that occur when you invoke the endpoint.



When you supply sample input and output to `SchemaBuilder`, the schema builder generates the corresponding marshalling functions for serializing and deserializing the input and output. You can further customize your serialization functions with CustomPayloadTranslator. But for most cases, a simple serializer such as the following would work:

```
input = "How is the demo going?"
output = "Comment la démo va-t-elle?"
schema = SchemaBuilder(input, output)
```

For further details about SchemaBuilder, see SchemaBuilder.

The following code snippet outlines an example where you want to customize both serialization and deserialization functions at the client and server sides. You can define your own request and response translators with CustomPayloadTranslator and pass these translators to SchemaBuilder.

By including the inputs and outputs with the translators, the model builder can extract the data format the model expects. For example, suppose the sample input is a raw image, and your custom translators crop the image and send the cropped image to the server as a tensor. ModelBuilder needs both the raw input and any custom preprocessing or postprocessing code to derive a method to convert data on both the client and server sides.

```
from sagemaker.serve import CustomPayloadTranslator

# request translator
class MyRequestTranslator(CustomPayloadTranslator):
    # This function converts the payload to bytes - happens on client side
    def serialize_payload_to_bytes(self, payload: object) -> bytes:
        # converts the input payload to bytes
        ... ...
        return  //return object as bytes

    # This function converts the bytes to payload - happens on server side
    def deserialize_payload_from_stream(self, stream) -> object:
        # convert bytes to in-memory object
        ... ...
        return //return in-memory object

# response translator
class MyResponseTranslator(CustomPayloadTranslator):
    # This function converts the payload to bytes - happens on server side
    def serialize_payload_to_bytes(self, payload: object) -> bytes:
        # converts the response payload to bytes
```

```
        ... ...
        return //return object as bytes

    # This function converts the bytes to payload - happens on client side
    def deserialize_payload_from_stream(self, stream) -> object:
        # convert bytes to in-memory object
        ... ...
        return //return in-memory object
```

You pass in the sample input and output along with the previously-defined custom translators when you create the `SchemaBuilder` object, as shown in the following example:

```
my_schema = SchemaBuilder(
    sample_input=image,
    sample_output=output,
    input_translator=MyRequestTranslator(),
    output_translator=MyResponseTranslator()
)
```

Then you pass in the sample input and output, along with the custom translators defined previously, to the `SchemaBuilder` object.

```
my_schema = SchemaBuilder(
    sample_input=image,
    sample_output=output,
    input_translator=MyRequestTranslator(),
    output_translator=MyResponseTranslator()
)
```

The following sections explain in detail how to build your model with `ModelBuilder` and use its supporting classes to customize the experience for your use case.

Topics

Customize model loading and handling of requests

Providing your own inference code through `InferenceSpec` offers an additional layer of customization. With `InferenceSpec`, you can customize how the model is loaded and how it handles incoming inference requests, bypassing its default loading and inference handling mechanisms. This flexibility is particularly beneficial when working with non-standard models or custom inference pipelines. You can customize the `invoke` method to control how the model preprocesses and postprocesses incoming requests. The `invoke` method ensures that the model handles inference requests correctly. The following example uses `InferenceSpec` to generate a model with the HuggingFace pipeline. For further details about `InferenceSpec`, refer to the InferenceSpec.

```
from sagemaker.serve.spec.inference_spec import InferenceSpec
from transformers import pipeline

class MyInferenceSpec(InferenceSpec):
    def load(self, model_dir: str):
        return pipeline("translation_en_to_fr", model="t5-small")

    def invoke(self, input, model):
        return model(input)

inf_spec = MyInferenceSpec()

model_builder = ModelBuilder(
    inference_spec=your-inference-spec,
    schema_builder=SchemaBuilder(X_test, y_pred)
)
```

The following example illustrates a more customized variation of a previous example. A model is defined with an inference specification that has dependencies. In this case, the code in the inference specification is dependent on the *lang-segment* package. The argument for `dependencies` contains a statement that directs the builder to install *lang-segment* using Git. Since the model builder is directed by the user to custom install a dependency, the `auto` key is `False` to turn off autocapture of dependencies.

```
model_builder = ModelBuilder(
    mode=Mode.LOCAL_CONTAINER,
    model_path=model-artifact-directory,
    inference_spec=your-inference-spec,
```

```
    schema_builder=SchemaBuilder(input, output),
    role_arn=execution-role,
    dependencies={"auto": False, "custom": ["-e git+https://github.com/luca-medeiros/
lang-segment-anything.git#egg=lang-sam"],}
)
```

Build your model and deploy

Call the `build` function to create your deployable model. This step creates inference code (as `inference.py`) in your working directory with the code necessary to create your schema, run serialization and deserialization of inputs and outputs, and run other user-specified custom logic.

As an integrity check, SageMaker AI packages and pickles the necessary files for deployment as part of the `ModelBuilder` build function. During this process, SageMaker AI also creates HMAC signing for the pickle file and adds the secret key in the CreateModel API as an environment variable during `deploy` (or `create`). The endpoint launch uses the environment variable to validate the integrity of the pickle file.

```
# Build the model according to the model server specification and save it as files in
 the working directory
model = model_builder.build()
```

Deploy your model with the model's existing `deploy` method. In this step, SageMaker AI sets up an endpoint to host your model as it starts making predictions on incoming requests. Although the `ModelBuilder` infers the endpoint resources needed to deploy your model, you can override those estimates with your own parameter values. The following example directs SageMaker AI to deploy the model on a single `ml.c6i.xlarge` instance. A model constructed from `ModelBuilder` enables live logging during deployment as an added feature.

```
predictor = model.deploy(
    initial_instance_count=1,
    instance_type="ml.c6i.xlarge"
)
```

If you want more fine-grained control over the endpoint resources assigned to your model, you can use a `ResourceRequirements` object. With the `ResourceRequirements` object, you can request a minimum number of CPUs, accelerators, and copies of models you want to deploy. You can also request a minimum and maximum bound of memory (in MB). To use this feature, you need to specify your endpoint type as `EndpointType.INFERENCE_COMPONENT_BASED`. The following example requests four accelerators, a minimum memory size of 1024 MB, and one copy of your model to be deployed to an endpoint of type `EndpointType.INFERENCE_COMPONENT_BASED`.

```
resource_requirements = ResourceRequirements(
    requests={
        "num_accelerators": 4,
        "memory": 1024,
        "copies": 1,
    },
    limits={},
)
predictor = model.deploy(
    mode=Mode.SAGEMAKER_ENDPOINT,
    endpoint_type=EndpointType.INFERENCE_COMPONENT_BASED,
    resources=resource_requirements,
    role="role"
)
```

Bring your own container (BYOC)

If you want to bring your own container (extended from a SageMaker AI container), you can also specify the image URI as shown in the following example. You also need to identify the model server that corresponds to the image for `ModelBuilder` to generate artifacts specific to the model server.

```
model_builder = ModelBuilder(
    model=model,
    model_server=ModelServer.TORCHSERVE,
    schema_builder=SchemaBuilder(X_test, y_pred),
    image_uri="123123123123.dkr.ecr.ap-southeast-2.amazonaws.com/byoc-image:xgb-1.7-1")
)
```

Using ModelBuilder in local mode

You can deploy your model locally by using the `mode` argument to switch between local testing and deployment to an endpoint. You need to store the model artifacts in the working directory, as shown in the following snippet:

```
model = XGBClassifier()
model.fit(X_train, y_train)
```

```
model.save_model(model_dir + "/my_model.xgb")
```

Pass the model object, a `SchemaBuilder` instance, and set mode to `Mode.LOCAL_CONTAINER`. When you call the `build` function, `ModelBuilder` automatically identifies the supported framework container and scans for dependencies. The following example demonstrates model creation with an XGBoost model in local mode.

```
model_builder_local = ModelBuilder(
    model=model,
    schema_builder=SchemaBuilder(X_test, y_pred),
    role_arn=execution-role,
    mode=Mode.LOCAL_CONTAINER
)
xgb_local_builder = model_builder_local.build()
```

Call the `deploy` function to deploy locally, as shown in the following snippet. If you specify parameters for instance type or count, these arguments are ignored.

```
predictor_local = xgb_local_builder.deploy()
```

Troubleshooting local mode

Depending on your individual local setup, you may encounter difficulties running `ModelBuilder` smoothly in your environment. See the following list for some issues you may face and how to resolve them.

- **Already already in use**: You may encounter an `Address already in use` error. In this case, it is possible that a Docker container is running on that port or another process is utilizing it. You can follow the approach outlined in [Linux documentation](#) to identify the process and gracefully redirect your local process from port 8080 to another port or clean up the Docker instance.
- **IAM Permission Issue**: You might encounter a permission issue when trying to pull an Amazon ECR image or access Amazon S3. In this case, navigate to the execution role of the notebook or Studio Classic instance to verify the policy for `SageMakerFullAccess` or the respective API permissions.
- **EBS volume capacity issue**: If you deploy a large language model (LLM), you might run out of space while running Docker in local mode or experience space limitations for the Docker cache. In this case, you can try to move your Docker volume to a filesystem that has enough space. To move your Docker volume, complete the following steps:

1. Open a terminal and run `df` to display disk usage, as shown in the following output:

```
(python3) sh-4.2$ df
Filesystem      1K-blocks      Used Available Use% Mounted on
devtmpfs        195928700         0 195928700   0% /dev
tmpfs           195939296         0 195939296   0% /dev/shm
tmpfs           195939296      1048 195938248   1% /run
tmpfs           195939296         0 195939296   0% /sys/fs/cgroup
/dev/nvme0n1p1 141545452 135242112   6303340  96% /
tmpfs            39187860         0  39187860   0% /run/user/0
/dev/nvme2n1    264055236  76594068 176644712  31% /home/ec2-user/SageMaker
tmpfs            39187860         0  39187860   0% /run/user/1002
tmpfs            39187860         0  39187860   0% /run/user/1001
tmpfs            39187860         0  39187860   0% /run/user/1000
```

2. Move the default Docker directory from `/dev/nvme0n1p1` to `/dev/nvme2n1` so you can fully utilize the 256 GB SageMaker AI volume. For more details, see documentation about how to move your Docker directory.

3. Stop Docker with the following command:

```
sudo service docker stop
```

4. Add a `daemon.json` to `/etc/docker` or append the following JSON blob to the existing one.

```
{
    "data-root": "/home/ec2-user/SageMaker/{created_docker_folder}"
}
```

5. Move the Docker directory in `/var/lib/docker` to `/home/ec2-user/SageMaker AI` with the following command:

```
sudo rsync -aP /var/lib/docker/ /home/ec2-user/SageMaker/{created_docker_folder}
```

6. Start Docker with the following command:

```
sudo service docker start
```

7. Clean trash with the following command:

```
cd /home/ec2-user/SageMaker/.Trash-1000/files/*
sudo rm -r *
```

8. If you are using a SageMaker notebook instance, you can follow the steps in the Docker prep file to prepare Docker for local mode.

ModelBuilder examples

For more examples of using `ModelBuilder` to build your models, see ModelBuilder sample notebooks.

Inference optimization for Amazon SageMaker AI models

With Amazon SageMaker AI, you can improve the performance of your generative AI models by applying inference optimization techniques. By optimizing your models, you can attain better cost-performance for your use case. When you optimize a model, you choose which of the supported optimization techniques to apply, including quantization, speculative decoding, and compilation. After your model is optimized, you can run an evaluation to see performance metrics for latency, throughput, and price.

For many models, SageMaker AI also provides several pre-optimized versions, where each caters to different applications needs for latency and throughput. For such models, you can deploy one of the optimized versions without first optimizing the model yourself.

Optimization techniques

Amazon SageMaker AI supports the following optimization techniques.

Compilation

Compilation optimizes the model for the best available performance on the chosen hardware type without a loss in accuracy. You can apply model compilation to optimize LLMs for accelerated hardware, such as GPU instances, AWS Trainium instances, or AWS Inferentia instances.

When you optimize a model with compilation, you benefit from ahead-of-time compilation. You reduce the model's deployment time and auto-scaling latency because the model weights don't require just-in-time compilation when the model deploys to a new instance.

If you choose to compile your model for a GPU instance, SageMaker AI uses the TensorRT-LLM library to run the compilation. If you choose to compile your model for an AWS Trainium or AWS Inferentia instance, SageMaker AI uses the AWS Neuron SDK to run the compilation.

Quantization

Quantization is a technique to reduce the hardware requirements of a model by using a less precise data type for the weights and activations. After you optimize a model with quantization, you can host it on less expensive and more available GPUs. However, the quantized model might be less accurate than the source model that you optimized.

The data formats that SageMaker AI supports for quantization vary from model to model. The supported formats include the following:

- INT4-AWQ – A 4-bit data format. Activation-aware Weight Quantization (AWQ) is a quantization technique for LLMs that is efficient, accurate, low-bit, and weight-only.
- FP8 – 8-bit Floating Point (FP8) is a low-precision format for floating point numbers. It balances memory efficiency and model accuracy by representing values with fewer bits than standard FP16 floating point format.
- INT8-SmoothQuant – AN 8-bit data format. SmoothQuant is a mixed-precision quantization method that scales activations and weights jointly by balancing their dynamic ranges.

Speculative decoding

Speculative decoding is a technique to speed up the decoding process of large LLMs. It optimizes models for latency without compromising the quality of the generated text.

This technique uses a smaller but faster model called the *draft* model. The draft model generates candidate tokens, which are then validated by the larger but slower *target* model. At each iteration, the draft model generates multiple candidate tokens. The target model verifies the tokens, and if it finds that a particular token is not acceptable, it rejects the token and regenerates it. So, the target model both verifies tokens and generates a small amount of them.

The draft model is significantly faster than the target model. It generates all the tokens quickly and then sends batches of them to the target model for verification. The target model evaluate them all in parallel, which speeds up the final response.

SageMaker AI offers a pre-built draft model that you can use, so you don't have to build your own. If you prefer to use your own custom draft model, SageMaker AI also supports this option.

Fast model loading

The *fast model loading* technique prepares an LLM so that SageMaker AI can load it onto an ML instance more quickly.

To prepare the model, SageMaker AI shards it in advance by dividing it into portions that can each reside on a separate GPU for distributed inference. Also, SageMaker AI stores the model weights in equal-sized chunks that SageMaker AI can load onto the instance concurrently.

When SageMaker AI loads the optimized model onto the instance, it streams the model weights directly from Amazon S3 onto the GPUs of the instance. By streaming the weights, SageMaker AI omits several time-consuming steps that are normally necessary. These steps include downloading the model artifacts from Amazon S3 to disk, loading the model artifacts onto the host memory, and sharding the model on the host before finally loading the shards onto the GPUs.

After you optimize your model for faster loading, you can deploy it more quickly to a SageMaker AI endpoint. Also, if you configure the endpoint to use auto scaling, it scales out more quickly to accommodate increases in traffic.

Deploy a pre-optimized model

Some models in JumpStart are pre-optimized by SageMaker AI, which means that you can deploy optimized versions of these models without first creating an inference optimization job.

For the list of models with pre-optimized options, see [Pre-optimized JumpStart models](#).

Amazon SageMaker Studio

Use the following procedure to deploy a pre-optimized JumpStart model using Amazon SageMaker Studio.

To deploy a pre-optimized model

1. In Studio, in the navigation menu on the left, choose **JumpStart**.
2. On the **All public models** page, choose one of the models that are pre-optimized.
3. On the model details page, choose **Deploy**.
4. On the deployment page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the

License agreement section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**

For more information, see End-user license agreements.

5. For **Endpoint name** and **Initial instance count**, accept the default values or set custom ones.
6. For **Instance type**, keep the default value. Otherwise, you can't deploy a pre-optimized configuration.
7. Under **Models**, expand the model configuration. Studio shows a table that provides the pre-optimized configurations that you can choose from. Each option has metrics for latency and throughput. Choose the option that best suits your application needs.
8. Choose **Deploy**.

SageMaker AI Python SDK

You can deploy a pre-optimized model by using the SageMaker AI Python SDK in your project. First, you define a `Model` instance by using the `ModelBuilder` class. Then, you use the `set_deployment_config()` method to set the pre-optimized configuration that you want to deploy. Then, you use the `build()` method to build the model. Finally, you use the `deploy()` method to deploy it to an inference endpoint.

For more information about the classes and methods used in the following examples, see APIs in the SageMaker AI Python SDK documentation.

To set up your project

1. In your application code, import the necessary libraries. The following example imports the SDK for Python (Boto3). It also imports the modules from the SageMaker AI Python SDK that you use to define and work with models:

```
import boto3
from sagemaker.serve.builder.model_builder import ModelBuilder
from sagemaker.serve.builder.schema_builder import SchemaBuilder
from sagemaker.session import Session
```

2. Initialize a SageMaker AI session. The following example uses the `Session()` class:

```
sagemaker_session = Session()
```

To define your model

1. Create a `SchemaBuilder` instance, and provide input and output samples. You supply this instance to the `ModelBuilder` class when you define a model. With it, SageMaker AI automatically generates the marshalling functions for serializing and deserializing the input and output.

   For more information about using the `SchemaBuilder` and `ModelBuilder` classes, see Create a model in Amazon SageMaker AI with ModelBuilder.

   The following example provides sample input and output strings to the `SchemaBuilder` class:

```
response = "Jupiter is the largest planet in the solar system. It is the fifth
 planet from the sun."
sample_input = {
    "inputs": "What is the largest planet in the solar system?",
    "parameters": {"max_new_tokens": 128, "top_p": 0.9, "temperature": 0.6},
}
sample_output = [{"generated_text": response}]
schema_builder = SchemaBuilder(sample_input, sample_output)
```

2. Define your model to SageMaker AI. The following example sets the parameters to initialize a `ModelBuilder` instance:

```
model_builder = ModelBuilder(
    model="jumpstart-model-id",
    schema_builder=schema_builder,
    sagemaker_session=sagemaker_session,
    role_arn=sagemaker_session.get_caller_identity_arn(),
)
```

   This example uses a JumpStart model. Replace *`jumpstart-model-id`* with the ID of a JumpStart model, such as `meta-textgeneration-llama-3-70b`.

To retrieve benchmark metrics

1. To determine which pre-optimized configuration you want to deploy, look up the options that SageMaker AI provides. The following example displays them:

```
model_builder.display_benchmark_metrics()
```

This `display_benchmark_metrics()` method prints a table like the following:

```
| Instance Type   | Config Name   |   Concurrent Users |   Latency, TTFT (P50 in
 sec) |   Throughput (P50 in tokens/sec/user) |
|:----------------|:--------------|-------------------:|----------------------------:|----
| ml.g5.48xlarge  | lmi-optimized |                  1 |
 2.25 |                               49.70 |
| ml.g5.48xlarge  | lmi-optimized |                  2 |
 2.28 |                               21.10 |
| ml.g5.48xlarge  | lmi-optimized |                  4 |
 2.37 |                               14.10 |
. . .
| ml.p4d.24xlarge | lmi-optimized |                  1 |
 0.10 |                              137.40 |
| ml.p4d.24xlarge | lmi-optimized |                  2 |
 0.11 |                              109.20 |
| ml.p4d.24xlarge | lmi-optimized |                  4 |
 0.13 |                               85.00 |
. . .
```

In the first column, the table lists potential instance types that you can use to host your chosen JumpStart model. For each instance type, under `Config Name`, it lists the names of the pre-optimized configurations. The configurations that SageMaker AI provides are named `lmi-optimized`. For each instance type and configuration, the table provides benchmark metrics. These metrics indicate the throughput and latency that your model will support for different numbers of concurrent users.

2. Based on the benchmark metrics, pick the instance type and configuration name that best supports your performance needs. You will use these values when you create a deployment configuration.

To deploy a pre-optimized model

1. Create a deployment configuration. The following example uses a `ModelBuilder` instance. It passes an instance type and configuration name to the to the `set_deployment_config()` method:

```
model_builder.set_deployment_config(
    config_name="config-name",
    instance_type="instance-type",
```

```
)
```

Replace *config-name* with a configuration name from the table, such as such as `lmi-optimized`. Replace *instance-type* with an instance type from the table, such as `ml.p4d.24xlarge`.

2. Build your model. The following example uses the `.build()` method of the `ModelBuilder` instance:

```
optimized_model = model_builder.build()
```

The `.build()` method returns a deployable `Model` instance.

3. Deploy your model to an inference endpoint. The following example uses the `.deploy()` method of the `Model` instance:

```
predictor = optimized_model.deploy(accept_eula=True)
```

The `deploy()` method returns a `Predictor` instance, which you can use to send inference requests to the model.

To test your model with an inference request

- After you deploy your model to an inference endpoint, test the model's predictions. The following example sends an inference request by using the `Predictor` instance:

```
predictor.predict(sample_input)
```

The model returns the text that it generates with a response like the following:

```
{'generated_text': ' Jupiter is the largest planet in the solar system. It is the
 fifth planet from the sun. It is a gas giant with . . .'}
```

Pre-optimized JumpStart models

The following are the JumpStart models that have pre-optimized configurations.

Meta

- Llama 3.1 70B Instruct
- Llama 3.1 70B
- Llama 3.1 405B Instruct FP8
- Llama 3.1 405B FP8
- Llama 3 8B Instruct
- Llama 3 8B
- Llama 3 70B Instruct
- Llama 3 70B
- Llama 2 70B Chat
- Llama 2 7B Chat
- Llama 2 13B Chat

HuggingFace

- Mixtral 8x7B Instruct
- Mixtral 8x7B
- Mistral 7B Instruct
- Mistral 7B

Pre-compiled JumpStart models

For some models and configurations, SageMaker AI provides models that are pre-compiled for specific AWS Inferentia and AWS Trainium instances. For these, if you create a compilation optimization job, and you choose ml.inf2.48xlarge or ml.trn1.32xlarge as the deployment instance type, SageMaker AI fetches the compiled artifacts. Because the job uses a model that's already compiled, it completes quickly without running the compilation from scratch.

The following are the JumpStart models for which SageMaker AI has pre-compiled models:

Meta

- Llama3 8B

- Llama3 70B
- Llama2 7B
- Llama2 70B
- Llama2 13B
- Code Llama 7B
- Code Llama 70B

HuggingFace

- Mistral 7B

Create an inference optimization job

You can create an inference optimization job by using Studio or the SageMaker AI Python SDK. The job optimizes your model by applying the techniques that you choose. For more information, see Optimization techniques.

> **Instance pricing for inference optimization jobs**
>
> When you create a inference optimization job that applies quantization or compilation, SageMaker AI chooses which instance type to use to run the job. You are charged based on the instance used.
> For the possible instance types and their pricing details, see the inference optimization pricing information on the Amazon SageMaker pricing page.
> You incur no additional costs for jobs that apply speculative decoding.

For the supported models that you can optimize, see Supported models reference.

Amazon SageMaker Studio

Complete the following steps to create an inference optimization job in Studio.

To begin creating an optimization job

1. In SageMaker AI Studio, create an optimization job through any of the following paths:
   - To create a job for a JumpStart model, do the following:

a. In the navigation menu, choose **JumpStart**.

b. On the **All public models** page, choose a model provider, and then choose one of the models that supports optimization.

c. On the model details page, choose **Optimize**. This button is enabled only for models that support optimization.

d. On the **Create inference optimization job** page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the **License agreement** section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**

- To create a job for a fine-tuned JumpStart model, do the following:

  a. In the navigation menu, under **Jobs**, choose **Training**.

  b. On the **Training Jobs** page, choose the name of a job that you used to fine tune a JumpStart model. These jobs have the type **JumpStart training** in the **Job type** column.

  c. On the details page for the training job, choose **Optimize**.

- To create a job for a custom model, do the following:

  a. In the navigation menu, under **Jobs**, choose **Inference optimization**.

  b. Choose **Create new job**.

  c. On the **Create inference optimization job** page, choose **Add model**.

  d. In the **Add model** window, choose **Custom Model**.

  e. For **Custom model name**, enter a name.

  f. For **S3 URI**, enter the URI for the location in Amazon S3 where you've stored your model artifacts.

2. On the **Create inference optimization job** page, for **Job name**, you can accept the default name that SageMaker AI assigns. Or, to enter a custom job name, choose the **Job name** field, and choose **Enter job name**.

To set the optimization configurations

1. For **Deployment instance type**, choose the instance type that you want to optimize the model for.

The instance type affects what optimization techniques you can choose. For most types that use GPU hardware, the supported techniques are **Quantization** and **Speculative decoding**. If you choose an instance that uses custom silicon, like the AWS Inferentia instance ml.inf2.8xlarge, the supported technique is **Compilation**, which you can use to compile the model for that specific hardware type.

2. Select one or more of the optimization techniques that Studio provides:

   - If you select **Quantization**, choose a data type for **Precision data type**.
   - If you select **Speculative decoding**, choose one of the following options:
     - **Use SageMaker AI draft model** – Choose to use the draft model that SageMaker AI provides.

       > **Note**
       >
       > If you choose to use the SageMaker AI draft model, you must also enable network isolation. Studio provides this option under **Security**.

     - **Choose JumpStart draft model** – Choose to select a model from the JumpStart catalog to use as your draft model.
     - **Choose your own draft model** – Choose to use your own draft model, and provide the S3 URI that locates it.
   - If you choose **Fast model loading**, Studio shows the `OPTION_TENSOR_PARALLEL_DEGREE` environment variable. Use the **Value** field to set the degree of tensor parallelism. The value must evenly divide the number of GPUs in the instance you chose for **Deployment instance type**. For example, to shard your model while using an instance with 8 GPUs, use the values 2, 4, or 8.
   - If you set **Deployment instance type** to an AWS Inferentia or AWS Trainium instance, Studio might show that **Compilation** is the one supported option. In that case, Studio selects this option for you.

3. For **Output**, enter the URI of a location in Amazon S3. There, SageMaker AI stores the artifacts of the optimized model that your job creates.

4. (Optional) Expand **Advanced options** for more fine-grained control over settings such as the IAM role, VPC, and environment variables. For more information, see *Advanced options* below.

5. When you're finished configuring the job, choose **Create job**.

Studio shows the job details page, which shows the job status and all of its settings.

Advanced options

You can set the following advanced options when you create an inference optimization job.

Under **Configurations**, you can set the following options:

Tensor parallel degree

A value for the degree of *tensor parallelism*. Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. The value must evenly divide the number of GPUs in your cluster.

Maximum token length

The limit for the number of tokens to be generated by the model. Note that the model might not always generate the maximum number of tokens.

Concurrency

The ability to run multiple instances of a model on the same underlying hardware. Use concurrency to serve predictions to multiple users and to maximize hardware utilization.

Batch size

If your model does *batch inferencing*, use this option to control the size of the batches that your model processes.

Batch inferencing generates model predictions on a batch of observations. It's a good option for large datasets or if you don't need an immediate response to an inference request.

Under **Security**, you can set the following options:

IAM Role

An IAM role that enables SageMaker AI to perform tasks on your behalf. During model optimization, SageMaker AI needs your permission to:

- Read input data from an S3 bucket
- Write model artifacts to an S3 bucket
- Write logs to Amazon CloudWatch Logs

- Publish metrics to Amazon CloudWatch

You grant permissions for all of these tasks to an IAM role.

For more information, see How to use SageMaker AI execution roles.

Encryption KMS key

A key in AWS Key Management Service (AWS KMS). SageMaker AI uses they key to encrypt the artifacts of the optimized model when SageMaker AI uploads the model to Amazon S3.

VPC

SageMaker AI uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

For more information, see Give SageMaker AI Hosted Endpoints Access to Resources in Your Amazon VPC.

Enable network isolation

Activate this option if you want to restrict your container's internet access. Containers that run with network isolation can’t make any outbound network calls.

> **Note**
> You must activate this option when you optimize with speculative decoding and you use the SageMaker AI draft model.
> For more information about network isolation, see Network Isolation.

Under **Advanced container definition**, you can set the following options:

Stopping condition

Specifies a limit to how long a job can run. When the job reaches the time limit, SageMaker AI ends the job. Use this option to cap costs.

Tags

Key-value pairs associated with the optimization job.

For more information about tags, see Tagging your AWS resources in the *AWS General Reference*.

Environment variables

Key-value pairs that define the environment variables to set in the model container.

SageMaker AI Python SDK

You can create an inference optimization job by using the SageMaker AI Python SDK in your project. First, you define a `Model` instance by using the `ModelBuilder` class. Then, you use the `optimize()` method to run a job that optimizes your model with quantization, speculative decoding, or compilation. When the job completes, you deploy the model to an inference endpoint by using the `deploy()` method.

For more information about the classes and methods used in the following examples, see APIs in the SageMaker AI Python SDK documentation.

To set up your project

1. In your application code, import the necessary libraries. The following example imports the SDK for Python (Boto3). It also imports the classes from the SageMaker AI Python SDK that you use to define and work with models:

```
import boto3
from sagemaker.serve.builder.model_builder import ModelBuilder
from sagemaker.serve.builder.schema_builder import SchemaBuilder
from sagemaker.session import Session
from pathlib import Path
```

2. Initialize a SageMaker AI session. The following example uses the `Session()` class:

```
sagemaker_session = Session()
```

To define your model

1. Create a `SchemaBuilder` instance, and provide input and output samples. You supply this instance to the `ModelBuilder` class when you define a model. With it, SageMaker AI automatically generates the marshalling functions for serializing and deserializing the input and output.

For more information about using the `SchemaBuilder` and `ModelBuilder` classes, see [Create a model in Amazon SageMaker AI with ModelBuilder](#).

The following example provides sample input and output strings to the `SchemaBuilder` class:

```
response = "Jupiter is the largest planet in the solar system. It is the fifth
 planet from the sun."
sample_input = {
    "inputs": "What is the largest planet in the solar system?",
    "parameters": {"max_new_tokens": 128, "top_p": 0.9, "temperature": 0.6},
}
sample_output = [{"generated_text": response}]
schema_builder = SchemaBuilder(sample_input, sample_output)
```

2. Define your model to SageMaker AI. The following example sets the parameters to initialize a `ModelBuilder` instance:

```
model_builder = ModelBuilder(
    model="jumpstart-model-id",
    schema_builder=schema_builder,
    sagemaker_session=sagemaker_session,
    role_arn=sagemaker_session.get_caller_identity_arn(),
)
```

This example uses a JumpStart model. Replace *`jumpstart-model-id`* with the ID of a JumpStart model, such as `meta-textgeneration-llama-3-70b`.

Note

If you want to optimize with speculative decoding, and you want to use the SageMaker AI draft, you must enable network isolation. To enable it, include the following argument when you initialize a `ModelBuilder` instance:

```
enable_network_isolation=True,
```

For more information about network isolation, see [Network Isolation](#).

To optimize with quantization

1. To run a quantization job, use the `optimize()` method, and set the `quantization_config` argument. The following example sets `OPTION_QUANTIZE` as an environment variable in the optimization container:

   ```
   optimized_model = model_builder.optimize(
       instance_type="instance-type",
       accept_eula=True,
       quantization_config={
           "OverrideEnvironment": {
               "OPTION_QUANTIZE": "awq",
           },
       },
       output_path="s3://output-path",
   )
   ```

   In this example, replace *`instance-type`* with an ML instance, such as `ml.p4d.24xlarge`. Replace *`s3://output-path`* with the path to the S3 location where you store the optimized model that the job creates.

   The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

   ```
   predictor = optimized_model.deploy(
       instance_type="instance-type",
       accept_eula=True,
   )
   ```

   In this example, replace *`instance-type`* with an ML instance, such as `ml.p4d.24xlarge`.

   The `deploy()` method returns a predictor object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with speculative decoding using the SageMaker AI draft model

When you optimize your model with speculative decoding, you can choose to use a draft model that SageMaker AI provides, or you can use your own. The following examples use the SageMaker AI draft model.

> **Prerequisite**
>
> To optimize with speculative decoding and the SageMaker AI draft model, you must enable network isolation when you define your model.

1. To run a speculative decoding job, use the `optimize()` method, and set the `speculative_decoding_config` argument. The following example sets the `ModelProvider` key to `SAGEMAKER` to use the draft model that SageMaker AI provides.

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    speculative_decoding_config={
        "ModelProvider": "SAGEMAKER",
    },
)
```

   In this example, replace *`instance-type`* with an ML instance, such as `ml.p4d.24xlarge`.

   The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
predictor = optimized_model.deploy(accept_eula=True)
```

   The `deploy()` method returns a predictor object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with speculative decoding using a custom draft model

Before you can provide your custom draft model to SageMaker AI, you must first upload the model artifacts to Amazon S3.

The following examples demonstrate one possible way to provide a custom draft model. The examples download the draft model from the Hugging Face Hub, upload it to Amazon S3, and provide the S3 URI to the `speculative_decoding_config` argument.

1. If you want to download a model from the Hugging Face Hub, add the `huggingface_hub` library to your project, and download a model with the `snapshot_download()` method. The following example downloads a model to a local directory:

   ```
   import huggingface_hub

   huggingface_hub.snapshot_download(
       repo_id="model-id",
       revision="main",
       local_dir=download-dir,
       token=hf-access-token,
   )
   ```

   In this example, replace *`model-id`* with the ID of a model the Hugging Face Hub, such as `meta-llama/Meta-Llama-3-8B`. Replace *`download-dir`* with a local directory. Replace *`hf-access-token`* with your user access token. To learn how to get your access token, see User access tokens in the Hugging Face documentation.

   For more information about the `huggingface_hub` library, see Hub client library in the Hugging Face documentation.

2. To make your downloaded model available to SageMaker AI, upload it to Amazon S3. The following example uploads the model with the `sagemaker_session` object:

   ```
   custom_draft_model_uri = sagemaker_session.upload_data(
       path=hf_local_download_dir.as_posix(),
       bucket=sagemaker_session.default_bucket(),
       key_prefix="prefix",
   )
   ```

   In this example, replace *`prefix`* with a qualifier that helps you distinguish the draft model in S3, such as `spec-dec-custom-draft-model`.

The `upload_data()` method returns the S3 URI for the model artifacts.

3. To run a speculative decoding job, use the `optimize()` method, and set the `speculative_decoding_config` argument. The following example sets the `ModelSource` key to the S3 URI of the custom draft model:

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    speculative_decoding_config={
        "ModelSource": custom_draft_model_uri + "/",
    },
)
```

   In this example, replace *`instance-type`* with an ML instance, such as `ml.p4d.24xlarge`.

   The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

4. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
predictor = optimized_model.deploy(accept_eula=True)
```

   The `deploy()` method returns a predictor object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with compilation

1. To run a compilation job, use the `optimize()` method, and set the `compilation_config` argument. The following example uses the `OverrideEnvironment` key to set the necessary environment variables in the optimization container:

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    compilation_config={
        "OverrideEnvironment": {
            "OPTION_TENSOR_PARALLEL_DEGREE": "24",
            "OPTION_N_POSITIONS": "8192",
```

```
            "OPTION_DTYPE": "fp16",
            "OPTION_ROLLING_BATCH": "auto",
            "OPTION_MAX_ROLLING_BATCH_SIZE": "4",
            "OPTION_NEURON_OPTIMIZE_LEVEL": "2",
        }
    },
    output_path="s3://output-path",
)
```

In this example, set *instance-type* to an ML instance type with accelerated hardware. For example, for accelerated inference with AWS Inferentia, you could set the type to an Inf2 instance, such as `ml.inf2.48xlarge`. Replace *s3://output-path* with the path to the S3 location where you store the optimized model that the job creates.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
predictor = optimized_model.deploy(accept_eula=True)
```

The `deploy()` method returns a predictor object, which you can use to send inference requests to the endpoint that hosts the model.

To test your model with an inference request

- To send a test inference request to your deployed model, use the `predict()` method of a predictor object. The following example passes the `sample_input` variable that was also passed to the `SchemaBuilder` class in the examples to define your model:

```
predictor.predict(sample_input)
```

The sample input has the prompt, "`What is the largest planet in the solar system?`". The `predict()` method returns the response that the model generated, as shown by the following example:

```
{'generated_text': ' Jupiter is the largest planet in the solar system. It is the
 fifth planet from the sun. It is a gas giant with . . .'}
```

Limitations of the SageMaker AI draft model

For any model that you optimize with the SageMaker AI draft model, be aware of the requirements, restrictions, and supported environment variables.

Requirements

You must do the following:

- Use a model that's provided by SageMaker JumpStart.
- Enable network isolation for the model deployment.
- If you deploy the model to a Large Model Inference (LMI) container, use a DJLServing container at version 0.28.0 or above.

  For the available containers, see Large Model Inference Containers in the Deep Learning Containers GitHub repository.
- If you fine tune the JumpStart model, use the safetensors format for the model weights.

  For more information about this format, see Safetensors in the Hugging Face documentation.

Restrictions

You can't do the following:

- Use the model in local test environments that you create with local mode.

  For more information about local mode, see Local Mode in the SageMaker AI Python SDK documentation.
- Access the model container through the AWS Systems Manager Agent (SSM Agent). The SSM Agent provides shell-level access to your model container so that you can debug processes and log commands with Amazon CloudWatch.

  For more information about this feature, see Access containers through SSM.
- Configure the model container for a core dump that occurs if the process crashes.

  For more information about core dumps from model containers, see ProductionVariantCoreDumpConfig.
- Deploy the model to multi-model endpoints, multi-container endpoints, or endpoints that host inference components.

For more information about these endpoint types, see Multi-model endpoints, Multi-container endpoints, and Inference components.

- Create a model package for the model. You use model packages to create deployable models that you publish on AWS Marketplace.

  For more information about this feature, see Create a Model Package Resource.
- Use your own inference code in the model container.
- Use a `requirements.txt` file in the model container. This type of file lists package dependencies.
- Enable the Hugging Face parameter `trust_remote_code`.

Supported environment variables

You can configure the container only with the following environment variables:

- Common environment variables for large model inference (LMI) containers.

  For more information about these variables, see Environment Variable Configurations in the LMI container documentation.
- Common environment variables for packages that the Hugging Face Hub provides in its Git repositories.

  For the repositories, see Hugging Face on GitHub.
- Common PyTorch & CUDA environment variables.

  For more information about these variables, see Torch Environment Variables in the PyTorch documentation.

View the optimization job results

After you've created one or more optimization jobs, you can use Studio to view a summary table of all of your jobs, and you can view the details for any individual job.

Amazon SageMaker Studio

To view the optimization job summary table

- In the Studio navigation menu, under **Jobs**, choose **Inference optimization**.

  The **Inference optimization** page shows a table that displays the jobs that you've created. For each job, it shows the optimization configurations that you applied and the job status.

To view the details for a job

- On the **Inference optimization** page, in the summary table, choose the name of the job.

  Studio shows the job details page, which shows the job status and all of the settings that you applied when you created the job. If the job completed successfully, SageMaker AI stored the optimized model artifacts in the Amazon S3 location under **Optimized model S3 URI**.

Evaluate the performance of optimized models

After you use an optimization job to create an optimized model, you can run an evaluation of model performance. This evaluation yields metrics for latency, throughput, and price. Use these metrics to determine whether the optimized model meets the needs of your use case or whether it requires further optimization.

You can run performance evaluations only by using Studio. This feature is not provided through the Amazon SageMaker AI API or Python SDK.

Before you begin

Before you can create a performance evaluation, you must first optimize a model by creating an inference optimization job. In Studio, you can evaluate only the models that you create with these jobs.

Create the performance evaluation

Complete the following steps in Studio to create a performance evaluation for an optimized model.

1. In the Studio navigation menu, under **Jobs**, choose **Inference optimization**.
2. Choose the name of the job that created the optimized model that you want to evaluate.

3. On the job details page, choose **Evaluate performance**.
4. On the **Evaluate performance** page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the **License agreement** section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**
5. For **Select a model for tokenizer**, accept the default, or a choose a specific model to act as the tokenizer for your evaluation.
6. For **Input datasets**, choose whether to:
   - Use the default sample datasets from SageMaker AI.
   - Provide an S3 URI that points to your own sample datasets.
7. For **S3 URI for performance results**, provide a URI that points to the location in Amazon S3 where you want to store the evaluation results.
8. Choose **Evaluate**.

   Studio shows the **Performance evaluations** page, where your evaluation job is shown in the table. The **Status** column shows the status of your evaluation.
9. When the status is **Completed**, choose the name of the job to see the evaluation results.

The evaluation details page shows tables that provide the performance metrics for latency, throughput, and price. For more information about each metric, see the Metrics reference for inference performance evaluations.

Metrics reference for inference performance evaluations

After you successfully evaluate the performance of an optimized model, the evaluation details page in Studio shows the following metrics.

Latency metrics

The **Latency** section shows the following metrics

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Time to first token (ms)

The time that elapsed between when request is sent and when the first token of a streaming response is received.

Inter-token latency (ms)

The time to generate an output token for each request.

Client latency (ms)

The request latency from the time the request is sent to the time the entire response is received.

Input tokens/sec (count)

The total number of generated input tokens, across all requests, divided by the total duration in seconds for the concurrency.

Output tokens/sec (count)

The total number of generated output tokens, across all requests, divided by total duration in seconds for the concurrency.

Client invocations (count)

The total number of inference requests sent to the endpoint across all users at a concurrency.

Client invocation errors (count)

The total number of inference requests sent to the endpoint across all users at a given concurrency that resulted in an invocation error.

Tokenizer failed (count)

The total number of inference requests where the tokenizer failed to parse the request or the response.

Empty inference response (count)

The total number of inference requests that resulted in zero output tokens or the tokenizer failing to parse the response.

Throughput metrics

The **Throughput** section shows the following metrics.

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Input tokens/sec/req (count)

The total number of generated input tokens per second per request.

Output tokens/sec/req (count)

The total number of generated output tokens per second per request.

Input tokens (count)

The total number of generated input tokens per request.

Output tokens (count)

The total number of generated output tokens per request.

Price metrics

The **Price** section shows the following metrics.

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Price per million input tokens

Cost of processing 1M input tokens.

Price per million output tokens

Cost of generating 1M output tokens.

Supported models reference

The following tables show the models for which SageMaker AI support inference optimization, and they show the supported optimization techniques.

Supported Llama models

Model Name	Supported Data Formats for Quantization	Supports Speculative Decoding	Supports Fast Model Loading	Libraries Used for Compilation
Meta Llama 2 13B	INT4-AWQ INT8-SmoothQuant FP8	Yes	Yes	AWS Neuron TensorRT-LLM

Options for evaluating your machine learning model in Amazon SageMaker AI

After training a model, evaluate it to determine whether its performance and accuracy enable you to achieve your business goals. You might generate multiple models using different methods and evaluate each. For example, you could apply different business rules for each model, and then apply various measures to determine each model's suitability. You might consider whether your model needs to be more sensitive than specific (or vice versa).

You can evaluate your model using historical data (offline) or live data:

- **Offline testing**—Use historical, not live, data to send requests to the model for inferences.

  Deploy your trained model to an alpha endpoint, and use historical data to send inference requests to it. To send the requests, use a Jupyter notebook in your Amazon SageMaker AI notebook instance and either the AWS SDK for Python (Boto) or the high-level Python library provided by SageMaker AI.
- **Online testing with live data**—SageMaker AI supports A/B testing for models in production by using production variants. Production variants are models that use the same inference code and are deployed on the same SageMaker AI endpoint. You configure the production variants so that a small portion of the live traffic goes to the model that you want to validate. For example, you might choose to send 10% of the traffic to a model variant for evaluation. After you are satisfied

with the model's performance, you can route 100% traffic to the updated model. For an example of testing models in production, see Testing models with production variants.

For more information, see articles and books about how to evaluate models, for example, Evaluating Machine Learning Models.

Options for offline model evaluation include:

- **Validating using a holdout set**—Machine learning practitioners often set aside a part of the data as a "holdout set." They don't use this data for model training.

  With this approach, you evaluate how well your model provides inferences on the holdout set. You then assess how effectively the model generalizes what it learned in the initial training, as opposed to using model memory. This approach to validation gives you an idea of how often the model is able to infer the correct answer.

  In some ways, this approach is similar to teaching elementary school students. First, you provide them with a set of examples to learn, and then test their ability to generalize from their learning. With homework and tests, you pose problems that were not included in the initial learning and determine whether they are able to generalize effectively. Students with perfect memories could memorize the problems, instead of learning the rules.

  Typically, the holdout dataset is of 20-30% of the training data.

- **k-fold validation**—In this validation approach, you split the example dataset into *k* parts. You treat each of these parts as a holdout set for *k* training runs, and use the other *k*-1 parts as the training set for that run. You produce *k* models using a similar process, and aggregate the models to generate your final model. The value *k* is typically in the range of 5-10.

Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender is a capability of Amazon SageMaker AI. It reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker AI ML instances. You can use Inference Recommender to deploy your model to a real-time or serverless inference endpoint that delivers the best performance at the lowest cost. Inference Recommender helps you select the best instance type and configuration for your ML models and workloads. It considers factors like instance count, container parameters, model optimizations, max concurrency, and memory size.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you can either create a SageMaker AI model or register a model to the SageMaker Model Registry with your model artifacts. Use the AWS SDK for Python (Boto3) or the SageMaker AI console to run benchmarking jobs for different SageMaker AI endpoint configurations. Inference Recommender jobs help you collect and visualize metrics across performance and resource utilization to help you decide on which endpoint type and configuration to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites for using Amazon SageMaker Inference Recommender section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
2. Read through the Recommendation jobs with Amazon SageMaker Inference Recommender section to launch your first Inference Recommender recommendation jobs.
3. Explore the introductory Amazon SageMaker Inference Recommender Jupyter notebook example, or review the example notebooks in the following section.

Example notebooks

The following example Jupyter notebooks can help you with the workflows for multiple use cases in Inference Recommender:

- If you want an introductory notebook that benchmarks a TensorFlow model, see the SageMaker Inference Recommender TensorFlow notebook.

- If you want to benchmark a HuggingFace model, see the SageMaker Inference Recommender for HuggingFace notebook.
- If you want to benchmark an XGBoost model, see the SageMaker Inference Recommender XGBoost notebook.
- If you want to review CloudWatch metrics for your Inference Recommender jobs, see the SageMaker Inference Recommender CloudWatch metrics notebook.

Prerequisites for using Amazon SageMaker Inference Recommender

Before you can use Amazon SageMaker Inference Recommender, you must complete the prerequisite steps. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs. The examples shown use the AWS SDK for Python (Boto3).

> **Note**
>
> - The following code examples use Python. Remove the `!` prefix character if you run any of the following code samples in your terminal or AWS CLI.
> - You can run the following examples with the Python 3 (TensorFlow 2.6 Python 3.8 CPU Optimized) kernel in an Amazon SageMaker Studio notebook. For more information about Studio, see Amazon SageMaker Studio.

1. **Create an IAM role for Amazon SageMaker AI.**

   Create an IAM role for Amazon SageMaker AI that has the `AmazonSageMakerFullAccess` IAM managed policy attached.
2. **Set up your environment.**

   Import dependencies and create variables for your AWS Region, your SageMaker AI IAM role (from Step 1), and the SageMaker AI client.

   ```
   !pip install --upgrade pip awscli botocore boto3  --quiet
   from sagemaker import get_execution_role, Session, image_uris
   import boto3

   region = boto3.Session().region_name
   ```

```
role = get_execution_role()
sagemaker_client = boto3.client("sagemaker", region_name=region)
sagemaker_session = Session()
```

3. **(Optional) Review existing models benchmarked by Inference Recommender.**

   Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

   Use `ListModelMetaData` to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

   You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

```
list_model_metadata_response=sagemaker_client.list_model_metadata()
```

   The output includes model summaries (`ModelMetadataSummaries`) and response metadata (`ResponseMetadata`) similar to the following example:

```
{
    'ModelMetadataSummaries': [{
            'Domain': 'NATURAL_LANGUAGE_PROCESSING',
            'Framework': 'PYTORCH:1.6.0',
             'Model': 'bert-base-cased',
             'Task': 'FILL_MASK'
             },
            {
             'Domain': 'NATURAL_LANGUAGE_PROCESSING',
             'Framework': 'PYTORCH:1.6.0',
             'Model': 'bert-base-uncased',
             'Task': 'FILL_MASK'
             },
            {
            'Domain': 'COMPUTER_VISION',
             'Framework': 'MXNET:1.8.0',
             'Model': 'resnet18v2-gluon',
             'Task': 'IMAGE_CLASSIFICATION'
             },
             {
```

```
                'Domain': 'COMPUTER_VISION',
                'Framework': 'PYTORCH:1.6.0',
                'Model': 'resnet152',
                'Task': 'IMAGE_CLASSIFICATION'
                }],
     'ResponseMetadata': {
                               'HTTPHeaders': {
                               'content-length': '2345',
                               'content-type': 'application/x-amz-json-1.1',
                               'date': 'Tue, 19 Oct 2021 20:52:03 GMT',
                               'x-amzn-requestid': 'xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx'
                             },
     'HTTPStatusCode': 200,
     'RequestId': 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx',
     'RetryAttempts': 0
     }
}
```

For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```
# ML framework details
framework = 'pytorch'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

4. **Upload your machine learning model to Amazon S3.**

   Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets

# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)
```

```
# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is
 required for Inferentia compilation.
model.eval()
model_trace = torch.jit.trace(model, image)

# Save your traced model
model_trace.save('model.pth')
```

Download a sample inference script `inference.py`. Create a `code` directory and move the inference script to the `code` directory.

```
# Download the inference script
!wget https://aws-ml-blog-artifacts.s3.us-east-2.amazonaws.com/inference.py

# move it into a code/ directory
!mkdir code
!mv inference.py code/
```

Amazon SageMaker AI requires pre-trained machine learning models to be packaged as a compressed TAR file (`*.tar.gz`). Compress your model and inference script to satisfy this requirement:

```
!tar -czf test.tar.gz model.pth code/inference.py
```

When your endpoint is provisioned, the files in the archive are extracted to `/opt/ml/model/` on the endpoint.

After you compress your model and model artifacts as a `.tar.gz` file, upload them to your Amazon S3 bucket. The following example demonstrates how to upload your model to Amazon S3 using the AWS CLI:

```
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

5. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

SageMaker AI provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker AI images, see Available Deep Learning Containers Images.

If none of the existing SageMaker AI containers meet your needs and you don't have an existing container of your own, create a new Docker image. See Containers with custom inference code for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```
from sagemaker import image_uris

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'pytorch'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework,
                                region,
                                version=framework_version,
                                py_version='py3',
                                instance_type=instance_type,
                                image_scope='inference')
```

For a list of available SageMaker AI Instances, see Amazon SageMaker AI Pricing.

6. **Create a sample payload archive.**

   Create an archive that contains individual files that the load testing tool can send to your SageMaker AI endpoints. Your inference code must be able to read the file formats from the sample payload.

   The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.

```
!wget https://cdn.pixabay.com/photo/2020/12/18/05/56/flowers-5841251_1280.jpg
```

Compress the sample payload as a tarball:

```
!tar -cvzf payload.tar.gz flowers-5841251_1280.jpg
```

Upload the sample payload to Amazon S3 and note the Amazon S3 URI:

```
!aws s3 cp payload.tar.gz s3://{bucket}/models/
```

You need the Amazon S3 URI in a later step, so store it in a variable:

```
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
payload_s3_key = f"{bucket_prefix}/payload.tar.gz"
sample_payload_url= f"s3://{bucket}/{payload_s3_key}"
```

7. **Prepare your model input for the recommendations job**

   For the last prerequisite, you have two options to prepare your model input. You can either register your model with SageMaker Model Registry, which you can use to catalog models for production, or you can create a SageMaker AI model and specify it in the `ContainerConfig` field when creating a recommendations job. The first option is best if you want to take advantage of the features that Model Registry provides, such as managing model versions and automating model deployment. The second option is ideal if you want to get started quickly. For the first option, go to step 7. For the second option, skip step 7 and go to step 8.

8. **Option 1: Register your model in the model registry**

   With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

   When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the AWS SDK for Python (Boto3) or with Amazon SageMaker Studio Classic. To create a versioned model package programmatically, first create a model package group with the `CreateModelPackageGroup` API. Next, create a model package using the `CreateModelPackage` API. Calling this method makes a versioned model package.

See Create a Model Group and Register a Model Version for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the AWS SDK for Python (Boto3) and Amazon SageMaker Studio Classic.

The following code sample demonstrates how to create a versioned model package using the AWS SDK for Python (Boto3).

> **Note**
>
> You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the `CreateModelPackageGroup` API. Provide a name to the model package group for the `ModelPackageGroupName` and optionally provide a description of the model package in the `ModelPackageGroupDescription` field.

```
model_package_group_name = '<INSERT>'
model_package_group_description = '<INSERT>'

model_package_group_input_dict = {
 "ModelPackageGroupName" : model_package_group_name,
 "ModelPackageGroupDescription" : model_package_group_description,
}
```

```
model_package_group_response = 
 sagemaker_client.create_model_package_group(**model_package_group_input_dict)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateModelPackageGroup`.

Create a model package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for `InferenceSpecification`. `InferenceSpecification` should contain information about inference jobs that can be run with models based on this model package, including the following:

- The Amazon ECR paths of images that run your inference code.
- (Optional) The instance types that the model package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the model package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- Domain: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- Task: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification. Specify "OTHER" if none of the tasks listed in the API Reference Guide satisfy your use case. See the Task API field descriptions for a list of supported machine learning tasks.
- SamplePayloadUrl: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single GZIP compressed TAR archive (.tar.gz suffix).
- Framework: The machine learning framework of the model package container image.
- FrameworkVersion: The framework version of the model package container image.

If you provide an allow list of instance types to use to generate inferences in real-time for the SupportedRealtimeInferenceInstanceTypes, Inference Recommender limits the search space for instance types during a `Default` job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step, we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. Use those variables in the following code sample to define a dictionary used as input to the [`CreateModelPackage`] API.

```
# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f"{bucket_prefix}/test.tar.gz"
model_url= f"s3://{bucket}/{model_s3_key}"

# Similar open source model to the packaged model
# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input.
input_content_type='image/jpeg'

# Optional - provide a description of your model.
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier
## step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version
## in a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"
```

```
# Create a dictionary to use as input for creating a model pacakge group
model_package_input_dict = {
        "ModelPackageGroupName" : model_package_group_name,
        "ModelPackageDescription" : model_package_description,
        "Domain": ml_domain,
        "Task": ml_task,
        "SamplePayloadUrl": sample_payload_url,
        "InferenceSpecification": {
                "Containers": [
                    {
                        "Image": image_uri,
                        "ModelDataUrl": model_url,
                        "Framework": framework.upper(),
                        "FrameworkVersion": framework_version,
                        "NearestModelName": nearest_model_name,
                        "ModelInput": {"DataInputConfig":
 data_input_configuration}
                    }
                    ],
                "SupportedContentTypes": [input_content_type]
        }
    }
```

b. **Create a model package**

Use the `CreateModelPackage` API to create a model package. Pass the input dictionary defined in the previous step:

```
model_package_response =
 sagemaker_client.create_model_package(**model_package_input_dict)
```

You need the model package ARN to use Amazon SageMaker Inference Recommender. Note the ARN of the model package or store it in a variable:

```
model_package_arn = model_package_response["ModelPackageArn"]

print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

9. **Option 2: Create a model and configure the `ContainerConfig` field**

Use this option if you want to start an inference recommendations job and don't need to register your model in the Model Registry. In the following steps, you create a model in

SageMaker AI and configure the `ContainerConfig` field as input for the recommendations job.

a. **Create a model**

Create a model with the `CreateModel` API. For an example that calls this method when deploying a model to SageMaker AI Hosting, see [Create a Model (AWS SDK for Python (Boto3))](#).

In a previous step, we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. We use those variables in the following code example where we define a dictionary used as input to the [`CreateModel`](#) API.

```
model_name = '<name_of_the_model>'
# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>:<account>:role/*"

# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f"{bucket_prefix}/test.tar.gz"
model_url= f"s3://{bucket}/{model_s3_key}"

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': image_uri,
        'ModelDataUrl': model_url,
    })
```

b. **Configure the `ContainerConfig` field**

Next, you must configure the [ContainerConfig](#) field with the model you just created and specify the following parameters in it:

- `Domain`: The machine learning domain of the model and its components, such as computer vision or natural language processing.
- `Task`: The machine learning task that the model accomplishes, such as image classification or object detection.
- `PayloadConfig`: The configuration for the payload for a recommendation job. For more information about the subfields, see [`RecommendationJobPayloadConfig`].
- `Framework`: The machine learning framework of the container image, such as PyTorch.
- `FrameworkVersion`: The framework version of the container image.
- (Optional) `SupportedInstanceTypes`: A list of the instance types that are used to generate inferences in real-time.

If you use the `SupportedInstanceTypes` parameter, Inference Recommender limits the search space for instance types during a `Default` job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In the following code example, we use the previously defined parameters, along with `NearestModelName`, to define a dictionary used as input to the [`CreateInferenceRecommendationsJob`] API.

```
## Uncomment if you did not store the domain and task in a previous step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version in a
 previous step
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input
input_content_type='image/jpeg'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
```

```
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating an inference recommendation
 job
container_config = {
        "Domain": ml_domain,
        "Framework": framework.upper(),
        "FrameworkVersion": framework_version,
        "NearestModelName": nearest_model_name,
        "PayloadConfig": {
            "SamplePayloadUrl": sample_payload_url,
            "SupportedContentTypes": [ input_content_type ]
         },
        "DataInputConfig": data_input_configuration
        "Task": ml_task,
        }
```

Recommendation jobs with Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. Inference recommendations (`Default` job type) run a set of load tests on the recommended instance types. You can also load test for a serverless endpoint.. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Inference recommendation jobs complete within 45 minutes.
2. Endpoint recommendations (`Advanced` job type) are based on a custom load test where you select your desired ML instances or a serverless endpoint, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of inference configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Recommendation jobs also provide an initial instance count, which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, when you're creating a job through either the SageMaker AI console or the APIs, specify

`Default` to create preliminary endpoint recommendations and `Advanced` for custom load testing and endpoint recommendations.

> **Note**
>
> You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of the other.

Inference Recommender can also provide you with a list of prospective instances, or the top five instance types that are optimized for cost, throughput and latency for model deployment, along with a confidence score. You can choose these instances when deploying your model. Inference Recommender automatically performs benchmarking against your model for you to provide the prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results. To view the prospective instances, go to your SageMaker AI model details page. For more information, see Get instant prospective instances.

Topics

- Get instant prospective instances
- Inference recommendations
- Get an inference recommendation for an existing endpoint
- Stop your inference recommendation
- Compiled recommendations with Neo
- Recommendation results
- Get autoscaling policy recommendations
- Run a custom load test
- Stop your load test
- Troubleshoot Inference Recommender errors

Get instant prospective instances

Inference Recommender can also provide you with a list of *prospective instances*, or instance types that might be suitable for your model, on your SageMaker AI model details page. Inference Recommender automatically performs preliminary benchmarking against your model for you to provide the top five prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results.

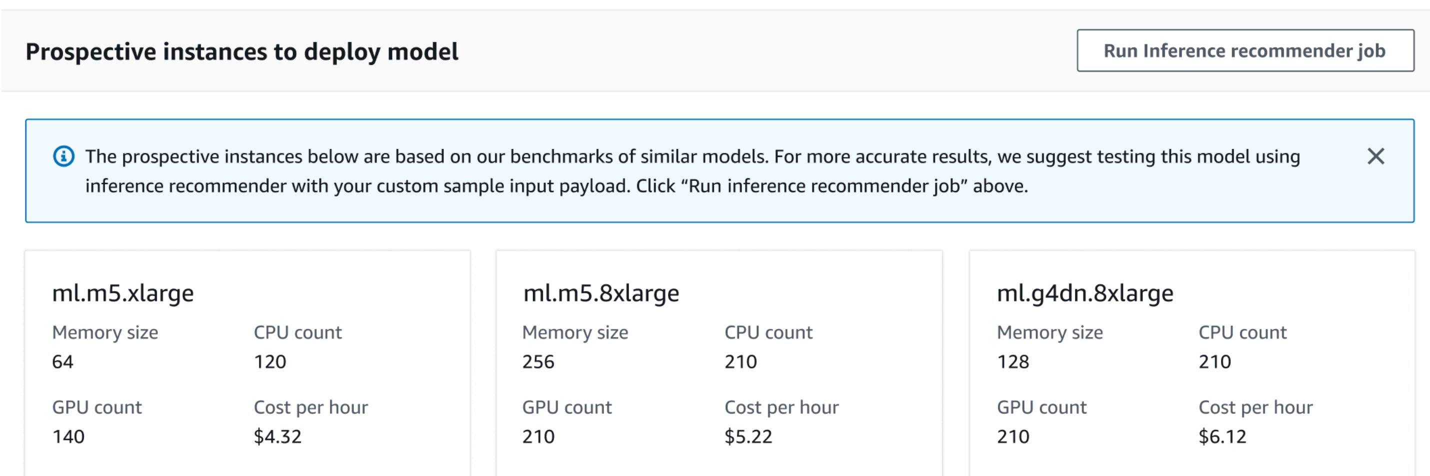
You can view a list of prospective instances for your model either programmatically by using the [DescribeModel](#) API, the SageMaker Python SDK, or the SageMaker AI console.

> **Note**
>
> You won't get prospective instances for models that you created in SageMaker AI before this feature became available.

To view the prospective instances for your model through the console, do the following:

1. Go to the SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Models**.
3. From the list of models, choose your model.

On the details page for your model, go to the **Prospective instances to deploy model** section. The following screenshot shows this section.



In this section, you can view the prospective instances that are optimized for cost, throughput, and latency for model deployment, along with additional information for each instance type such as the memory size, CPU and GPU count, and cost per hour.

If you decide that you want to benchmark a sample payload and run a full inference recommendation job for your model, you can start a default inference recommendation job from this page. To start a default job through the console, do the following:

1. On your model details page in the **Prospective instances to deploy model section**, choose **Run Inference recommender job**.
2. In the dialog box that pops up, for **S3 bucket for benchmarking payload**, enter the Amazon S3 location where you've stored a sample payload for your model.
3. For **Payload content type**, enter the MIME types for your payload data.
4. (Optional) In the **Model compilation using SageMaker Neo** section, for the **Data input configuration**, enter a data shape in dictionary format.
5. Choose **Run job**.

Inference Recommender starts the job, and you can view the job and its results from the **Inference recommender** list page in the SageMaker AI console.

If you want to run an advanced job and perform custom load tests, or if you want to configure additional settings and parameters for your job, see Run a custom load test.

Inference recommendations

Inference recommendation jobs run a set of load tests on recommended instance types or a serverless endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

> **Note**
>
> Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites for using Amazon SageMaker Inference Recommender.

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an inference recommendation based on your model type using the AWS SDK for Python (Boto3), AWS CLI, and Amazon SageMaker Studio Classic, and the SageMaker AI console

Topics

- Get your inference recommendation job results

Create an inference recommendation

Create an inference recommendation programmatically using the AWS SDK for Python (Boto3) or the AWS CLI, or interactively using Studio Classic or the SageMaker AI console. Specify a job name for your inference recommendation, an AWS IAM role ARN, an input configuration, and either a model package ARN when you registered your model with the model registry, or your model name and a `ContainerConfig` dictionary from when you created your model in the **Prerequisites** section.

AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to start an inference recommendation job. Set the `JobType` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following:
  - The ARN of the versioned model package you created when you registered your model with SageMaker AI model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
  - The name of the model you created. Define this for `ModelName` in the `InputConfig` field. Also, provide the `ContainerConfig` dictionary, which includes the required fields that need to be provided with the model name. Define this for `ContainerConfig` in the `InputConfig` field. In the `ContainerConfig`, you can also optionally specify the `SupportedEndpointType` field as either `RealTime` or `Serverless`. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

Import the AWS SDK for Python (Boto3) package and create a SageMaker AI client object using the client class. If you followed the steps in the **Prerequisites** section, only specify one of the following:

- Option 1: If you would like to create an inference recommendations job with a model package ARN, then store the model package group ARN in a variable named `model_package_arn`.
- Option 2: If you would like to create an inference recommendations job with a model name and `ContainerConfig`, store the model name in a variable named `model_name` and the `ContainerConfig` dictionary in a variable named `container_config`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide only one of model package ARN or model name, not both.
# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<INSERT>'
## Uncomment if you would like to create an inference recommendations job with a
## model name instead of a model package ARN, and comment out model_package_arn
 above
## Provide your model name
# model_name = '<INSERT>'
## Provide your container config
# container_config = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = 'arn:aws:iam::<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
```

```
    # Provide only one of model package ARN or model name, not both.
    # If you would like to create an inference recommendations job with a model
 name,
    # uncomment ModelName and ContainerConfig, and comment out
 ModelPackageVersionArn.
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn
        # 'ModelName': model_name,
        # 'ContainerConfig': container_config
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

AWS CLI

Use the `create-inference-recommendations-job` API to start an inference recommendation job. Set the `job-type` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.
- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following
  - The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.
  - The name of the model you created. Define this for `ModelName` in the `input-config` field. Also, provide the `ContainerConfig` dictionary which includes the required fields that need to be provided with the model name. Define this for `ContainerConfig` in the `input-config` field. In the `ContainerConfig`, you can also optionally specify the `SupportedEndpointType` field as either `RealTime` or `Serverless`. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

To create an inference recommendation jobs with a model package ARN, use the following example:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region:account:role/*>\",
        }"
```

To create an inference recommendation jobs with a model name and `ContainerConfig`, use the following example. The example uses the `SupportedEndpointType` field to specify that we only want to return real-time inference recommendations:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelName\": \"model-name\",
        \"ContainerConfig\" : {
                \"Domain\": \"COMPUTER_VISION\",
                \"Framework\": \"PYTORCH\",
                \"FrameworkVersion\": \"1.7.1\",
                \"NearestModelName\": \"resnet18\",
                \"PayloadConfig\":
                    {
                        \"SamplePayloadUrl\": \"s3://{bucket}/{payload_s3_key}\",
                        \"SupportedContentTypes\": [\"image/jpeg\"]
                    },
                \"SupportedEndpointType\": \"RealTime\",
                \"DataInputConfig\": \"[[1,3,256,256]]\",
                \"Task\": \"IMAGE_CLASSIFICATION\",
            },
        }"
```

Amazon SageMaker Studio Classic

Create an inference recommendation job in Studio Classic.

1. In your Studio Classic application, choose the home icon ().
2. In the left sidebar of Studio Classic, choose **Models**.
3. Choose **Model Registry** from the dropdown list to display models you have registered with the model registry.

   The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio Classic.
4. Select the name of your model group. When you select your model group, the right pane of Studio Classic displays column heads such as **Versions** and **Setting**.

   If you have one or more model packages within your model group, you see a list of those model packages within the **Versions** column.
5. Choose the **Inference recommender** column.
6. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the `AmazonSageMakerFullAccess` IAM managed policy to accomplish this. Or you can let Studio Classic create a role for you.
7. Choose **Get recommendations**.

   The inference recommendation can take up to 45 minutes.

   > **Warning**
   >
   > Do not close this tab. If you close this tab, you cancel the instance recommendation job.

SageMaker AI console

Create an instance recommendation job through the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose **Create job**.

4. For **Step 1: Model configuration**, do the following:

   a. For **Job type**, choose **Default recommender job**.

   b. If you're using a model registered in the SageMaker AI model registry, then turn on the **Choose a model from the model registry** toggle and do the following:

      i. From the **Model group** dropdown list, choose the model group in SageMaker AI model registry where your model is located.

      ii. From the **Model version** dropdown list, choose the desired version of your model.

   c. If you're using a model that you've created in SageMaker AI, then turn off the **Choose a model from the model registry toggle** and do the following:

      - For the **Model name** field, enter the name of your SageMaker AI model.

   d. From the **IAM role** dropdown list, you can select an existing AWS IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose **Create a new role** to open the role creation pop-up, and SageMaker AI adds the necessary permissions to the new role that you create.

   e. For **S3 bucket for benchmarking payload**, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.

   f. For **Payload content type**, enter the MIME types of your sample payload data.

   g. (Optional) If you turned off the **Choose a model from the model registry toggle** and specified a SageMaker AI model, then for **Container configuration**, do the following:

      i. For the **Domain** dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.

      ii. For the **Framework** dropdown list, select the framework of your container, such as TensorFlow or XGBoost.

      iii. For **Framework version**, enter the framework version of your container image.

      iv. For the **Nearest model name** dropdown list, select the pre-trained model that mostly closely matches your own.

      v. For the **Task** dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

h. (Optional) For **Model compilation using SageMaker Neo**, you can configure the recommendation job for a model that you've compiled using SageMaker Neo. For **Data input configuration**, enter the correct input data shape for your model in a format similar to `{'input':[1,1024,1024,3]}`.

i. Choose **Next**.

5. For **Step 2: Instances and environment parameters**, do the following:

   a. (Optional) For **Select instances for benchmarking**, you can select up to 8 instance types that you want to benchmark. If you don't select any instances, Inference Recommender considers all instance types.

   b. Choose **Next**.

6. For **Step 3: Job parameters**, do the following:

   a. (Optional) For the **Job name** field, enter a name for your instance recommendation job. When you create the job, SageMaker AI appends a timestamp to the end of this name.

   b. (Optional) For the **Job description** field, enter a description for the job.

   c. (Optional) For the **Encryption key** dropdown list, choose an AWS KMS key by name or enter its ARN to encrypt your data.

   d. (Optional) For **Max test duration (s)**, enter the maximum number of seconds you want each test to run for.

   e. (Optional) For **Max invocations per minute**, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker AI ends the job.

   f. (Optional) For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

   g. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.

Get your inference recommendation job results

Collect the results of your inference recommendation job programmatically with AWS SDK for Python (Boto3), the AWS CLI, Studio Classic, or the SageMaker AI console.

AWS SDK for Python (Boto3)

Once an inference recommendation is complete, you can use `DescribeInferenceRecommendationsJob` to get the job details and recommendations. Provide the job name that you used when you created the inference recommendation job.

```
job_name='<INSERT>'
response = sagemaker_client.describe_inference_recommendations_job(
                    JobName=job_name)
```

Print the response object. The previous code sample stored the response in a variable named `response`.

```
print(response['Status'])
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-

        'RetryAttempts': 0
        }
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See [Amazon SageMaker AI metrics in Amazon CloudWatch]() for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for an inference recommendations job configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
```

```
    {
       "EndpointConfiguration": {
          "EndpointName": "value",
          "InitialInstanceCount": value,
          "InstanceType": "value",
          "VariantName": "value",
          "ServerlessConfig": {
              "MaxConcurrency": value,
              "MemorySizeInMb": value
          }
       },
       "InvocationEndTime": value,
       "InvocationStartTime": value,
       "Metrics": {
          "CostPerHour": value,
          "CostPerInference": value,
          "CpuUtilization": value,
          "MaxInvocations": value,
          "MemoryUtilization": value,
          "ModelLatency": value,
          "ModelSetupTime": value
       },
       "ModelConfiguration": {
          "Compiled": "False",
          "EnvironmentParameters": [],
          "InferenceSpecificationName": "value"
       },
       "RecommendationId": "value"
    }
 ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the metrics returned for a serverless endpoint with the given `MemorySizeInMB` and when `MaxConcurrency = 1`. To increase the throughput possible on the endpoint, increase the value of `MaxConcurrency` linearly. For example, if the inference recommendation shows `MaxInvocations` as `1000`, then increasing `MaxConcurrency` to 2 would support 2000 `MaxInvocations`. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

AWS CLI

Once an inference recommendation is complete, you can use `describe-inference-recommendations-job` to get the job details and recommended instance types. Provide the job name that you used when you created the inference recommendation job.

```
aws sagemaker describe-inference-recommendations-job\
    --job-name <job-name>\
    --region <aws-region>
```

The JSON response similar should resemble the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000,
 tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000,
 tzinfo=tzlocal()),
    'InputConfig': {
                'ModelPackageVersionArn': 'arn:aws:sagemaker:region:account-
id:model-package/resource-id',
                'JobDurationInSeconds': 0
                },
    'InferenceRecommendations': [{
            'Metrics': {
                'CostPerHour': 0.20399999618530273,
                'CostPerInference': 5.246913588052848e-06,
                'MaximumInvocations': 648,
                'ModelLatency': 263596
                },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
```

```
                'InstanceType': 'ml.c5.xlarge',
                'InitialInstanceCount': 1
                },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
                }
        },
        {
            'Metrics': {
                'CostPerHour': 0.11500000208616257,
                'CostPerInference': 2.92620870823157e-06,
                'MaximumInvocations': 655,
                'ModelLatency': 826019
                },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
                'InstanceType': 'ml.c5d.large',
                'InitialInstanceCount': 1
                },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
                }
            },
            {
                'Metrics': {
                    'CostPerHour': 0.11500000208616257,
                    'CostPerInference': 3.3625731248321244e-06,
                    'MaximumInvocations': 570,
                    'ModelLatency': 1085446
                    },
                'EndpointConfiguration': {
                    'EndpointName': 'endpoint-name',
                    'VariantName': 'variant-name',
                    'InstanceType': 'ml.m5.large',
                    'InitialInstanceCount': 1
                    },
                'ModelConfiguration': {
                    'Compiled': False,
                    'EnvironmentParameters': []
                    }
            }],
```

```
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {
            'x-amzn-requestid': 'x-amzn-requestid',
            'content-type': 'content-type',
            'content-length': '1685',
            'date': 'Tue, 26 Oct 2021 20:31:10 GMT'
            },
        'RetryAttempts': 0
        }
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See [Amazon SageMaker AI metrics in Amazon CloudWatch](#) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for an inference recommendations job configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
```

```
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
        },
        "InvocationEndTime": value,
        "InvocationStartTime": value,
        "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
        },
        "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
        },
        "RecommendationId": "value"
    }
]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the metrics returned for a serverless endpoint with the given `MemorySizeInMB` and when `MaxConcurrency = 1`. To increase the throughput possible on the endpoint, increase the value of `MaxConcurrency` linearly. For example, if the inference recommendation shows `MaxInvocations` as `1000`, then increasing `MaxConcurrency` to 2 would support 2000 `MaxInvocations`. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/serverless-endpoints.html).

Amazon SageMaker Studio Classic

The inference recommendations populate in a new **Inference recommendations** tab within Studio Classic. It can take up to 45 minutes for the results to show up. This tab contains **Results** and **Details** column headings.

The **Details** column provides information about the inference recommendation job, such as the name of the inference recommendation, when the job was created (**Creation time**), and more. It also provides **Settings** information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides a **Deployment goals** and **SageMaker AI recommendations** window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances. For serverless recommendations, you can see the ideal values for the maximum concurrency and endpoint memory size.

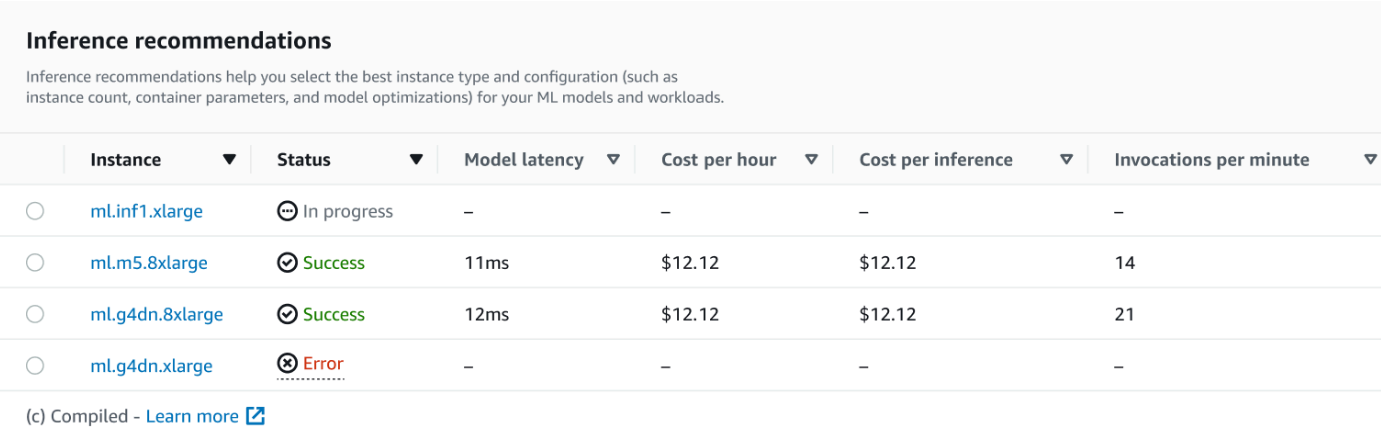
In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

SageMaker AI console

You can view your instance recommendation jobs in the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose the name of your inference recommendation job.

On the details page for your job, you can view the **Inference recommendations**, which are the instance types SageMaker AI recommends for your model, as shown in the following screenshot.



Inference recommendations

Inference recommendations help you select the best instance type and configuration (such as instance count, container parameters, and model optimizations) for your ML models and workloads.

	Instance	Status	Model latency	Cost per hour	Cost per inference	Invocations per minute
○	ml.inf1.xlarge	In progress	–	–	–	–
○	ml.m5.8xlarge	Success	11ms	$12.12	$12.12	14
○	ml.g4dn.8xlarge	Success	12ms	$12.12	$12.12	21
○	ml.g4dn.xlarge	Error	–	–	–	–

(c) Compiled - Learn more

In this section, you can compare the instance types by various factors such as **Model latency**, **Cost per hour**, **Cost per inference**, and **Invocations per minute**.

On this page, you can also view the configurations you specified for your job. In the **Monitor** section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see Interpret results.

For more information about interpreting the results of your recommendation job, see Recommendation results.

Get an inference recommendation for an existing endpoint

Inference recommendation jobs run a set of load tests on recommended instance types and an existing endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

You can benchmark and get inference recommendations for an existing SageMaker AI Inference endpoint to help you improve the performance of your endpoint. The procedure of getting recommendations for an existing SageMaker AI Inference endpoint is similar to the procedure for getting inference recommendations without an endpoint. There are several feature exclusions to take note of when benchmarking an existing endpoint:

- You can only use one existing endpoint per Inference Recommender job.
- You can only have one variant on your endpoint.
- You can't use an endpoint that enables autoscaling.
- This functionality is only supported for Real-Time Inference.
- This functionality doesn't support Real-Time Multi-Model Endpoints.

> **Warning**
>
> We strongly recommend that you don't run an Inference Recommender job on a production endpoint that handles live traffic. The synthetic load during benchmarking can affect your production endpoint and cause throttling or provide inaccurate benchmark results. We recommend that you use a non-production or developer endpoint for comparison purposes.

The following sections demonstrate how to use Amazon SageMaker Inference Recommender to create an inference recommendation for an existing endpoint based on your model type using the AWS SDK for Python (Boto3) and the AWS CLI.

> **Note**
>
> Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites for using Amazon SageMaker Inference Recommender.

Prerequisites

If you don't already have a SageMaker AI Inference endpoint, you can either get an inference recommendation without an endpoint, or you can create a Real-Time Inference endpoint by following the instructions in Create your endpoint and deploy your model.

Create an inference recommendation job for an existing endpoint

Create an inference recommendation programmatically using AWS SDK for Python (Boto3), or the AWS CLI. Specify a job name for your inference recommendation, the name of an existing SageMaker AI Inference endpoint, an AWS IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry.

AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to get an inference recommendation. Set the `JobType` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
- Provide the name of an existing SageMaker AI Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `InputConfig` field.

Import the AWS SDK for Python (Boto3) package and create a SageMaker AI client object using the client class. If you followed the steps in the **Prerequisites** section, the model package group ARN was stored in a variable named `model_package_arn`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<model-package-arn>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<job-name>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = '<arn:aws:iam::<account>:role/*>'

# Provide endpoint name for your endpoint that want to benchmark in Inference
 Recommender
endpoint_name = '<existing-endpoint-name>'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
```

```
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn,
        'Endpoints': [{'EndpointName': endpoint_name}]
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

AWS CLI

Use the `create-inference-recommendations-job` API to get an instance endpoint recommendation. Set the `job-type` field to `'Default'` for instance endpoint recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.
- The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.
- Provide the name of an existing SageMaker AI Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `input-config` field.

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region:account:role/*>\",
        \"Endpoints\": [{\"EndpointName\": <endpoint_name>}]
        }"
```

Get your inference recommendation job results

You can collect the results of your inference recommendation job programmatically with the same procedure for standard inference recommendation jobs. For more information, see Get your inference recommendation job results.

When you get inference recommendation job results for an existing endpoint, you should receive a JSON response similar to the following:

```
{
    "JobName": "job-name",
    "JobType": "Default",
    "JobArn": "arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id",
    "RoleArn": "iam-role-arn",
    "Status": "COMPLETED",
    "CreationTime": 1664922919.2,
    "LastModifiedTime": 1664924208.291,
    "InputConfig": {
        "ModelPackageVersionArn": "arn:aws:sagemaker:region:account-id:model-
package/resource-id",
        "Endpoints": [
            {
                "EndpointName": "endpoint-name"
            }
        ]
    },
    "InferenceRecommendations": [
        {
            "Metrics": {
                "CostPerHour": 0.7360000014305115,
                "CostPerInference": 7.456940238625975e-06,
                "MaxInvocations": 1645,
                "ModelLatency": 171
            },
            "EndpointConfiguration": {
                "EndpointName": "sm-endpoint-name",
                "VariantName": "variant-name",
                "InstanceType": "ml.g4dn.xlarge",
                "InitialInstanceCount": 1
            },
            "ModelConfiguration": {
                "EnvironmentParameters": [
```

```
                    {
                        "Key": "TS_DEFAULT_WORKERS_PER_MODEL",
                        "ValueType": "string",
                        "Value": "4"
                    }
                ]
            }
        }
    ],
    "EndpointPerformances": [
        {
            "Metrics": {
                "MaxInvocations": 184,
                "ModelLatency": 1312
            },
            "EndpointConfiguration": {
                "EndpointName": "endpoint-name"
            }
        }
    ]
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and latest modification times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The `EndpointPerformances` nested dictionary contains the name of your existing endpoint on which the recommendation job was run (`EndpointName`) and the performance metrics for your endpoint (`MaxInvocations` and `ModelLatency`).

Stop your inference recommendation

You might want to stop a job that is currently running if you began a job by mistake or no longer need to run the job. Stop your Inference Recommender inference recommendation jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio Classic.

AWS SDK for Python (Boto3)

Specify the name of the inference recommendation job for the `JobName` field:

```
sagemaker_client.stop_inference_recommendations_job(
                                    JobName='<INSERT>'
                                    )
```

AWS CLI

Specify the job name of the inference recommendation job for the `job-name` flag:

```
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio Classic

Close the tab in which you initiated the inference recommendation to stop your Inference Recommender inference recommendation.

SageMaker AI console

To stop your instance recommendation job through the SageMaker AI console, do the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, select your instance recommendation job.
4. Choose **Stop job**.
5. In the dialog box that pops up, choose **Confirm**.

After stopping your job, the job's **Status** should change to **Stopping**.

Compiled recommendations with Neo

In Inference Recommender, you can compile your model with Neo and get endpoint recommendations for your compiled model. SageMaker Neo is a service that can optimize your model for a target hardware platform (that is, a specific instance type or environment). Optimizing a model with Neo might improve the performance of your hosted model.

For Neo-supported frameworks and containers, Inference Recommender automatically suggests Neo-optimized recommendations. To be eligible for Neo compilation, your input must meet the following prerequisites:

- You are using a SageMaker AI owned DLC or XGBoost container.
- You are using a framework version supported by Neo. For the framework versions supported by Neo, see Cloud Instances in the SageMaker Neo documentation.
- Neo requires that you provide a correct input data shape for your model. You can specify this data shape as the `DataInputConfig` in the `InferenceSpecification` when you create a model package. For information about the correct data shapes for each framework, see Prepare Model for Compilation in the SageMaker Neo documentation.

  The following example shows how to specify the `DataInputConfig` field in the `InferenceSpecification`, where `data_input_configuration` is a variable that contains the data shape in dictionary format (for example, `{'input':[1,1024,1024,3]}`).

```
"InferenceSpecification": {
        "Containers": [
            {
                "Image": dlc_uri,
                "Framework": framework.upper(),
                "FrameworkVersion": framework_version,
                "NearestModelName": model_name,
                "ModelInput": {"DataInputConfig": data_input_configuration},
            }
        ],
        "SupportedContentTypes": input_mime_types,  # required, must be non-null
        "SupportedResponseMIMETypes": [],
        "SupportedRealtimeInferenceInstanceTypes":
 supported_realtime_inference_types,  # optional
```

```
    }
```

If these conditions are met in your request, then Inference Recommender runs scenarios for both compiled and uncompiled versions of your model, giving you multiple recommendation combinations to choose from. You can compare the configurations for compiled and uncompiled versions of the same inference recommendation and determine which one best suits your use case. The recommendations are ranked by cost per inference.

To get the Neo compilation recommendations, you don't have to do any additional configuration besides making sure that your input meets the preceding requirements. Inference Recommender automatically runs Neo compilation on your model if your input meets the requirements, and you receive a response that includes Neo recommendations.

If you run into errors during your Neo compilation, see [Troubleshoot Neo Compilation Errors](#).

The following table is an example of a response you might get from an Inference Recommender job that includes recommendations for compiled models. If the `InferenceSpecificationName` field is `None`, then the recommendation is an uncompiled model. The last row, in which the value for the **InferenceSpecificationName** field is `neo-00011122-2333-4445-5566-677788899900`, is for a model compiled with Neo. The value in the field is the name of the Neo job used to compile and optimize your model.

EndpointName	InstanceType	InitialInstanceCount	EnvironmentParameters	CostPerHour	CostPerInference	MaxInvocations	ModelLatency	InferenceSpecificationName
sm-epc-example-00111222	ml.c5.9xlarge	1	[]	1.836	9.15E-07	33456	7	None

sm-epc-example-33444555	ml.c5.xlarge	1	[]	0.204	1.60E-07	21286	42	neo-00011122-2333-4445-5566-677788899900

Get started

The general steps for creating an Inference Recommender job that includes Neo-optimized recommendations are as follows:

- Prepare your ML model for compilation. For more information, see Prepare Model for Compilation in the Neo documentation.
- Package your model in a model archive (`.tar.gz` file).
- Create a sample payload archive.
- Register your model in SageMaker Model Registry.
- Create an Inference Recommender job.
- View the results of the Inference Recommender job and choose a configuration.
- Debug compilation failures, if any. For more information, see Troubleshoot Neo Compilation Errors.

For an example that demonstrates the previous workflow and how to get Neo-optimized recommendations using XGBoost, see the following example notebook. For an example that show how to get Neo-optimized recommendations using TensorFlow, see the following example notebook.

Recommendation results

Each Inference Recommender job result includes `InstanceType`, `InitialInstanceCount`, and `EnvironmentParameters`, which are tuned environment variable parameters for your container to improve its latency and throughput. The results also include performance and cost metrics such as `MaxInvocations`, `ModelLatency`, `CostPerHour`, `CostPerInference`, `CpuUtilization`, and `MemoryUtilization`.

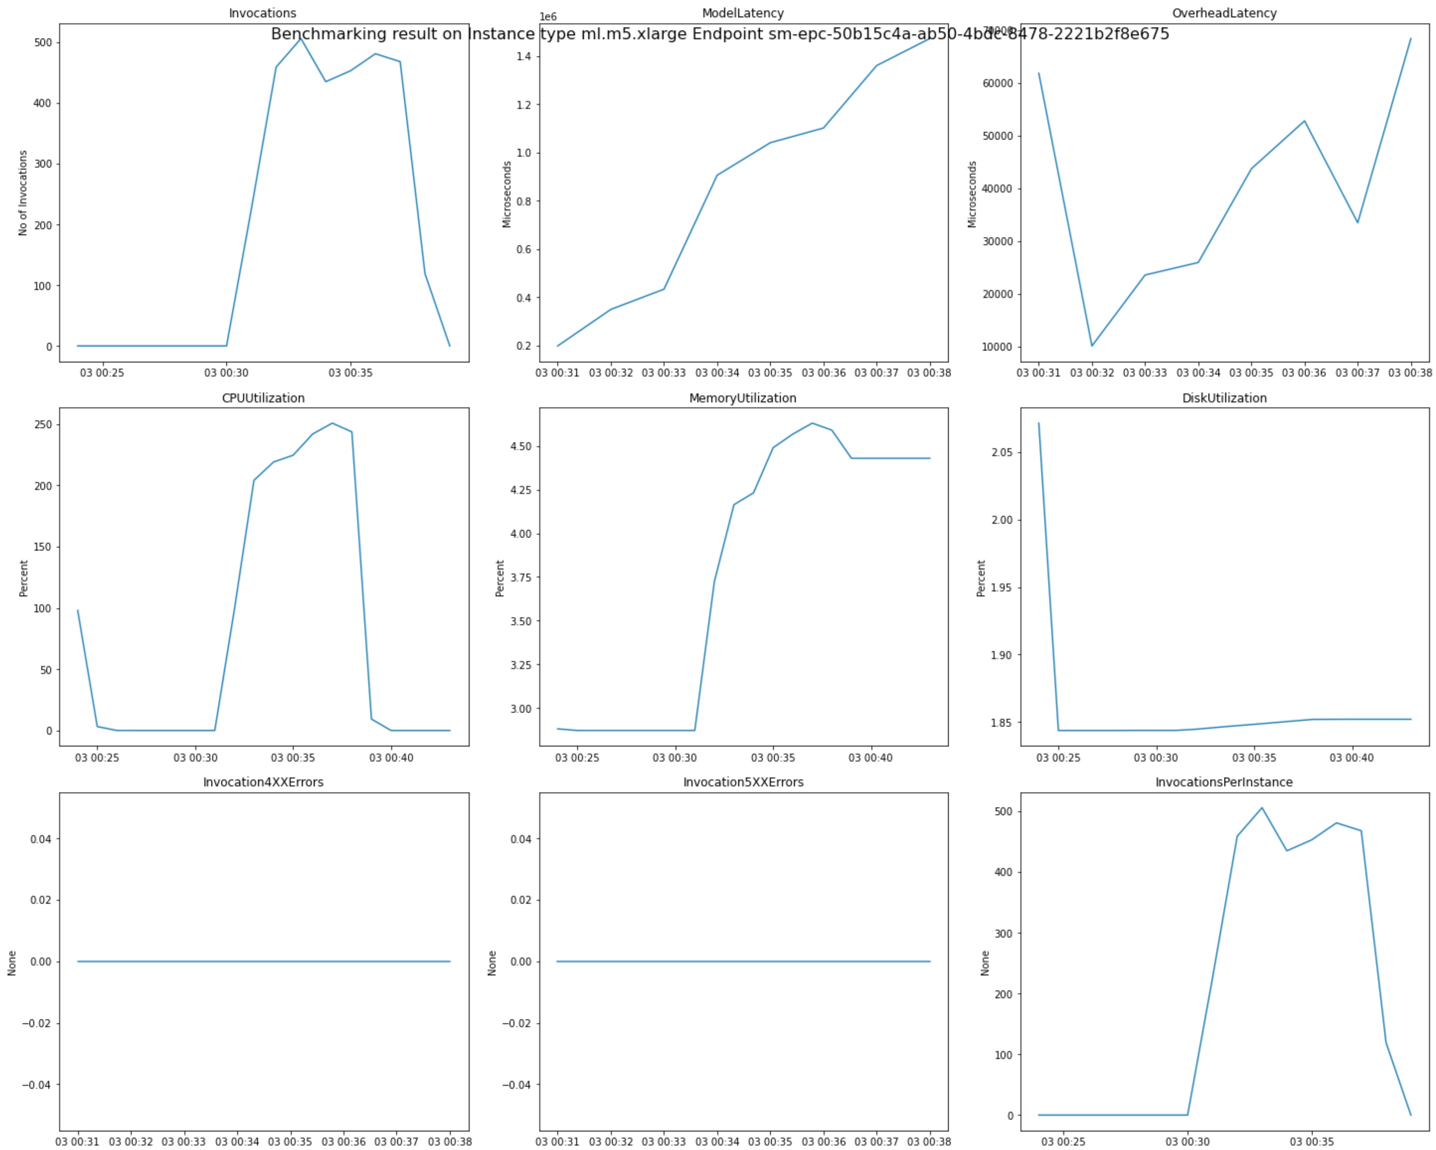
In the table below we provide a description of these metrics. These metrics can help you narrow down your search for the best endpoint configuration that suits your use case. For example, if your motivation is overall price performance with an emphasis on throughput, then you should focus on `CostPerInference`.

Metric	Description	Use case
`ModelLatency`	The interval of time taken by a model to respond as viewed from SageMaker AI. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. Units: Milliseconds	Latency sensitive workloads such as ad serving and medical diagnosis
`MaximumInvocations`	The maximum number of `InvokeEndpoint` requests sent to a model endpoint in a minute. Units: None	Throughput-focused workloads such as video processing or batch inference
`CostPerHour`	The estimated cost per hour for your real-time endpoint. Units: US Dollars	Cost sensitive workloads with no latency deadlines

Metric	Description	Use case
`CostPerInference`	The estimated cost per inference call for your real-time endpoint. Units: US Dollars	Maximize overall price performance with a focus on throughput
`CpuUtilization`	The expected CPU utilizati on at maximum invocations per minute for the endpoint instance. Units: Percent	Understand instance health during benchmarking by having visibility into core CPU utilization of the instance
`MemoryUtilization`	The expected memory utilization at maximum invocations per minute for the endpoint instance. Units: Percent	Understand instance health during benchmarking by having visibility into core memory utilization of the instance

In some cases you might want to explore other SageMaker AI Endpoint Invocation metrics such as `CPUUtilization`. Every Inference Recommender job result includes the names of endpoints spun up during the load test. You can use CloudWatch to review the logs for these endpoints even after they've been deleted.

The following image is an example of CloudWatch metrics and charts you can review for a single endpoint from your recommendation result. This recommendation result is from a Default job. The way to interpret the scalar values from the recommendation results is that they are based on the time point when the Invocations graph first begins to level out. For example, the `ModelLatency` value reported is at the beginning of the plateau around `03:00:31`.



For full descriptions of the CloudWatch metrics used in the preceding charts, see [SageMaker AI Endpoint Invocation metrics](#).

You can also see performance metrics like `ClientInvocations` and `NumberOfUsers` published by Inference Recommender in the `/aws/sagemaker/InferenceRecommendationsJobs` namespace. For a full list of metrics and descriptions published by Inference Recommender, see [SageMaker Inference Recommender jobs metrics](#).

See the [Amazon SageMaker Inference Recommender - CloudWatch Metrics](#) Jupyter notebook in the [amazon-sagemaker-examples](#) Github repository for an example of how to use the AWS SDK for Python (Boto3) to explore CloudWatch metrics for your endpoints.

Get autoscaling policy recommendations

With Amazon SageMaker Inference Recommender, you can get recommendations for autoscaling policies for your SageMaker AI endpoint based on your anticipated traffic pattern. If you've already completed an inference recommendation job, you can provide the details of the job to get a recommendation for an autoscaling policy that you can apply to your endpoint.

Inference Recommender benchmarks different values for each metric to determine the ideal autoscaling configuration for your endpoint. The autoscaling recommendation returns a recommended autoscaling policy for each metric that was defined in your inference recommendation job. You can save the policies and apply them to your endpoint with the PutScalingPolicy API.

To get started, review the following prerequisites.

Prerequisites

Before you begin, you must have completed a successful inference recommendation job. In the following section, you can provide either an inference recommendation ID or the name of a SageMaker AI endpoint that was benchmarked during an inference recommendation job.

To retrieve your recommendation job ID or endpoint name, you can either view the details of your inference recommendation job in the SageMaker AI console, or you can use the `RecommendationId` or `EndpointName` fields returned by the DescribeInferenceRecommendationsJob API.

Create an autoscaling configuration recommendation

To create an autoscaling recommendation policy, you can use the AWS SDK for Python (Boto3).

The following example shows the fields for the GetScalingConfigurationRecommendation API. Use the following fields when you call the API:

- `InferenceRecommendationsJobName` – Enter the name of your inference recommendation job.
- `RecommendationId` – Enter the ID of an inference recommendation from a recommendation job. This is optional if you've specified the `EndpointName` field.
- `EndpointName` – Enter the name of an endpoint that was benchmarked during an inference recommendation job. This is optional if you've specified the `RecommendationId` field.

- `TargetCpuUtilizationPerCore` – (Optional) Enter a percentage value of how much utilization you want an instance on your endpoint to use before autoscaling. The default value if you don't specify this field is 50%.
- `ScalingPolicyObjective` – (Optional) An object where you specify your anticipated traffic pattern.
  - `MinInvocationsPerMinute` – (Optional) The minimum number of expected requests to your endpoint per minute.
  - `MaxInvocationsPerMinute` – (Optional) The maximum number of expected requests to your endpoint per minute.

```
{
    "InferenceRecommendationsJobName": "string", // Required
    "RecommendationId": "string", // Optional, provide one of RecommendationId or
 EndpointName
    "EndpointName": "string", // Optional, provide one of RecommendationId or
 EndpointName
    "TargetCpuUtilizationPerCore": number, // Optional
    "ScalingPolicyObjective": { // Optional
        "MinInvocationsPerMinute": number,
        "MaxInvocationsPerMinute": number
    }
}
```

After submitting your request, you'll receive a response with autoscaling policies defined for each metric. See the following section for information about interpreting the response.

Review your autoscaling configuration recommendation results

The following example shows the response from the GetScalingConfigurationRecommendation API:

```
{
    "InferenceRecommendationsJobName": "string",
    "RecommendationId": "string", // One of RecommendationId or EndpointName is shown
    "EndpointName": "string",
    "TargetUtilizationPercentage": Integer,
    "ScalingPolicyObjective": {
        "MinInvocationsPerMinute": Integer,
        "MaxInvocationsPerMinute": Integer
    },
```

```
    "Metric": {
        "ModelLatency": Integer,
        "InvocationsPerInstance": Integer
    },
    "DynamicScalingConfiguration": {
        "MinCapacity": number,
        "MaxCapacity": number,
        "ScaleInCooldown": number,
        "ScaleOutCooldown": number,
        "ScalingPolicies": [
            {
                "TargetTracking": {
                    "MetricSpecification": {
                        "Predefined" {
                            "PredefinedMetricType": "string"
                         },
                        "Customized": {
                            "MetricName": "string",
                            "Namespace": "string",
                            "Statistic": "string"
                         }
                    },
                    "TargetValue": Double
                }
            }
        ]
    }
}
```

The `InferenceRecommendationsJobName`, `RecommendationID` or `EndpointName`, `TargetCpuUtilizationPerCore`, and the `ScalingPolicyObjective` object fields are copied from your initial request.

The `Metric` object lists the metrics that were benchmarked in your inference recommendation job, along with a calculation of the values for each metric when the instance utilization would be the same as the `TargetCpuUtilizationPerCore` value. This is useful for anticipating the performance metrics on your endpoint when it scales in and out with the recommended autoscaling policy. For example, consider if your instance utilization was 50% in your inference recommendation job and your `InvocationsPerInstance` value was originally `4`. If you specify the `TargetCpuUtilizationPerCore` value to be 100% in your autoscaling recommendation request, then the `InvocationsPerInstance` metric value returned in the response is 2 because you anticipated allocating twice as much instance utilization.

The `DynamicScalingConfiguration` object returns the values that you should specify for the [TargetTrackingScalingPolicyConfiguration](#) when you call the [PutScalingPolicy](#) API. This includes the recommended minimum and maximum capacity values, the recommended scale in and scale out cooldown times, and the `ScalingPolicies` object, which contains the recommended `TargetValue` you should specify for each metric.

Run a custom load test

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and either serverless endpoints or real-time instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programmatically using the AWS SDK for Python (Boto3) and the AWS CLI, or interactively using Amazon SageMaker Studio Classic or the SageMaker AI console.

Create a load test job

Create a load test programmatically using the AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio Classic or the SageMaker AI console. As with Inference Recommender inference recommendations, specify a job name for your load test, an AWS IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`JobName`). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- An endpoint configuration dictionary (`InputConfig`) where you specify the following:
  - For `TrafficPattern`, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or *steps*) at a rate you specify. Choose one of the following:

    - For `TrafficType`, specify PHASES. Then, for the `Phases` array, specify the `InitialNumberOfUsers` (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), `SpawnRate` (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
    - For `TrafficType`, specify STAIRS. Then, for the `Stairs` array, specify the `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), `NumberOfSteps` (how many intervals are used during the phase), and `UsersPerStep` (how many users are added during each interval). Note that the length of each step is the value of `DurationInSeconds / NumberOfSteps`. For example, if your `DurationInSeconds` is `600` and you specify 5 steps, then each step is 120 seconds long.

    > **Note**
    >
    > A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an `ml.c5.large` instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.

  - For `ResourceLimit`, specify `MaxNumberOfTests` (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and `MaxParallelOfTests` (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
  - For `EndpointConfigurations`, you can specify one of the following:
    - The `InstanceType` field, where you specify the instance type on which you want to run your load tests.
    - The `ServerlessConfig`, in which you specify your ideal values for `MaxConcurrency` and `MemorySizeInMB` for a serverless endpoint. For more information, see the [Serverless Inference documentation](#).
- A stopping conditions dictionary (`StoppingConditions`), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:

- For `MaxInvocations`, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
- For `ModelLatencyThresholds`, specify `Percentile` (the model latency percentile threshold) and `ValueInMilliseconds` (the model latency percentile value in milliseconds).
- (Optional) For `FlatInvocations`, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint under full capacity conditions. To continue the load test when this happens, specify this value as `Continue`. Otherwise, the default value is `Stop`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region=<INSERT>
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name="<INSERT>"

# Provide the name of the sagemaker instance type
instance_type="<INSERT>"

# Provide the IAM Role that gives SageMaker permission to access AWS services
role_arn='arn:aws:iam::<account>:role/*'

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn='arn:aws:sagemaker:<region>:<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
                        JobName=load_test_job_name,

                                },
                            "EndpointConfigurations" : [{
                                        'InstanceType': 'ml.c5.xlarge'
                                    },
                                    {
                                        'InstanceType': 'ml.m5.xlarge'
                                    },
                                    {
                                        'InstanceType': 'ml.r5.xlarge'
                                    }]
                                    # Uncomment the ServerlessConfig and comment out 
the InstanceType field if you want recommendations for a serverless endpoint
                                    # "ServerlessConfig": {
                                    #     "MaxConcurrency": value,
                                    #     "MemorySizeInMB": value
                                    # }
                        },
                        StoppingConditions={
                            'MaxInvocations': 1000,
                            'ModelLatencyThresholds':[{
                                'Percentile': 'P95',
```

```
                                    'ValueInMilliseconds': 100
                                }],
                                # Change 'Stop' to 'Continue' to let the load test
continue if invocations flatten
                                'FlatInvocations': 'Stop'
                            }
                )
```

See the [Amazon SageMaker API Reference Guide](https://docs.aws.amazon.com/sagemaker/latest/APIReference/) for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

AWS CLI

Use the `create-inference-recommendations-job` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`job-name`). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.
- An endpoint configuration dictionary (`input-config`) where you specify the following:
  - For `TrafficPattern`, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or *steps*) at a rate you specify. Choose one of the following:
    - For `TrafficType`, specify `PHASES`. Then, for the `Phases` array, specify the `InitialNumberOfUsers` (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), `SpawnRate` (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
    - For `TrafficType`, specify `STAIRS`. Then, for the `Stairs` array, specify the `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), `NumberOfSteps` (how many intervals are used during the phase), and `UsersPerStep` (how many users are added during each interval). Note that the length of each step is the value of `DurationInSeconds / NumberOfSteps`. For example, if your `DurationInSeconds` is `600` and you specify `5` steps, then each step is 120 seconds long.

> **Note**
>
> A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an `ml.c5.large` instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.

- For `ResourceLimit`, specify `MaxNumberOfTests` (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and `MaxParallelOfTests` (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
- For `EndpointConfigurations`, you can specify one of the following:
  - The `InstanceType` field, where you specify the instance type on which you want to run your load tests.
  - The `ServerlessConfig`, in which you specify your ideal values for `MaxConcurrency` and `MemorySizeInMB` for a serverless endpoint.

- A stopping conditions dictionary (`stopping-conditions`), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:
  - For `MaxInvocations`, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
  - For `ModelLatencyThresholds`, specify `Percentile` (the model latency percentile threshold) and `ValueInMilliseconds` (the model latency percentile value in milliseconds).
  - (Optional) For `FlatInvocations`, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint under full capacity conditions. To continue the load test when this happens, specify this value as `Continue`. Otherwise, the default value is `Stop`.

```
aws sagemaker create-inference-recommendations-job\
    --region <region>\
    --job-name <job-name>\
```

```
    --job-type ADVANCED\
    --role-arn arn:aws:iam::<account>:role/*\
    --input-config \"{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region>:<account>:role/*\",

        \"MaxInvocations\": 1000,
        \"ModelLatencyThresholds\":[
                {
                    \"Percentile\": \"P95\",
                    \"ValueInMilliseconds\": 100
                }
        ],
        # Change 'Stop' to 'Continue' to let the load test continue if invocations
 flatten
        \"FlatInvocations\": \"Stop\"
    }\"
```

Amazon SageMaker Studio Classic

Create a load test with Studio Classic.

1. In your Studio Classic application, choose the home icon ().
2. In the left sidebar of Studio Classic, choose **Deployments**.
3. Choose **Inference recommender** from the dropdown list.
4. Choose **Create inference recommender job**. A new tab titled **Create inference recommender job** opens.
5. Select the name of your model group from the dropdown **Model group** field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio Classic.
6. Select a model version from the dropdown **Model version** field.
7. Choose **Continue**.
8. Provide a name for the job in the **Name** field.
9. (Optional) Provide a description of your job in the **Description** field.
10. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the `AmazonSageMakerFullAccess` IAM managed policy to accomplish this, or you can let Studio Classic create a role for you.
11. Choose **Stopping Conditions** to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.

   a. Specify the maximum number of requests per minute expected for the endpoint in the **Max Invocations Per Minute** field.

   b. Specify the model latency threshold in microseconds in the **Model Latency Threshold** field. The **Model Latency Threshold** depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

12. Choose **Traffic Pattern** to expand the available input fields.

   a. Set the initial number of virtual users by specifying an integer in the **Initial Number of Users** field.

   b. Provide an integer number for the **Spawn Rate** field. The spawn rate sets the number of users created per second.

   c. Set the duration for the phase in seconds by specifying an integer in the **Duration** field.

   d. (Optional) Add additional traffic patterns. To do so, choose **Add**.

13. Choose the **Additional** setting to reveal the **Max test duration** field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.

14. Choose **Continue**.

15. Choose **Selected Instances**.

16. In the **Instances for benchmarking** field, choose **Add instances to test**. Select up to 10 instances for Inference Recommender to use for load testing.

17. Choose **Additional settings**.

   a. Provide an integer that sets an upper limit on the number of tests a job can make for the **Max number of tests field**. Note that each endpoint configuration results in a new load test.

   b. Provide an integer for the **Max parallel** test field. This setting defines an upper limit on the number of load tests that can run in parallel.

18. Choose **Submit**.

    The load test can take up to 2 hours.

> **Warning**
>
> Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

SageMaker AI console

Create a custom load test through the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose **Create job**.
4. For **Step 1: Model configuration**, do the following:

   a. For **Job type**, choose **Advanced recommender job**.

   b. If you're using a model registered in the SageMaker AI model registry, then turn on the **Choose a model from the model registry** toggle and do the following:

      i. For the **Model group** dropdown list, choose the model group in SageMaker AI model registry where your model is.

      ii. For the **Model version** dropdown list, choose the desired version of your model.

   c. If you're using a model that you've created in SageMaker AI, then turn off the **Choose a model from the model registry** toggle and do the following:

      - For the **Model name** field, enter the name of your SageMaker AI model.

   d. For **IAM role**, you can select an existing AWS IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose **Create a new role** to open the role creation pop-up, and SageMaker AI adds the necessary permissions to the new role that you create.

   e. For **S3 bucket for benchmarking payload**, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.

   f. For **Payload content type**, enter the MIME types of your sample payload data.

   g. For **Traffic pattern**, configure phases for the load test by doing the following:

i. For **Initial number of users**, specify how many concurrent users you want to start with (with a minimum of 1 and a maximum of 3).

ii. For **Spawn rate**, specify the number of users to be spawned in a minute for the phase (with a minimum of 0 and a maximum of 3).

iii. For **Duration (seconds)**, specify how low the traffic phase should be in seconds (with a minimum of 120 and a maximum of 3600).

h. (Optional) If you turned off the **Choose a model from the model registry toggle** and specified a SageMaker AI model, then for **Container configuration**, do the following:

i. For the **Domain** dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.

ii. For the **Framework** dropdown list, select the framework of your container, such as TensorFlow or XGBoost.

iii. For **Framework version**, enter the framework version of your container image.

iv. For the **Nearest model name** dropdown list, select the pre-trained model that mostly closely matches your own.

v. For the **Task** dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

i. (Optional) For **Model compilation using SageMaker Neo**, you can configure the recommendation job for a model that you've compiled using SageMaker Neo. For **Data input configuration**, enter the correct input data shape for your model in a format similar to `{'input':[1,1024,1024,3]}`.

j. Choose **Next**.

5. For **Step 2: Instances and environment parameters**, do the following:

a. For **Select instances for benchmarking**, select up to 8 instance types that you want to benchmark against.

b. (Optional) For **Environment parameter ranges**, you can specify environment parameters that help optimize your model. Specify the parameters as **Key** and **Value** pairs.

c. Choose **Next**.

6. For **Step 3: Job parameters**, do the following:

a. (Optional) For the **Job name** field, enter a name for your instance recommendation job. When you create the job, SageMaker AI appends a timestamp to the end of this name.

b. (Optional) For the **Job description** field, enter a description for the job.

c. (Optional) For the **Encryption key** dropdown list, choose an AWS KMS key by name or enter its ARN to encrypt your data.

d. (Optional) For **Max number of tests**, enter the number of test that you want to run during the recommendation job.

e. (Optional) For **Max parallel tests**, enter the maximum number of parallel tests that you want to run during the recommendation job.

f. For **Max test duration (s)**, enter the maximum number of seconds you want each test to run for.

g. For **Max invocations per minute**, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker AI ends the job.

h. For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

i. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.

Get your load test results

You can programmatically collect metrics across all load tests once the load tests are done with AWS SDK for Python (Boto3), the AWS CLI, Studio Classic, or the SageMaker AI console.

AWS SDK for Python (Boto3)

Collect metrics with the `DescribeInferenceRecommendationsJob` API. Specify the job name of the load test for the `JobName` field:

```
load_test_response = sagemaker_client.describe_inference_recommendations_job(
                                                        JobName=load_test_job_name
                                                        )
```

Print the response object.

```
load_test_response['Status']
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',

            'content-type': 'content-type',
            'content-length': '1199',
            'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
            },
        'RetryAttempts': 0}
    }
```

The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See [Amazon SageMaker AI metrics in Amazon CloudWatch](#) for more information.

The `EndpointConfiguration` nested dictionary also contains the instance count (`InitialInstanceCount`) recommendation. This is the number of instances that you should provision in the endpoint to meet the `MaxInvocations` specified in the `StoppingConditions`. For example, if the `InstanceType` is `ml.m5.large` and the

`InitialInstanceCount` is 2, then you should provision 2 `ml.m5.large` instances for your endpoint so that it can handle the TPS specified in the `MaxInvocations` stopping condition.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
         },
```

```
            "RecommendationId": "value"
        }
    ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the values you specified for `MaxConcurrency` and `MemorySizeInMB` when setting up the load test. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch compute resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/serverless-endpoints.html).

AWS CLI

Collect metrics with the `describe-inference-recommendations-job` API. Specify the job name of the load test for the `job-name` flag:

```
aws sagemaker describe-inference-recommendations-job --job-name <job-name>
```

This returns a response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing Serverless Inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000,
 tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000,
 tzinfo=tzlocal()),
    'InputConfig': {
        'ModelPackageVersionArn': 'arn:aws:sagemaker:region:account-id:model-
package/resource-id',
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
            },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
```

```
            'MaxParallelOfTests': 100
            },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
            }]
        },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
            }]
        },
    'InferenceRecommendations': [{
        'Metrics': {
        'CostPerHour': 0.6899999976158142,
        'CostPerInference': 1.0332434612791985e-05,
        'MaximumInvocations': 1113,
        'ModelLatency': 100000
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5d.xlarge',
            'InitialInstanceCount': 3
            },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
            }
        }],
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {
            'x-amzn-requestid': 'x-amzn-requestid',
            'content-type': 'content-type',
            'content-length': '1199',
            'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
            },
        'RetryAttempts': 0
        }
    }
```

The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See [Amazon SageMaker AI metrics in Amazon CloudWatch]() for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
```

```
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
         },
         "RecommendationId": "value"
      }
   ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the values you specified for `MaxConcurrency` and `MemorySizeInMB` when setting up the load test. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](#).

Amazon SageMaker Studio Classic

The recommendations populate in a new tab called **Inference recommendations** within Studio Classic. It can take up to 2 hours for the results to show up. This tab contains **Results** and **Details** columns.

The **Details** column provides information about the load test job, such as the name given to the load test job, when the job was created (**Creation time**), and more. It also contains **Settings** information, such as the maximum number of invocation that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides **Deployment goals** and **SageMaker AI recommendations** windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides Information about the expected model latency, maximum number of invocations, and the number of instances.

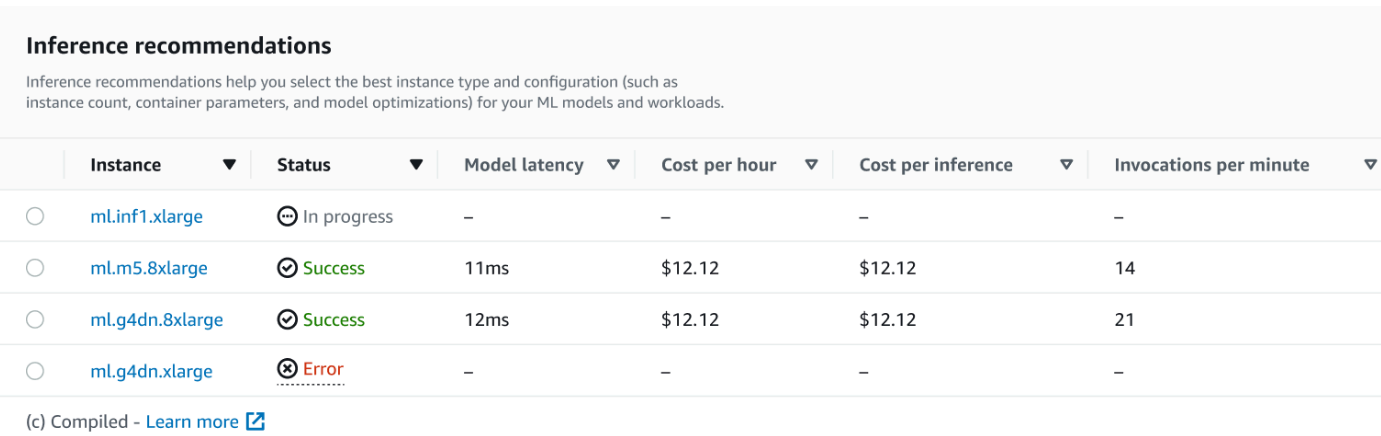
In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

SageMaker AI console

You can view your custom load test job results in the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose the name of your inference recommendation job.

On the details page for your job, you can view the **Inference recommendations**, which are the instance types SageMaker AI recommends for your model, as shown in the following screenshot.



In this section, you can compare the instance types by various factors such as **Model latency**, **Cost per hour**, **Cost per inference**, and **Invocations per minute**.

On this page, you can also view the configurations you specified for your job. In the **Monitor** section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see [Interpret results](#).

Stop your load test

You might want to stop a job that is currently running if you began a job by mistake or no longer need to run the job. Stop your load test jobs programmatically with the `StopInferenceRecommendationsJob` API, or through Studio Classic or the SageMaker AI console.

AWS SDK for Python (Boto3)

Specify the job name of the load test for the `JobName` field:

```
sagemaker_client.stop_inference_recommendations_job(
                                    JobName='<INSERT>'
                                    )
```

AWS CLI

Specify the job name of the load test for the `job-name` flag:

```
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio Classic

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

SageMaker AI console

To stop your load test job through the SageMaker AI console, do the following:

1. Go to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, select your load test job.
4. Choose **Stop job**.
5. In the dialog box that pops up, choose **Confirm**.

After stopping your job, the job's **Status** should change to **Stopping**.

Troubleshoot Inference Recommender errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors.

How to troubleshoot

You can attempt to resolve your error by going through the following steps:

- Check if you've covered all the prerequisites to use Inference Recommender. See the Inference Recommender Prerequisites.
- Check that you are able to deploy your model from Model Registry to an endpoint and that it can process your payloads without errors. See Deploy a Model from the Registry.
- When you kick off an Inference Recommender job, you should see endpoints being created in the console and you can review the CloudWatch logs.

Common errors

Review the following table for common Inference Recommender errors and their solutions.

Error	Solution
Specify `Domain` in the Model Package version 1. `Domain` is a mandatory parameter for the job.	Make sure you provide the ML domain or `OTHER` if unknown.
Provided role ARN cannot be assumed and an `AWSSecurityTokenServiceException` error occurred.	Make sure the execution role provided has the necessary permissions specified in the prerequisites.
Specify `Framework` in the Model Package version 1.`Framework` is a mandatory parameter for the job.	Make sure you provide the ML Framework or `OTHER` if unknown.
Users at the end of prev phase is 0 while initial users of current phase is 1.	Users here refers to virtual users or threads used to send requests. Each phase starts with A users and ends with B users such that B > A.

Error	Solution
	Between sequential phases, x_1 and x_2, we require that abs(x_2.A - x_1.B) <= 3 and >= 0.
Total Traffic duration (across) should not be more than Job duration.	The total duration of all your Phases cannot exceed the Job duration.
Burstable instance type ml.t2.medium is not allowed.	Inference Recommender doesn't support load testing on t2 instance family because burstable instances do not provide consistent performance.
ResourceLimitExceeded when calling CreateEndpoint operation	You have exceeded a SageMaker AI resource limit. For example, Inference Recommender might be unable to provision endpoints for benchmarking if the account has reached the endpoint quota. For more information about SageMaker AI limits and quotas, see [Amazon SageMaker AI endpoints and quotas]().
ModelError when calling InvokeEndpoint operation	A model error can happen for the following reasons: • The invocation timed out while waiting for a response from the model container. • The model couldn't process the input payload.

Error	Solution
PayloadError when calling InvokeEndpoint operation	A payload error can happen for following reasons: • The payload source isn't in the Amazon S3 bucket. • The payload is in a non-file object format. • The payload is in an invalid file type. For example, a model expects an image type payload but is passed a text file. • The payload is empty.

Check CloudWatch

When you kick off an Inference Recommender job, you should see endpoints being created in the console. Select one of the endpoints and view the CloudWatch logs to monitor for any 4xx/5xx errors. If you have a successful Inference Recommender job, you will be able to see the endpoint names as part of the results. Even if your Inference Recommender job is unsuccessful, you can still check the CloudWatch logs for the deleted endpoints by following the steps below:

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Select the Region in which you created the Inference Recommender job from the **Region** dropdown list in the top right.
3. In the navigation pane of CloudWatch, choose **Logs**, and then select **Log groups**.
4. Search for the log group called `/aws/sagemaker/Endpoints/sm-epc-*`. Select the log group based on your most recent Inference Recommender job.

You can also troubleshoot your job by checking the Inference Recommender CloudWatch logs. The Inference Recommender logs, which are published in the `/aws/sagemaker/InferenceRecommendationsJobs` CloudWatch log group, give a high level view on the progress of the job in the `<jobName>/execution` log stream. You can find detailed information on each of the endpoint configurations being tested in the `<jobName>/Endpoint/<endpointName>` log stream.

Overview of the Inference Recommender log streams

- *<jobName>*/execution contains overall job information such as endpoint configurations scheduled for benchmarking, compilation job skip reason, and validation failure reason.
- *<jobName>*/Endpoint/*<endpointName>* contains information such as resource creation progress, test configuration, load test stop reason, and resource cleanup status.
- *<jobName>*/CompilationJob/*<compilationJobName>* contains information on compilation jobs created by Inference Recommender, such as the compilation job configuration and compilation job status.

Create an alarm for Inference Recommender error messages

Inference Recommender outputs log statements for errors that might be helpful while troubleshooting. With a CloudWatch log group and a metric filter, you can look for terms and patterns in this log data as the data is sent to CloudWatch. Then, you can create a CloudWatch alarm based on the log group-metric filter. For more information, see Create a CloudWatch alarm based on a log group-metric filter.

Check benchmarks

When you kick off an Inference Recommender job, Inference Recommender creates several benchmarks to evaluate the performance of your model on different instance types. You can use the ListInferenceRecommendationsJobSteps API to view the details for all the benchmarks. If you have a failed benchmark, you can see the failure reasons as part of the results.

To use the ListInferenceRecommendationsJobSteps API, provide the following values:

- For JobName, provide the name of the Inference Recommender job.
- For StepType, use BENCHMARK to return details about the job's benchmarks.
- For Status, use FAILED to return details about only the failed benchmarks. For a list of the other status types, see the Status field in the ListInferenceRecommendationsJobSteps API.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide the job name for the SageMaker Inference Recommender job
job_name = '<job-name>'
```

```
# Filter for benchmarks
step_type = 'BENCHMARK'

# Filter for benchmarks that have a FAILED status
status = 'FAILED'

response = sagemaker_client.list_inference_recommendations_job_steps(
    JobName = job_name,
    StepType = step_type,
    Status = status
)
```

You can print the response object to view the results. The preceding code example stored the response in a variable called `response`:

```
print(response)
```

Real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker AI hosting services and get an endpoint that can be used for inference. These endpoints are fully managed and support autoscaling (see Automatic scaling of Amazon SageMaker AI models).

Topics

- Deploy models for real-time inference
- Invoke models for real-time inference
- Endpoints
- Hosting options
- Automatic scaling of Amazon SageMaker AI models
- Instance storage volumes
- Validation of models in production
- Online explainability with SageMaker Clarify
- Fine-tune models with adapter inference components

Deploy models for real-time inference

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.

AWS managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

There are several options to deploy a model using SageMaker AI hosting services. You can interactively deploy a model with SageMaker Studio. Or, you can programmatically deploy a model using an AWS SDK, such as the SageMaker Python SDK or the SDK for Python (Boto3). You can also deploy by using the AWS CLI.

Before you begin

Before you deploy a SageMaker AI model, locate and make note of the following:

- The AWS Region where your Amazon S3 bucket is located
- The Amazon S3 URI path where the model artifacts are stored
- The IAM role for SageMaker AI
- The Docker Amazon ECR URI registry path for the custom image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by AWS

For a list of AWS services available in each AWS Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

> **Important**
>
> The Amazon S3 bucket where the model artifacts are stored must be in the same AWS Region as the model that you are creating.

Shared resource utilization with multiple models

You can deploy one or more models to an endpoint with Amazon SageMaker AI. When multiple models share an endpoint, they jointly utilize the resources that are hosted there, such as the ML compute instances, CPUs, and accelerators. The most flexible way to deploy multiple models to an endpoint is to define each model as an *inference component*.

Inference components

An inference component is a SageMaker AI hosting object that you can use to deploy a model to an endpoint. In the inference component settings, you specify the model, the endpoint, and how the model utilizes the resources that the endpoint hosts. To specify the model, you can specify a SageMaker AI Model object, or you can directly specify the model artifacts and image.

In the settings, you can optimize resource utilization by tailoring how the required CPU cores, accelerators, and memory are allocated to the model. You can deploy multiple inference components to an endpoint, where each inference component contains one model and the resource utilization needs for that model.

After you deploy an inference component, you can directly invoke the associated model when you use the InvokeEndpoint action in the SageMaker API.

Inference components provide the following benefits:

Flexibility

The inference component decouples the details of hosting the model from the endpoint itself. This provides more flexibility and control over how models are hosted and served with an endpoint. You can host multiple models on the same infrastructure, and you can add or remove models from an endpoint as needed. You can update each model independently.

Scalability

You can specify how many copies of each model to host, and you can set a minimum number of copies to ensure that the model loads in the quantity that you require to serve requests. You can scale any inference component copy down to zero, which makes room for another copy to scale up.

SageMaker AI packages your models as inference components when you deploy them by using:

- SageMaker Studio Classic.
- The SageMaker Python SDK to deploy a Model object (where you set the endpoint type to `EndpointType.INFERENCE_COMPONENT_BASED`).
- The AWS SDK for Python (Boto3) to define `InferenceComponent` objects that you deploy to an endpoint.

Deploy models with SageMaker Studio

Complete the following steps to create and deploy your model interactively through SageMaker Studio. For more information about Studio, see the Studio documentation. For more walkthroughs of various deployment scenarios, see the blog Package and deploy classical ML models and LLMs easily with Amazon SageMaker AI – Part 2.

Prepare your artifacts and permissions

Complete this section before creating a model in SageMaker Studio.

You have two options for bringing your artifacts and creating a model in Studio:

1. You can bring a pre-packaged `tar.gz` archive, which should include your model artifacts, any custom inference code, and any dependencies listed in a `requirements.txt` file.
2. SageMaker AI can package your artifacts for you. You only have to bring your raw model artifacts and any dependencies in a `requirements.txt` file, and SageMaker AI can provide default inference code for you (or you can override the default code with your own custom inference code). SageMaker AI supports this option for the following frameworks: PyTorch, XGBoost.

In addition to bringing your model, your AWS Identity and Access Management (IAM) role, and a Docker container (or desired framework and version for which SageMaker AI has a pre-built container), you must also grant permissions to create and deploy models through SageMaker AI Studio.

You should have the AmazonSageMakerFullAccess policy attached to your IAM role so that you can access SageMaker AI and other relevant services. To see the prices of the instance types in Studio, you also must attach the AWSPriceListServiceFullAccess policy (or if you don't want to attach the whole policy, more specifically, the `pricing:GetProducts` action).

If you choose to upload your model artifacts when creating a model (or upload a sample payload file for inference recommendations), then you must create an Amazon S3 bucket. The bucket name must be prefixed by the word `SageMaker AI`. Alternate capitalizations of SageMaker AI are also acceptable: `Sagemaker` or `sagemaker`.

We recommend that you use the bucket naming convention `sagemaker-{`*`Region`*`}-{`*`accountID`*`}`. This bucket is used to store the artifacts that you upload.

After creating the bucket, attach the following CORS (cross-origin resource sharing) policy to the bucket:

```
[
    {
        "AllowedHeaders": ["*"],
        "ExposeHeaders": ["Etag"],
        "AllowedMethods": ["PUT", "POST"],
        "AllowedOrigins": ['https://*.sagemaker.aws'],
    }
]
```

You can attach a CORS policy to an Amazon S3 bucket by using any of the following methods:

- Through the Edit cross-origin resource sharing (CORS) page in the Amazon S3 console
- Using the Amazon S3 API PutBucketCors
- Using the put-bucket-cors AWS CLI command:

  ```
  aws s3api put-bucket-cors --bucket="..." --cors-configuration="..."
  ```

Create a deployable model

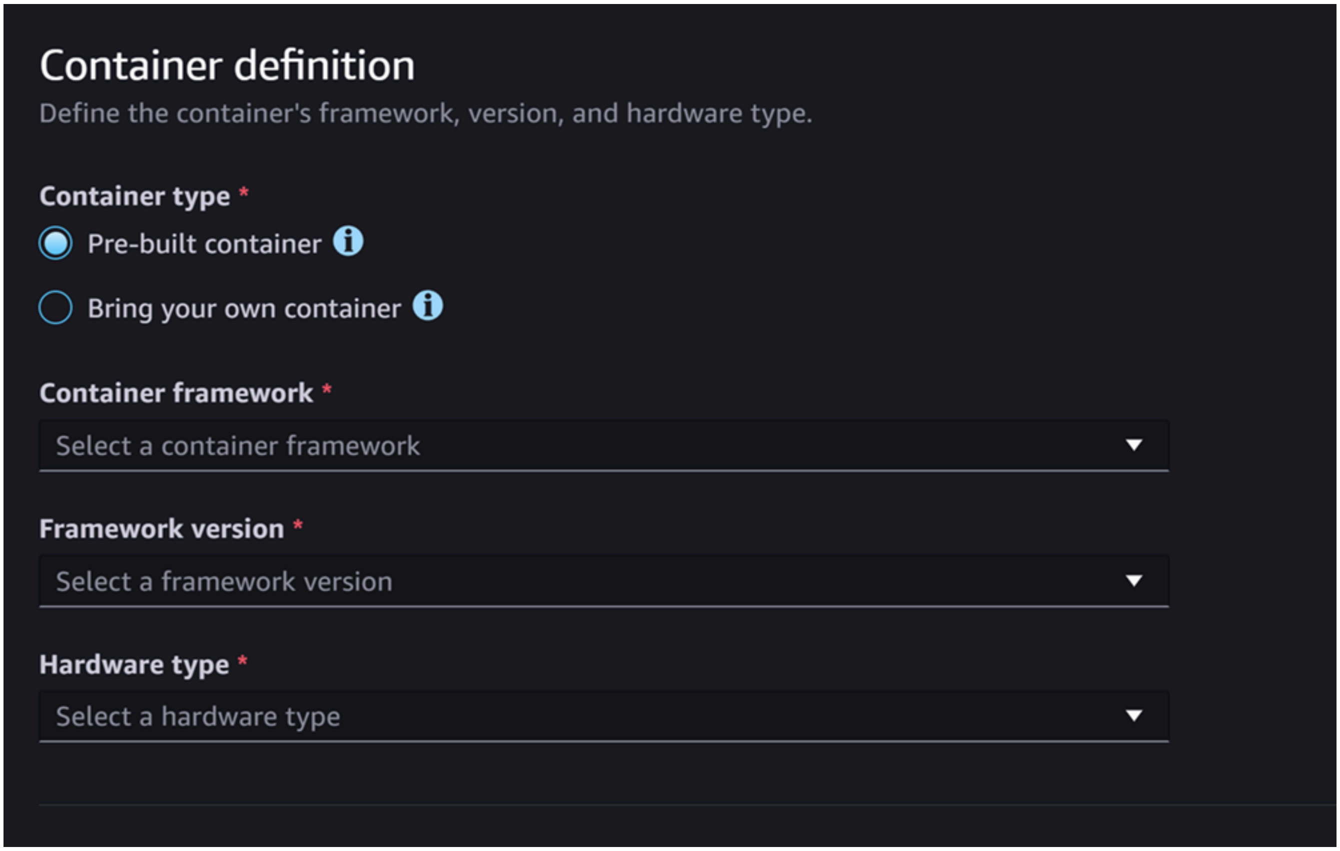
In this step, you create a deployable version of your model in SageMaker AI by providing your artifacts along with additional specifications, such as your desired container and framework, any custom inference code, and network settings.

Create a deployable model in SageMaker Studio by doing the following:

1. Open the SageMaker Studio application.
2. In the left navigation pane, choose **Models**.
3. Choose the **Deployable models** tab.
4. On the **Deployable models** page, choose **Create**.
5. On the **Create deployable model** page, for the **Model name** field, enter a name for the model.

There are several more sections for you to fill out on the **Create deployable model** page.

The **Container definition** section looks like the following screenshot:

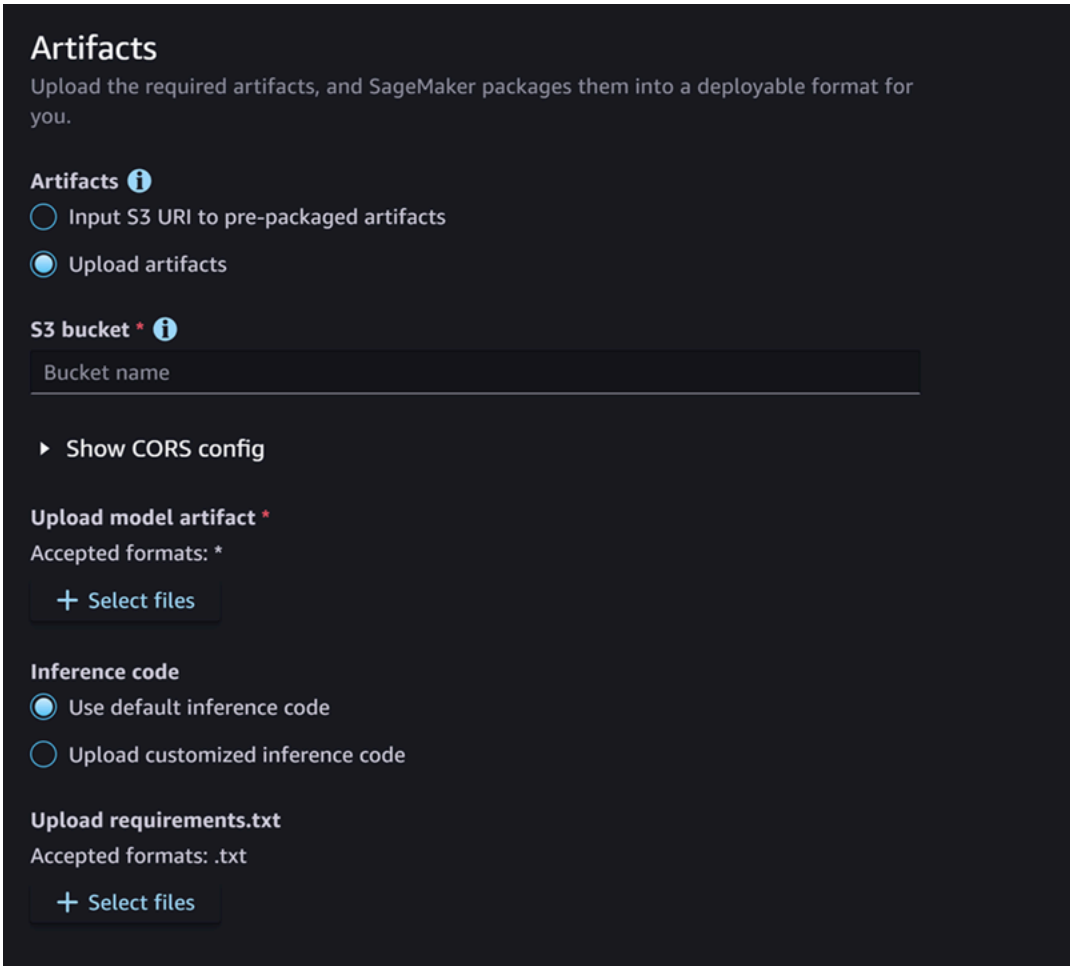


For the Container definition section, do the following:

1. For **Container type**, select **Pre-built container** if you'd like to use a SageMaker AI managed container, or select **Bring your own container** if you have your own container.
2. If you selected **Pre-built container**, select the **Container framework**, **Framework version**, and **Hardware type** that you'd like to use.

3. If you selected **Bring your own container**, enter an Amazon ECR path for **ECR path to container image**.

Then, fill out the **Artifacts** section, which looks like the following screenshot:



For the Artifacts section, do the following:

1. If you're using one of the frameworks that SageMaker AI supports for packaging model artifacts (PyTorch or XGBoost), then for **Artifacts**, you can choose the **Upload artifacts** option. With this option, you can simply specify your raw model artifacts, any custom inference code you have, and your requirements.txt file, and SageMaker AI handles packaging the archive for you. Do the following:

   a. For **Artifacts**, select **Upload artifacts** to continue providing your files. Otherwise, if you already have a `tar.gz` archive that contains your model files, inference code, and `requirements.txt` file, then select **Input S3 URI to pre-packaged artifacts**.

b. If you chose to upload your artifacts, then for **S3 bucket**, enter the Amazon S3 path to a bucket where you'd like SageMaker AI to store your artifacts after packaging them for you. Then, complete the following steps.

c. For **Upload model artifacts**, upload your model files.

d. For **Inference code**, select **Use default inference code** if you'd like to use default code that SageMaker AI provides for serving inference. Otherwise, select **Upload customized inference code** to use your own inference code.

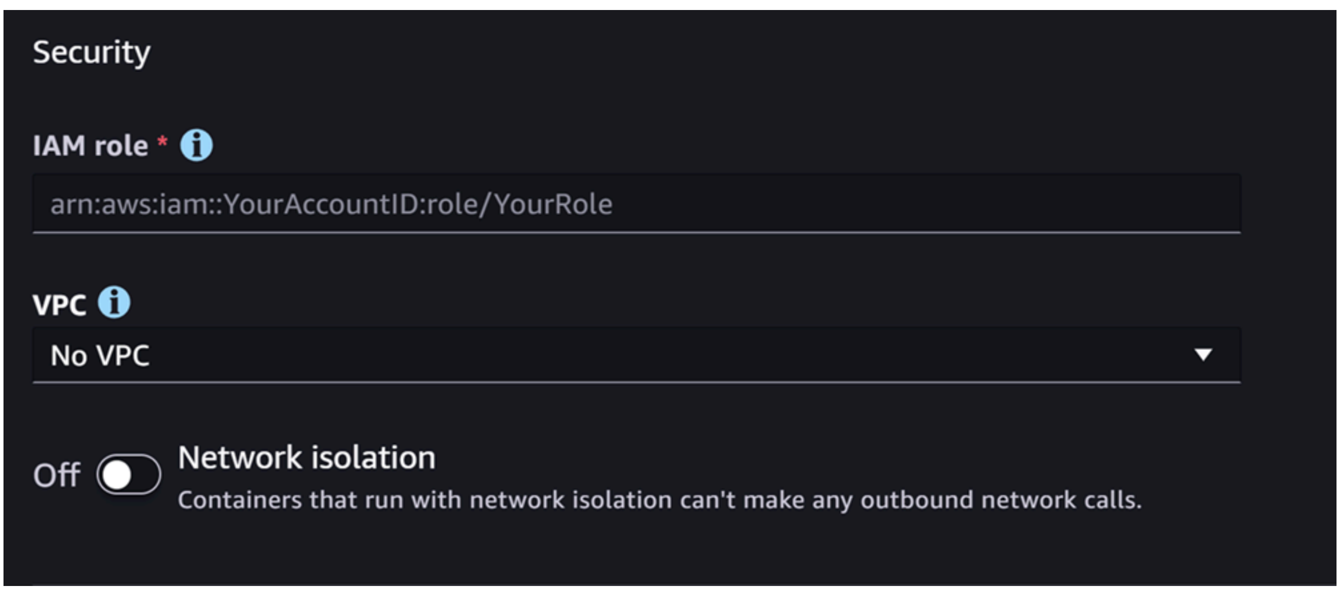
e. For **Upload requirements.txt**, upload a text file that lists any dependencies that you want to install at runtime.

2. If you're not using a framework that SageMaker AI supports for packaging model artifacts, then Studio shows you the **Pre-packaged artifacts** option, and you must provide all of your artifacts already packaged as a `tar.gz` archive. Do the following:

   a. For **Pre-packaged artifacts**, select **Input S3 URI for pre-packaged model artifacts** if you have your `tar.gz` archive already uploaded to Amazon S3. Select **Upload pre-packaged model artifacts** if you want to directly upload your archive to SageMaker AI.

   b. If you selected **Input S3 URI for pre-packaged model artifacts**, enter the Amazon S3 path to your archive for **S3 URI**. Otherwise, select and upload the archive from your local machine.

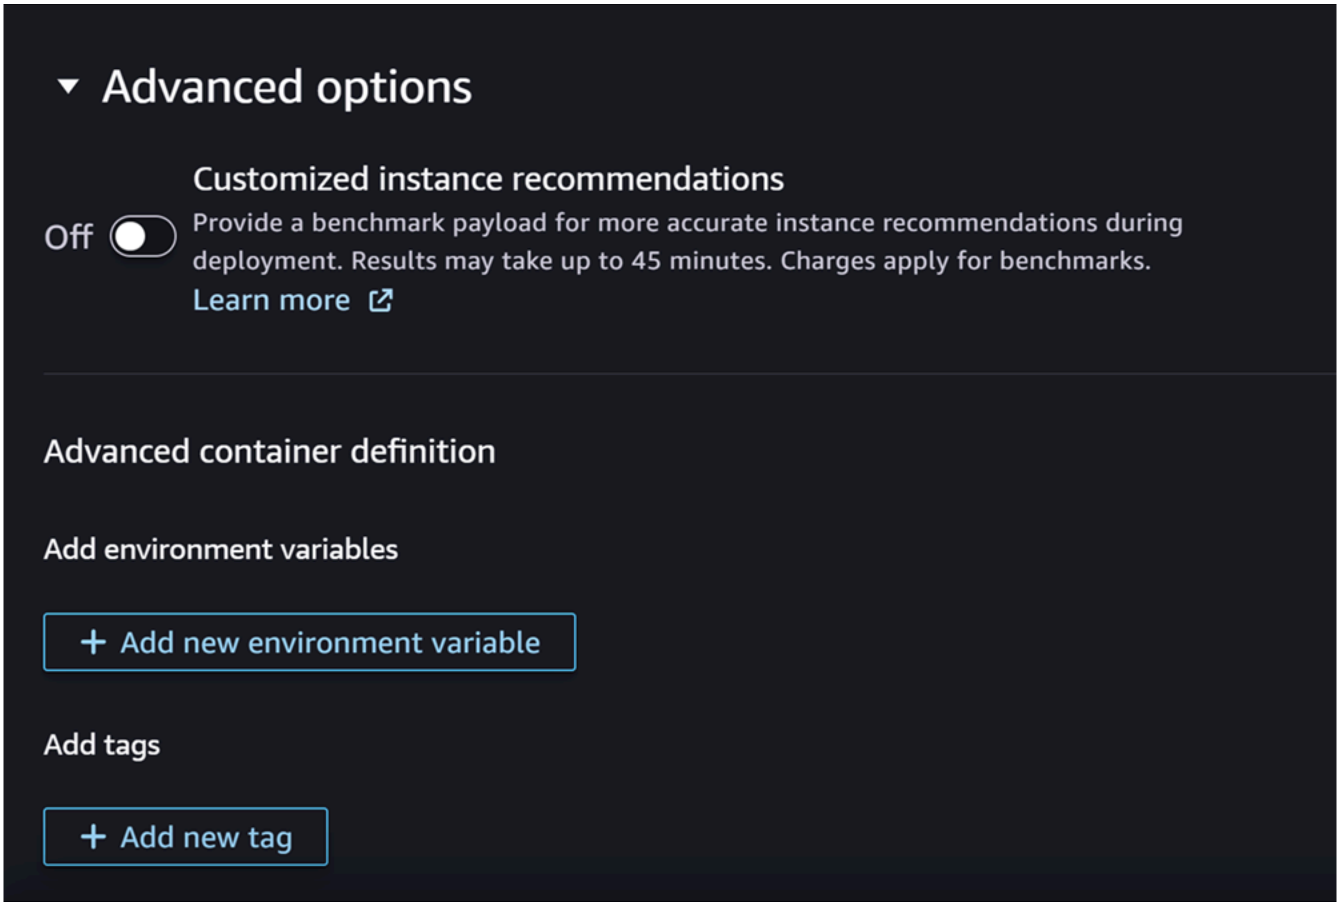
The next section is **Security**, which looks like the following screenshot:



For the Security section, do the following:

1. For **IAM role**, enter the ARN for an IAM role.
2. (Optional) For **Virtual Private Cloud (VPC)**, you can select an Amazon VPC for storing your model configuration and artifacts.
3. (Optional) Turn on the **Network isolation** toggle if you want to restrict your container's internet access.

Finally, you can optionally fill out the **Advanced options** section, which looks like the following screenshot:



(Optional) For the Advanced options section, do the following:

1. Turn on the **Customized instance recommendations** toggle if you want to run an Amazon SageMaker Inference Recommender job on your model after its creation. Inference Recommender is a feature that provides you with recommended instance types for optimizing inference performance and cost. You can view these instance recommendations when preparing to deploy your model.

2. For **Add environment variables**, enter an environment variables for your container as key-value pairs.
3. For **Tags**, enter any tags as key-value pairs.
4. After finishing your model and container configuration, choose **Create deployable model**.

You should now have a model in SageMaker Studio that is ready for deployment.

Deploy your model

Finally, you deploy the model you configured in the previous step to an HTTPS endpoint. You can deploy either a single model or multiple models to the endpoint.

Model and endpoint compatibility

Before you can deploy a model to an endpoint, the model and endpoint must be compatible by having the same values for the following settings:

- The IAM role
- The Amazon VPC, including its subnets and security groups
- The network isolation (enabled or disabled)

Studio prevents you from deploying models to incompatible endpoints in the following ways:

- If you attempt to deploy a model to a new endpoint, SageMaker AI configures the endpoint with initial settings that are compatible. If you break the compatibility by changing these settings, Studio shows an alert and prevents your deployment.
- If you attempt to deploy to an existing endpoint, and that endpoint is incompatible, Studio shows an alert and prevents your deployment.
- If you attempt to add multiple models to a deployment, Studio prevents you from deploying models that are incompatible with each other.

When Studio shows the alert about model and endpoint incompatibility, you can choose **View details** in the alert to see which settings are incompatible.

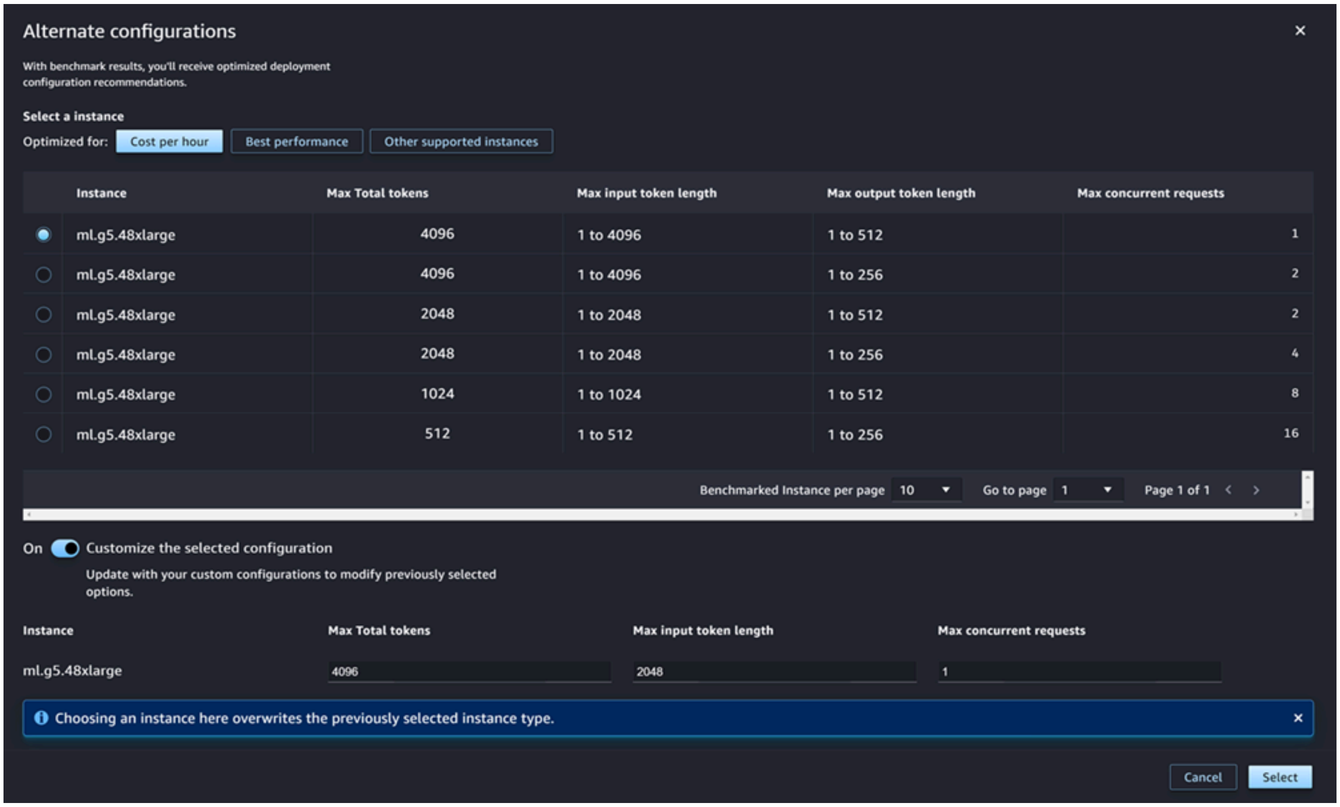
One way to deploy a model is by doing the following in Studio:

1. Open the SageMaker Studio application.
2. In the left navigation pane, choose **Models**.
3. On the **Models** page, select one or more models from the list of SageMaker AI models.
4. Choose **Deploy**.
5. For **Endpoint name**, open the dropdown menu. You can either select an existing endpoint or you can create a new endpoint to which you deploy the model.
6. For **Instance type**, select the instance type that you want to use for the endpoint. If you previously ran an Inference Recommender job for the model, your recommended instance types appear in the list under the title **Recommended**. Otherwise, you'll see a few **Prospective instances** that might be suitable for your model.

   > **Instance type compatibility for JumpStart**
   >
   > If you're deploying a JumpStart model, Studio only shows instance types that the model supports.

7. For **Initial instance count**, enter the initial number of instances that you'd like to provision for your endpoint.
8. For **Maximum instance count**, specify the maximum number of instances that the endpoint can provision when it scales up to accommodate an increase in traffic.
9. If the model you're deploying is one of the most used JumpStart LLMs from the model hub, then the **Alternate configurations** option appears after the instance type and instance count fields.

   For the most popular JumpStart LLMs, AWS has pre-benchmarked instance types to optimize for either cost or performance. This data can help you decide which instance type to use for deploying your LLM. Choose **Alternate configurations** to open a dialog box that contains the pre-benchmarked data. The panel looks like the following screenshot:



In the **Alternate configurations** box, do the following:

a. Select an instance type. You can choose **Cost per hour** or **Best performance** to see instance types that optimize either cost or performance for the specified model. You can also choose **Other supported instances** to see a list of other instance types that are compatible with the JumpStart model. Note that selecting an instance type here overwrites any previous instance selection specified in Step 6.

b. (Optional) Turn on the **Customize the selected configuration** toggle to specify **Max total tokens** (the maximum number of tokens that you want to allow, which is the sum of your input tokens and the model's generated output), **Max input token length** (the maximum number of tokens you want to allow for the input of each request), and **Max concurrent requests** (the maximum number of requests that the model can process at a time).

c. Choose **Select** to confirm your instance type and configuration settings.

10. The **Model** field should already be populated with the name of the model or models that you're deploying. You can choose **Add model** to add more models to the deployment. For each model that you add, fill out the following fields:

    a. For **Number of CPU cores**, enter the CPU cores that you'd like to dedicate for the model's usage.

b. For **Min number of copies**, enter the minimum number of model copies that you want to have hosted on the endpoint at any given time.

c. For **Min CPU memory (MB)**, enter the minimum amount of memory (in MB) that the model requires.

d. For **Max CPU memory (MB)**, enter the maximum amount of memory (in MB) that you'd like to allow the model to use.

11. (Optional) For the **Advanced options**, do the following:

    a. For **IAM role**, use either the default SageMaker AI IAM execution role, or specify your own role that has the permissions you need. Note that this IAM role must be the same as the role that you specified when creating the deployable model.

    b. For **Virtual Private Cloud (VPC)**, you can specify a VPC in which you want to host your endpoint.

    c. For **Encryption KMS key**, select an AWS KMS key to encrypt data on the storage volume attached to the ML compute instance that hosts the endpoint.

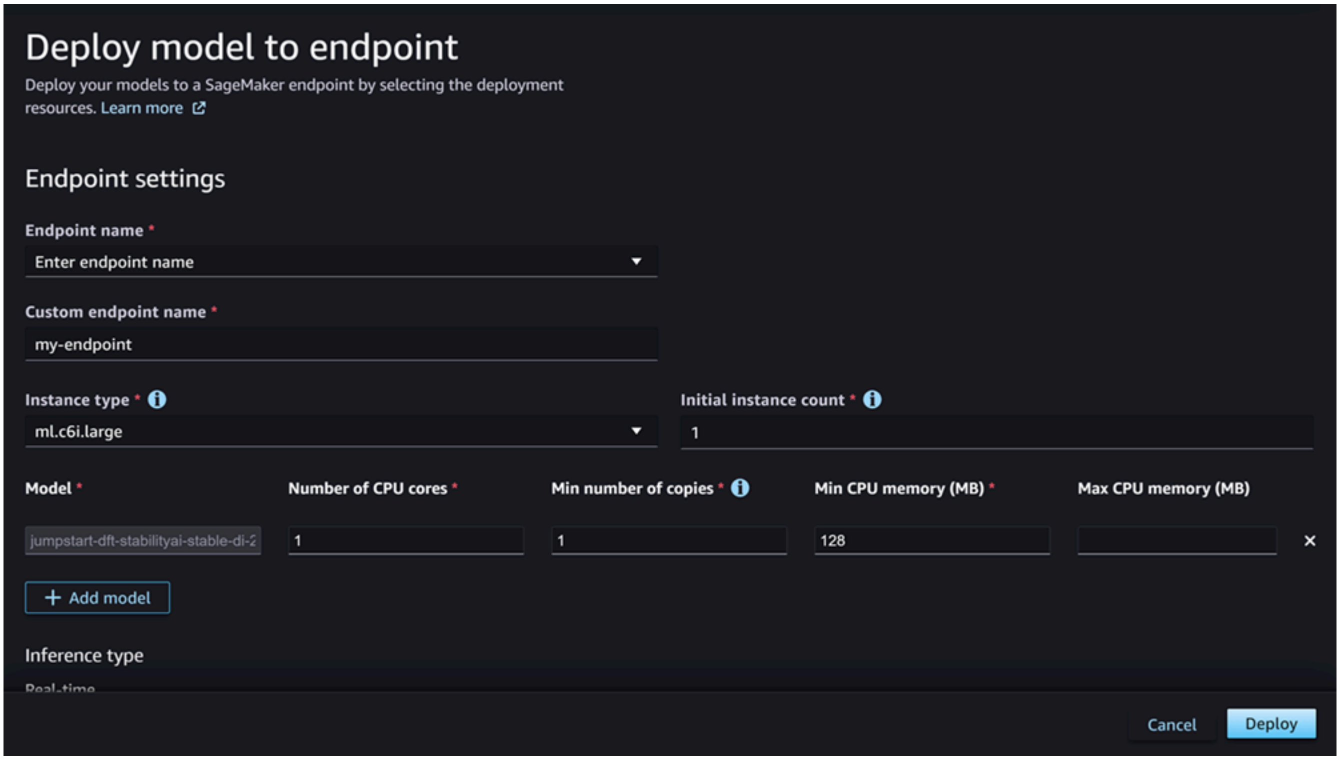
    d. Turn on the **Enable network isolation** toggle to restrict your container's internet access.

    e. For **Timeout configuration**, enter values for the **Model data download timeout (seconds)** and **Container startup health check timeout (seconds)** fields. These values determine the maximum amount of time that SageMaker AI allows for downloading the model to the container and starting up the container, respectively.

    f. For **Tags**, enter any tags as key-value pairs.

> **Note**
>
> SageMaker AI configures the IAM role, VPC, and network isolation settings with initial values that are compatible with the model that you're deploying. If you break the compatibility by changing these settings, Studio shows an alert and prevents your deployment.

After configuring your options, the page should look like the following screenshot.



After configuring your deployment, choose **Deploy** to create the endpoint and deploy your model.

Deploy models with the Python SDKs

Using the SageMaker Python SDK, you can build your model in two ways. The first is to create a model object from the `Model` or `ModelBuilder` class. If you use the `Model` class to create your `Model` object, you need to specify the model package or inference code (depending on your model server), scripts to handle serialization and deserialization of data between the client and server, and any dependencies to be uploaded to Amazon S3 for consumption. The second way to build your model is to use `ModelBuilder` for which you provide model artifacts or inference code. `ModelBuilder` automatically captures your dependencies, infers the needed serialization and deserialization functions, and packages your dependencies to create your `Model` object. For more information about `ModelBuilder`, see Create a model in Amazon SageMaker AI with ModelBuilder.

The following section describes both methods to create your model and deploy your model object.

Set up

The following examples prepare for the model deployment process. They import the necessary libraries and define the S3 URL that locates the model artifacts.

SageMaker Python SDK

Example import statements

The following example imports modules from the SageMaker Python SDK, the SDK for Python (Boto3), and the Python Standard Library. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
from datetime import datetime
from sagemaker.compute_resource_requirements.resource_requirements import
 ResourceRequirements
from sagemaker.predictor import Predictor
from sagemaker.enums import EndpointType
from sagemaker.model import Model
from sagemaker.session import Session
```

boto3 inference components

Example import statements

The following example imports modules from the SDK for Python (Boto3) and the Python Standard Library. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
import botocore
import sys
import time
```

boto3 models (without inference components)

Example import statements

The following example imports modules from the SDK for Python (Boto3) and the Python Standard Library. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
import botocore
```

```
import datetime
from time import gmtime, strftime
```

Example model artifact URL

The following code builds an example Amazon S3 URL. The URL locates the model artifacts for a pre-trained model in an Amazon S3 bucket.

```
# Create a variable w/ the model S3 URL

# The name of your S3 bucket:
s3_bucket = "amzn-s3-demo-bucket"
# The directory within your S3 bucket your model is stored in:
bucket_prefix = "sagemaker/model/path"
# The file name of your model artifact:
model_filename = "my-model-artifact.tar.gz"
# Relative S3 path:
model_s3_key = f"{bucket_prefix}/"+model_filename
# Combine bucket name, model file name, and relate S3 path to create S3 model URL:
model_url = f"s3://{s3_bucket}/{model_s3_key}"
```

The full Amazon S3 URL is stored in the variable `model_url`, which is used in the examples that follow.

Overview

There are multiple ways that you can deploy models with the SageMaker Python SDK or the SDK for Python (Boto3). The following sections summarize the steps that you complete for several possible approaches. These steps are demonstrated by the examples that follow.

SageMaker Python SDK

Using the SageMaker Python SDK, you can build your model in either of the following ways:

- **Create a model object from the `Model` class** – You must specify the model package or inference code (depending on your model server), scripts to handle serialization and deserialization of data between the client and server, and any dependencies to be uploaded to Amazon S3 for consumption.
- **Create a model object from the `ModelBuilder` class** – You provide model artifacts or inference code, and `ModelBuilder` automatically captures your dependencies, infers the

needed serialization and deserialization functions, and packages your dependencies to create your `Model` object.

For more information about `ModelBuilder`, see Create a model in Amazon SageMaker AI with ModelBuilder. You can also see the blog Package and deploy classical ML models and LLMs easily with SageMaker AI – Part 1 for more information.

The examples that follow describe both methods to create your model and deploy your model object. To deploy a model in these ways, you complete the following steps:

1. Define the endpoint resources to allocate to the model with a `ResourceRequirements` object.
2. Create a model object from the `Model` or `ModelBuilder` classes. The `ResourceRequirements` object is specified in the model settings.
3. Deploy the model to an endpoint by using the `deploy` method of the `Model` object.

boto3 inference components

The examples that follow demonstrate how to assign a model to an inference component and then deploy the inference component to an endpoint. To deploy a model in this way, you complete the following steps:

1. (Optional) Create a SageMaker AI model object by using the `create_model` method.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the `create_endpoint_config` method.
3. Create your endpoint by using the `create_endpoint` method, and in your request, provide the endpoint configuration that you created.
4. Create an inference component by using the `create_inference_component` method. In the settings, you specify a model by doing either of the following:

   - Specifying a SageMaker AI model object
   - Specifying the model image URI and S3 URL

   You also allocate endpoint resources to the model. By creating the inference component, you deploy the model to the endpoint. You can deploy multiple models to an endpoint by creating multiple inference components — one for each model.

boto3 models (without inference components)

The examples that follow demonstrate how to create a model object and then deploy the model to an endpoint. To deploy a model in this way, you complete the following steps:

1. Create a SageMaker AI model by using the create_model method.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the create_endpoint_config method. In the endpoint configuration, you assign the model object to a production variant.
3. Create your endpoint by using the create_endpoint method. In your request, provide the endpoint configuration that you created.

   When you create the endpoint, SageMaker AI provisions the endpoint resources, and it deploys the model to the endpoint.

Configure

The following examples configure the resources that you require to deploy a model to an endpoint.

SageMaker Python SDK

The following example assigns endpoint resources to a model with a `ResourceRequirements` object. These resources include CPU cores, accelerators, and memory. Then, the example creates a model object from the `Model` class. Alternatively you can create a model object by instantiating the ModelBuilder class and running `build`—this method is also shown in the example. `ModelBuilder` provides a unified interface for model packaging, and in this instance, prepares a model for a large model deployment. The example utilizes `ModelBuilder` to construct a Hugging Face model. (You can also pass a JumpStart model). Once you build the model, you can specify resource requirements in the model object. In the next step, you use this object to deploy the model to an endpoint.

```
resources = ResourceRequirements(
    requests = {
        "num_cpus": 2,  # Number of CPU cores required:
        "num_accelerators": 1, # Number of accelerators required
        "memory": 8192,  # Minimum memory required in Mb (required)
        "copies": 1,
    },
    limits = {},
```

```
)

now = datetime.now()
dt_string = now.strftime("%d-%m-%Y-%H-%M-%S")
model_name = "my-sm-model"+dt_string

# build your model with Model class
model = Model(
    name = "model-name",
    image_uri = "image-uri",
    model_data = model_url,
    role = "arn:aws:iam::111122223333:role/service-role/role-name",
    resources = resources,
    predictor_cls = Predictor,
)

# Alternate mechanism using ModelBuilder
# uncomment the following section to use ModelBuilder
/*
model_builder = ModelBuilder(
    model="<HuggingFace-ID>", # like "meta-llama/Llama-2-7b-hf"
    schema_builder=SchemaBuilder(sample_input,sample_output),
    env_vars={ "HUGGING_FACE_HUB_TOKEN": "<HuggingFace_token>}" }
)

# build your Model object
model = model_builder.build()

# create a unique name from string 'mb-inference-component'
model.model_name = unique_name_from_base("mb-inference-component")

# assign resources to your model
model.resources = resources
*/
```

boto3 inference components

The following example configures an endpoint with the `create_endpoint_config` method. You assign this configuration to an endpoint when you create it. In the configuration, you define one or more production variants. For each variant, you can choose the instance type that you want Amazon SageMaker AI to provision, and you can enable managed instance scaling.

```
endpoint_config_name = "endpoint-config-name"
```

```
endpoint_name = "endpoint-name"
inference_component_name = "inference-component-name"
variant_name = "variant-name"

sagemaker_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ExecutionRoleArn = "arn:aws:iam::111122223333:role/service-role/role-name",
    ProductionVariants = [
        {
            "VariantName": variant_name,
            "InstanceType": "ml.p4d.24xlarge",
            "InitialInstanceCount": 1,
            "ManagedInstanceScaling": {
                "Status": "ENABLED",
                "MinInstanceCount": 1,
                "MaxInstanceCount": 2,
            },
        }
    ],
)
```

boto3 models (without inference components)

Example model definition

The following example defines a SageMaker AI model with the `create_model` method in the AWS SDK for Python (Boto3).

```
model_name = "model-name"

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = "arn:aws:iam::111122223333:role/service-role/role-name",
    PrimaryContainer = {
        "Image": "image-uri",
        "ModelDataUrl": model_url,
    }
)
```

This example specifies the following:

- `ModelName`: A name for your model (in this example it is stored as a string variable called `model_name`).

- `ExecutionRoleArn`: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker AI can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- `PrimaryContainer`: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

Example endpoint configuration

The following example configures an endpoint with the `create_endpoint_config` method. Amazon SageMaker AI uses this configuration to deploy models. In the configuration, you identify one or more models, created with the `create_model` method, to deploy the resources that you want Amazon SageMaker AI to provision.

```
endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName = "endpoint-config-name",
    # List of ProductionVariant objects, one for each model that you want to host at
 this endpoint:
    ProductionVariants = [
        {
            "VariantName": "variant-name", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.p4d.24xlarge",
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ]
)
```

This example specifies the following keys for the `ProductionVariants` field:

- `VariantName`: The name of the production variant.
- `ModelName`: The name of the model that you want to host. This is the name that you specified when creating the model.
- `InstanceType`: The compute instance type. See the `InstanceType` field in https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html and [SageMaker AI Pricing]() for a list of supported compute instance types and pricing for each instance type.

Deploy

The following examples deploy a model to an endpoint.

SageMaker Python SDK

The following example deploys the model to a real-time, HTTPS endpoint with the `deploy` method of the model object. If you specify a value for the `resources` argument for both model creation and deployment, the resources you specify for deployment take precedence.

```
predictor = model.deploy(
    initial_instance_count = 1,
    instance_type = "ml.p4d.24xlarge",
    endpoint_type = EndpointType.INFERENCE_COMPONENT_BASED,
    resources = resources,
)
```

For the `instance_type` field, the example specifies the name of the Amazon EC2 instance type for the model. For the `initial_instance_count` field, it specifies the initial number of instances to run the endpoint on.

The following code sample demonstrates another case where you deploy a model to an endpoint and then deploy another model to the same endpoint. In this case you must supply the same endpoint name to the `deploy` methods of both models.

```
# Deploy the model to inference-component-based endpoint
falcon_predictor = falcon_model.deploy(
    initial_instance_count = 1,
    instance_type = "ml.p4d.24xlarge",
    endpoint_type = EndpointType.INFERENCE_COMPONENT_BASED,
    endpoint_name = "<endpoint_name>"
    resources = resources,
)

# Deploy another model to the same inference-component-based endpoint
llama2_predictor = llama2_model.deploy( # resources already set inside llama2_model
    endpoint_type = EndpointType.INFERENCE_COMPONENT_BASED,
    endpoint_name = "<endpoint_name>"  # same endpoint name as for falcon model
)
```

boto3 inference components

Once you have an endpoint configuration, use the [create_endpoint](#) method to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following example creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources.

```
sagemaker_client.create_endpoint(
    EndpointName = endpoint_name,
    EndpointConfigName = endpoint_config_name,
)
```

After you've created an endpoint, you can deploy one or models to it by creating inference components. The following example creates one with the `create_inference_component` method.

```
sagemaker_client.create_inference_component(
    InferenceComponentName = inference_component_name,
    EndpointName = endpoint_name,
    VariantName = variant_name,
    Specification = {
        "Container": {
            "Image": "image-uri",
            "ArtifactUrl": model_url,
        },
        "ComputeResourceRequirements": {
            "NumberOfCpuCoresRequired": 1,
            "MinMemoryRequiredInMb": 1024
        }
    },
    RuntimeConfig = {"CopyCount": 2}
)
```

boto3 models (without inference components)

Example deployment

Provide the endpoint configuration to SageMaker AI. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the create_endpoint method to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following example creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources and deploy models.

```
create_endpoint_response = sagemaker_client.create_endpoint(
    # The endpoint name must be unique within an AWS Region in your AWS account:
    EndpointName = "endpoint-name"
    # The name of the endpoint configuration associated with this endpoint:
    EndpointConfigName = "endpoint-config-name")
```

Deploy models with the AWS CLI

You can deploy a model to an endpoint by using the AWS CLI.

Overview

When you deploy a model with the AWS CLI, you can deploy it with or without using an inference component. The following sections summarize the commands that you run for both approaches. These commands are demonstrated by the examples that follow.

With inference components

To deploy a model with an inference component, do the following:

1. (Optional) Create a model with the `create-model` command.
2. Specify the settings for your endpoint by creating an endpoint configuration. To create one, you run the `create-endpoint-config` command.
3. Create your endpoint by using the `create-endpoint` command. In the command body, specify the endpoint configuration that you created.
4. Create an inference component by using the `create-inference-component` command. In the settings, you specify a model by doing either of the following:
    - Specifying a SageMaker AI model object
    - Specifying the model image URI and S3 URL

You also allocate endpoint resources to the model. By creating the inference component, you deploy the model to the endpoint. You can deploy multiple models to an endpoint by creating multiple inference components — one for each model.

Without inference components

To deploy a model without using an inference component, do the following:

1. Create a SageMaker AI model by using the `create-model` command.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the `create-endpoint-config` command. In the endpoint configuration, you assign the model object to a production variant.
3. Create your endpoint by using the `create-endpoint` command. In your command body, specify the endpoint configuration that you created.

   When you create the endpoint, SageMaker AI provisions the endpoint resources, and it deploys the model to the endpoint.

Configure

The following examples configure the resources that you require to deploy a model to an endpoint.

With inference components

Example create-endpoint-config command

The following example creates an endpoint configuration with the create-endpoint-config command.

```
aws sagemaker create-endpoint-config \
--endpoint-config-name endpoint-config-name \
--execution-role-arn arn:aws:iam::111122223333:role/service-role/role-name\
--production-variants file://production-variants.json
```

In this example, the file `production-variants.json` defines a production variant with the following JSON:

```
[
```

```
    {
        "VariantName": "variant-name",
        "ModelName": "model-name",
        "InstanceType": "ml.p4d.24xlarge",
        "InitialInstanceCount": 1
    }
]
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "EndpointConfigArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint-config/
endpoint-config-name"
}
```

Without inference components

Example create-model command

The following example creates a model with the create-model command.

```
aws sagemaker create-model \
--model-name model-name \
--execution-role-arn arn:aws:iam::111122223333:role/service-role/role-name \
--primary-container "{ \"Image\": \"image-uri\", \"ModelDataUrl\": \"model-s3-
url\"}"
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "ModelArn": "arn:aws:sagemaker:us-west-2:111122223333:model/model-name"
}
```

Example create-endpoint-config command

The following example creates an endpoint configuration with the create-endpoint-config command.

```
aws sagemaker create-endpoint-config \
--endpoint-config-name endpoint-config-name \
```

```
--production-variants file://production-variants.json
```

In this example, the file `production-variants.json` defines a production variant with the following JSON:

```
[
    {
        "VariantName": "variant-name",
        "ModelName": "model-name",
        "InstanceType": "ml.p4d.24xlarge",
        "InitialInstanceCount": 1
    }
]
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "EndpointConfigArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint-config/endpoint-config-name"
}
```

Deploy

The following examples deploy a model to an endpoint.

With inference components

Example create-endpoint command

The following example creates an endpoint with the create-endpoint command.

```
aws sagemaker create-endpoint \
--endpoint-name endpoint-name \
--endpoint-config-name endpoint-config-name
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "EndpointArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint/endpoint-name"
}
```

Example create-inference-component command

The following example creates an inference component with the create-inference-component command.

```
aws sagemaker create-inference-component \
--inference-component-name inference-component-name \
--endpoint-name endpoint-name \
--variant-name variant-name \
--specification file://specification.json \
--runtime-config "{\"CopyCount\": 2}"
```

In this example, the file `specification.json` defines the container and compute resources with the following JSON:

```
{
    "Container": {
        "Image": "image-uri",
        "ArtifactUrl": "model-s3-url"
    },
    "ComputeResourceRequirements": {
        "NumberOfCpuCoresRequired": 1,
        "MinMemoryRequiredInMb": 1024
    }
}
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "InferenceComponentArn": "arn:aws:sagemaker:us-west-2:111122223333:inference-
component/inference-component-name"
}
```

Without inference components

Example create-endpoint command

The following example creates an endpoint with the create-endpoint command.

```
aws sagemaker create-endpoint \
--endpoint-name endpoint-name \
```

```
--endpoint-config-name endpoint-config-name
```

If the command succeeds, the AWS CLI responds with the ARN for the resource you created.

```
{
    "EndpointArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint/endpoint-name"
}
```

Invoke models for real-time inference

After you use Amazon SageMaker AI to deploy a model to an endpoint, you can interact with the model by sending inference requests to it. To send an inference request to a model, you invoke the endpoint that hosts it. You can invoke your endpoints using Amazon SageMaker Studio, the AWS SDKs, or the AWS CLI.

Invoke Your Model Using Amazon SageMaker Studio

After you deploy your model to an endpoint, you can view the endpoint through Amazon SageMaker Studio and test your endpoint by sending single inference requests.

> **Note**
>
> SageMaker AI only supports endpoint testing in Studio for real-time endpoints.

To send a test inference request to your endpoint

1. Launch Amazon SageMaker Studio.
2. In the navigation pane on the left, choose **Deployments**.
3. From the dropdown, choose **Endpoints**.
4. Find for your endpoint by name, and choose the name in the table. The endpoint names listed in the **Endpoints** panel are defined when you deploy a model. The Studio workspace opens the **Endpoint** page in a new tab.
5. Choose the **Test inference** tab.
6. For **Testing Options**, select one of the following:

   a. Select **Test the sample request** to immediately send a request to your endpoint. Use the **JSON editor** to provide sample data in JSON format, and choose **Send Request** to submit the request to your endpoint. After submitting your request, Studio shows the inference output in a card to the right of the JSON editor.

b. Select **Use Python SDK example code** to view the code for sending a request to the endpoint. Then, copy the code example from the **Example inference request** section and run the code from your testing environment.

The top of the card shows the type of request that was sent to the endpoint (only JSON is accepted). The card shows the following fields:

- **Status** – displays one of the following status types:
  - `Success` – The request succeeded.
  - `Failed` – The request failed. A response appears under **Failure Reason**.
  - `Pending` – While the inference request is pending, the status shows a spinning, circular icon.
- **Execution Length** – How long the invocation took (end time minus the start time) in milliseconds.
- **Request Time** – How many minutes have passed since the request was sent.
- **Result Time** – How many minutes have passed since the result was returned.

Invoke Your Model by Using the AWS SDK for Python (Boto3)

If you want to invoke a model endpoint in your application code, you can use one of the AWS SDKs, including the AWS SDK for Python (Boto3). To invoke your endpoint with this SDK, you use one of the following Python methods:

- `invoke_endpoint` – Sends an inference request to a model endpoint and returns the response that the model generates.

  This method returns the inference payload as one response after the model finishes generating it. For more information, see invoke_endpoint in the *AWS SDK for Python (Boto3) API Reference*.
- `invoke_endpoint_with_response_stream` – Sends an inference request to a model endpoint and streams the response incrementally while the model generates it.

  With this method, your application receives parts of the response as soon as the parts become available. For more information, see invoke_endpoint in the *AWS SDK for Python (Boto3) API Reference*.

Use this method only to invoke models that support inference streaming.

Before you can use these methods in your application code, you must initialize a SageMaker AI Runtime client, and you must specify the name of your endpoint. The following example sets up the client and endpoint for the rest of the examples that follow:

```
import boto3

sagemaker_runtime = boto3.client(
    "sagemaker-runtime", region_name='aws_region')

endpoint_name='endpoint-name'
```

Invoke to Get an Inference Response

The following example uses the `invoke_endpoint` method to invoke an endpoint with the AWS SDK for Python (Boto3):

```
# Gets inference from the model hosted at the specified endpoint:
response = sagemaker_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    Body=bytes('{"features": ["This is great!"]}', 'utf-8')
    )

# Decodes and prints the response body:
print(response['Body'].read().decode('utf-8'))
```

This example provide input data in the Body field for SageMaker AI to pass to the model. This data must be in the same format that was used for training. The example assigns the response to the `response` variable.

The `response` variable provides access to the HTTP status, the name of the deployed model, and other fields. The following snippet prints the HTTP status code:

```
print(response["HTTPStatusCode"])
```

Invoke to Stream an Inference Response

If you deployed a model that supports inference streaming, you can invoke the model to receive its inference payload as a stream of parts. The model delivers these parts incrementally as the model generates them. When an application receives an inference stream, the application doesn't need to wait for the model to generate the whole response payload. Instead, the application immediately receives parts of the response as they become available.

By consuming an inference stream in your application, you can create interactions where your users perceive the inference to be fast because they get the first part immediately. You can implement streaming to support fast interactive experiences, such as chatbots, virtual assistants, and music generators. For example, you could create a chatbot that incrementally shows the text generated by a large language model (LLM).

To get an inference stream, you can use the `invoke_endpoint_with_response_stream` method. In the response body, the SDK provides an `EventStream` object, which gives the inference as a series of `PayloadPart` objects.

Example Inference Stream

The following example is a stream of `PayloadPart` objects:

```
{'PayloadPart': {'Bytes': b'{"outputs": [" a"]}\n'}}
{'PayloadPart': {'Bytes': b'{"outputs": [" challenging"]}\n'}}
{'PayloadPart': {'Bytes': b'{"outputs": [" problem"]}\n'}}
. . .
```

In each payload part, the `Bytes` field provides a portion of the inference response from the model. This portion can be any content type that a model generates, such as text, image, or audio data. In this example, the portions are JSON objects that contain generated text from an LLM.

Usually, the payload part contains a discrete chunk of data from the model. In this example, the discrete chunks are whole JSON objects. Occasionally, the streaming response splits the chunks over multiple payload parts, or it combines multiple chunks into one payload part. The following example shows a chunk of data in JSON format that's split over two payload parts:

```
{'PayloadPart': {'Bytes': b'{"outputs": '}}
{'PayloadPart': {'Bytes': b'[" problem"]}\n'}}
```

When you write application code that processes an inference stream, include logic that handles these occasional splits and combinations of data. As one strategy, you could write code that concatenates the contents of `Bytes` while your application receives the payload parts. By concatenating the example JSON data here, you would combine the data into a newline-delimited

JSON body. Then, your code could process the stream by parsing the whole JSON object on each line.

The following example shows the newline-delimited JSON that you would create when you concatenate the example contents of `Bytes`:

```
{"outputs": [" a"]}
{"outputs": [" challenging"]}
{"outputs": [" problem"]}
. . .
```

Example Code to Process an Inference Stream

The following example Python class, `SmrInferenceStream`, demonstrates how you can process an inference stream that sends text data in JSON format:

```
import io
import json

# Example class that processes an inference stream:
class SmrInferenceStream:

    def __init__(self, sagemaker_runtime, endpoint_name):
        self.sagemaker_runtime = sagemaker_runtime
        self.endpoint_name = endpoint_name
        # A buffered I/O stream to combine the payload parts:
        self.buff = io.BytesIO()
        self.read_pos = 0

    def stream_inference(self, request_body):
        # Gets a streaming inference response
        # from the specified model endpoint:
        response = self.sagemaker_runtime\
            .invoke_endpoint_with_response_stream(
                EndpointName=self.endpoint_name,
                Body=json.dumps(request_body),
                ContentType="application/json"
        )
        # Gets the EventStream object returned by the SDK:
        event_stream = response['Body']
        for event in event_stream:
            # Passes the contents of each payload part
            # to be concatenated:
```

```
            self._write(event['PayloadPart']['Bytes'])
            # Iterates over lines to parse whole JSON objects:
            for line in self._readlines():
                resp = json.loads(line)
                part = resp.get("outputs")[0]
                # Returns parts incrementally:
                yield part

    # Writes to the buffer to concatenate the contents of the parts:
    def _write(self, content):
        self.buff.seek(0, io.SEEK_END)
        self.buff.write(content)

    # The JSON objects in buffer end with '\n'.
    # This method reads lines to yield a series of JSON objects:
    def _readlines(self):
        self.buff.seek(self.read_pos)
        for line in self.buff.readlines():
            self.read_pos += len(line)
            yield line[:-1]
```

This example processes the inference stream by doing the following:

- Initializes a SageMaker AI Runtime client and sets the name of a model endpoint. Before you can get an inference stream, the model that the endpoint hosts must support inference streaming.
- In the example `stream_inference` method, receives a request body and passes it to the `invoke_endpoint_with_response_stream` method of the SDK.
- Iterates over each event in the `EventStream` object that the SDK returns.
- From each event, gets the contents of the `Bytes` object in the `PayloadPart` object.
- In the example `_write` method, writes to a buffer to concatenate the contents of the `Bytes` objects. The combined contents form a newline-delimited JSON body.
- Uses the example `_readlines` method to get an iterable series of JSON objects.
- In each JSON object, gets a piece of the inference.
- With the `yield` expression, returns the pieces incrementally.

The following example creates and uses a `SmrInferenceStream` object:

```
request_body = {"inputs": ["Large model inference is"],
                "parameters": {"max_new_tokens": 100,
```

```
                                "enable_sampling": "true"}}
smr_inference_stream = SmrInferenceStream(
    sagemaker_runtime, endpoint_name)
stream = smr_inference_stream.stream_inference(request_body)
for part in stream:
    print(part, end='')
```

This example passes a request body to the `stream_inference` method. It iterates over the response to print each piece that the inference stream returns.

The example assumes that the model at the specified endpoint is an LLM that generates text. The output from this example is a body of generated text that prints incrementally:

```
a challenging problem in machine learning. The goal is to . . .
```

Invoke Your Model by Using the AWS CLI
