4. A **Connect to cluster** UI screen will appear. Choose a cluster and select **Connect**. Not all Amazon EMR clusters can be connected to Studio. For more information, see [Perform interactive data processing using Spark in Studio Notebooks](#).

When you connect to a cluster, it adds a code block to an active cell to establish the connection.
5. If the cluster that you're connecting to does not use Kerberos or Lightweight Directory Access Protocol (LDAP) connection, you will be prompted to select the credential type. You can choose **HTTP basic authentication** or **No credential**.
6. An active cell will populate. This will contain the connection information that you need for connecting to the Amazon EMR cluster that you selected.

- When the authentication type is Kerberos and HTTP Basic Auth, a widget will be created in an active cell for you to provide your **Username** and **Password**.
- If the cluster that you are connecting to does not use Kerberos or LDAP, and you selected No credentials, you will automatically connect to an Amazon EMR cluster.

7. This step is optional. If you want to change the Amazon EMR cluster that the Studio notebook is connected to, select **Cluster** at the top-right of your notebook. After selecting **Cluster**, browse the list of clusters and select a different cluster.

For more information on required permissions, see Required Permissions (p. 1016).

**Connect Amazon EMR Clusters Across Accounts**

If you have set up cross-account discoverability and connectivity, when you select **Cluster**, all clusters from both Studio and remote accounts will show. After you select **Connect**, Studio will initiate and establish a connection to the Amazon EMR cluster in the remote account. The following screenshot shows this connection.
Create and manage Amazon EMR Clusters from here. Use "View Clusters" to see a list of Amazon EMR clusters visible to you. Use "Create Cluster" to create an EMR cluster based on a template provided by your administrator.

Create cluster
Troubleshoot and Monitor Workloads in Amazon EMR

The following sections give instructions for accessing the Spark UI from SageMaker Studio notebooks. The Spark UI allows you to monitor and debug your Spark Jobs submitted to run on Amazon EMR from Studio notebooks. SSH tunneling and presigned URLs are two ways for accessing the Spark UI.

Set up SSH tunneling for Spark UI access

To set up SSH tunneling to access the Spark UI, follow one of the two options in this section. Note that the screenshot in Step 6b of Connect to an Amazon EMR Cluster from Studio (p. 988) shows links under Spark UI and Driver log. These links will activate only after you complete the SSH tunneling setup.

Options for setting up SSH tunneling:

- Option 1: Set up an SSH tunnel to the master node using local port forwarding
- Option 2, part 1: Set up an SSH tunnel to the master node using dynamic port forwarding
  - Option 2, part 2: Configure proxy settings to view websites hosted on the master node

For information about viewing web interfaces hosted on Amazon EMR clusters, see View web interfaces hosted on Amazon EMR Clusters. You can also visit your Amazon EMR console to get access to the Spark UI.

Note
You can set up an SSH tunnel even if presigned URLs are not available to you.

Presigned URLs

To create one-click URLs that can access Spark UI on Amazon EMR from SageMaker Studio notebooks, you must enable the following IAM permissions. Choose the option that applies to you:

- For Amazon EMR clusters that are in the same account as the SageMaker Studio notebook: Add the following permissions to the SageMaker Studio IAM execution role.
- For Amazon EMR clusters that are in a different account (not SageMaker Studio notebook): Add the following permissions to the cross-account role that you created for Discover Amazon EMR Clusters from Studio (p. 985).

Note
You can access presigned URLs from the console in the following regions:

- US East (N. Virginia) Region
- US West (N. California) Region
- Canada (Central) Region
- Europe (Frankfurt) Region
- Europe (Stockholm) Region
- Europe (Ireland) Region
- Europe (London) Region
- Europe (Paris) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Sydney) Region
- Asia Pacific (Mumbai) Region
• Asia Pacific (Singapore) Region
• South America (São Paulo)

The following policy gives access to presigned URLs for your execution role.

```json
{
    "Sid": "AllowPresignedUrl",
    "Effect": "Allow",
    "Action": [
        "elasticmapreduce:DescribeCluster",
        "elasticmapreduce:ListInstanceGroups",
        "elasticmapreduce:CreatePersistentAppUI",
        "elasticmapreduce:DescribePersistentAppUI",
        "elasticmapreduce:GetPersistentAppUIPresignedURL",
        "elasticmapreduce:GetOnClusterAppUIPresignedURL"
    ],
    "Resource": [
        "arn:aws:elasticmapreduce:<region>:<account-id>:cluster/*"
    ]
}
```

For more information about required permissions, see Required Permissions (p. 1016).

**Manage Amazon EMR Clusters from Studio**

Administrators can use AWS Service Catalog to define templates. These templates allow you to create Amazon EMR clusters and make them available to selected users. Using AWS Service Catalog, administrators can fully control the organizational, security, and networking in Amazon EMR clusters. Administrators can view, select, and customize templates for their specific workloads. If they choose, admins can limit exposure to selected configuration parameters, such as only to specific data workers. Admins can create on-demand Amazon EMR clusters within SageMaker Studio. This can be done without manually setting up complex configurations. Users can also terminate Amazon EMR clusters after use, directly from SageMaker Studio.

The topics in this guide provide more details about setting up and using AWS Service Catalog templates, and creating and terminating Amazon EMR clusters.

**Topics**

- Configure AWS Service Catalog Products (p. 1000)
- Provision Amazon EMR Clusters from Studio (p. 1004)

**Configure AWS Service Catalog Products**

In this guide, you get parameters for configuring AWS Service Catalog products so you can discover CloudFormation (CFN) templates. CFN templates are used to create and manage Amazon EMR clusters. The AWS Service Catalog product can associate with an AWS Service Catalog portfolio that is shared with the Studio execution role IAM entity.

To enable Amazon EMR cluster management from Studio, you need a CloudFormation (CFN) template with Amazon EMR cluster details and configurable parameters. For information about how you can use CloudFormation, see Getting started with CloudFormation. For more information about AWS Service Catalog products, see Step 4: Create an AWS Service Catalog Product.

The AWS Service Catalog product with the Amazon EMR resource must have the following tags:

```plaintext
sagemaker:studio-visibility:emr true
```
The CFN templates in the AWS Service Catalog product must have the following mandatory stack parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMakerProjectName</td>
<td>String</td>
<td>Name of the project</td>
</tr>
<tr>
<td>SageMakerProjectId</td>
<td>String</td>
<td>Service generated Id of the project</td>
</tr>
</tbody>
</table>

For more information about creating AWS Service Catalog portfolios and products, see Step 3: Create an AWS Service Catalog Portfolio and its subsequent sections.

Optional template parameters

When creating Amazon EMR templates from within SageMaker Studio, you can include additional options in the parameters section of your template. This section lets users input or select custom values for a cluster. The following example parameters define additional input parameters that you can use when creating an Amazon EMR template from within Studio.

```json
"Parameters": {
    "EmrClusterName": {
        "Type": "String",
        "Description": "EMR cluster Name."
    },
    "MasterInstanceType": {
        "Type": "String",
        "Description": "Instance type of the EMR master node.",&quot;
        "Default": "m5.xlarge",
        "AllowedValues": [
            "m5.xlarge",
            "m5.2xlarge",
            "m5.4xlarge"
        ]
    },
    "CoreInstanceType": {
        "Type": "String",
        "Description": "Instance type of the EMR core nodes.",&quot;
        "Default": "m5.xlarge",
        "AllowedValues": [
            "m5.xlarge",
            "m5.2xlarge",
            "m5.4xlarge",
            "m3.medium",
            "m3.large",
            "m3.xlarge",
            "m3.2xlarge"
        ]
    },
    "CoreInstanceCount": {
        "Type": "String",
        "Description": "Number of core instances in the EMR cluster.",&quot;
        "Default": "2",
        "AllowedValues": [
            "2",
            "5",
            "10"
        ]
    },
    "EmrReleaseVersion": {
        "Type": "String",
        "Description": "The release version of EMR to launch."
    }
}
```
"Default": "emr-5.33.1",
"AllowedValues": [
  "emr-5.33.1",
  "emr-6.4.0"
]
}

The following image shows how the Studio UI will look when you create an Amazon EMR cluster from Studio.
Provision Amazon EMR Clusters from Studio

This section provides guided instructions with screenshots from Studio that show how to create a cluster, view a list of available clusters, and terminate a cluster.

If you configured cross-account discovery, you will see a consolidated list of clusters in Studio, and in the remote account.

To start, add the following permissions to the IAM execution role that will be accessing Studio. For more information about required permissions, see Required Permissions (p. 1016).

```json
{
    "Sid": "AllowSagemakerProjectManagement",
    "Effect": "Allow",
    "Action": [
        "sagemaker:CreateProject",
        "sagemaker:DeleteProject"
    ],
    "Resource": "arn:aws:sagemaker:<region>:<account-id>:project/*"
}
```

After you’ve added the previous permissions, you can connect to Studio. If you have an existing Studio notebook instance, you can open it. Otherwise, if you want to create a new notebook instance, select File, and then select New.

- To open the cluster management page, select Clusters from the left-side panel.
Amazon SageMaker Studio

SageMaker resources
Select the resource to

Clusters

Data wrangler

Feature Store

Pipelines
The following screenshot shows the cluster management page. From here, you can create and manage your Amazon EMR clusters.
A cluster can be in different statuses. To filter clusters by status, select the dropdown arrow icon. A cluster can only be in one status at a time.

Status options include Starting, Bootstrapping, Running/Walking, Terminating, Terminated, and Terminated with error. The following screenshot shows the cluster status options in the status dropdown.
Amazon SageMaker Developer Guide
Prepare Data using Amazon EMR

SageMaker resources
Select the resource to:

Clusters
Create and manage
"View Clusters" to see what's available to you. Use "Create Cluster" to create a new cluster with this.
The following procedure shows how to create a cluster using a template from Studio.

**To create a cluster from a template:**

1. Navigate to the cluster management page by selecting the **Clusters** from the left-side panel. Then, select **Create cluster**.
Amazon SageMaker Developer Guide
Prepare Data using Amazon EMR

Amazon SageMaker Studio

SageMaker resources
Select the resource to view.

Clusters
Create and manage Amazon EMR clusters. Use "View Clusters" to see a list of available clusters and select one for you. Use "Create Cluster" to create a new cluster using the template provided by your administrator.

Manage Amazon EMR Clusters

Prepare data at scale with Studio
2. Enter your SageMaker Studio subnet ID, Amazon EMR cluster name, Amazon VPC ID, and SageMaker Studio security group ID.
Create and manage Amazon EMR Clusters from "View Clusters" to see a list of Amazon EMR clusters assigned to you. Use "Create Cluster" to create an EMR cluster from a template provided by your administrator.

Manage Amazon EMR Clusters from Studio

Prepare data at scale with Studio Notebooks

View clusters
3. After entering the information from the previous step, select **Create cluster**.

The following procedure shows how to terminate a cluster.

**To terminate a cluster**

1. Navigate to the cluster management page by selecting the **Clusters** from the left-side panel.

   Select the cluster that you want to terminate, then choose **Terminate** next to **Create cluster** in the UI.

2. A window will appear advising that any pending work or data on your cluster will be lost after termination, and termination is irreversible. Select **Terminate**.
Required Permissions

This guide shows you how to apply an example IAM policy to your execution role. The examples in this guide provide you with various permissions and monitoring capabilities. At the end of this guide, you will find a comprehensive IAM policy role that includes all required permissions. These permissions provide access to Amazon EMR clusters from within Studio, and allow discoverability of clusters from within Studio (for presigned URLs). Access the IAM console to add the policy to your role.

To discover and connect to Amazon EMR clusters from within Studio, ensure that your execution role has the following permissions:

```json
{
    "Sid": "AllowClusterDetailsDiscovery",
    "Effect": "Allow",
    "Action": ["elasticmapreduce:DescribeCluster", "elasticmapreduce:ListInstanceGroups"],
},
{
    "Sid": "AllowClusterDiscovery",
    "Effect": "Allow",
    "Action": ["elasticmapreduce:ListClusters"],
    "Resource": "*"
}
```

To enhance monitoring capabilities, attach the following permissions to your Studio execution role:

```json
{
    "Sid": "AllowPresignedUrl",
    "Effect": "Allow",
}
```

To allow users to create Amazon EMR clusters, add the following permission to your Studio execution role:

```json
{
    "Sid": "AllowSagemakerProjectManagement",
    "Effect": "Allow",
    "Action": ["sagemaker:CreateProject", "sagemaker:DeleteProject"],
    "Resource": "arn:aws:sagemaker:<region>:<account-id>:project/*"
}
```
If you have provided Studio with a cross-account discovery and connectivity role, the role in the non-Studio account must allow "assume role" permissions to the Studio execution role. This can be done by attaching the following permissions to your Studio execution role:

**Note**
For all cross-account use cases, the Studio execution role must have the `sts:AssumeRole` permission added to allow Studio to assume a role in the remote account.

```json
{
    "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": ["arn:aws:iam::<cross-account>:role/<studio-execution-role>"
}
```

To allow discoverability for Amazon EMR templates, attach the following permissions to your Studio execution role:

```json
{
    "Sid": "AllowEMRTemplateDiscovery",
    "Effect": "Allow",
    "Action": [ "servicecatalog:SearchProducts"
    ],
    "Resource": "*"
}
```

The following is a comprehensive example IAM policy that includes all of the previous permissions in this guide:

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "AllowPresignedUrl",
        "Effect": "Allow",
        "Action": [ "elasticmapreduce:DescribeCluster",
                    "elasticmapreduce:ListInstanceGroups",
                    "elasticmapreduce:CreatePersistentAppUI",
                    "elasticmapreduce:DescribePersistentAppUI",
                    "elasticmapreduce:GetPersistentAppUIPresignedURL",
                    "elasticmapreduce:GetOnClusterAppUIPresignedURL"
        ],
        ]
    },
    {
        "Sid": "AllowClusterDetailsDiscovery",
        "Effect": "Allow",
        "Action": [ "elasticmapreduce:DescribeCluster",
                    "elasticmapreduce:ListInstanceGroups"
        ],
        ]
    },
    {
        "Sid": "AllowClusterDiscovery",
        "Effect": "Allow",
        "Action": [ "elasticmapreduce:DescribeCluster",
                    "elasticmapreduce:ListInstanceGroups"
        ],
        ]
    }
]
```
Prepare Data using AWS Glue Interactive Sessions

AWS Glue Interactive Sessions is a serverless service that equips you with the tools to collect, transform, cleanse, and prepare the data that will populate your data lakes and pipelines. Glue Interactive Sessions provides an on-demand, serverless Apache Spark runtime environment that data scientists and engineers can use to rapidly build, test, and run data preparation and analytics applications.

Starting a Glue interactive session from a SageMaker Studio notebook is simple. When you create your Studio notebook, choose the built-in Glue PySpark or Glue Spark kernel and start coding in your interactive, serverless Spark session in just seconds. You don't have worry about provisioning or managing complex compute cluster infrastructure. After initialization, you can quickly browse the Glue data catalog, run large queries, and interactively analyze and prepare data using Spark, all within your Studio notebook. You can then use the prepared data to build, train, tune, and deploy models using the purpose-built ML tools within SageMaker Studio.

Before you start your AWS Glue interactive session in SageMaker Studio, you need to set the appropriate roles and policies. You may also need access to additional resources, such as Amazon S3, which may require additional policies. For more information about required and additional IAM policies, see Permissions for Glue Interactive Sessions in SageMaker Studio (p. 1019).

SageMaker Studio provides a default configuration for your AWS Glue interactive session, but you can use Glue's full catalog of Jupyter magic commands to further customize your environment. For information about the default and additional Jupyter magics that you can use in your Glue interactive session, see Configure your Glue interactive session in SageMaker Studio (p. 1021).

The supported images and kernels for connecting to a Glue interactive session are as follows:

- Images: SparkAnalytics 1.0
- Kernel: PySpark and Spark
Prerequisites:

The SparkAnalytics image that you select to launch your Glue session in Studio is a combination of two frameworks - the SparkMagic framework (used with Amazon EMR), and AWS Glue. For this reason, the prerequisites for both frameworks apply. However, you do not have to set up the EMR cluster if you only plan to use Glue Interactive Sessions. Before you start your first Glue interactive session in Studio, complete the following:

- Complete the prerequisites required to use the SparkMagic image. For a list of the prerequisites, see the Prerequisites section in Prepare Data at Scale with Studio Notebooks.
- Create an execution role with permissions for both AWS Glue and SageMaker Studio. Add the managed policy AwsGlueSessionUserRestrictedServiceRole, and create a custom policy that includes permissions sts:GetCallerIdentity, iam:GetRole, and IAM:Passrole. For instructions about how to create the necessary permissions, see Permissions for Glue Interactive Sessions in SageMaker Studio (p. 1019).
- Create a SageMaker domain with the execution role you created. For instructions about how to create a domain, see Onboard to Amazon SageMaker Domain Using IAM (p. 40).

Get Started with AWS Glue Interactive Sessions

This guide will show you how set up the necessary permissions, launch your first Glue interactive session in Studio, and manage your environment with Jupyter magics.

Permissions for Glue Interactive Sessions in SageMaker Studio

This guide will show you how to obtain the required permissions to use Glue Interactive Sessions in Studio. You will attach two managed policies, then create and attach a custom policy, and lastly, modify the trust relationship.

To add the managed policies to your execution role

1. Open the IAM console.
2. Select Roles in the left-side panel.
3. Find the Studio execution role that you will use, and choose the role name to go to the role summary page.
4. Under the Permissions tab, select Attach policies from the Add Permissions dropdown menu.
5. Select the checkbox next to the managed policy AwsGlueSessionUserRestrictedServiceRole.
6. Choose Attach policies.

The summary page shows your newly-added managed policies.

To create the custom policy and attach it to your execution role

1. Select Create inline policy in the Add Permissions dropdown menu.
2. Select the JSON tab.
3. Copy and paste in the following policy.

```json

{  
   "Version": "2012-10-17",
   "Statement": [
      
      "Sid": "unique_statement_id",
      
```
5. Enter a Name and choose Create policy.

The summary page shows your newly-added custom policy.

To modify the trust relationship
1. Select the Trust relationships tab.
2. Choose Edit trust policy.
3. Copy and paste in the following policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["glue.amazonaws.com", "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
4. Choose Update policy.

You can add additional roles and policies if you need to access other AWS resources. For a description of the additional roles and policies you can include, see Interactive sessions with IAM in the AWS Glue documentation.

Launch your Glue interactive session on SageMaker Studio

After you create the roles, policies, and SageMaker domain, you can launch your Glue interactive session in SageMaker Studio.

To launch Glue in SageMaker Studio
1. Create a SageMaker domain. For instructions on how to create a new domain, see Onboard to Amazon SageMaker Domain (p. 35).
3. Select Control Panel in the left-side panel.
4. In the Launch App dropdown menu next to the user name, select Studio.
5. In the Jupyter view, choose File, then New, then Notebook.
6. In the Image dropdown menu, select SparkAnalytics 1.0. In the kernel dropdown menu, select Glue Spark or Glue PySpark. Choose Select.

7. (optional) Use Jupyter magics to customize your environment. For more information about Jupyter magics, see Configure your Glue interactive session in SageMaker Studio (p. 1021).

8. Start writing your Spark data processing scripts.

Configure your Glue interactive session in SageMaker Studio

You can use Jupyter magics in your AWS Glue interactive session to modify your session and configuration parameters. Magics are short commands prefixed with % at the start of Jupyter cells that provide a quick and easy way to help you control your environment. In your Glue interactive session, the following magics are set for you by default:

<table>
<thead>
<tr>
<th>Magic</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>%glue_version</td>
<td>3.0</td>
</tr>
<tr>
<td>%iam_policy</td>
<td>execution role attached to your SageMaker domain</td>
</tr>
<tr>
<td>%region</td>
<td>your region</td>
</tr>
</tbody>
</table>

You can use magics to further customize your environment. For example, if you want to change the number of workers allocated to your job from the default five to 10, you can specify %number_of_workers 10. If you want to configure your session to stop after 10 minutes of idle time instead of the default 2880, you can specify %idle_timeout 10.

All of the Jupyter magics currently available in AWS Glue are also available in SageMaker Studio. For the complete list of AWS Glue magics available, see Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks.

AWS Glue Interactive Session Pricing

When you use AWS Glue Interactive Sessions on SageMaker Studio notebooks, you are charged separately for resource usage on AWS Glue and Studio notebooks.

AWS charges for Glue Interactive Sessions based on how long the session is active and the number of Data Processing Units (DPU) used. You are charged an hourly rate for the number of DPUs used to run your workloads, billed in increments of one second. Glue Interactive Sessions assigns a default of five DPUs and requires a minimum of two DPUs. There is also a one-minute minimum billing duration for each interactive session. To see the AWS Glue rates and pricing examples, or to estimate your costs using the AWS Pricing Calculator, see AWS Glue pricing.

Your SageMaker Studio notebook runs on an Amazon EC2 instance and you are charged for the instance type you choose, based on the duration of use. Studio assigns you a default EC2 instance type of ml-t3-medium when you select the SparkAnalytics image and associated kernel. You can change the instance type for of your Studio notebook to suit your workload. For information about SageMaker Studio pricing, see Amazon SageMaker Pricing.
Process Data

To analyze data and evaluate machine learning models on Amazon SageMaker, use Amazon SageMaker Processing. With Processing, you can use a simplified, managed experience on SageMaker to run your data processing workloads, such as feature engineering, data validation, model evaluation, and model interpretation. You can also use the Amazon SageMaker Processing APIs during the experimentation phase and after the code is deployed in production to evaluate performance.

The preceding diagram shows how Amazon SageMaker spins up a Processing job. Amazon SageMaker takes your script, copies your data from Amazon Simple Storage Service (Amazon S3), and then pulls a processing container. The processing container image can either be an Amazon SageMaker built-in image or a custom image that you provide. The underlying infrastructure for a Processing job is fully managed by Amazon SageMaker. Cluster resources are provisioned for the duration of your job, and cleaned up when a job completes. The output of the Processing job is stored in the Amazon S3 bucket you specified.

**Note**
Your input data must be stored in an Amazon S3 bucket. Alternatively, you can use Amazon Athena or Amazon Redshift as input sources.

Use Amazon SageMaker Processing Sample Notebooks

We provide two sample Jupyter notebooks that show how to perform data preprocessing, model evaluation, or both.

For a sample notebook that shows how to run scikit-learn scripts to perform data preprocessing and model training and evaluation with the SageMaker Python SDK for Processing, see scikit-learn Processing. This notebook also shows how to use your own custom container to run processing workloads with your Python libraries and other specific dependencies.

For a sample notebook that shows how to use Amazon SageMaker Processing to perform distributed data preprocessing with Spark, see Distributed Processing (Spark). This notebook also shows how to train a regression model using XGBoost on the preprocessed dataset.

For instructions on how to create and access Jupyter notebook instances that you can use to run these samples in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have
Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

Amazon SageMaker Processing provides Amazon CloudWatch logs and metrics to monitor processing jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3663) and Log Amazon SageMaker Events with Amazon CloudWatch (p. 3675).

Data Processing with Apache Spark

Apache Spark is a unified analytics engine for large-scale data processing. Amazon SageMaker provides prebuilt Docker images that include Apache Spark and other dependencies needed to run distributed data processing jobs. With the Amazon SageMaker Python SDK, you can easily apply data transformations and extract features (feature engineering) using the Spark framework. For information about using the SageMaker Python SDK to run Spark processing jobs, see Data Processing with Spark in the Amazon SageMaker Python SDK.

A code repository that contains the source code and Dockerfiles for the Spark images is available on GitHub.

Running a Spark Processing Job

You can use the `sagemaker.spark.PySparkProcessor` or `sagemaker.spark.SparkJarProcessor` class to run your Spark application inside of a processing job. Note you can set MaxRuntimeInSeconds to a maximum runtime limit of 5 days. With respect to execution time, and number of instances used, simple spark workloads see a near linear relationship between the number of instances vs. time to completion.

The following code example shows how to run a processing job that invokes your PySpark script `preprocess.py`.

```python
from sagemaker.spark.processing import PySparkProcessor

spark_processor = PySparkProcessor(
    base_job_name="spark-preprocessor",
    framework_version="2.4",
    role=role,
    instance_count=2,
    instance_type="ml.m5.xlarge",
    max_runtime_in_seconds=1200,
)

spark_processor.run(
    submit_app="preprocess.py",
    arguments=['s3_input_bucket', bucket,
              's3_input_key_prefix', input_prefix,
              's3_output_bucket', bucket,
              's3_output_key_prefix', output_prefix]
)
```
For an in-depth look, see the Distributed Data Processing with Apache Spark and SageMaker Processing example notebook.

If you are not using the Amazon SageMaker Python SDK and one of its Processor classes to retrieve the pre-built images, you can retrieve these images yourself. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). For a complete list of the available pre-built Docker images, see the available images document.

To learn more about using the SageMaker Python SDK with Processing containers, see Amazon SageMaker Python SDK.

Data Processing with scikit-learn

For a sample notebook that shows how to run scikit-learn scripts using a Docker image provided and maintained by SageMaker to preprocess data and evaluate models, see scikit-learn Processing. To use this notebook, you need to install the SageMaker Python SDK for Processing.

This notebook runs a processing job using SKLearnProcessor class from the the SageMaker Python SDK to run a scikit-learn script that you provide. The script preprocesses data, trains a model using a SageMaker training job, and then runs a processing job to evaluate the trained model. The processing job estimates how the model is expected to perform in production.

To learn more about using the SageMaker Python SDK with Processing containers, see the SageMaker Python SDK. For a complete list of pre-built Docker images available for processing jobs, see Docker Registry Paths and Example Code (p. 1105) and choose your region.

The following code example shows how the notebook uses SKLearnProcessor to run your own scikit-learn script using a Docker image provided and maintained by SageMaker, instead of your own Docker image.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput

sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                      role=role,
                                      instance_type='ml.m5.xlarge',
                                      instance_count=1)

sklearn_processor.run(code='preprocessing.py',
                       inputs=[ProcessingInput(source='s3://path/to/my/input-data.csv',
                                               destination='/opt/ml/processing/input')],
                       outputs=[ProcessingOutput(source='/opt/ml/processing/output/train'),
                                 ProcessingOutput(source='/opt/ml/processing/output/validation'),
                                 ProcessingOutput(source='/opt/ml/processing/output/test')])
```

To process data in parallel using Scikit-Learn on Amazon SageMaker Processing, you can shard input objects by S3 key by setting s3_data_distribution_type='ShardedByS3Key' inside a ProcessingInput so that each instance receives about the same number of input objects.

Data Processing with Framework Processors

A FrameworkProcessor can run Processing jobs with a specified machine learning framework, providing you with an Amazon SageMaker–managed container for whichever machine learning
framework you choose. FrameworkProcessor provides premade containers for the following machine
learning frameworks: Hugging Face, MXNet, PyTorch, TensorFlow, and XGBoost.

The FrameworkProcessor class also provides you with customization over the container configuration.
The FrameworkProcessor class supports specifying a source directory source_dir for your
processing scripts and dependencies. With this capability, you can give the processor access to multiple
scripts in a directory instead of only specifying one script. FrameworkProcessor also supports
including a requirements.txt file in the source_dir for customizing the Python libraries to install in
the container.

For more information on the FrameworkProcessor class and its methods and parameters, see
FrameworkProcessor in the Amazon SageMaker Python SDK.

To see examples of using a FrameworkProcessor for each of the supported machine learning
frameworks, see the following topics.

Topics
- Hugging Face Framework Processor (p. 1025)
- MXNet Framework Processor (p. 1026)
- PyTorch Framework Processor (p. 1027)
- TensorFlow Framework Processor (p. 1028)
- XGBoost Framework Processor (p. 1029)

Hugging Face Framework Processor

Hugging Face is an open-source provider of natural language processing (NLP) models. The
HuggingFaceProcessor in the Amazon SageMaker Python SDK provides you with the ability to
run processing jobs with Hugging Face scripts. When you use the HuggingFaceProcessor, you can
leverage an Amazon-built Docker container with a managed Hugging Face environment so that you don't
need to bring your own container.

The following code example shows how you can use the HuggingFaceProcessor to run your
Processing job using a Docker image provided and maintained by SageMaker. Note that when you
run the job, you can specify a directory containing your scripts and dependencies in the source_dir
argument, and you can have a requirements.txt file located inside your source_dir directory that
specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies
in requirements.txt in the container for you.

```python
from sagemaker.huggingface import HuggingFaceProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the HuggingFaceProcessor
hfp = HuggingFaceProcessor(
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.g4dn.xlarge',
    transformers_version='4.4.2',
    pytorch_version='1.6.0',
    base_job_name='frameworkprocessor-hf'
)

#Run the processing job
hfp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
```
MXNet Framework Processor

Apache MXNet is an open-source deep learning framework commonly used for training and deploying neural networks. The MXNetProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with MXNet scripts. When you use the MXNetProcessor, you can leverage an Amazon-built Docker container with a managed MXNet environment so that you don't need to bring your own container.

The following code example shows how you can use the MXNetProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.mxnet import MXNetProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the MXNetProcessor
mxp = MXNetProcessor(
    framework_version='1.8.0',
    py_version='py37',
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.c5.xlarge',
    base_job_name='frameworkprocessor-mxnet'
)

#Run the processing job
mxp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://(BUCKET)/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data/
        ),
    ],
    outputs=[
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train/',
            destination=f's3://(BUCKET)/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test/',
            destination=f's3://(BUCKET)/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='val', source='/opt/ml/processing/output/val/',
            destination=f's3://(BUCKET)/{S3_OUTPUT_PATH}')
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the HuggingFaceProcessor class, see Hugging Face Estimator in the Amazon SageMaker Python SDK.
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the MXNetProcessor class, see MXNet Estimator in the Amazon SageMaker Python SDK.

**PyTorch Framework Processor**

PyTorch is an open-source machine learning framework. The PyTorchProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with PyTorch scripts. When you use the PyTorchProcessor, you can leverage an Amazon-built Docker container with a managed PyTorch environment so that you don't need to bring your own container.

The following code example shows how you can use the PyTorchProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.pytorch.processing import PyTorchProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the PyTorchProcessor
pytorch_processor = PyTorchProcessor(
    framework_version='1.8',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-PT'
)

#Run the processing job
pytorch_processor.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input'
        )
    ],
    outputs=[
        ProcessingOutput(output_name='processed_data', source='/opt/ml/processing/output/',
                        destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train',
                         destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='validation', source='/opt/ml/processing/output/val',
                         destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test',
                         destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
    ]
)
```
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the PyTorchProcessor class, see PyTorch Estimator in the Amazon SageMaker Python SDK.

TensorFlow Framework Processor

TensorFlow is an open-source machine learning and artificial intelligence library. The TensorFlowProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with TensorFlow scripts. When you use the TensorFlowProcessor, you can leverage an Amazon-built Docker container with a managed TensorFlow environment so that you don’t need to bring your own container.

The following code example shows how you can use the TensorFlowProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```
from sagemaker.tensorflow import TensorFlowProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the TensorFlowProcessor
tp = TensorFlowProcessor(
    framework_version='2.3',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-TF',
    py_version='py37'
)

#Run the processing job
tp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://(BUCKET)/(S3_INPUT_PATH)',
            destination='/opt/ml/processing/input/data'
        ),
        ProcessingInput(
            input_name='model',
            source=f's3://(BUCKET)/(S3_PATH_TO_MODEL)',
            destination='/opt/ml/processing/input/model'
        )
    ],
    outputs=[
        ProcessingOutput(
            output_name='predictions',
            source='/opt/ml/processing/output',
            destination=f's3://(BUCKET)/(S3_OUTPUT_PATH)'
        )
    ]
)
```
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the TensorFlowProcessor class, see TensorFlow Estimator in the Amazon SageMaker Python SDK.

XGBoost Framework Processor

XGBoost is an open-source machine learning framework. The XGBoostProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with XGBoost scripts. When you use the XGBoostProcessor, you can leverage an Amazon-built Docker container with a managed XGBoost environment so that you don't need to bring your own container.

The following code example shows how you can use the XGBoostProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.xgboost import XGBoostProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the XGBoostProcessor
xgb = XGBoostProcessor(
    framework_version='1.2-2',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-XGB',
)

#Run the processing job
xgb.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        )
    ],
    outputs=[
        ProcessingOutput(
            output_name='processed_data',
            source='/opt/ml/processing/output/',
            destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'
        )
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you
specify for source_dir. To learn more about the XGBoostProcessor class, see XGBoost Estimator in the Amazon SageMaker Python SDK.

Use Your Own Processing Code

You can install libraries to run your scripts in your own processing container or, in a more advanced scenario, you can build your own processing container that satisfies the contract to run in Amazon SageMaker. For more information about containers in SageMaker, see Using Docker containers with SageMaker (p. 3149). For a formal specification that defines the contract for an Amazon SageMaker Processing container, see Build Your Own Processing Container (Advanced Scenario) (p. 1031).

Topics
- Run Scripts with Your Own Processing Container (p. 1030)
- Build Your Own Processing Container (Advanced Scenario) (p. 1031)

Run Scripts with Your Own Processing Container

You can use scikit-learn scripts to preprocess data and evaluate your models. To see how to run scikit-learn scripts to perform these tasks, see the scikit-learn Processing sample notebook. This notebook uses the ScriptProcessor class from the Amazon SageMaker Python SDK for Processing.

The following example shows a general workflow for using a ScriptProcessor class with your own processing container. The workflow shows how to create your own image, build your container, and use a ScriptProcessor class to run a Python preprocessing script with the container. The processing job processes your input data and saves the processed data in Amazon Simple Storage Service (Amazon S3).

Before using the following examples, you need to have your own input data and a Python script prepared to process your data. For an end-to-end, guided example of this process, refer back to the scikit-learn Processing sample notebook.

1. Create a Docker directory and add the Dockerfile used to create the processing container. Install pandas and scikit-learn into it. (You could also install your own dependencies with a similar RUN command.)

```
mkdir docker
%%writefile docker/Dockerfile
FROM python:3.7-slim-buster
RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3
ENV PYTHONUNBUFFERED=True
ENTRYPOINT ["python3"]
```

2. Build the container using the docker command, create an Amazon Elastic Container Registry (Amazon ECR) repository, and push the image to Amazon ECR.

```
import boto3
account_id = boto3.client('sts').get_caller_identity().get('Account')
region = boto3.Session().region_name
ecr_repository = 'sagemaker-processing-container'
tag = ':latest'
processing_repository_uri = '{}.dkr.ecr.{}.amazonaws.com/{}'.format(account_id, region, ecr_repository + tag)
```
# Create ECR repository and push docker image
`docker build -t $ecr_repository docker`
`aws ecr get-login-password --region {region} | docker login --username AWS --password-stdin {account_id}.dkr.ecr.{region}.amazonaws.com`
`aws ecr create-repository --repository-name $ecr_repository`
`docker tag {ecr_repository + tag} $processing_repository_uri`
`docker push $processing_repository_uri`

3. Set up the `ScriptProcessor` from the SageMaker Python SDK to run the script. Replace `image_uri` with the URI for the image you created, and replace `role_arn` with the ARN for an AWS Identity and Access Management role that has access to your target Amazon S3 bucket.

```python
from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput

script_processor = ScriptProcessor(command=['python3'],
                                   image_uri='image_uri',
                                   role='role_arn',
                                   instance_count=1,
                                   instance_type='ml.m5.xlarge')
```

4. Run the script. Replace `preprocessing.py` with the name of your own Python processing script, and replace `s3://path/to/my/input-data.csv` with the Amazon S3 path to your input data.

```python
script_processor.run(code='preprocessing.py',
                     inputs=[ProcessingInput(
                         source='s3://path/to/my/input-data.csv',
                         destination='/opt/ml/processing/input')],
                     outputs=[ProcessingOutput(source='/opt/ml/processing/output/train'),
                              ProcessingOutput(source='/opt/ml/processing/output/validation'),
                              ProcessingOutput(source='/opt/ml/processing/output/test')])
```

You can use the same procedure with any other library or system dependencies. You can also use existing Docker images. This includes images that you run on other platforms such as Kubernetes.

## Build Your Own Processing Container (Advanced Scenario)

You can provide Amazon SageMaker Processing with a Docker image that has your own code and dependencies to run your data processing, feature engineering, and model evaluation workloads.

The following example of a Dockerfile builds a container with the Python libraries scikit-learn and pandas, which you can run as a processing job.

```Dockerfile
FROM python:3.7-slim-buster
# Install scikit-learn and pandas
RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3
# Add a Python script and configure Docker to run it
ADD processing_script.py /
ENTRYPOINT ["python3", "/processing_script.py"]
```

Build and push this Docker image to an Amazon Elastic Container Registry (Amazon ECR) repository and ensure that your SageMaker IAM role can pull the image from Amazon ECR. Then you can run this image on Amazon SageMaker Processing.
How Amazon SageMaker Processing Runs Your Processing Container Image

Amazon SageMaker Processing runs your processing container image in a similar way as the following command, where AppSpecification.ImageUri is the Amazon ECR image URI that you specify in a CreateProcessingJob operation.

```
docker run [AppSpecification.ImageUri]
```

This command runs the ENTRYPOINT command configured in your Docker image.

You can also override the entrypoint command in the image or give command-line arguments to your entrypoint command using the AppSpecification.ContainerEntrypoint and AppSpecification.ContainerArguments parameters in your CreateProcessingJob request. Specifying these parameters configures Amazon SageMaker Processing to run the container similar to the way that the following command does.

```
```

For example, if you specify the ContainerEntrypoint to be `[python3, -v, /processing_script.py]` in your CreateProcessingJob request, and ContainerArguments to be `[data-format, csv]`, Amazon SageMaker Processing runs your container with the following command.

```
python3 -v /processing_script.py data-format csv
```

When building your processing container, consider the following details:

- Amazon SageMaker Processing decides whether the job completes or fails depending on the exit code of the command run. A processing job completes if all of the processing containers exit successfully with an exit code of 0, and fails if any of the containers exit with a non-zero exit code.
- Amazon SageMaker Processing lets you override the processing container's entrypoint and set command-line arguments just like you can with the Docker API. Docker images can also configure the entrypoint and command-line arguments using the ENTRYPOINT and CMD instructions. The way CreateProcessingJob's ContainerEntrypoint and ContainerArgument parameters configure a Docker image's entrypoint and arguments mirrors how Docker overrides the entrypoint and arguments through the Docker API:
  - If neither ContainerEntrypoint nor ContainerArguments are provided, Processing uses the default ENTRYPOINT or CMD in the image.
  - If ContainerEntrypoint is provided, but not ContainerArguments, Processing runs the image with the given entrypoint, and ignores the ENTRYPOINT and CMD in the image.
  - If ContainerArguments is provided, but not ContainerEntrypoint, Processing runs the image with the default ENTRYPOINT in the image and with the provided arguments.
  - If both ContainerEntrypoint and ContainerArguments are provided, Processing runs the image with the given entrypoint and arguments, and ignores the ENTRYPOINT and CMD in the image.
  - You must use the exec form of the ENTRYPOINT instruction in your Dockerfile (ENTRYPOINT ["executable", "param1", "param2"]) instead of the shell form (ENTRYPOINT command param1 param2). This lets your processing container receive SIGINT and SIGKILL signals, which Processing uses to stop processing jobs with the StopProcessingJob API.
  - `/opt/ml` and all its subdirectories are reserved by SageMaker. When building your Processing Docker image, don't place any data required by your processing container in these directories.
• If you plan to use GPU devices, make sure that your containers are nvidia-docker compatible. Include only the CUDA toolkit in containers. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

How Amazon SageMaker Processing Configures Input and Output For Your Processing Container

When you create a processing job using the CreateProcessingJob operation, you can specify multiple ProcessingInput and ProcessingOutput values.

You use the ProcessingInput parameter to specify an Amazon Simple Storage Service (Amazon S3) URI to download data from, and a path in your processing container to download the data to. The ProcessingOutput parameter configures a path in your processing container from which to upload data, and where in Amazon S3 to upload that data to. For both ProcessingInput and ProcessingOutput, the path in the processing container must begin with /opt/ml/processing/.

For example, you might create a processing job with one ProcessingInput parameter that downloads data from s3://your-data-bucket/path/to/input/csv/data into /opt/ml/processing/csv in your processing container, and a ProcessingOutput parameter that uploads data from /opt/ml/processing/processed_csv to s3://your-data-bucket/path/to/output/csv/data. Your processing job would read the input data, and write output data to /opt/ml/processing/processed_csv. Then it uploads the data written to this path to the specified Amazon S3 output location.

Important
Symbolic links (symlinks) cannot be used to upload output data to Amazon S3. Symlinks are not followed when uploading output data.

How Amazon SageMaker Processing Provides Logs and Metrics for Your Processing Container

When your processing container writes to stdout or stderr, Amazon SageMaker Processing saves the output from each processing container and puts it in Amazon CloudWatch logs. For information about logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3675).

Amazon SageMaker Processing also provides CloudWatch metrics for each instance running your processing container. For information about metrics, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3663).

How Amazon SageMaker Processing Configures Your Processing Container

Amazon SageMaker Processing provides configuration information to your processing container through environment variables and two JSON files—/opt/ml/config/processingjobconfig.json and /opt/ml/config/resourceconfig.json—at predefined locations in the container.

When a processing job starts, it uses the environment variables that you specified with the Environment map in the CreateProcessingJob request. The /opt/ml/config/processingjobconfig.json file contains information about the hostnames of your processing containers, and is also specified in the CreateProcessingJob request.

The following example shows the format of the /opt/ml/config/processingjobconfig.json file.

```
{
"ProcessingJobArn": "<processing_job_arn>",
"ProcessingJobName": "<processing_job_name>"
}
```
The `/opt/ml/config/resourceconfig.json` file contains information about the hostnames of your processing containers. Use the following hostnames when creating or running distributed processing code.

```json
{
    "current_host": "algo-1",
    "hosts": ["algo-1","algo-2","algo-3"]
}
```

Don't use the information about hostnames contained in `/etc/hostname` or `/etc/hosts` because it might be inaccurate.

Hostname information might not be immediately available to the processing container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.
Save and Access Metadata Information About Your Processing Job

To save metadata from the processing container after exiting it, containers can write UTF-8 encoded text to the /opt/ml/output/message file. After the processing job enters any terminal status ("Completed", "Stopped", or "Failed"), the "ExitMessage" field in DescribeProcessingJob contains the first 1 KB of this file. Access that initial part of file with a call to DescribeProcessingJob, which returns it through the ExitMessage parameter. For failed processing jobs, you can use this field to communicate information about why the processing container failed.

**Important**
Don't write sensitive data to the /opt/ml/output/message file.

If the data in this file isn't UTF-8 encoded, the job fails and returns a ClientError. If multiple containers exit with an ExitMessage, the content of the ExitMessage from each processing container is concatenated, then truncated to 1 KB.

Run Your Processing Container Using the SageMaker Python SDK

You can use the SageMaker Python SDK to run your own processing image by using the Processor class. The following example shows how to run your own processing container with one input from Amazon Simple Storage Service (Amazon S3) and one output to Amazon S3.

```python
from sagemaker.processing import Processor, ProcessingInput, ProcessingOutput

processor = Processor(image_uri='<your_ecc_image_uri>',
                       role=role,
                       instance_count=1,
                       instance_type="ml.m5.xlarge")

processor.run(inputs=[
    ProcessingInput(
        source='<s3_uri or local path>',
        destination='/opt/ml/processing/input_data')],
    outputs=[
        ProcessingOutput(
            source='/opt/ml/processing/processed_data',
            destination='<s3_uri>')])
```

Instead of building your processing code into your processing image, you can provide a ScriptProcessor with your image and the command that you want to run, along with the code that you want to run inside that container. For an example, see Run Scripts with Your Own Processing Container (p. 1030).

You can also use the scikit-learn image that Amazon SageMaker Processing provides through SKLearnProcessor to run scikit-learn scripts. For an example, see Data Processing with scikit-learn (p. 1024).
Create, Store, and Share Features with Amazon SageMaker Feature Store

The machine learning (ML) development process often begins with extracting data signals also known as features from data to train ML models. Amazon SageMaker Feature Store makes it easy for data scientists, machine learning engineers, and general practitioners to create, share, and manage features for machine learning (ML) development. Feature Store accelerates this process by reducing repetitive data processing and curation work required to convert raw data into features for training an ML algorithm.

Further, the processing logic for your data is authored only once, and features generated are used for both training and inference, reducing the training-serving skew. Feature Store is a centralized store for features and associated metadata so features can be easily discovered and reused. You can create an online or an offline store. The online store is used for low latency real-time inference use cases, and the offline store is used for training and batch inference.

The following diagram shows how you can use Amazon SageMaker Feature Store as part of your machine learning pipeline. First, you read in your raw data and process it. You can ingest data via streaming to the online and offline store, or in batches directly to the offline store. You first create a FeatureGroup and configure it to an online or offline store, or both. Then, you can ingest data into your FeatureGroup and store it in your store. A FeatureGroup is a group of features that is defined via a schema in Feature Store to describe a record.

Online store is primarily designed for supporting real-time predictions that need low millisecond latency reads and high throughput writes. Offline store is primarily intended for batch predictions and model training. Offline store is an append only store and can be used to store and access historical feature data. The offline store can help you store and serve features for exploration and model training. The online store retains only the latest feature data. Feature group definitions are immutable after they are created.

How Feature Store Works

In Feature Store, features are stored in a collection called a feature group. You can visualize a feature group as a table in which each column is a feature, with a unique identifier for each row. In principle, a
feature group is composed of features and values specific to each feature. A Record is a collection of values for features that correspond to a unique RecordIdentifier. Altogether, a FeatureGroup is a group of features defined in your FeatureStore to describe a Record.

You can use Feature Store in the following modes:

- **Online** – In online mode, features are read with low latency (milliseconds) reads and used for high throughput predictions. This mode requires a feature group to be stored in an online store.
- **Offline** – In offline mode, large streams of data are fed to an offline store, which can be used for training and batch inference. This mode requires a feature group to be stored in an offline store. The offline store uses your S3 bucket for storage and can also fetch data using Athena queries.
- **Online and Offline** – This includes both online and offline modes.

You can ingest data into feature groups in Feature Store in two ways: streaming or in batches. When you ingest data through streaming, a collection of records are pushed to Feature Store by calling a synchronous PutRecord API call. This API enables you to maintain the latest feature values in Feature Store and to push new feature values as soon an update is detected.

Alternatively, Feature Store can process and ingest data in batches. You can author features using Amazon SageMaker Data Wrangler, create feature groups in Feature Store and ingest features in batches using a SageMaker Processing job with a notebook exported from Data Wrangler. This mode allows for batch ingestion into the offline store. It also supports ingestion into the online store if the feature group is configured for both online and offline use.

### Create Feature Groups

To ingest features into Feature Store, you must first define the feature group and the feature definitions (feature name and data type) for all features that belong to the feature group. After they are created, feature groups are immutable. Feature group names are unique within an AWS Region and AWS account. When creating a feature group, you can also create the metadata for the feature group, such as a short description, storage configuration, features for identifying each record, and the event time, as well as tags to store information such as the author, data source, version, and more.

**Important**

FeatureGroup names or associated metadata such as description or tags should not contain any personal identifiable information (PII) or confidential information.

### Find, Discover, and Share Features

After you create a feature group in Feature Store, other authorized users of the feature store can share and discover it. Users can browse through a list of all feature groups in Feature Store or discover existing feature groups by searching by feature group name, description, record identifier name, creation date, and tags.

### Real-Time Inference for Features Stored in the Online Store

With Feature Store, you can enrich your features stored in the online store in real time with data from a streaming source (clean stream data from another application) and serve the features with low millisecond latency for real-time inference.
You can also perform joins across different FeatureGroups for real-time inference by querying two different FeatureGroups in the client application.

Offline Store for Model Training and Batch Inference

Feature Store provides offline storage for feature values in your S3 bucket. Your data is stored in your S3 bucket using a prefixing scheme based on event time. The offline store is an append-only store, enabling Feature Store to maintain a historical record of all feature values. Data is stored in the offline store in Parquet format for optimized storage and query access.

You can query, explore, and visualize features using Data Wrangler from Amazon SageMaker Studio. Feature Store supports combining data to produce, train, validate, and test data sets, and allows you to extract data at different points in time.

Feature Data Ingestion

Feature generation pipelines can be created to process large batches (1 million rows of data or more) or small batches, and to write feature data to the offline or online store. Streaming sources such as Amazon Managed Streaming for Apache Kafka or Amazon Kinesis can also be used as data sources from which features are extracted and directly fed to the online store for training, inference, or feature creation.

You can push records to Feature Store by calling the synchronous PutRecord API call. Since this is a synchronous API call, it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon as an update is detected. These are also called streaming features.

When feature data is ingested and updated, Feature Store stores historical data for all features in the offline store. For batch ingest, you can pull feature values from your S3 bucket or use Athena to query. You can also use Data Wrangler to process and engineer new features that can then be exported to a chosen S3 bucket to be accessed by Feature Store. For batch ingestion, you can configure a processing job to batch ingest your data into Feature Store, or you can pull feature values from your S3 bucket using Athena.

To remove a Record from your online store, use the DeleteRecord API call. This will also add the deleted record to the offline store.

Get started with Amazon SageMaker Feature Store

To get started using Amazon SageMaker Feature Store, review the basic concepts, learn how to ingest data for your feature store, and then walk through a Feature Store example. The following sections explain how to create feature groups, ingest data into the groups, and how to manage security for your feature store.

Topics
- Feature Store Concepts (p. 1039)
- Create Feature Groups (p. 1039)
- Adding required policies to your IAM role (p. 1051)
Feature Store Concepts

The following list of terms are key to understanding the capabilities of Amazon SageMaker Feature Store:

• **Feature store** – Serves as the single source of truth to store, retrieve, remove, track, share, discover, and control access to features.

• **Feature** – A measurable property or characteristic that encapsulates an observed phenomenon. In the Amazon SageMaker Feature Store API, a feature is an attribute of a record. You can define a name and type for every feature stored in Feature Store. Name uniquely identifies a feature within a feature group. Type identifies the datatype for the values of the feature. Supported datatypes are: String, Integral and Fractional.

• **Feature group** – A FeatureGroup is the main Feature Store resource that contains the metadata for all the data stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features, defined in the feature store, to describe records. A feature group’s definition is composed of a list of feature definitions, a record identifier name, and configurations for its online and offline store.

• **Feature definition** – A FeatureDefinition consists of a name and one of the following data types: an Integral, String or Fractional. A FeatureGroup contains a list of feature definitions.

• **Record identifier name** – Each feature group is defined with a record identifier name. The record identifier name must refer to one of the names of a feature defined in the feature group’s feature definitions.

• **Record** – A Record is a collection of values for features for a single record identifier value. A combination of record identifier name and a timestamp uniquely identify a record within a feature group.

• **Event time** – A point in time when a new event occurs that corresponds to the creation or update of a record in a feature group. All records in the feature group must have a corresponding EventTime. It can be used to track changes to a record over time. The online store contains the record corresponding to the last EventTime for a record identifier name, whereas the offline store contains all historic records. Event time values can either be of a fractional or string type. Fractional values must be UNIX timestamps. Strings must follow the ISO 8601 standard. The following formats are supported yyyy-MM-dd’T’HH:mm:ssZ and yyyy-MM-dd’T’HH:mm:ss.SSSZ where yyyy, MM, dd represent the year, month, and day respectively and HH, mm, ss, and if applicable, SSS represent the hour, month, second and milliseconds respectively. T and Z are constants.

• **Online Store** – The low latency, high availability cache for a feature group that enables real-time lookup of records. The online store allows quick access to the latest value for a Record via the GetRecord API. A feature group contains an OnlineStoreConfig controlling where the data is stored.

• **Offline store** – The OfflineStore, stores historical data in your S3 bucket. It is used when low (sub-second) latency reads are not needed. For example, when you want to store and serve features for exploration, model training, and batch inference. A feature group contains an OfflineStoreConfig controlling where the data is stored.

• **Ingestion** – The act of populating feature groups in the feature store.

Create Feature Groups

A FeatureGroup is the main Feature Store resource that contains the metadata for all the data stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features, defined in the feature store, to describe records. A feature group’s definition is composed of a list of feature definitions, a record identifier name, and configurations for its online and offline store. The example code in this
topic uses the SageMaker Python SDK. The underlying APIs are available for developers using other languages.

Prior to using a feature store you typically load your dataset, run transformations, and set up your features for ingestion. This process has a lot of variation and is highly dependent on your data. The example code in the following topics refer to the Introduction to Feature Store, Fraud Detection with Amazon SageMaker FeatureStore example notebooks respectively. We recommend that you run this notebook in Amazon SageMaker Studio because the code in this guide is conceptual and not fully functional if copied.

Feature Store supports the following data types: String, Fractional (IEEE 64-bit floating point value), and Integral (Int64 - 64 bit signed integral value). The default type is set to String. This means that, if a column in your dataset is not a float or long type, it defaults to String in your feature store.

You may use a schema to describe your data's columns and data types. You pass this schema into FeatureDefinitions, a required parameter for a FeatureGroup. You can use the SageMaker Python SDK, which has automatic data type detection when you use the load_feature_definitions function.

The default behavior when a new feature record is added with an already existing record ID is as follows. In the offline store, the new record will be appended. In the online store, if the event time of the new record is less than the existing event time than nothing will happen, however if the event time of the new record is greater than or equal to the existing event time, the record will be over written.

Topics
- Introduction to Feature Store (p. 1040)
- Fraud Detection with Feature Store (p. 1045)

Introduction to Feature Store

The example code in this topic refers to the Introduction to Amazon SageMaker Feature Store example notebook. It is recommended that you run this notebook in Amazon SageMaker Studio because the code in this guide is conceptual and not fully functional if copied.

Step 1: Set Up

To start using Feature Store, create SageMaker, boto3 and a Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**

The role that you use must have the following managed policies attached to it:

AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
global sys
import sagemaker
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker import get_execution_role
from sagemaker.session import Session
```
prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()  

**Step 2: Inspect your data**

In this notebook example we ingest synthetic data from the Github repository that hosts the full notebook.

```python
import pandas as pd

customer_data = pd.read_csv("data/feature_store_introduction_customer.csv")
orders_data = pd.read_csv("data/feature_store_introduction_orders.csv")

print(customer_data.head())
print(orders_data.head())
```

The following diagram illustrates the steps the data goes through before it is ingested into Feature Store. In this notebook, we illustrate the use-case where you have data from multiple sources and want to store them independently in a feature store. Our example considers data from a data warehouse (customer data), and data from a real-time streaming service (order data).
Create Feature Groups
Step 3: Create feature groups

We first start by creating feature group names for customer_data and orders_data. Following this, we create two Feature Groups, one for customer_data and another for orders_data.

```python
import time
from time import strftime, gmtime

customers_feature_group_name = 'customers-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
orders_feature_group_name = 'orders-feature-group-' + strftime('%d-%H-%M-%S', gmtime())

customers_feature_group = FeatureGroup(name=customers_feature_group_name, sagemaker_session=sagemaker_session)
orders_feature_group = FeatureGroup(name=orders_feature_group_name, sagemaker_session=sagemaker_session)
```

Instantiate a FeatureGroup object for customers_data and orders_data.

```python
from sagemaker.feature_store.feature_group import FeatureGroup

customers_feature_group = FeatureGroup(
   name=customers_feature_group_name, sagemaker_session=sagemaker_session)
orders_feature_group = FeatureGroup(
   name=orders_feature_group_name, sagemaker_session=sagemaker_session)
```

```python
import time
current_time_sec = int(round(time.time()))
record_identifier_feature_name = "customer_id"
```

Append EventTime feature to your data frame. This parameter is required, and time stamps each data point.

```python
customer_data["EventTime"] = pd.Series([current_time_sec]*len(customer_data), dtype="float64")
orders_data["EventTime"] = pd.Series([current_time_sec]*len(orders_data), dtype="float64")
```

Load feature definitions to your feature group.

```python
customers_feature_group.load_feature_definitions(data_frame=customer_data)
orders_feature_group.load_feature_definitions(data_frame=orders_data)
```

Below we call create to create two feature groups, customers_feature_group and orders_feature_group respectively.

```python
customers_feature_group.create(
   s3_uri=f"s3://{s3_bucket_name}/{prefix}",
   record_identifier_name=record_identifier_feature_name,
   event_time_feature_name="EventTime",
   role_arn=role,
   enable_online_store=True
)

orders_feature_group.create(
   s3_uri=f"s3://{s3_bucket_name}/{prefix}",
   record_identifier_name=record_identifier_feature_name,
   event_time_feature_name="EventTime",
   role_arn=role,
   enable_online_store=True
)
```
To confirm that your FeatureGroup has been created we use DescribeFeatureGroup and ListFeatureGroups APIs to display the created feature group.

```python
customers_feature_group.describe()
orders_feature_group.describe()
sagemaker_session.boto_session.client('sagemaker', region_name=region).list_feature_groups() # We use the boto client to list FeatureGroups
```

**Step 4: Ingest data into a feature group**

After the FeatureGroups have been created, we can put data into the FeatureGroups. If you are using the SageMaker Python SDK, use the `ingest` API call. If you are using boto3 then use the `PutRecord` API. It will take less than 1 minute to ingest data both of these FeatureGroups. This example uses the SageMaker Python SDK, and so it uses the `ingest` API call.

```python
def check_feature_group_status(feature_group):
    status = feature_group.describe().get("FeatureGroupStatus")
    while status == "Creating":
        print("Waiting for Feature Group to be Created")
        time.sleep(5)
        status = feature_group.describe().get("FeatureGroupStatus")
        print(f"FeatureGroup {feature_group.name} successfully created.")
check_feature_group_status(customers_feature_group)
check_feature_group_status(orders_feature_group)

customers_feature_group.ingest(  
data_frame=customer_data, max_workers=3, wait=True
)

orders_feature_group.ingest(  
data_frame=orders_data, max_workers=3, wait=True
)
```

Using an arbitrary customer record id, 573291 we use get_record to check that the data has been ingested into the feature group.

```python
customer_id = 573291
sample_record = sagemaker_session.boto_session.client('sagemaker-featurestore-runtime', region_name=region).get_record(FeatureGroupName=customers_feature_group_name, RecordIdentifierValueAsString=str(customer_id))
print(sample_record)
```

Below demonstrates how to use the `batch_get_record` to get a batch of records.

```python
all_records = sagemaker_session.boto_session.client(  
    "sagemaker-featurestore-runtime", region_name=region
).batch_get_record(
    Identifiers=[
        
        "FeatureGroupName": customers_feature_group_name,
        "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
    ]
)
Step 5: Clean up

Here we remove the Feature Groups we created.

```python
customers_feature_group.delete()
orders_feature_group.delete()
```

Step 6: Next steps

In this example notebook, you learned how to quickly get started with Feature Store, create feature groups, and ingest data into them.

For an advanced example on how to use Feature Store for a Fraud Detection use-case, see Fraud Detection with Feature Store.

Step 7: Programmers note

In this notebook we used a variety of different API calls. Most of them are accessible through the Python SDK, however some only exist within boto3. You can invoke the Python SDK API calls directly on your Feature Store objects, whereas to invoke API calls that exist within boto3, you must first access a boto client through your boto and sagemaker sessions: e.g., `sagemaker_session.boto_session.client()`.

Below we list API calls used in this notebook that exist within the Python SDK and ones that exist in boto3 for your reference.

**Python SDK API Calls**

- `describe()`
- `ingest()`
- `delete()`
- `create()`
- `load_feature_definitions()`

**Boto3 API Calls**

- `list_feature_groups()`
- `get_record()`

Fraud Detection with Feature Store

Step 1: Set Up Feature Store

To start using Feature Store, create a SageMaker session, boto3 session, and a Feature Store session. Also, set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.
Note
The role that you use must have the following managed policies attached to it:
AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess.

```python
import boto3
import sagemaker
from sagemaker.session import Session

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
boto_session = boto3.Session(region_name=region)
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
offline_feature_store_bucket = 's3://{}/{}'.format(default_bucket, prefix)

sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
featurestore_runtime = boto_session.client(service_name='sagemaker-featurestore-runtime', region_name=region)

feature_store_session = Session(
boto_session=boto_session,
sagemaker_client=sagemaker_client,
sagemaker_featurestore_runtime_client=featurestore_runtime
)
```

**Step 2: Load Datasets and Partition Data into Feature Groups**

Load your data into data frames for each of your features. You use these data frames after you set up the feature group. In the fraud detection example, you can see these steps in the following code.

```python
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import io

fraud_detection_bucket_name = 'sagemaker-featurestore-fraud-detection'
identity_file_key = 'sampled_identity.csv'
transaction_file_key = 'sampled_transactions.csv'

identity_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
Key=identity_file_key)
transaction_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
Key=transaction_file_key)

identity_data = pd.read_csv(io.BytesIO(identity_data_object['Body'].read()))
transaction_data = pd.read_csv(io.BytesIO(transaction_data_object['Body'].read()))

identity_data = identity_data.round(5)
transaction_data = transaction_data.round(5)

identity_data = identity_data.fillna(0)
transaction_data = transaction_data.fillna(0)

# Feature transformations for this dataset are applied before ingestion into FeatureStore.
# One hot encode card4, card6
encoded_card_bank = pd.get_dummies(transaction_data['card4'], prefix = 'card_bank')
encoded_card_type = pd.get_dummies(transaction_data['card6'], prefix = 'card_type')

transformed_transaction_data = pd.concat([transaction_data, encoded_card_type, encoded_card_bank], axis=1)
```
transformed_transaction_data =
transformed_transaction_data.rename(columns={"card_bank_american express": "card_bank_american_express"})

Step 3: Set Up Feature Groups

When you set up your feature groups, you need to customize the feature names with a unique name and set up each feature group with the FeatureGroup class.

```python
from sagemaker.feature_store.feature_group import FeatureGroup
feature_group_name = "some string for a name"
feature_group = FeatureGroup(name=feature_group_name,
sagemaker_session=feature_store_session)
```

For example, in the fraud detection example, the two feature groups are `identity` and `transaction`.
In the following code you can see how the names are customized with a timestamp, and then each group is set up by passing in the name and the session.

```python
import time
from time import gmtime, strftime, sleep
from sagemaker.feature_store.feature_group import FeatureGroup

identity_feature_group_name = 'identity-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
transaction_feature_group_name = 'transaction-feature-group-' + strftime('%d-%H-%M-%S', gmtime())

identity_feature_group = FeatureGroup(name=identity_feature_group_name,
sagemaker_session=feature_store_session)
transaction_feature_group = FeatureGroup(name=transaction_feature_group_name,
sagemaker_session=feature_store_session)
```

Step 4: Set Up Record Identifier and Event Time Features

In this step, you specify a record identifier name and an event time feature name. This name maps to the column of the corresponding features in your data. For example, in the fraud detection example, the column of interest is `TransactionID`. `EventTime` can be appended to your data when no timestamp is available. In the following code, you can see how these variables are set, and then `EventTime` is appended to both feature's data.

```python
record_identifier_name = "TransactionID"
event_time_feature_name = "EventTime"
current_time_sec = int(round(time.time()))
identity_data[event_time_feature_name] = pd.Series([current_time_sec]*len(identity_data),
dtype="float64")
transformed_transaction_data[event_time_feature_name] =
pd.Series([current_time_sec]*len(transaction_data), dtype="float64")
```

Step 5: Load Feature Definitions

You can now load the feature definitions by passing a data frame containing the feature data. In the following code for the fraud detection example, the identity feature and transaction feature are each loaded by using `load_feature_definitions`, and this function automatically detects the data type of each column of data. For developers using a schema rather than automatic detection, see the Export Feature Groups from Data Wrangler example for code that shows how to load the schema, map it, and add it as a FeatureDefinition that you can use to create the FeatureGroup. This example also covers a boto3 implementation, which you can use instead of the SageMaker Python SDK.

```python
identity_feature_group.load_feature_definitions(data_frame=identity_data); # output is suppressed
```
Step 6: Create a Feature Group

In this step, you use the `create` function to create the feature group. The following code shows all of the available parameters. The online store is not created by default, so you must set this as `True` if you want to enable it. The `s3_uri` is the S3 bucket location of your offline store.

```python
# create a FeatureGroup
feature_group.create(  
    description = "Some info about the feature group",  
    feature_group_name = feature_group_name,  
    record_identifier_name = record_identifier_name,  
    event_time_feature_name = event_time_feature_name,  
    feature_definitions = feature_definitions,  
    role_arn = role,  
    s3_uri = offline_feature_store_bucket,  
    enable_online_store = True,  
    online_store_kms_key_id = None,  
    offline_store_kms_key_id = None,  
    disable_glue_table_creation = False,  
    data_catalog_config = None,  
    tags = ["tag1","tag2"])
```

The following code from the fraud detection example shows a minimal `create` call for each of the two features groups being created.

```python
identity_feature_group.create(  
    s3_uri=offline_feature_store_bucket,  
    record_identifier_name=record_identifier_name,  
    event_time_feature_name=event_time_feature_name,  
    role_arn=role,  
    enable_online_store=True  
)

transaction_feature_group.create(  
    s3_uri=offline_feature_store_bucket,  
    record_identifier_name=record_identifier_name,  
    event_time_feature_name=event_time_feature_name,  
    role_arn=role,  
    enable_online_store=True  
)
```

When you create a feature group, it takes time to load the data, and you need to wait until the feature group is created before you can use it. You can check status using the following method.

```python
status = feature_group.describe().get("FeatureGroupStatus")
```

While the feature group is being created, you receive `Creating` as a response. When this step has finished successfully, the response is `Created`. Other possible statuses are `CreateFailed`, `Deleting`, or `DeleteFailed`.

Step 7: Work with Feature Groups

Now that you've set up your feature group, you can perform any of the following tasks:
• Describe a Feature Group (p. 1049)
• List Feature Groups (p. 1049)
• Put Records in a Feature Group (p. 1049)
• Get Records from a Feature Group (p. 1049)
• Generate Hive DDL Commands (p. 1050)
• Build a Training Dataset (p. 1050)
• Write and Execute an Athena Query (p. 1050)
• Delete a Feature Group (p. 1050)

Describe a Feature Group

You can retrieve information about your feature group with the `describe` function.

```python
feature_group.describe()
```

List Feature Groups

You can list all of your feature groups with the `list_feature_groups` function.

```python
sagemaker_client.list_feature_groups()
```

Put Records in a Feature Group

You can use the `ingest` function to load your feature data. You pass in a data frame of feature data, set the number of workers, and choose to wait for it to return or not. The following example demonstrates using the `ingest` function.

```python
feature_group.ingest(
    data_frame=feature_data, max_workers=3, wait=True
)
```

For each feature group you have, run the `ingest` function on the feature data you want to load.

Get Records from a Feature Group

You can use the `get_record` function to retrieve the data for a specific feature by its record identifier. The following example uses an example identifier to retrieve the record.

```python
record_identifier_value = str(2990130)
featurestore_runtime.get_record(FeatureGroupName=transaction_feature_group_name,
    RecordIdentifierValueAsString=record_identifier_value)
```

An example response from the fraud detection example:

```python
...
'Record': [{'FeatureName': 'TransactionID', 'ValueAsString': '2990130'},
    {'FeatureName': 'isFraud', 'ValueAsString': '0'},
    {'FeatureName': 'TransactionDT', 'ValueAsString': '152647'},
    {'FeatureName': 'TransactionAmt', 'ValueAsString': '75.0'},
    {'FeatureName': 'ProductCD', 'ValueAsString': 'H'},
    {'FeatureName': 'card1', 'ValueAsString': '4577'},
    ...
...
Generate Hive DDL Commands

The SageMaker Python SDK's FeatureStore class also provides the functionality to generate Hive DDL commands. The schema of the table is generated based on the feature definitions. Columns are named after feature name and data-type are inferred based on feature type.

```python
print(feature_group.as_hive_ddl())
```

Example output:

```
CREATE EXTERNAL TABLE IF NOT EXISTS sagemaker_featurestore.identity-feature-group-27-19-33-00 (
    TransactionID INT
    id_01 FLOAT
    id_02 FLOAT
    id_03 FLOAT
    id_04 FLOAT
    ...
```

Build a Training Dataset

Feature Store automatically builds an AWS Glue data catalog when you create feature groups and you can turn this off if you want. The following describes how to create a single training dataset with feature values from both identity and transaction feature groups created earlier in this topic. Also, the following describes how to run an Amazon Athena query to join data stored in the offline store from both identity and transaction feature groups.

To start, create an Athena query using `athena_query()` for both identity and transaction feature groups. The `table_name` is the AWS Glue table that is autogenerated by Feature Store.

```python
identity_query = identity_feature_group.athena_query()
transaction_query = transaction_feature_group.athena_query()

identity_table = identity_query.table_name
transaction_table = transaction_query.table_name
```

Write and Execute an Athena Query

You write your query using SQL on these feature groups, and then execute the query with the `.run()` command and specify your S3 bucket location for the data set to be saved there.

```python
# Athena query
query_string = 'SELECT * FROM "' + transaction_table + '" LEFT JOIN "' + identity_table + '" ON ' + transaction_table + '.transactionid = ' + identity_table + '.transactionid'

# run Athena query. The output is loaded to a Pandas dataframe.
dataset = pd.DataFrame()
identity_query.run(query_string=query_string,
                  output_location='s3://'+default_s3_bucket_name+'/query_results/)
identity_query.wait()
dataset = identity_query.as_dataframe()
```

From here you can train a model using this data set and then perform inference.

Delete a Feature Group

You can delete a feature group with the `delete` function.
Adding required policies to your IAM role

To get started with Amazon SageMaker Feature Store you must add the required policy to your role, AmazonSageMakerFeatureStoreAccess. Below is a walkthrough on how to add it to your role through the console.

Step 1: Access AWS Management Console

Sign in to the AWS Management Console and open the IAM console.

Step 2: Choose Roles

In the navigation pane on the left, choose Roles. The navigation pane is illustrated below with Roles outlined in red.
Identity and Access Management (IAM)

Dashboard

- Access management
  - Groups
  - Users
    - Roles
  - Policies
    - Identity providers
    - Account settings

- Access reports
  - Access analyzer
    - Archive rules
    - Analyzers
    - Settings
  - Credential report
  - Organization activity
  - Service control policies (SCPs)
Step 3: Find your role

In the search bar, enter the role you are using for Amazon SageMaker Feature Store. Below illustrates with a red arrow where you enter your role.

Roles

What are IAM roles?

IAM roles are a secure way to grant permissions to entities that you trust. Examples of entities include:

- IAM user in another account
- Application code running on an EC2 instance that needs to perform actions on AWS resources
- An AWS service that needs to act on resources in your account to provide its features
- Users from a corporate directory who use identity federation with SAML

IAM roles issue keys that are valid for short durations, making them a more secure way to grant access.

Additional resources:

- IAM Roles FAQ
- IAM Roles Documentation
- Tutorial: Setting Up Cross Account Access
- Common Scenarios for Roles

Step 4: Attach policy

After you find your role, choose Attach policies. Below illustrates this with a red arrow.
Next you will enter in the search bar the required policy. Below illustrates the search bar you will use to enter the policy.

The policy you will need to add is AmazonSageMakerFeatureStoreAccess. After you enter the policy, select the check box and then choose Attach policy. Below illustrates the this step.
After you have attached both policies to your role, the policy should appear under your IAM role. The following illustrates how it appears under your IAM role.
Use Amazon SageMaker Feature Store with Amazon SageMaker Studio

You can use Studio to create and view details about your feature groups.

**Topics**
- Create a Feature Group in Studio (p. 1056)
- View Feature Group Details in Studio (p. 1061)

**Create a Feature Group in Studio**

The create feature group process in Studio has four steps: enter details, definitions, required features, and tags.

Consider the following options before you start:

- If you plan to only use an online store, you just need the schema for your features. This is your columns and each column’s data type.
- If you plan to use an offline store, you need an S3 bucket URI and a Role ARN.
- If you plan to use encryption, you need a KMS key. You can use the same one for both the online store and your offline store, or have a unique key for each.
- If you plan to use AWS Glue integration, be prepared to provide a data catalog name, database name, and table name.

**To create a feature group in Studio**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. In the file and resource browser, choose Feature Store.
4. The Feature Store tab lists your feature groups.
5. The **Feature Store** tab, choose **Create Feature Group**.

6. Enter the feature group details.

7. (Optional) If you’re using Glue, enter the data catalog details.

8. Enter feature definitions. You have two options for providing a schema for your features: a JSON editor, or a Table editor.
9. The table editor accepts a column name and a data type. In a minimal example, you will need at least two for the next step: one for a record identifier and one for a time event feature. You can have up to 2,500 feature definitions.

10. Set a record identifier and a time feature to use for this feature group.
11. (Optional) Enter tags as key value pairs.

12. Choose **Create feature group**.
13. In the **Actions** column, choose **Open feature store**.

14. When the feature group is finished being created, it appears in your feature groups list. Choose the refresh button to refresh the list.

### View Feature Group Details in Studio

You can view details about your feature groups, and get sample queries to run against your data sources to gather the data for features you have defined.

**To view feature group details in Studio**

1. Double-click or right-click a feature group from your list, and then choose **Open feature group detail**.

2. In the details view, you can review your feature group summary, feature definitions, feature group tags, and sample query.
3. On the **Feature definitions** tab, you can search for features by name.

4. On the **Feature group tags** tab, you can add and remove tags.
5. On the Sample query tab, you can see a variety of sample queries: interactive exploration, time travel, remove tombstone, and remove duplicates.

Data Sources and Ingestion

There are multiple ways to bring your data into Amazon SageMaker Feature Store. Feature Store offers a single API call for data ingestion called PutRecord that enables you to ingest data in batches or from streaming sources. You can use Amazon SageMaker Data Wrangler to engineer features and then ingest your features into your Feature Store. You can also use Amazon EMR for batch data ingestion through a Spark connector.

Topics
- Stream Ingestion (p. 1063)
- Data Wrangler with Feature Store (p. 1064)
- Batch Ingestion Spark Connector Setup (p. 1066)

Stream Ingestion

You can use streaming sources such as Kafka or Kinesis as a data source where features are extracted from there and directly fed to the online feature store for training, inference or feature creation. Records can be pushed into the feature store by calling the synchronous PutRecord API call. Since this is a
synchronous API call it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon an update is detected. These are also called *streaming* features.

**Data Wrangler with Feature Store**

Data Wrangler is a feature of Studio that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. Data Wrangler enables you to engineer your features and ingest them into a feature store.

In Studio, after interacting with Data Wrangler, choose the **Export** tab, choose **Export Step**, and the choose **Feature Store**, as shown in the following screenshot. This exports a Jupyter notebook that has all the source code in it to create a Feature Store feature group that adds your features from Data Wrangler to an offline or online feature store.
After the feature group has been created, you can also select and join data across multiple feature groups to create new engineered features in Data Wrangler and then export your data set to an S3 bucket.
For more information on how to export to Feature Store, see Export to SageMaker Feature Store.

Batch Ingestion Spark Connector Setup

Introduction

Amazon SageMaker Feature Store supports batch data ingestion with Spark, using your existing ETL pipeline, or a pipeline on Amazon EMR. You can also use this functionality from a Amazon SageMaker Notebook Instance.

Methods for installing and implementing batch data ingestion are provided for Python and Scala. Python developers can use the sagemaker-feature-store-pyspark Python library for local development, installation on Amazon EMR, or run it from Jupyter notebooks. Scala developers can use the Feature Store Spark connector available in Maven.

You can use the Spark connector to ingest data in the following ways:

1. Ingest by default – Ingest your dataframe into the online store. When you use the connector to update the online store, The Spark connector uses the PutRecord operation to make the update. Within 15 minutes, Feature Store syncs the data between the online store and the offline store. The online store contains the latest value for the record. For more information about how the online and offline stores work, see Feature Store Concepts (p. 1039).

2. Offline store direct ingestion – Use the Spark connector to ingest your dataframe directly into the offline store. Ingesting the dataframe directly into the offline store doesn't update the online store. For information about using the different ingestion methods, see Example Implementations (p. 1067).

Installation

Scala Users

Requirements

- Spark >= 3.0.0
- Scala >= 2.12.x
- Amazon EMR > 6.x (only if you are using Amazon EMR)

Declare the Dependency in POM.xml

The Feature Store Spark connector is available in the Maven central repository. Declare the following in your project's POM.xml:

```xml
<dependency>
    <groupId>software.amazon.sagemaker.featurestore</groupId>
    <artifactId>sagemaker-feature-store-spark-sdk_2.12</artifactId>
    <version>1.0.0</version>
</dependency>
```

Python Users

Requirements

- PySpark >= 3.0.0
- Python >= 3.8
- Amazon EMR > 6.x (only if you are using Amazon EMR)
A library is available for Python developers, `sagemaker-feature-store-pyspark`. The following sections describe how to install the library locally, on Amazon EMR, and on Amazon SageMaker.

**Local Installation**

To find more info about the installation, enable verbose mode by appending `--verbose` to the following installation command.

```bash
pip3 install sagemaker-feature-store-pyspark --no-binary :all:
```

**Installation on Amazon EMR**

Create the cluster with the latest version of container (version 6) and enable SSH for troubleshooting.

You can either create a custom step to start the library installation or SSH to your cluster to install the library directly in console.

```bash
sudo -E pip3 install sagemaker-feature-store-pyspark --no-binary :all: --verbose
```

**Installation on a Amazon SageMaker Notebook Instance**

Amazon SageMaker Notebook Instances are using older version of Spark that is not compatible with Feature Store Spark Connector. You must upgrade Spark, then install `sagemaker-feature-store-pyspark`.

Inside your notebook, add and run a cell like the following:

```python
import os
original_spark_version = "2.4.0"
# Install a newer version of Spark which is compatible with spark library
!pip3 install pyspark==3.1.1
!pip3 install sagemaker-feature-store-pyspark --no-binary :all:
```

**Example Implementations**

**Scala**

`FeatureStoreBatchIngestion.scala`

```scala
import software.amazon.sagemaker.featurestore.sparksdk.FeatureStoreManager
import org.apache.spark.sql.types.{StringType, StructField, StructType}
import org.apache.spark.sql.{Row, SparkSession}

object ProgramOffline {
  def main(args: Array[String]): Unit = {
    val spark = SparkSession.builder().getOrCreate()
    // Add your code here
  }
}
```
// Construct test DataFrame
val data = List(
    Row("1", "2021-07-01T12:20:12Z"),
    Row("2", "2021-07-02T12:20:13Z"),
    Row("3", "2021-07-03T12:20:14Z")
)

val schema = StructType(
    List(StructField("RecordIdentifier", StringType), StructField("EventTime", StringType))
)

val df = spark.createDataFrame(spark.sparkContext.parallelize(data), schema)
val featureStoreManager = new FeatureStoreManager()

// Load the feature definitions from input schema. The feature definitions can be used to create a feature group
val featureDefinitions = featureStoreManager.loadFeatureDefinitionsFromSchema(df)

// Ingest by default
featureStoreManager.ingestData(df, featureGroupArn)

// Offline store direct ingestion, flip the flag of direct_offline_store
featureStoreManager.ingestData(df, featureGroupArn, directOfflineStore = true)

---

Python

FeatureStoreBatchIngestion.py

```python
from pyspark.sql import SparkSession
from feature_store_pyspark.FeatureStoreManager import FeatureStoreManager
import feature_store_pyspark
extra_jars = ",".join(feature_store_pyspark.classpath_jars())
spark = SparkSession.builder \
    .config("spark.jars", extra_jars) \
    .getOrCreate()

# Construct test DataFrame
columns = ["RecordIdentifier", "EventTime"]
data = [(["1", "2021-03-02T12:20:12Z"], ["2", "2021-03-02T12:20:13Z"],
        ["3", "2021-03-02T12:20:14Z")]

df = spark.createDataFrame(data).toDF(*columns)
feature_store_manager= FeatureStoreManager()

# Load the feature definitions from input schema. The feature definitions can be used to create a feature group
feature_definitions = feature_store_manager.load_feature_definitions_from_schema(df)

feature_group_arn = "arn:aws:sagemaker:us-west-2:<your-account-id>:feature-group/<your-feature-group-name>"

# Ingest by default
feature_store_manager.ingest_data(input_data_frame=df, feature_group_arn=feature_group_arn)

# Offline store direct ingestion, flip the flag of direct_offline_store
```
Add Features to a Feature Group

You can use the Amazon SageMaker Feature Store API or Amazon SageMaker Studio to add features to your feature group. You can think of a feature group as a data table and a feature as a column in the table. When you add a feature to the feature group, you're effectively adding a column to the table.

The features that you've added don't have any data. You can add new records to the feature group or overwrite them. You can think of a record as a row in the data table.

The following sections provide an overview of using the API and Studio to add features to a feature group. With the API, you can also add or overwrite records after you've updated the feature group.

Studio

To search through your features, do the following.

1. In Amazon SageMaker Studio, navigate to SageMaker resources.
2. On the navigation pane, choose Feature Store.
3. Choose Feature group catalog.
4. Under Feature group name, choose a feature group.
5. From the dropdown list that says Actions, choose Add feature definitions.
6. Specify a name for the Feature name field.
7. For Type, select the feature's data type.
8. Choose **Add new feature definition**.
9. (Optional) Choose **Add new feature definition** to add feature definitions.
10. Specify information for the additional features.
11. Choose **Save changes**.
12. Choose **Confirm**.

**API**

Use the **UpdateFeatureGroup** operation to add features to a feature group.

You can use the **DescribeFeatureGroup** operation to see if you've added the features successfully.

To add or overwrite records, use the **PutRecord** operation.

To see the updates that you've made to a record, use the **GetRecord** operation. To see the updates that you've made to multiple records, use the **BatchGetRecord** operation. It can take up to five minutes for the updates that you've made to appear.

You can use the example code in the following section to walk through adding features and records using the AWS SDK for Python (Boto3).

**Example Code**

The example code walks you through the following process:

1. Adding features to the feature group
2. Verifying that you've added them successfully
3. Adding a record to the feature group
4. Verifying that you've added it successfully

**Step 1: Add Features To a Feature Group**

The following code uses the **UpdateFeatureGroup** operation to add new features to the feature group. It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see **Introduction to Feature Store** (p. 1040).

```python
import boto3

sagemaker_client = boto3.client("sagemaker")

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    FeatureAdditions=[
        {"FeatureName": "new-feature-1", "FeatureType": "Integral"},
        {"FeatureName": "new-feature-2", "FeatureType": "Fractional"},
        {"FeatureName": "new-feature-3", "FeatureType": "String"}
    ]
)
```

The following code uses the **DescribeFeatureGroup** operation to check the status of the update. If the **LastUpdateStatus** field is **Successful**, you've added the features successfully.
Step 2: Add a New Record To The Feature Group

The following code uses the `PutRecord` operation to add records to the feature group that you've created.

```python
record_identifier_value = 'new_record'
sagemaker_featurestore_runtime_client = boto3.client("sagemaker-featurestore-runtime")
sagemaker_runtime_client.put_record(
    FeatureGroupName=feature_group_name,
    Record=[
        {
            'FeatureName': "record-identifier-feature-name",
            'ValueAsString': record_identifier_value
        },
        {
            'FeatureName': "event-time-feature",
            'ValueAsString': "timestamp-that-feature-store-returns"
        },
        {
            'FeatureName': "new-feature-1",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-2",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-3",
            'ValueAsString': "value-as-string"
        }
    ]
)
```

Use the `GetRecord` operation to see which records in your feature group don't have data for the features that you've added. You can use the `PutRecord` operation to overwrite the records that don't have data for the features that you've added.

Find Features in Your Feature Groups

With Amazon SageMaker Feature Store, you can search for the features that you've created in your feature groups. You can search through all of your features without needing to first select a feature group. You can use the search functionality to quickly find the features that are relevant to your use case.

To search for features in your feature groups, the feature groups must be within the same AWS account and Region.

**Important**
Use the latest version of Amazon SageMaker Studio to make sure that you're using the most recent version of the search functionality. For information on updating Studio, see Shut down and Update SageMaker Studio (p. 179).
If you’re on a team, you might have teammates that are looking for features to use in their models, they can search through all the features in all of the feature groups.

You can add searchable parameters and descriptions to make your features more discoverable. For more information, see Adding Searchable Metadata to Your Features (p. 1074).

The following are the types of metadata that you can use in your search.

You can search for features using either Amazon SageMaker Studio or the Search operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in Studio.

<table>
<thead>
<tr>
<th>Searchable metadata</th>
<th>API field name</th>
<th>Searchable in Studio?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feature name</td>
<td>FeatureName</td>
<td>Yes</td>
</tr>
<tr>
<td>Feature group name</td>
<td>FeatureGroupName</td>
<td>No</td>
</tr>
<tr>
<td>Description</td>
<td>Description</td>
<td>Yes</td>
</tr>
<tr>
<td>Parameters</td>
<td>Parameters_key</td>
<td>Yes</td>
</tr>
<tr>
<td>All Parameters</td>
<td>AllParameters</td>
<td>Yes</td>
</tr>
<tr>
<td>Feature type</td>
<td>FeatureType</td>
<td>No</td>
</tr>
<tr>
<td>Creation time</td>
<td>CreationTime</td>
<td>Yes</td>
</tr>
<tr>
<td>Last modified time</td>
<td>LastModifiedTime</td>
<td>No</td>
</tr>
</tbody>
</table>

The following sections show you how to search for your features.

**Studio**

Use the following procedure to search through all the features that you’ve created.

To search through your features, do the following.

1. In Amazon SageMaker Studio, navigate to SageMaker resources.
2. On the navigation pane, choose Feature Store.
3. Choose Feature Catalog.
4. Specify a text query with at least three characters to search for your features.
5. (Optional) Use advanced filters after you’ve specified a query. You can use filters to specify parameters or date ranges in your search results. If you’re searching for a parameter, specify both its key and value. To find your features more easily, you can do the following:

   • Specify time ranges.
   • Deselect columns that you don’t want to query.

**SDK for Python (Boto3)**

The example uses the Search operation in the AWS SDK for Python (Boto3) to run the search query. For information about the other languages to submit a query, see See Also in the Amazon SageMaker API Reference.

The following code shows different example search queries using the API.
# Return all features in your feature groups
```python
sagemaker_client.search(
    Resource="FeatureMetadata",
)
```

# Search for all features that belong to a feature group that contain the "ver" substring
```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Contains', 'Value': 'ver'},
        ],
    },
)
```

# Search for all features that belong to a feature group that have the EXACT name "airport"
```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Equals', 'Value': 'airport'},
        ],
    },
)
```

# Search for all features that belong to a feature group that contains the name "ver" AND have a name that contains "wha" AND have a parameter (key or value) that contains "hea"
```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Contains', 'Value': 'ver'},
            {'Name': 'FeatureName', 'Operator': 'Contains', 'Value': 'wha'},
            {'Name': 'AllParameters', 'Operator': 'Contains', 'Value': 'hea'},
        ],
    },
)
```

# Search for all features that belong to a feature group with substring "ver" in its name OR features that have a name that contain "wha" OR features that have a parameter (key or value) that contains "hea"
```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Contains', 'Value': 'ver'},
            {'Name': 'FeatureName', 'Operator': 'Contains', 'Value': 'wha'},
            {'Name': 'AllParameters', 'Operator': 'Contains', 'Value': 'hea'},
        ],
    },
)
```
Adding Searchable Metadata to Your Features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:

```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Operator": "Contains",
                "Value": "ver"
            },
            {
                "Name": "FeatureName",
                "Operator": "Contains",
                "Value": "wha"
            },
            {
                "Name": "AllParameters",
                "Operator": "Contains",
                "Value": "hea"
            }
        ],
        "Operator": "Or" # note that this is explicitly set to "Or"- the default is "And"
    }
)
```

# Search for all features that belong to a feature group with substring "ver" in its name
OR features that have a name that contain "wha"
OR parameters with the value 'Sage' for the 'org' key

```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Operator": "Contains",
                "Value": "ver"
            },
            {
                "Name": "FeatureName",
                "Operator": "Contains",
                "Value": "wha"
            },
            {
                "Name": "Parameters.org",
                "Operator": "Contains",
                "Value": "Sage"
            }
        ],
        "Operator": "Or" # note that this is explicitly set to "Or"- the default is "And"
    }
)
```
• Description – A searchable description of the feature.
• Parameters – Searchable key-value pairs.

The description can have up to 255 characters.

For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either Amazon SageMaker Studio or the UpdateFeatureMetadata operation.

Use the following procedure to update the metadata using Amazon SageMaker Studio.

To update the feature metadata with Studio, do the following.

1. In Amazon SageMaker Studio, navigate to SageMaker resources.
2. On the navigation pane, choose Feature Store.
3. Choose Feature catalog.
4. In the Feature name column, choose a feature name.
5. Choose Edit metadata.
6. In the Description field, add or update the description.
7. In the Parameters field under Parameters, specify a key-value pair for the parameter.
8. (Optional) Choose Add new parameter to add another parameter.
9. Choose Save changes.
10. Choose Confirm.

The following describes how you can use the UpdateFeatureMetadata operation for different scenarios.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

• FeatureGroupName
• Feature
• Parameters

The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="/feature_group_name",
    FeatureName="/feature-name",
    ParameterAdditions=[
        {"Key": "example-key-0", "Value": "example-value-0"},
        {"Key": "example-key-1", "Value": "example-value-1"},
    ]
)
```

Add a description to a feature

To add a description to a feature, specify values for the following fields:

• FeatureGroupName
Adding Searchable Metadata to Your Features

- Feature
- Description

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify the keys for the parameters that you're removing under ParameterRemovals.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify an empty string for Description.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description=""
)
```

After you've updated the metadata for a feature, you can use the `DescribeFeatureMetadata` operation to see the updates that you've made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3).
Example Code

The example code does the following:

1. Sets up your SageMaker environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

Step 1: Setup

To start using Feature Store, create SageMaker, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

Note
The role that you use must have the following managed policies attached to it:
AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
!pip install 'sagemaker>=2.0.0'
import sagemaker
import sys
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```

Step 2: Create a Feature Group and Add Features

```python
feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {
        "FeatureName": "feature-1", "FeatureType": "String"},
    {
        "FeatureName": "feature-2", "FeatureType": "String"},
    {
        "FeatureName": "feature-3", "FeatureType": "String"},
    {
        "FeatureName": "feature-4", "FeatureType": "String"},
    {
        "FeatureName": "feature-5", "FeatureType": "String"
    }
]
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
```
FeatureDefinitions=feature_definitions,
OnlineStoreConfig={"EnableOnlineStore": True}
)
except ClientError as e:
    if e.response["Error"]["Code"] == "ResourceInUse":
        pass
    else:
        raise e

### Step 3: Add Metadata

Before you add metadata, use the `DescribeFeatureGroup` operation to make sure that the status of the feature group is `Created`.

```python
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

Add a description to the feature.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    Description="new description"
)
```

You can use the `DescribeFeatureMetadata` operation to see if you have successfully updated the description for the feature group.

```python
sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

You can also use it to add parameters to the feature group.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    ParameterAdditions=[
        {"Key": "team", "Value": "featurestore"},
        {"Key": "org", "Value": "sagemaker"},
    ]
)
```

You can use the `DescribeFeatureMetadata` operation again to see if you have successfully added the parameters.

```python
sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```
Query Feature Store with Athena and AWS Glue

After a Feature Store feature group has been created in an offline feature store, you can choose to run queries using Amazon Athena on a AWS Glue catalog. This requires data to be registered in a data catalog with other catalog details which is auto-registered for you in Feature Store. In other words, Feature Store automatically builds an AWS Glue data catalog when feature groups are created and you can turn them off. This is particularly useful when you want to build a dataset by executing SQL queries and then train a model for inference.

After your FeatureStore has been created and populated with your data in the offline store, you have the capability to write SQL queries to join data stored in the offline store from different FeatureGroups. To do this, you can use Amazon Athena to write and execute SQL queries. You can set up a AWS Glue crawler to run on a schedule to ensure your catalog is always up to date as well.

If you want to do this please define a role which can be used by the AWS Glue crawler to access the offline store's S3 buckets. For more information, see Create an IAM role.

For more information on how to use AWS Glue and Athena to build a training dataset for model training and inference, see Build Training Dataset: Create Feature Groups.

Sample Athena Queries

Below we provide some sample queries that act as a template for you to quickly write queries using Athena.

Interactive Exploration

This query selects the first 1000 records.

```
SELECT *
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
LIMIT 1000
```

Latest snapshot without duplicates

This query selects the latest non-duplicate records.

```
SELECT *
FROM (SELECT *,
    row_number() OVER (PARTITION BY <RecordIdentifierFeatureName>
    ORDER BY <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC) AS row_num
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1;
```

Latest snapshot without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from the offline store.

```
SELECT *
FROM (SELECT *,
    row_number()...
Cross-Account Offline Store Access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). This can be set up using the steps in the following section.

Topics
- **Step 1:** Set Up the Offline Store Access Role in Account A (p. 1080)
- **Step 2:** Set up an Offline Store S3 Bucket in Account B (p. 1081)
- **Step 3:** Set up an Offline Store KMS Encryption Key in Account A (p. 1082)
- **Step 4:** Create a Feature Group in Account A (p. 1083)

### Step 1: Set Up the Offline Store Access Role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the AmazonSageMakerFeatureStoreAccess policy or to use an existing role that already has the AmazonSageMakerFeatureStoreAccess policy attached. This document refers to this policy as Account-A-Offline-Feature-Store-Role-ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [  
```
Step 2: Set up an Offline Store S3 Bucket in Account B

Create an S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3CrossAccountBucketAccess",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        }
    ]
}
```

The preceding code snippet shows the AmazonSageMakerFeatureStoreAccess policy. The Resource section of the policy is scoped down by default to S3 buckets with names that contain SageMaker, Sagemaker, or sagemaker. This means the offline store S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your S3 bucket policy in the console, customize the Resource section to be arn:aws:s3:::your-offline-store-bucket-name, and then attach to the role.

Additionally, this role must have KMS permissions attached. At a minimum, it requires the kms:GenerateDataKey permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross-account scenario and how to set it up. The following example shows an inline policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
        }
    ]
}
```

The Resource section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

Step 2: Set up an Offline Store S3 Bucket in Account B

Create an S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3CrossAccountBucketAccess",
            "Effect": "Allow",
```
Step 3: Set up an Offline Store KMS Encryption Key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for S3 objects in the offline store. For cross-account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, Account-A-Offline-Feature-Store-Role-ARN from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as Account-A-Offline-Feature-Store-KMS-Key-ARN.

```json
{
  "Version": "2012-10-17",
  "Id": "key-consolepolicy-3",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::Account-A-Account-Id:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::Account-A-Account-Id:role/Administrator",
          "arn:aws:iam::Account-A-Account-Id:root"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

In the preceding policy, the principal is Account-A-Offline-Feature-Store-Role-ARN, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under Principal.
Step 4: Create a Feature Group in Account A

Next, create the feature group in Account A, with an offline store S3 bucket in Account B. To do this, provide the following parameters for RoleArn, OfflineStoreConfig.S3StorageConfig.KmsKeyId and OfflineStoreConfig.S3StorageConfig.S3Uri respectively:

- Provide **Account-A-Offline-Feature-Store-Role-ARN** as the RoleArn.
- Provide **Account-A-Offline-Feature-Store-KMS-Key-ARN** for OfflineStoreConfig.S3StorageConfig.KmsKeyId.
- Provide **Account-B-Offline-Feature-Store-Bucket** for OfflineStoreConfig.S3StorageConfig.S3Uri.
Security and Access Control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide a AWS Key Management Service customer managed key to encrypt all your data at rest. In case you do not provide a AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide a AWS KMS key for encrypting data, then you can call various APIs for data management such as PutRecord, GetRecord, DeleteRecord.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

Using AWS KMS Permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore. Feature Store supports an option to encrypt your online or offline store under customer managed key. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only symmetric customer managed keys. You cannot use an asymmetric customer managed key to encrypt your data in your online or offline store. For help determining whether a customer managed key is symmetric or asymmetric, see Identifying symmetric and asymmetric customer managed keys.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the key policies, IAM policies and grants to control access to the customer managed key. You can enable and disable the customer managed key, enable and disable automatic key rotation, and delete the customer managed key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in AWS CloudTrail logs.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will incur a charge for each API call and AWS Key Management Service quotas apply to each customer managed key.
Authorizing Use of a Customer Managed Key for Your Online Store

If you use a customer managed key to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default AWS owned KMS key to protect your online or offline stores in your AWS account.

Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

- "kms:Encrypt", "kms:Decrypt", "kms:DescribeKey", "kms:CreateGrant", "kms:RetireGrant",
  "kms:ReEncryptFrom", "kms:ReEncryptTo", "kms:GenerateDataKey", "kms:ListAliases", "kms:ListGrants",
  "kms:RevokeGrant"

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for kms:ViaService should be sagemaker.*.amazonaws.com.
  
  **Note**
  The kms:ViaService condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to your customer managed key, and use the same AWS KMS key for both the online and offline store, then it will fail the CreateFeatureGroup API operation.
- Gives the customer managed key administrators read-only access to the customer managed key and permission to revoke grants, including the grants that Feature Store uses to protect your data.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```json
{"Id": "key-policy-feature-store",
 "Version":"2012-10-17",
 "Statement": [
  {"Sid": "Allow access through Amazon SageMaker Feature Store for all principals in the account that are authorized to use Amazon SageMaker Feature Store", 
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/featurestore-user"},
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:DescribeKey",
  ]
]
```
Using Grants to Authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the `ListGrants` operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per FeatureGroup using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

Monitoring Feature Store interaction with AWS KMS

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.
Accessing Data in Your Online Store

The caller (either IAM user or IAM role) to ALL DataPlane operations (Put, Get, DeleteRecord) must have below permissions on the customer managed key:

"kms:Decrypt"

Authorizing Use of a Customer Managed Key for your Offline Store

The roleArn that is passed as a parameter to createFeatureGroup must have below permissions to the OfflineStore KmsKeyId:

"kms:GenerateDataKey"

Note
The key policy for the online store also works for the offline store, only when the kms:ViaService condition is not specified.

Important
You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

Quotas, Naming Rules and Data Types

Limits and Quotas

Note
Soft limits can be increased based on your needs.

- Maximum number of feature groups per AWS account: Soft limit of 100.
- Maximum number of feature definitions per feature group: 2500.
- Maximum Transactions per second (TPS) per API per AWS account: Soft limit of 10000 TPS per API excluding the BatchGetRecord API call, which has a soft limit of 500 TPS.
- Maximum size of a record: 350KB.
- Maximum size of a record identifier: 2KB.
- Maximum size of a feature value: 350KB.
- Maximum number of concurrent feature group creation workflows: 4.
- BatchGetRecord API: Can contain as many as 100 records and can query up to 10 feature groups.

Naming Rules

- Reserved Words: The following are reserved words and cannot be used as feature names in feature definitions: is_deleted, write_time, and api_invocation_time.
Data Types

- **String Feature Type**: Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.

- **Fractional Feature Type**: Fractional feature values must conform to a double precision floating point number as defined by the IEEE 754 standard.

- **Integral Feature Type**: Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of \(-2^{63}\) and a maximum value: \(2^{63} - 1\).

- **Event Time Features**: All feature groups have an event time feature. The feature can have a feature type of either String or Fractional. A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): [yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-ddTH:mm:ss.SSSZ]. A fractional event time value is accepted as seconds from unix epoch, with millisecond precision. Event times must be in the range of \([0000-01-01T00:00:00.000Z, 9999-12-31T23:59:59.999Z]\).

Amazon SageMaker Feature Store Offline Store

Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call `PutRecord`, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format. Specifically, when your data is written to your offline store, the data can only be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple Records.

Files are organized with the following naming convention:

```
```

Records in the offline store are partitioned by event time into hourly partitions as shown in the preceding example. The partitioning scheme is not configurable. The following code shows an example of a Parquet file:

```
s3://my-bucket/my-prefix/123456789012/sagemaker/us-east-1/offline-store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/hour=00/20200631T064401Z_108934320012Az11.parquet
```

Feature Store also exposes the `OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri` field, which can be found from in the `DescribeFeatureGroup` API call. This is the S3 path under which the files for the specific feature group are written.

Example value of `ResolvedOutputS3Uri`:

```
```

The following additional fields are added by Feature Store to each Record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the `PutRecord` or `DeleteRecord` call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
Amazon SageMaker Developer Guide
Amazon SageMaker Feature Store Notebook Examples

- **write_time** – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.
- **is_deleted** – False by default. If `DeleteRecord` is called, a new `Record` is inserted into `RecordIdentifierValue` and set to `True` in the offline store.

Amazon SageMaker Feature Store Notebook Examples

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks in the table below. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: `AmazonSageMakerFeatureStoreAccess`.

See [IAM Roles](#) to access your role and attach this policy. For a walkthrough see [Adding policies to your IAM role](#). The following screenshot illustrates how the policy appears under your IAM role after it has been attached.

### Feature Store sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker Feature Store.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction to Feature Store</td>
<td>An introduction to key Feature Store capabilities such as how to create, configure a feature group, and how to ingest data into an online or offline feature store.</td>
<td></td>
</tr>
<tr>
<td>Fraud Detection with Feature Store</td>
<td>An advanced example on how to train a fraud detection model by ingesting data into a Feature Store, querying it to form a training dataset, and how to train a simple model for inference.</td>
<td></td>
</tr>
<tr>
<td>Encrypt Data in your Online or Offline Feature Store using KMS key</td>
<td>An advanced example on how to encrypt and decrypt data in an Online or Offline Feature Store using KMS key and how to verify that your data is encrypted. Note that this notebook tackles encryption at rest.</td>
<td></td>
</tr>
<tr>
<td>Notebook Title</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td><strong>Client-side Encryption with Feature Store using AWS Encryption SDK</strong></td>
<td>An advanced example how to do client-side encryption with Feature Store using the <em>AWS Encryption SDK library</em> which encrypts your data prior to ingesting it into your Online or Offline Feature Store.</td>
<td></td>
</tr>
<tr>
<td><strong>How to securely store an image dataset in Feature Store with KMS key?</strong></td>
<td>An advanced example that demonstrates how to securely store a dataset of images into your Feature Store using KMS key for server-side encryption.</td>
<td></td>
</tr>
<tr>
<td><strong>Create a machine learning workflow from a Ground Truth classification labelling job to Feature Store</strong></td>
<td>A machine learning (ML) workflow that demonstrates how to feed the output of an image or text classification labelling job from AWS Ground Truth to Feature Store.</td>
<td></td>
</tr>

Train Models

For an overview on training models with Amazon SageMaker, see Train a Model with Amazon SageMaker (p. 9).

SageMaker provides features to monitor and manage the training and validation of machine learning models. For guidance on metrics available, incremental training, automatic model tuning, and the use of augmented manifest files to label training data, see the following topics.

- For guidance on choosing a machine learning algorithm and its implementation for your task or problem, see Choose an Algorithm (p. 1092).
- For guidance on debugging and profiling the training of machine learning models, see Debug and Profile Training Jobs Using Amazon SageMaker Debugger (p. 2258).
- For guidance on distributed training of deep learning models, see Amazon SageMaker Distributed Training Libraries (p. 2466).
- For guidance on compiling and training deep learning models, see Amazon SageMaker Training Compiler (p. 2575).
- For guidance on metrics used to monitor and train models, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 2704).
- For guidance on metrics used to detect model post-processing bias, see Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 2630).
- For guidance on model explainability, see Amazon SageMaker Clarify Model Explainability (p. 2652).

Choose an Algorithm

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning (p. 1095)
- Unsupervised learning (p. 1095)
- Reinforcement learning (p. 1096)

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics
- Choose an algorithm implementation (p. 1092)
- Problem types for the basic machine learning paradigms (p. 1094)
- Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1096)
- Use Reinforcement Learning with Amazon SageMaker (p. 2225)

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker supports three implementation options that require increasing levels of effort.

- Pre-trained models require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
• **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.

• If there is no built-in solution that works, try to develop one that uses **pre-made images for machine and deep learning frameworks** for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.

• If you need to run custom packages or use any code which isn’t a part of a supported framework or available via PyPi, then you need to build your own custom **Docker image** that is configured to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

**Topics**
- Use a built-in algorithm (p. 1093)
- Use script mode in a supported framework (p. 1094)
- Use a custom Docker image (p. 1094)

**Use a built-in algorithm**

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker’s built-in algorithms. These built-in algorithms come with two major benefits.

• The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.

• The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.
For more information on the built-in algorithms provided by SageMaker, see **Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1096)**.

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see **Common Information About Built-in Algorithms (p. 1102)**.

**Use script mode in a supported framework**

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a .py extension. As the table above indicates, SageMaker supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework’s image.

For more information on the frameworks supported by SageMaker, see **Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13)**.

**Use a custom Docker image**

Amazon SageMaker’s built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker, see **Using Docker containers with SageMaker (p. 3149)**.

**Problem types for the basic machine learning paradigms**

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker provides to address these problem types, see **Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1096)**.

**Topics**
- Supervised learning (p. 1095)
- Unsupervised learning (p. 1095)
- Reinforcement learning (p. 1096)
Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a classification problem. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a regression problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker, see Supervised Learning (p. 1100).

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.

- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.

- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.

- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density
estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker, see Unsupervised Learning (p. 1101).

Reinforcement learning

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker’s frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker (p. 2225).

Use Amazon SageMaker Built-in Algorithms or Pre-trained Models

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker, choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

For important information about Docker registry paths, data formats, recommenced Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1102).

The following sections provide additional guidance for the Amazon SageMaker built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Choose an Algorithm (p. 1092). Sections are also provided for the SageMaker built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained Models and Solution Templates (p. 1100)
- Supervised Learning (p. 1100)
- Unsupervised Learning (p. 1101)
- Textual Analysis (p. 1101)
- Image Processing (p. 1102)

Pre-trained Models and Solution Templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types that use the SageMaker SDK as well as Studio. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart (p. 45).

Supervised Learning

Amazon SageMaker provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- AutoGluon-Tabular (p. 1971)—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost (p. 1978)—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm (p. 1986)—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- K-Nearest Neighbors (k-NN) Algorithm (p. 1996)—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- LightGBM (p. 2005)—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
• **Linear Learner Algorithm** (p. 2014)—learns a linear function for regression or a linear threshold function for classification.

• **TabTransformer** (p. 2031)—a novel deep tabular data modeling architecture built on self-attention-based Transformers.

• **XGBoost Algorithm** (p. 2038)—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker also provides several built-in supervised learning algorithms that are used for more specialized tasks during feature engineering and forecasting from time series data.

• **Object2Vec Algorithm** (p. 2087)—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, as it requires labeled data for training, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data, without any explicit human annotation.

• **DeepAR Forecasting Algorithm** (p. 2126)—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

### Unsupervised Learning

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

• **Principal Component Analysis (PCA) Algorithm** (p. 2159)—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.

• **K-Means Algorithm** (p. 2151)—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.

• **IP Insights** (p. 2142)—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.

• **Random Cut Forest (RCF) Algorithm** (p. 2163)—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

### Textual Analysis

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

• **BlazingText algorithm** (p. 2066)—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.

• **Sequence-to-Sequence Algorithm** (p. 2103)—a supervised algorithm commonly used for neural machine translation.

• **Latent Dirichlet Allocation (LDA) Algorithm** (p. 2076)—an algorithm suitable for determining topics in a set of documents. It is an *unsupervised algorithm*, which means that it doesn't use example data with answers during training.

• **Neural Topic Model (NTM) Algorithm** (p. 2081)—another unsupervised technique for determining topics in a set of documents, using a neural network approach.

• **Text Classification - TensorFlow** (p. 2116)—a supervised algorithm that supports transfer learning with available pretrained models for text classification.
Image Processing

SageMaker also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 2172)**—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 2183)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Semantic Segmentation Algorithm (p. 2215)**—provides a fine-grained, pixel-level approach to developing computer vision applications.
- **Object Detection - MXNet (p. 2196)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- **Object Detection - TensorFlow (p. 2207)**—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

</tbody>
</table>

Algorithms that are parallelizable can be deployed on multiple compute instances for distributed training.

The following topics provide information about Docker registry paths, data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by Amazon SageMaker.

**Topics**
- Docker Registry Paths and Example Code (p. 1105)
- Common Data Formats for Built-in Algorithms (p. 1959)
- Instance Types for Built-in Algorithms (p. 1968)
- Logs for Built-in Algorithms (p. 1969)

### Docker Registry Paths and Example Code

The following topics list the Docker registry path and other parameters for each of the Amazon SageMaker provided algorithms and Deep Learning Containers (DLC).

Use the path as follows:

- To create a training job (create_training_job), specify the Docker registry path (TrainingImage) and the training input mode (TrainingInputMode) for the training image. You create a training job to train a model using a specific dataset.
- To create a model (create_model), specify the Docker registry path (Image) for the inference image (PrimaryContainer Image). SageMaker launches machine learning compute instances that are based on the endpoint configuration and deploys the model, which includes the artifacts (the result of model training).

**Note**
For the registry path, use the :1 version tag to ensure that you are using a stable version of the algorithm/DLC. You can reliably host a model trained using an image with the :1 tag on an inference image that has the :1 tag. Using the :latest tag in the registry path provides you with the most up-to-date version of the algorithm/DLC, but might cause problems with backward compatibility. Avoid using the :latest tag for production purposes.

**Important**
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 2039) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

To find the registry path, choose the AWS Region, then choose the algorithm or DLC.

**Topics**
Docker Registry Paths and Example Code for US East (Ohio) (us-east-2) (p. 1106)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1107)
- BlazingText (algorithm) (p. 1108)
- Chainer (DLC) (p. 1109)
- Clarify (algorithm) (p. 1109)
- Data Wrangler (algorithm) (p. 1110)
- Debugger (algorithm) (p. 1110)
- DeepAR Forecasting (algorithm) (p. 1110)
- Factorization Machines (algorithm) (p. 1110)
- Hugging Face (algorithm) (p. 1111)
- IP Insights (algorithm) (p. 1114)
- Image classification (algorithm) (p. 1114)
- Inferentia MXNet (DLC) (p. 1114)
- Inferentia PyTorch (DLC) (p. 1115)
- K-Means (algorithm) (p. 1115)
- KNN (algorithm) (p. 1116)
Use Built-in Algorithms

Docker Registry Paths and Example Code for US East (N. Virginia) (us-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1143)
- BlazingText (algorithm) (p. 1144)
- Chainer (DLC) (p. 1144)
- Clarify (algorithm) (p. 1145)
- Data Wrangler (algorithm) (p. 1145)
- Debugger (algorithm) (p. 1146)
- DeepAR Forecasting (algorithm) (p. 1146)
- Factorization Machines (algorithm) (p. 1146)
- Hugging Face (algorithm) (p. 1147)
- IP Insights (algorithm) (p. 1150)
- Image classification (algorithm) (p. 1150)
- Inferentia MXNet (DLC) (p. 1151)
- Inferentia PyTorch (DLC) (p. 1151)
- K-Means (algorithm) (p. 1152)
- KNN (algorithm) (p. 1152)
- LDA (algorithm) (p. 1152)
- Linear Learner (algorithm) (p. 1153)
- MXNet (DLC) (p. 1153)
- MXNet Coach (DLC) (p. 1156)
- Model Monitor (algorithm) (p. 1156)
- NTM (algorithm) (p. 1157)
- Neo Image Classification (algorithm) (p. 1157)
- Neo MXNet (DLC) (p. 1157)
- Neo PyTorch (DLC) (p. 1158)
- Neo Tensorflow (DLC) (p. 1159)
- Neo XGBoost (algorithm) (p. 1159)
- Object Detection (algorithm) (p. 1159)
- Object2Vec (algorithm) (p. 1160)
- PCA (algorithm) (p. 1160)
- PyTorch (DLC) (p. 1160)
- Random Cut Forest (algorithm) (p. 1164)
- Ray PyTorch (DLC) (p. 1164)
- Scikit-learn (algorithm) (p. 1165)
- Semantic Segmentation (algorithm) (p. 1165)
- Seq2Seq (algorithm) (p. 1166)
Use Built-in Algorithms

- Spark (algorithm) (p. 1166)
- SparkML Serving (algorithm) (p. 1167)
- Tensorflow (DLC) (p. 1167)
- Tensorflow Coach (DLC) (p. 1175)
- Tensorflow Inferentia (DLC) (p. 1176)
- Tensorflow Ray (DLC) (p. 1177)
- VW (algorithm) (p. 1178)
- XGBoost (algorithm) (p. 1178)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='us-east-1',image_scope='inference',version='0.4')

# Output path
'763104351884.dkr.ecr.us-east-1.amazonaws.com/autogluon-inference:0.4-cpu-py38'
```

Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='us-east-1',version='1.0',image_scope='processing')

# Output path
'205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0'
```

Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='us-east-1')

# Output path
'663277389841.dkr.ecr.us-east-1.amazonaws.com/sagemaker-data-wrangler-container:1.x'
```
Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='us-east-1')
# Output path '503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest'
```

DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-east-1')
# Output path '522234722520.dkr.ecr.us-east-1.amazonaws.com/forecasting-deepar:1'
```

Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-east-1')
# Output path '382416733822.dkr.ecr.us-east-1.amazonaws.com/factorization-machines:1'

</tr>
</tbody>
</table>

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch',region='us-east-1',version='0.8.5',instance_type='ml.c5.4xlarge')
# Output path
'462105765813.dkr.ecr.us-east-1.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.5-torch-cpu-py36'
```
### Use Built-in Algorithms

#### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Package version</th>
<th>Job types (image scope)</th>

<td>inference, training</td>
<td></td>
</tr>
</tbody>
</table>

#### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='us-east-1')

# Output path
'811284229777.dkr.ecr.us-east-1.amazonaws.com/semantic-segmentation:1'
```
### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>811284229777.dkr.ecr.us-east-1.amazonaws.com/semantic-segmentation:&lt;tag&gt;</code></td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='us-east-1')
# Output path
'811284229777.dkr.ecr.us-east-1.amazonaws.com/seq2seq:1'
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>811284229777.dkr.ecr.us-east-1.amazonaws.com/seq2seq:&lt;tag&gt;</code></td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='us-east-1', version='3.0', image_scope='processing')
# Output path
'173754725891.dkr.ecr.us-east-1.amazonaws.com/sagemaker-spark-processing:3.0-cpu'
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>173754725891.dkr.ecr.us-east-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</code></td>
<td></td>
<td>processing</td>
</tr>
<tr>
<td><code>173754725891.dkr.ecr.us-east-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</code></td>
<td></td>
<td>processing</td>

<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='us-east-1', version='2.4')
# Output path
'683313688378.dkr.ecr.us-east-1.amazonaws.com/sagemaker-sparkml-serving:2.4'
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>683313688378.dkr.ecr.us-east-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
<tr>
<td>683313688378.dkr.ecr.us-east-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
</tbody>
</table>

Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='us-east-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
# Output path
'520713654638.dkr.ecr.us-east-1.amazonaws.com/sagemaker-tensorflow-serving:1.12.0-cpu'
```

## Docker Registry Paths and Example Code for US West (N. California) (us-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- AutoGluon (algorithm) (p. 1180)
- BlazingText (algorithm) (p. 1182)
- Chainer (DLC) (p. 1182)
- Clarify (algorithm) (p. 1182)
- Data Wrangler (algorithm) (p. 1183)
- Debugger (algorithm) (p. 1183)
- DeepAR Forecasting (algorithm) (p. 1183)
- Factorization Machines (algorithm) (p. 1184)
- Hugging Face (algorithm) (p. 1184)
- IP Insights (algorithm) (p. 1187)
- Image classification (algorithm) (p. 1187)
- Inferentia MXNet (DLC) (p. 1188)
- Inferentia PyTorch (DLC) (p. 1188)
- K-Means (algorithm) (p. 1189)
- KNN (algorithm) (p. 1189)
- LDA (algorithm) (p. 1189)
- Linear Learner (algorithm) (p. 1189)
- MXNet (DLC) (p. 1190)
- MXNet Coach (DLC) (p. 1193)
- Model Monitor (algorithm) (p. 1193)
- NTM (algorithm) (p. 1193)
- Neo Image Classification (algorithm) (p. 1194)
- Neo MXNet (DLC) (p. 1194)
- Neo PyTorch (DLC) (p. 1194)
- Neo Tensorflow (DLC) (p. 1195)
- Neo XGBoost (algorithm) (p. 1195)
- Object Detection (algorithm) (p. 1196)
- Object2Vec (algorithm) (p. 1196)
- PCA (algorithm) (p. 1196)
- PyTorch (DLC) (p. 1197)
- Random Cut Forest (algorithm) (p. 1200)
- Ray PyTorch (DLC) (p. 1200)
- Scikitlearn (algorithm) (p. 1201)
- Semantic Segmentation (algorithm) (p. 1201)
- Seq2Seq (algorithm) (p. 1201)
- Spark (algorithm) (p. 1202)
- SparkML Serving (algorithm) (p. 1202)
- Tensorflow (DLC) (p. 1203)
- Tensorflow Coach (DLC) (p. 1211)
- Tensorflow Inferentia (DLC) (p. 1212)
- Tensorflow Ray (DLC) (p. 1212)
- VW (algorithm) (p. 1213)
- XGBoost (algorithm) (p. 1214)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

Docker Registry Paths and Example Code for US West (Oregon) (us-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1216)
- BlazingText (algorithm) (p. 1217)
- Chainer (DLC) (p. 1217)
- Clarify (algorithm) (p. 1218)
- Data Wrangler (algorithm) (p. 1218)
- Debugger (algorithm) (p. 1218)
- DeepAR Forecasting (algorithm) (p. 1219)
- Factorization Machines (algorithm) (p. 1219)
- Hugging Face (algorithm) (p. 1219)
- IP Insights (algorithm) (p. 1223)
- Image classification (algorithm) (p. 1223)
- Inferentia MXNet (DLC) (p. 1223)
- Inferentia PyTorch (DLC) (p. 1223)
- K-Means (algorithm) (p. 1224)
- KNN (algorithm) (p. 1224)
- LDA (algorithm) (p. 1225)
- Linear Learner (algorithm) (p. 1225)
- MXNet (DLC) (p. 1225)
- MXNet Coach (DLC) (p. 1228)
- Model Monitor (algorithm) (p. 1228)
- NTM (algorithm) (p. 1229)
- Neo Image Classification (algorithm) (p. 1229)
- Neo MXNet (DLC) (p. 1229)
- Neo PyTorch (DLC) (p. 1230)
- Neo Tensorflow (DLC) (p. 1230)
- Neo XGBoost (algorithm) (p. 1231)
- Object Detection (algorithm) (p. 1231)
- Object2Vec (algorithm) (p. 1231)
- PCA (algorithm) (p. 1232)
- PyTorch (DLC) (p. 1232)
- Random Cut Forest (algorithm) (p. 1235)
- Ray PyTorch (DLC) (p. 1236)
Use Built-in Algorithms

- Scikit-learn (algorithm) (p. 1236)
- Semantic Segmentation (algorithm) (p. 1237)
- Seq2Seq (algorithm) (p. 1237)
- Spark (algorithm) (p. 1237)
- SparkML Serving (algorithm) (p. 1238)
- Tensorflow (DLC) (p. 1238)
- Tensorflow Coach (DLC) (p. 1247)
- Tensorflow Inference (DLC) (p. 1248)
- Tensorflow Ray (DLC) (p. 1248)
- VW (algorithm) (p. 1249)
- XGBoost (algorithm) (p. 1249)

AutoGluon (algorithm)

**Docker Registry Paths and Example Code for Africa (Cape Town) (af-south-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1251)
- BlazingText (algorithm) (p. 1253)
- Chainer (DLC) (p. 1253)
- Clarify (algorithm) (p. 1253)
- Data Wrangler (algorithm) (p. 1254)
- Debugger (algorithm) (p. 1254)
- DeepAR Forecasting (algorithm) (p. 1254)
- Factorization Machines (algorithm) (p. 1255)
- Hugging Face (algorithm) (p. 1255)
- IP Insights (algorithm) (p. 1258)
- Image classification (algorithm) (p. 1258)
• Inferentia MXNet (DLC) (p. 1259)
• Inferentia PyTorch (DLC) (p. 1259)
• K-Means (algorithm) (p. 1260)
• KNN (algorithm) (p. 1260)
• Linear Learner (algorithm) (p. 1260)
• MXNet (DLC) (p. 1260)
• MXNet Coach (DLC) (p. 1263)
• Model Monitor (algorithm) (p. 1264)
• NTM (algorithm) (p. 1264)
• Neo Image Classification (algorithm) (p. 1264)
• Neo MXNet (DLC) (p. 1265)
• Neo PyTorch (DLC) (p. 1265)
• Neo Tensorflow (DLC) (p. 1266)
• Neo XGBoost (algorithm) (p. 1266)
• Object Detection (algorithm) (p. 1266)
• Object2Vec (algorithm) (p. 1267)
• PCA (algorithm) (p. 1267)
• PyTorch (DLC) (p. 1267)
• Random Cut Forest (algorithm) (p. 1271)
• Scikit-learn (algorithm) (p. 1271)
• Semantic Segmentation (algorithm) (p. 1271)
• Seq2Seq (algorithm) (p. 1272)
• Spark (algorithm) (p. 1272)
• SparkML Serving (algorithm) (p. 1272)
• Tensorflow (DLC) (p. 1273)
• Tensorflow Coach (DLC) (p. 1281)
• Tensorflow Inferentia (DLC) (p. 1282)
• Tensorflow Ray (DLC) (p. 1282)
• XGBoost (algorithm) (p. 1283)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='af-south-1', image_scope='inference', version='0.4')
```

Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='af-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>455444449433.dkr.ecr.af-south-1.amazonaws.com/</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
### Semantic Segmentation

**Example**

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='af-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>455444449433.dkr.ecr.af-south-1.amazonaws.com/semantic-segmentation:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Seq2Seq (algorithm)

**Example**

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='af-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>455444449433.dkr.ecr.af-south-1.amazonaws.com/seq2seq:&lt;tag&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Spark (algorithm)

**Example**

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='af-south-1',version='3.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>309385258863.dkr.ecr.af-south-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>3.0</td>
<td>processing</td>
</tr>
<tr>
<td>309385258863.dkr.ecr.af-south-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>3.1</td>
<td>processing</td>
</tr>
<tr>
<td>309385258863.dkr.ecr.af-south-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>2.4</td>
<td>processing</td>
</tr>
</tbody>
</table>

### SparkML Serving (algorithm)

**Example**

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='af-south-1',version='2.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>510948584623.dkr.ecr.af-south-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td>2.4</td>
<td>inference</td>
</tr>
<tr>
<td>510948584623.dkr.ecr.af-south-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td>2.2</td>
<td>inference</td>
</tr>
</tbody>
</table>

**Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow',region='af-south-1',version='1.12.0',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>

**Docker Registry Paths and Example Code for Asia Pacific (Hong Kong) (ap-east-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1285)
- BlazingText (algorithm) (p. 1286)
- Chainer (DLC) (p. 1287)
- Clarify (algorithm) (p. 1287)
- Data Wrangler (algorithm) (p. 1287)
- Debugger (algorithm) (p. 1288)
- DeepAR Forecasting (algorithm) (p. 1288)
- Factorization Machines (algorithm) (p. 1288)
- Hugging Face (algorithm) (p. 1289)
- IP Insights (algorithm) (p. 1292)
- Image classification (algorithm) (p. 1292)
- Inferentia MXNet (DLC) (p. 1292)
- Inferentia PyTorch (DLC) (p. 1293)
- K-Means (algorithm) (p. 1293)
- KNN (algorithm) (p. 1294)
- Linear Learner (algorithm) (p. 1294)
- MXNet (DLC) (p. 1294)
- MXNet Coach (DLC) (p. 1297)
• Model Monitor (algorithm) (p. 1298)
• NTM (algorithm) (p. 1298)
• Neo Image Classification (algorithm) (p. 1298)
• Neo MXNet (DLC) (p. 1298)
• Neo PyTorch (DLC) (p. 1299)
• Neo Tensorflow (DLC) (p. 1300)
• Neo XGBoost (algorithm) (p. 1300)
• Object Detection (algorithm) (p. 1300)
• Object2Vec (algorithm) (p. 1301)
• PCA (algorithm) (p. 1301)
• PyTorch (DLC) (p. 1301)
• Random Cut Forest (algorithm) (p. 1304)
• Scikit-learn (algorithm) (p. 1305)
• Semantic Segmentation (algorithm) (p. 1305)
• Seq2Seq (algorithm) (p. 1305)
• Spark (algorithm) (p. 1306)
• SparkML Serving (algorithm) (p. 1306)
• Tensorflow (DLC) (p. 1307)
• Tensorflow Coach (DLC) (p. 1315)
• Tensorflow Inferentia (DLC) (p. 1316)
• Tensorflow Ray (DLC) (p. 1316)
• XGBoost (algorithm) (p. 1317)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-east-1', image_scope='inference', version='0.4')
```

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='ap-east-1')
```
### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='ap-east-1', version='0.23-1', image_scope='inference')
```

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='ap-east-1')
```

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
```
image_uris.retrieve(framework='seq2seq', region='ap-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>286214385809.dkr.ecr.ap-east-1.amazonaws.com/seq2seq:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Spark (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='ap-east-1', version='3.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>732049463269.dkr.ecr.ap-east-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
<tr>
<td>732049463269.dkr.ecr.ap-east-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>

<td>732049463269.dkr.ecr.ap-east-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**SparkML Serving (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='ap-east-1', version='2.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>651117190479.dkr.ecr.ap-east-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
<tr>
<td>651117190479.dkr.ecr.ap-east-1.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
</tbody>
</table>
## Use Built-in Algorithms

### TensorFlow (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='ap-east-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>

Docker Registry Paths and Example Code for Asia Pacific (Mumbai) (ap-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1319)
- BlazingText (algorithm) (p. 1320)
- Chainer (DLC) (p. 1321)
- Clarify (algorithm) (p. 1321)
- Data Wrangler (algorithm) (p. 1321)
- Debugger (algorithm) (p. 1322)
- DeepAR Forecasting (algorithm) (p. 1322)
- Factorization Machines (algorithm) (p. 1322)
- Hugging Face (algorithm) (p. 1323)
- IP Insights (algorithm) (p. 1326)
- Image classification (algorithm) (p. 1326)
- Inferentia MXNet (DLC) (p. 1326)
- Inferentia PyTorch (DLC) (p. 1327)
- K-Means (algorithm) (p. 1327)
- KNN (algorithm) (p. 1328)
- LDA (algorithm) (p. 1328)
- Linear Learner (algorithm) (p. 1328)
- MXNet (DLC) (p. 1329)
- MXNet Coach (DLC) (p. 1331)
- Model Monitor (algorithm) (p. 1332)
- NTM (algorithm) (p. 1332)
- Neo Image Classification (algorithm) (p. 1332)
- Neo MXNet (DLC) (p. 1333)
• Neo PyTorch (DLC) (p. 1333)
• Neo Tensorflow (DLC) (p. 1334)
• Neo XGBoost (algorithm) (p. 1334)
• Object Detection (algorithm) (p. 1335)
• Object2Vec (algorithm) (p. 1335)
• PCA (algorithm) (p. 1335)
• PyTorch (DLC) (p. 1335)
• Random Cut Forest (algorithm) (p. 1339)
• Ray PyTorch (DLC) (p. 1339)
• Scikit-learn (algorithm) (p. 1339)
• Semantic Segmentation (algorithm) (p. 1340)
• Seq2Seq (algorithm) (p. 1340)
• Spark (algorithm) (p. 1341)
• SparkML Serving (algorithm) (p. 1341)
• Tensorflow (DLC) (p. 1341)
• Tensorflow Coach (DLC) (p. 1350)
• Tensorflow Inferentia (DLC) (p. 1351)
• Tensorflow Ray (DLC) (p. 1351)
• VW (algorithm) (p. 1352)
• XGBoost (algorithm) (p. 1352)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-south-1',image_scope='inference',version='0.4')
```

**K-Means (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='ap-south-1')
### Registry path | Version | Job types (image scope)
---|---|---
991648021394.dkr.ecr.ap-south-1.amazonaws.com/kmeans:<tag> | | inference, training

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='ap-south-1')
```

### Registry path | Version | Job types (image scope)
---|---|---
991648021394.dkr.ecr.ap-south-1.amazonaws.com/knn:<tag> | | inference, training

**LDA (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='ap-south-1')
```

### Registry path | Version | Job types (image scope)
---|---|---
991648021394.dkr.ecr.ap-south-1.amazonaws.com/lda:<tag> | | inference, training

**Linear Learner (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='ap-south-1')
```

### Registry path | Version | Job types (image scope)
---|---|---
991648021394.dkr.ecr.ap-south-1.amazonaws.com/linear-learner:<tag> | | inference, training
**MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='ap-south-1', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<td>126357580389.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-model-monitor-analyzer:&lt;tag&gt;</td>
<td></td>
<td>monitoring</td>
</tr>
</tbody>
</table>

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ntm', region='ap-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>991648021394.dkr.ecr.ap-south-1.amazonaws.com/ntm:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='ap-south-1')
```
**Neo MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet',region='ap-south-1',version='1.8',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>763008648453.dkr.ecr.ap-south-1.amazonaws.com/image-classification-neo:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
<td>CPU, GPU</td>
<td>py3</td>
</tr>
</tbody>
</table>

**Neo PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch',region='ap-south-1',version='1.6',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>763008648453.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-inference-pytorch:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
<td>CPU, GPU</td>
<td>py3</td>

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.
Use Built-in Algorithms

from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='ap-south-1',version='0.23-1',image_scope='inference')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Package version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>720646828776.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-scikit-learn:&lt;tag&gt;</td>
<td>1.0.2</td>
<td>1.0.2</td>
<td>inference, training</td>
</tr>
<tr>
<td>720646828776.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-scikit-learn:&lt;tag&gt;</td>
<td>0.23.2</td>
<td>0.23.2</td>
<td>inference, training</td>
</tr>
<tr>
<td>720646828776.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-scikit-learn:&lt;tag&gt;</td>
<td>0.20.0</td>
<td>0.20.0</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Semantic Segmentation (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='ap-south-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>991648021394.dkr.ecr.ap-south-1.amazonaws.com/semantic-segmentation:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Seq2Seq (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='ap-south-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>991648021394.dkr.ecr.ap-south-1.amazonaws.com/seq2seq:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='ap-south-1', version='3.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>105495057255.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>3.1</td>
<td>processing</td>
</tr>
<tr>
<td>105495057255.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>

Docker Registry Paths and Example Code for Asia Pacific (Osaka) (ap-northeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1354)
- BlazingText (algorithm) (p. 1356)
- Clarify (algorithm) (p. 1356)
- Debugger (algorithm) (p. 1356)
• DeepAR Forecasting (algorithm) (p. 1356)
• Factorization Machines (algorithm) (p. 1357)
• Hugging Face (algorithm) (p. 1357)
• IP Insights (algorithm) (p. 1360)
• Image classification (algorithm) (p. 1360)
• Inferentia MXNet (DLC) (p. 1361)
• Inferentia PyTorch (DLC) (p. 1361)
• K-Means (algorithm) (p. 1362)
• KNN (algorithm) (p. 1362)
• Linear Learner (algorithm) (p. 1362)
• MXNet (DLC) (p. 1362)
• Model Monitor (algorithm) (p. 1364)
• NTM (algorithm) (p. 1364)
• Neo Image Classification (algorithm) (p. 1365)
• Neo MXNet (DLC) (p. 1365)
• Neo PyTorch (DLC) (p. 1365)
• Neo Tensorflow (DLC) (p. 1366)
• Neo XGBoost (algorithm) (p. 1367)
• Object Detection (algorithm) (p. 1367)
• Object2Vec (algorithm) (p. 1367)
• PCA (algorithm) (p. 1367)
• PyTorch (DLC) (p. 1368)
• Random Cut Forest (algorithm) (p. 1371)
• Scikit-learn (algorithm) (p. 1371)
• Semantic Segmentation (algorithm) (p. 1371)
• Seq2Seq (algorithm) (p. 1372)
• Tensorflow (DLC) (p. 1372)
• Tensorflow Inferentia (DLC) (p. 1378)
• XGBoost (algorithm) (p. 1378)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-northeast-3', image_scope='inference', version='0.4')
```

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor',region='ap-northeast-3')
```

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='ap-northeast-3')
```
### Neo Image Classification (algorithm)

Use the following Registry path for Neo Image Classification:

```
867004704886.dkr.ecr.ap-northeast-3.amazonaws.com/ntm:<tag>
```

This registry supports both inference and training jobs.

### Neo MXNet (DLC)

Use the following Registry path for Neo MXNet:

```
925152966179.dkr.ecr.ap-northeast-3.amazonaws.com/image-classification-neo:<tag>
```

### Neo PyTorch (DLC)

Use the following Registry path for Neo PyTorch:

```
925152966179.dkr.ecr.ap-northeast-3.amazonaws.com/sagemaker-inference-mxnet:<tag>
```

## Registration of Inference and Training Jobs

**Linux**

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='ap-northeast-3')
```

**Switch CPU/GPU instance type**

```
instance_type='ml.c5.4xlarge'
```

**Switch version**

```
version='1.6'
```

**Switch PyTorch version**

```
py_version='py3'
```

---

**Regional Registries**

- Inference
- Training

**Docker Registry Paths and Example Code for Asia Pacific (Seoul) (ap-northeast-2)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1380)
- BlazingText (algorithm) (p. 1382)
- Chainer (DLC) (p. 1382)
- Clarify (algorithm) (p. 1382)
- Data Wrangler (algorithm) (p. 1383)
• Debugger (algorithm) (p. 1383)
• DeepAR Forecasting (algorithm) (p. 1383)
• Factorization Machines (algorithm) (p. 1384)
• Hugging Face (algorithm) (p. 1384)
• IP Insights (algorithm) (p. 1387)
• Image classification (algorithm) (p. 1387)
• Inferentia MXNet (DLC) (p. 1388)
• Inferentia PyTorch (DLC) (p. 1388)
• K-Means (algorithm) (p. 1389)
• KNN (algorithm) (p. 1389)
• LDA (algorithm) (p. 1389)
• Linear Learner (algorithm) (p. 1389)
• MXNet (DLC) (p. 1390)
• MXNet Coach (DLC) (p. 1393)
• Model Monitor (algorithm) (p. 1393)
• NTM (algorithm) (p. 1393)
• Neo Image Classification (algorithm) (p. 1394)
• Neo MXNet (DLC) (p. 1394)
• Neo PyTorch (DLC) (p. 1394)
• Neo Tensorflow (DLC) (p. 1395)
• Neo XGBoost (algorithm) (p. 1396)
• Object Detection (algorithm) (p. 1396)
• Object2Vec (algorithm) (p. 1396)
• PCA (algorithm) (p. 1396)
• PyTorch (DLC) (p. 1397)
• Random Cut Forest (algorithm) (p. 1400)
• Ray PyTorch (DLC) (p. 1400)
• Scikit-learn (algorithm) (p. 1401)
• Semantic Segmentation (algorithm) (p. 1401)
• Seq2Seq (algorithm) (p. 1402)
• Spark (algorithm) (p. 1402)
• SparkML Serving (algorithm) (p. 1402)
• Tensorflow (DLC) (p. 1403)
• Tensorflow Coach (DLC) (p. 1411)
• Tensorflow Inferentia (DLC) (p. 1412)
• Tensorflow Ray (DLC) (p. 1413)
• VW (algorithm) (p. 1413)
• XGBoost (algorithm) (p. 1414)

AutoGluon (algorithm)

Docker Registry Paths and Example Code for Asia Pacific (Singapore) (ap-southeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1416)
- BlazingText (algorithm) (p. 1417)
- Chainer (DLC) (p. 1417)
- Clarify (algorithm) (p. 1418)
- Data Wrangler (algorithm) (p. 1418)
- Debugger (algorithm) (p. 1418)
- DeepAR Forecasting (algorithm) (p. 1419)
- Factorization Machines (algorithm) (p. 1419)
- Hugging Face (algorithm) (p. 1419)
- IP Insights (algorithm) (p. 1423)
- Image classification (algorithm) (p. 1423)
- Inferentia MXNet (DLC) (p. 1423)
- Inferentia PyTorch (DLC) (p. 1423)
- K-Means (algorithm) (p. 1424)
- KNN (algorithm) (p. 1424)
- LDA (algorithm) (p. 1425)
- Linear Learner (algorithm) (p. 1425)
- MXNet (DLC) (p. 1425)
- MXNet Coach (DLC) (p. 1428)
- Model Monitor (algorithm) (p. 1428)
- NTM (algorithm) (p. 1429)
- Neo Image Classification (algorithm) (p. 1429)
- Neo MXNet (DLC) (p. 1429)
- Neo PyTorch (DLC) (p. 1430)
- Neo Tensorflow (DLC) (p. 1430)
- Neo XGBoost (algorithm) (p. 1431)
- Object Detection (algorithm) (p. 1431)
- Object2Vec (algorithm) (p. 1431)
- PCA (algorithm) (p. 1432)
- PyTorch (DLC) (p. 1432)
- Random Cut Forest (algorithm) (p. 1435)
• Ray PyTorch (DLC) (p. 1436)
• Scikit-learn (algorithm) (p. 1436)
• Semantic Segmentation (algorithm) (p. 1437)
• Seq2Seq (algorithm) (p. 1437)
• Spark (algorithm) (p. 1437)
• SparkML Serving (algorithm) (p. 1438)
• Tensorflow (DLC) (p. 1438)
• Tensorflow Coach (DLC) (p. 1447)
• Tensorflow Inferentia (DLC) (p. 1448)
• Tensorflow Ray (DLC) (p. 1448)
• VW (algorithm) (p. 1449)
• XGBoost (algorithm) (p. 1449)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-southeast-1',image_scope='inference',version='0.4')
```

<table>

Docker Registry Paths and Example Code for Asia Pacific (Sydney) (ap-southeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1451)
- BlazingText (algorithm) (p. 1453)
- Chainer (DLC) (p. 1453)
- Clarify (algorithm) (p. 1453)
- Data Wrangler (algorithm) (p. 1454)
- Debugger (algorithm) (p. 1454)
- DeepAR Forecasting (algorithm) (p. 1454)
- Factorization Machines (algorithm) (p. 1455)
- Hugging Face (algorithm) (p. 1455)
- IP Insights (algorithm) (p. 1458)
- Image classification (algorithm) (p. 1458)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-southeast-2', image_scope='inference', version='0.4')
```

### Amazon SageMaker Developer Guide

#### Use Built-in Algorithms

**Registry path** | **Version** | **Job types (image scope)**
---|---|---
763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/huggingface-tensorflow-inference:tag | 4.6.1 | inference

763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/huggingface-pytorch-training:tag | 4.6.0 | training

763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/huggingface-pytorch-training:tag | 4.5.0 | training

763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/huggingface-tensorflow-training:tag | 4.5.0 | training

763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/huggingface-tensorflow-training:tag | 4.4.2 | training

#### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='ap-southeast-2')
```

**Registry path** | **Version** | **Job types (image scope)**
---|---|---
712309505854.dkr.ecr.ap-southeast-2.amazonaws.com/ipinsights:tag | 1 | inference, training

#### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='ap-southeast-2')
```
Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='ap-southeast-2', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='ap-southeast-2')
```

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='ap-southeast-2', version='0.8.5', instance_type='ml.c5.4xlarge')
```
Use Built-in Algorithms

### Scikit-learn (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='ap-southeast-2', version='0.23-1', image_scope='inference')
```

### Semantic Segmentation (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='ap-southeast-2')
```

### Seq2Seq (algorithm)
SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='ap-southeast-2')

Amazon SageMaker Developer Guide
Use Built-in Algorithms

Docker Registry Paths and Example Code for Asia Pacific (Jakarta) (ap-southeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1486)
- BlazingText (algorithm) (p. 1488)
- Clarify (algorithm) (p. 1488)
- DeepAR Forecasting (algorithm) (p. 1488)
- Factorization Machines (algorithm) (p. 1489)
- Hugging Face (algorithm) (p. 1489)
- IP Insights (algorithm) (p. 1492)
- Image classification (algorithm) (p. 1492)
- K-Means (algorithm) (p. 1493)
- KNN (algorithm) (p. 1493)
- Linear Learner (algorithm) (p. 1493)
- MXNet (DLC) (p. 1494)
- NTM (algorithm) (p. 1495)
- Object Detection (algorithm) (p. 1495)
- Object2Vec (algorithm) (p. 1495)
- PCA (algorithm) (p. 1496)
- PyTorch (DLC) (p. 1496)
- Random Cut Forest (algorithm) (p. 1499)
- Scikit-learn (algorithm) (p. 1499)
- Semantic Segmentation (algorithm) (p. 1500)
- Seq2Seq (algorithm) (p. 1500)
- Spark (algorithm) (p. 1500)
- Tensorflow (DLC) (p. 1501)
- XGBoost (algorithm) (p. 1507)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-southeast-3', image_scope='inference', version='0.4')
```

Use Built-in Algorithms

### BlazingText (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='ap-southeast-3')
```

### Clarify (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='ap-southeast-3', version='1.0', image_scope='processing')
```

### DeepAR Forecasting (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='ap-southeast-3')
```
Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='ap-southeast-3')
```

Docker Registry Paths and Example Code for Asia Pacific (Tokyo) (ap-northeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1509)
- BlazingText (algorithm) (p. 1510)
- Chainer (DLC) (p. 1511)
- Clarify (algorithm) (p. 1511)
- Data Wrangler (algorithm) (p. 1511)
- Debugger (algorithm) (p. 1512)
- DeepAR Forecasting (algorithm) (p. 1512)
- Factorization Machines (algorithm) (p. 1512)
- Hugging Face (algorithm) (p. 1513)
- IP Insights (algorithm) (p. 1516)
- Image classification (algorithm) (p. 1516)
- Inferentia MXNet (DLC) (p. 1516)
- Inferentia PyTorch (DLC) (p. 1517)
- K-Means (algorithm) (p. 1517)
- KNN (algorithm) (p. 1518)
- LDA (algorithm) (p. 1518)
- Linear Learner (algorithm) (p. 1518)
- MXNet (DLC) (p. 1519)
- MXNet Coach (DLC) (p. 1521)
- Model Monitor (algorithm) (p. 1522)
- NTM (algorithm) (p. 1522)
• Neo Image Classification (algorithm) (p. 1522)
• Neo MXNet (DLC) (p. 1523)
• Neo PyTorch (DLC) (p. 1523)
• Neo Tensorflow (DLC) (p. 1524)
• Neo XGBoost (algorithm) (p. 1524)
• Object Detection (algorithm) (p. 1525)
• Object2Vec (algorithm) (p. 1525)
• PCA (algorithm) (p. 1525)
• PyTorch (DLC) (p. 1525)
• Random Cut Forest (algorithm) (p. 1529)
• Ray PyTorch (DLC) (p. 1529)
• Scikit-learn (algorithm) (p. 1530)
• Semantic Segmentation (algorithm) (p. 1530)
• Seq2Seq (algorithm) (p. 1530)
• Spark (algorithm) (p. 1531)
• SparkML Serving (algorithm) (p. 1531)
• Tensorflow (DLC) (p. 1532)
• Tensorflow Coach (DLC) (p. 1540)
• Tensorflow Inferentia (DLC) (p. 1541)
• Tensorflow Ray (DLC) (p. 1541)
• VW (algorithm) (p. 1542)
• XGBoost (algorithm) (p. 1543)

**AutoGluon (algorithm)**

**XGBoost (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='ap-northeast-1', version='1.5-1')
```
### Docker Registry Paths and Example Code for Canada (Central) (ca-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1545)
- BlazingText (algorithm) (p. 1546)
- Chainer (DLC) (p. 1546)
- Clarify (algorithm) (p. 1547)
- Data Wrangler (algorithm) (p. 1547)
- Debugger (algorithm) (p. 1547)
- DeepAR Forecasting (algorithm) (p. 1548)
- Factorization Machines (algorithm) (p. 1548)
- Hugging Face (algorithm) (p. 1548)
- IP Insights (algorithm) (p. 1552)
- Image classification (algorithm) (p. 1552)
- Inferentia MXNet (DLC) (p. 1552)
- Inferentia PyTorch (DLC) (p. 1552)
- K-Means (algorithm) (p. 1553)
- KNN (algorithm) (p. 1553)
- LDA (algorithm) (p. 1554)
- Linear Learner (algorithm) (p. 1554)
- MXNet (DLC) (p. 1554)
- MXNet Coach (DLC) (p. 1557)
- Model Monitor (algorithm) (p. 1557)
- NTM (algorithm) (p. 1558)
- Neo Image Classification (algorithm) (p. 1558)
- Neo MXNet (DLC) (p. 1558)
- Neo PyTorch (DLC) (p. 1559)
- Neo Tensorflow (DLC) (p. 1559)
- Neo XGBoost (algorithm) (p. 1560)
- Object Detection (algorithm) (p. 1560)
- Object2Vec (algorithm) (p. 1560)
- PCA (algorithm) (p. 1561)
- PyTorch (DLC) (p. 1561)
- Random Cut Forest (algorithm) (p. 1564)
- Ray PyTorch (DLC) (p. 1565)
• Scikit-learn (algorithm) (p. 1565)
• Semantic Segmentation (algorithm) (p. 1566)
• Seq2Seq (algorithm) (p. 1566)
• Spark (algorithm) (p. 1566)
• SparkML Serving (algorithm) (p. 1567)
• Tensorflow (DLC) (p. 1567)
• Tensorflow Coach (DLC) (p. 1576)
• Tensorflow Inferentia (DLC) (p. 1577)
• Tensorflow Ray (DLC) (p. 1577)
• VW (algorithm) (p. 1578)
• XGBoost (algorithm) (p. 1578)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ca-central-1', image_scope='inference', version='0.4')
```

<table>

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='ca-central-1')
```
### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch',region='ca-central-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='ca-central-1',version='0.23-1',image_scope='inference')
```
### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='ca-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

Use Built-in Algorithms

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='ca-central-1',version='2.4')
```

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow',region='ca-central-1',version='1.12.0',image_scope='inference',instance_type='ml.c5.4xlarge')
```

### Docker Registry Paths and Example Code for China (Beijing) (cn-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics
- AutoGluon (algorithm) (p. 1580)
- BlazingText (algorithm) (p. 1581)
- Chainer (DLC) (p. 1581)
- Clarify (algorithm) (p. 1582)
- Data Wrangler (algorithm) (p. 1582)
- Debugger (algorithm) (p. 1582)
- DeepAR Forecasting (algorithm) (p. 1583)
- Factorization Machines (algorithm) (p. 1583)
- Hugging Face (algorithm) (p. 1583)
- IP Insights (algorithm) (p. 1587)
- Image classification (algorithm) (p. 1587)
• Inferentia MXNet (DLC) (p. 1587)
• Inferentia PyTorch (DLC) (p. 1587)
• K-Means (algorithm) (p. 1588)
• KNN (algorithm) (p. 1588)
• Linear Learner (algorithm) (p. 1589)
• MXNet (DLC) (p. 1589)
• MXNet Coach (DLC) (p. 1592)
• Model Monitor (algorithm) (p. 1592)
• NTM (algorithm) (p. 1592)
• Neo Image Classification (algorithm) (p. 1593)
• Neo MXNet (DLC) (p. 1593)
• Neo PyTorch (DLC) (p. 1593)
• Neo Tensorflow (DLC) (p. 1594)
• Neo XGBoost (algorithm) (p. 1595)
• Object Detection (algorithm) (p. 1595)
• Object2Vec (algorithm) (p. 1595)
• PCA (algorithm) (p. 1595)
• PyTorch (DLC) (p. 1596)
• Random Cut Forest (algorithm) (p. 1599)
• Scikit-learn (algorithm) (p. 1599)
• Semantic Segmentation (algorithm) (p. 1600)
• Seq2Seq (algorithm) (p. 1600)
• Spark (algorithm) (p. 1600)
• SparkML Serving (algorithm) (p. 1601)
• Tensorflow (DLC) (p. 1601)
• Tensorflow Coach (DLC) (p. 1610)
• Tensorflow Inferentia (DLC) (p. 1611)
• Tensorflow Ray (DLC) (p. 1611)
• XGBoost (algorithm) (p. 1612)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='cn-north-1',image_scope='inference',version='0.4')
```

<table>

Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1614)
- BlazingText (algorithm) (p. 1614)
- Chainer (DLC) (p. 1615)
- Clarify (algorithm) (p. 1615)
- Data Wrangler (algorithm) (p. 1616)
- Debugger (algorithm) (p. 1616)
- DeepAR Forecasting (algorithm) (p. 1616)
- Factorization Machines (algorithm) (p. 1616)
- Hugging Face (algorithm) (p. 1617)
- IP Insights (algorithm) (p. 1620)
- Image classification (algorithm) (p. 1620)
- Inferentia MXNet (DLC) (p. 1620)
- Inferentia PyTorch (DLC) (p. 1621)
- K-Means (algorithm) (p. 1621)
- KNN (algorithm) (p. 1622)
- Linear Learner (algorithm) (p. 1622)
- MXNet (DLC) (p. 1622)
- MXNet Coach (DLC) (p. 1625)
- Model Monitor (algorithm) (p. 1626)
- NTM (algorithm) (p. 1626)
- Neo Image Classification (algorithm) (p. 1626)
- Neo MXNet (DLC) (p. 1626)
- Neo PyTorch (DLC) (p. 1627)
- Neo Tensorflow (DLC) (p. 1628)
- Neo XGBoost (algorithm) (p. 1628)
- Object Detection (algorithm) (p. 1628)
- Object2Vec (algorithm) (p. 1629)
- PCA (algorithm) (p. 1629)
- PyTorch (DLC) (p. 1629)
- Random Cut Forest (algorithm) (p. 1632)
- Scikit-learn (algorithm) (p. 1633)
- Semantic Segmentation (algorithm) (p. 1633)
Use Built-in Algorithms

- Seq2Seq (algorithm) (p. 1633)
- Spark (algorithm) (p. 1634)
- SparkML Serving (algorithm) (p. 1634)
- Tensorflow (DLC) (p. 1635)
- Tensorflow Coach (DLC) (p. 1643)
- Tensorflow Inferentia (DLC) (p. 1644)
- Tensorflow Ray (DLC) (p. 1644)
- XGBoost (algorithm) (p. 1645)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='cn-northwest-1',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>

Docker Registry Paths and Example Code for Europe (Frankfurt) (eu-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1647)
- BlazingText (algorithm) (p. 1648)
- Chainer (DLC) (p. 1649)
- Clarify (algorithm) (p. 1649)
- Data Wrangler (algorithm) (p. 1649)
- Debugger (algorithm) (p. 1650)
- DeepAR Forecasting (algorithm) (p. 1650)
- Factorization Machines (algorithm) (p. 1650)
- Hugging Face (algorithm) (p. 1651)
- IP Insights (algorithm) (p. 1654)
- Image classification (algorithm) (p. 1654)
- Inferentia MXNet (DLC) (p. 1654)
- Inferentia PyTorch (DLC) (p. 1655)
- K-Means (algorithm) (p. 1655)
- KNN (algorithm) (p. 1656)
- LDA (algorithm) (p. 1656)
- Linear Learner (algorithm) (p. 1656)
- MXNet (DLC) (p. 1657)
- MXNet Coach (DLC) (p. 1659)
- Model Monitor (algorithm) (p. 1660)
- NTM (algorithm) (p. 1660)
- Neo Image Classification (algorithm) (p. 1660)
- Neo MXNet (DLC) (p. 1661)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='eu-central-1',image_scope='inference',version='0.4')
```

<table>

Docker Registry Paths and Example Code for Europe (Ireland) (eu-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1682)
- BlazingText (algorithm) (p. 1684)
- Chainer (DLC) (p. 1684)
- Clarify (algorithm) (p. 1684)
• Data Wrangler (algorithm) (p. 1685)
• Debugger (algorithm) (p. 1685)
• DeepAR Forecasting (algorithm) (p. 1685)
• Factorization Machines (algorithm) (p. 1686)
• Hugging Face (algorithm) (p. 1686)
• IP Insights (algorithm) (p. 1689)
• Image classification (algorithm) (p. 1689)
• Inferentia MXNet (DLC) (p. 1690)
• Inferentia PyTorch (DLC) (p. 1690)
• K-Means (algorithm) (p. 1691)
• KNN (algorithm) (p. 1691)
• LDA (algorithm) (p. 1691)
• Linear Learner (algorithm) (p. 1691)
• MXNet (DLC) (p. 1692)
• MXNet Coach (DLC) (p. 1695)
• Model Monitor (algorithm) (p. 1695)
• NTM (algorithm) (p. 1695)
• Neo Image Classification (algorithm) (p. 1696)
• Neo MXNet (DLC) (p. 1696)
• Neo PyTorch (DLC) (p. 1696)
• Neo Tensorflow (DLC) (p. 1697)
• Neo XGBoost (algorithm) (p. 1698)
• Object Detection (algorithm) (p. 1698)
• Object2Vec (algorithm) (p. 1698)
• PCA (algorithm) (p. 1698)
• PyTorch (DLC) (p. 1699)
• Random Cut Forest (algorithm) (p. 1702)
• Ray PyTorch (DLC) (p. 1702)
• Scikit-learn (algorithm) (p. 1703)
• Semantic Segmentation (algorithm) (p. 1703)
• Seq2Seq (algorithm) (p. 1704)
• Spark (algorithm) (p. 1704)
• SparkML Serving (algorithm) (p. 1704)
• Tensorflow (DLC) (p. 1705)
• Tensorflow Coach (DLC) (p. 1713)
• Tensorflow Inferentia (DLC) (p. 1714)
• Tensorflow Ray (DLC) (p. 1715)
• VW (algorithm) (p. 1715)
• XGBoost (algorithm) (p. 1716)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
```python
image_uris.retrieve(framework='autogluon',region='eu-west-1',image_scope='inference',version='0.4')
```

**Semantic Segmentation (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='eu-west-1')
```
### Registry path | Version | Job types (image scope)
--- | --- | ---
685385470294.dkr.ecr.eu-west-1.amazonaws.com/semantic-segmentation: | 1 | inference, training

**Seq2Seq (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='eu-west-1')
```

### Registry path | Version | Job types (image scope)
--- | --- | ---
685385470294.dkr.ecr.eu-west-1.amazonaws.com/seq2seq: | 1 | inference, training

**Spark (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='eu-west-1', version='3.0', image_scope='processing')
```

### Registry path | Version | Job types (image scope)
--- | --- | ---
571004829621.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-spark-processing: | 3.1 | processing

Docker Registry Paths and Example Code for Europe (London) (eu-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1718)
- BlazingText (algorithm) (p. 1719)
- Chainer (DLC) (p. 1719)
- Clarify (algorithm) (p. 1720)
- Data Wrangler (algorithm) (p. 1720)
- Debugger (algorithm) (p. 1720)
- DeepAR Forecasting (algorithm) (p. 1721)
- Factorization Machines (algorithm) (p. 1721)
- Hugging Face (algorithm) (p. 1721)
- IP Insights (algorithm) (p. 1725)
- Image classification (algorithm) (p. 1725)
- Inferentia MXNet (DLC) (p. 1725)
- Inferentia PyTorch (DLC) (p. 1725)
- K-Means (algorithm) (p. 1726)
- KNN (algorithm) (p. 1726)
- LDA (algorithm) (p. 1727)
- Linear Learner (algorithm) (p. 1727)
- MXNet (DLC) (p. 1727)
- MXNet Coach (DLC) (p. 1730)
- Model Monitor (algorithm) (p. 1730)
- NTM (algorithm) (p. 1731)
- Neo Image Classification (algorithm) (p. 1731)
- Neo MXNet (DLC) (p. 1731)
- Neo PyTorch (DLC) (p. 1732)
- Neo Tensorflow (DLC) (p. 1732)
- Neo XGBoost (algorithm) (p. 1733)
- Object Detection (algorithm) (p. 1733)
- Object2Vec (algorithm) (p. 1733)
- PCA (algorithm) (p. 1734)
- PyTorch (DLC) (p. 1734)
- Random Cut Forest (algorithm) (p. 1737)

Docker Registry Paths and Example Code for Europe (Stockholm) (eu-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1786)
- BlazingText (algorithm) (p. 1788)
• Chainer (DLC) (p. 1788)
• Clarify (algorithm) (p. 1788)
• Data Wrangler (algorithm) (p. 1789)
• Debugger (algorithm) (p. 1789)
• DeepAR Forecasting (algorithm) (p. 1789)
• Factorization Machines (algorithm) (p. 1790)
• Hugging Face (algorithm) (p. 1790)
• IP Insights (algorithm) (p. 1793)
• Image classification (algorithm) (p. 1793)
• Inferentia MXNet (DLC) (p. 1794)
• Inferentia PyTorch (DLC) (p. 1794)
• K-Means (algorithm) (p. 1795)
• KNN (algorithm) (p. 1795)
• Linear Learner (algorithm) (p. 1795)
• MXNet (DLC) (p. 1795)
• MXNet Coach (DLC) (p. 1798)
• Model Monitor (algorithm) (p. 1799)
• NTM (algorithm) (p. 1799)
• Neo Image Classification (algorithm) (p. 1799)
• Neo MXNet (DLC) (p. 1800)
• Neo PyTorch (DLC) (p. 1800)
• Neo Tensorflow (DLC) (p. 1801)
• Neo XGBoost (algorithm) (p. 1801)
• Object Detection (algorithm) (p. 1802)
• Object2Vec (algorithm) (p. 1802)
• PCA (algorithm) (p. 1802)
• PyTorch (DLC) (p. 1802)
• Random Cut Forest (algorithm) (p. 1806)
• Scikit-learn (algorithm) (p. 1806)
• Semantic Segmentation (algorithm) (p. 1807)
• Seq2Seq (algorithm) (p. 1807)
• Spark (algorithm) (p. 1807)
• SparkML Serving (algorithm) (p. 1808)
• Tensorflow (DLC) (p. 1808)
• Tensorflow Coach (DLC) (p. 1816)
• Tensorflow Inferentia (DLC) (p. 1817)
• Tensorflow Ray (DLC) (p. 1818)
• XGBoost (algorithm) (p. 1818)

AutoGluon (algorithm)

Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1820)
- BlazingText (algorithm) (p. 1821)
- Chainer (DLC) (p. 1822)
- Clarify (algorithm) (p. 1822)
- Data Wrangler (algorithm) (p. 1823)
- Debugger (algorithm) (p. 1823)
- DeepAR Forecasting (algorithm) (p. 1823)
- Factorization Machines (algorithm) (p. 1823)
- Hugging Face (algorithm) (p. 1824)
- IP Insights (algorithm) (p. 1827)
- Image classification (algorithm) (p. 1827)
- Inferentia MXNet (DLC) (p. 1827)
- Inferentia PyTorch (DLC) (p. 1828)
- K-Means (algorithm) (p. 1828)
- KNN (algorithm) (p. 1829)
• Linear Learner (algorithm) (p. 1829)
• MXNet (DLC) (p. 1829)
• MXNet Coach (DLC) (p. 1832)
• Model Monitor (algorithm) (p. 1833)
• NTM (algorithm) (p. 1833)
• Neo Image Classification (algorithm) (p. 1833)
• Neo MXNet (DLC) (p. 1833)
• Neo PyTorch (DLC) (p. 1834)
• Neo Tensorflow (DLC) (p. 1835)
• Neo XGBoost (algorithm) (p. 1835)
• Object Detection (algorithm) (p. 1835)
• Object2Vec (algorithm) (p. 1836)
• PCA (algorithm) (p. 1836)
• PyTorch (DLC) (p. 1836)
• Random Cut Forest (algorithm) (p. 1839)
• Scikit-learn (algorithm) (p. 1840)
• Semantic Segmentation (algorithm) (p. 1840)
• Seq2Seq (algorithm) (p. 1840)
• Spark (algorithm) (p. 1841)
• SparkML Serving (algorithm) (p. 1841)
• Tensorflow (DLC) (p. 1842)
• Tensorflow Coach (DLC) (p. 1850)
• Tensorflow Inference (DLC) (p. 1851)
• Tensorflow Ray (DLC) (p. 1851)
• XGBoost (algorithm) (p. 1852)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='eu-south-1',image_scope='inference',version='0.4')
```

<table>

</tbody>
</table>

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
### Use Built-in Algorithms

```python
image_uris.retrieve(framework='blazingtext',region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
dl = image_uris.retrieve(framework='chainer',region='eu-south-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>

<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
Data Wrangler (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>488287956546.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

Debugger (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>563282790590.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

DeepAR Forecasting (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>

Docker Registry Paths and Example Code for Middle East (Bahrain) (me-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1854)
- BlazingText (algorithm) (p. 1855)
- Chainer (DLC) (p. 1856)
- Clarify (algorithm) (p. 1856)
- Data Wrangler (algorithm) (p. 1856)
- Debugger (algorithm) (p. 1857)
- DeepAR Forecasting (algorithm) (p. 1857)
- Factorization Machines (algorithm) (p. 1857)
- Hugging Face (algorithm) (p. 1858)
- IP Insights (algorithm) (p. 1861)
- Image classification (algorithm) (p. 1861)
- Inferentia MXNet (DLC) (p. 1861)
- Inferentia PyTorch (DLC) (p. 1862)
- K-Means (algorithm) (p. 1862)
- KNN (algorithm) (p. 1863)
- Linear Learner (algorithm) (p. 1863)
- MXNet (DLC) (p. 1863)
- MXNet Coach (DLC) (p. 1866)
- Model Monitor (algorithm) (p. 1867)
- NTM (algorithm) (p. 1867)
- Neo Image Classification (algorithm) (p. 1867)
- Neo MXNet (DLC) (p. 1867)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='me-south-1',image_scope='inference',version='0.4')
```

Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1888)
- BlazingText (algorithm) (p. 1889)
- Chainer (DLC) (p. 1890)
- Clarify (algorithm) (p. 1890)
- Data Wrangler (algorithm) (p. 1890)
- Debugger (algorithm) (p. 1891)
- DeepAR Forecasting (algorithm) (p. 1891)
- Factorization Machines (algorithm) (p. 1891)
- Hugging Face (algorithm) (p. 1892)
- IP Insights (algorithm) (p. 1895)
- Image classification (algorithm) (p. 1895)
- Inferentia MXNet (DLC) (p. 1895)
- Inferentia PyTorch (DLC) (p. 1896)
- K-Means (algorithm) (p. 1896)
- KNN (algorithm) (p. 1897)
- Linear Learner (algorithm) (p. 1897)
- MXNet (DLC) (p. 1897)
- MXNet Coach (DLC) (p. 1900)
- Model Monitor (algorithm) (p. 1901)
- NTM (algorithm) (p. 1901)
- Neo Image Classification (algorithm) (p. 1901)
- Neo MXNet (DLC) (p. 1901)
- Neo PyTorch (DLC) (p. 1902)
- Neo Tensorflow (DLC) (p. 1903)
- Neo XGBoost (algorithm) (p. 1903)
- Object Detection (algorithm) (p. 1903)
- Object2Vec (algorithm) (p. 1904)
- PCA (algorithm) (p. 1904)
- PyTorch (DLC) (p. 1904)
- Random Cut Forest (algorithm) (p. 1907)
- Scikit-learn (algorithm) (p. 1908)
- Semantic Segmentation (algorithm) (p. 1908)
- Seq2Seq (algorithm) (p. 1908)
- Spark (algorithm) (p. 1909)
- SparkML Serving (algorithm) (p. 1909)
- Tensorflow (DLC) (p. 1910)
- Tensorflow Coach (DLC) (p. 1918)
- Tensorflow Inferentia (DLC) (p. 1919)
- Tensorflow Ray (DLC) (p. 1919)
- XGBoost (algorithm) (p. 1920)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python

<td>py3</td>
</tr>
</tbody>
</table>

**Tensorflow Ray (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
g ray_tensorflow = image_uris.retrieve(framework='ray-tensorflow', region='saaeast-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```
### Amazon SageMaker Developer Guide

Docker Registry Paths and Example Code for AWS GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1922)
- BlazingText (algorithm) (p. 1923)
- Chainer (DLC) (p. 1924)
- Clarify (algorithm) (p. 1924)
- Debugger (algorithm) (p. 1925)
- DeepAR Forecasting (algorithm) (p. 1925)
- Factorization Machines (algorithm) (p. 1925)
- Hugging Face (algorithm) (p. 1925)
- IP Insights (algorithm) (p. 1929)
- Image classification (algorithm) (p. 1930)
- Inferentia MXNet (DLC) (p. 1930)
- Inferentia PyTorch (DLC) (p. 1930)
- K-Means (algorithm) (p. 1931)
- KNN (algorithm) (p. 1931)
- LDA (algorithm) (p. 1931)
- Linear Learner (algorithm) (p. 1932)
- MXNet (DLC) (p. 1932)
- MXNet Coach (DLC) (p. 1935)
- NTM (algorithm) (p. 1936)
- Neo Image Classification (algorithm) (p. 1936)
- Neo MXNet (DLC) (p. 1937)
- Neo PyTorch (DLC) (p. 1937)
- Neo Tensorflow (DLC) (p. 1938)
- Neo XGBoost (algorithm) (p. 1938)
- Object Detection (algorithm) (p. 1939)
- Object2Vec (algorithm) (p. 1939)
- PCA (algorithm) (p. 1939)
- PyTorch (DLC) (p. 1939)
- Random Cut Forest (algorithm) (p. 1943)
- Scikit-learn (algorithm) (p. 1944)
- Semantic Segmentation (algorithm) (p. 1944)
- Seq2Seq (algorithm) (p. 1945)
- Spark (algorithm) (p. 1945)
- SparkML Serving (algorithm) (p. 1945)
- Tensorflow (DLC) (p. 1946)
- Tensorflow Coach (DLC) (p. 1956)
- Tensorflow Inference (DLC) (p. 1957)
- Tensorflow Ray (DLC) (p. 1957)
- XGBoost (algorithm) (p. 1958)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='us-gov-west-1',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>442386744353.dkr.ecr.us-gov-west-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>
<td>0.5.2</td>
<td>training</td>
</tr>
<tr>
<td>442386744353.dkr.ecr.us-gov-west-1.amazonaws.com/autogluon-inference:&lt;tag&gt;</td>
<td>0.5.2</td>
<td>inference</td>
</tr>
<tr>
<td>442386744353.dkr.ecr.us-gov-west-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>
<td>0.4.3</td>
<td>training</td>
</tr>
<tr>
<td>442386744353.dkr.ecr.us-gov-west-1.amazonaws.com/autogluon-inference:&lt;tag&gt;</td>

<td>inference</td>
</tr>
</tbody>
</table>
## BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='us-gov-west-1')
```
### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='us-gov-west-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='us-gov-west-1',version='1.0',image_scope='processing')
```

Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

Topics
- Common Data Formats for Training (p. 1959)
- Common Data Formats for Inference (p. 1963)

Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)
When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics
- Content Types Supported by Built-In Algorithms (p. 1960)
- Using Pipe Mode (p. 1960)
- Using CSV Format (p. 1960)
- Using RecordIO Format (p. 1961)
- Trained Model Deserialization (p. 1963)

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported ContentType values and the algorithms that use them:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>application/x-recordio</td>
<td>Object Detection Algorithm</td>
</tr>
<tr>
<td>application/x-recordio-protobuf</td>
<td>Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>BlazingText, DeepAR</td>
</tr>
<tr>
<td>image/jpeg</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>image/png</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>text/libsvm</td>
<td>XGBoost</td>
</tr>
</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

Using Pipe Mode

In Pipe mode, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to File mode, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the AlgorithmSpecification for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify text/csv as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable
is in the first column. To run unsupervised learning algorithms that don’t have a target, specify the number of label columns in the content type. For example, in this case `content_type=text/csv;label_size=0`. For a notebook example that uses CSV format, see Breast Cancer Prediction. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**
For an example that shows how to convert the commonly used numPy array into the protobuf recordIO format, see An Introduction to Factorization Machines with MNIST.

```proto
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 20) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated double values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 20) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  repeated int32 values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 20) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```
// dense vector.
repeated int32 values = 1 [packed = true];

// If this is not empty, the vector is treated as sparse with
// each key specifying the location of the value in the sparse vector.
repeated uint64 keys = 2 [packed = true];

// An optional shape that allows the vector to represent a matrix.
// For example, if shape = [10, 20], floor(keys[i] / 10) gives the row,
// and keys[i] % 20 gives the column.
// This also supports n-dimensional tensors.
// Note: If the tensor is sparse, you must specify this value.
repeated uint64 shape = 3 [packed = true];

} // Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
    repeated bytes value = 1;

    // If the content type of the data is known, stores it.
    // This allows for the possibility of using decoders for common formats
    // in the future.
    optional string content_type = 2;
}

message Value {
    oneof value {
        // The numbering assumes the possible use of:
        // - float16, float128
        // - int8, int16, int32
        Float32Tensor float32_tensor = 2;
        Float64Tensor float64_tensor = 3;
        Int32Tensor int32_tensor = 7;
        Bytes bytes = 9;
    }
}

message Record {
    // Map from the name of the feature to the value.
    // For vectors and libsvm-like datasets,
    // a single feature with the name 'values'
    // should be specified.
    map<string, Value> features = 1;

    // An optional set of labels for this record.
    // Similar to the features field above, the key used for
    // generic scalar / vector labels should be 'values'.
    map<string, Value> label = 2;

    // A unique identifier for this record in the dataset.
    // Whilst not necessary, this allows better
    // debugging where there are data issues.
    // This is not used by the algorithm directly.
    optional string uid = 3;

    // Textual metadata describing the record.
    // This may include JSON-serialized information
    // about the source of the record.
    // This is not used by the algorithm directly.
    optional string metadata = 4;
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

Note

For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channel. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

Trained Model Deserialization

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is unarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

Common Data Formats for Inference

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

Topics

- Convert Data for Inference Request Serialization (p. 1963)
- Convert Data for Inference Response Deserialization (p. 1965)
- Common Request Formats for All Algorithms (p. 1966)
- Use Batch Transform with Built-in Algorithms (p. 1967)

Convert Data for Inference Request Serialization

Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don't support all of
these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5, 16.0, 14, 23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
  // Instances might contain multiple rows that predictions are sought for.
  "instances": [
    // Request and algorithm specific inference parameters.
    "configuration": {},
    // Data in the specific format required by the algorithm.
    "data": {
      "<field name>": dataElement
    }
  ]
}
```

You have the following options for specifying the dataElement:

**Protocol buffers equivalent**

```javascript
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}
```

**Simple numeric vector**

```javascript
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": dataElement
}
```

**For multiple records**

```javascript
let request = {
  "instances": [
    // First instance.
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    },
    // Second instance.
    {
      "features": [-2.0, 100.2, 15.2, 9.2]
    }
  ]
}
```
Convert Data for Inference Response Deserialization

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```json
let response = {
  "predictions": [{
      // Fields in the response object are defined on a per algorithm-basis.
  }]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

**Single-record inference**

```json
let response = {
  "predictions": [
      {"closest_cluster": 5,
       "distance_to_cluster": 36.5}
  ]
}
```

**Multi-record inference**

```json
let response = {
  "predictions": [
      // First instance prediction.
      {"closest_cluster": 5,
       "distance_to_cluster": 36.5},
      // Second instance prediction.
      {"closest_cluster": 2,
       "distance_to_cluster": 90.3}
  ]
}
```

**Multi-record inference with protobuf input**

```json
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [5.0] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [36.5]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response
Use Built-in Algorithms

objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```json
[{
  "distance_to_cluster": 23.40593910217285,
  "closest_cluster": 0.0
},
{
  "distance_to_cluster": 27.250282287597656,
  "closest_cluster": 0.0
}]
```

While running batch transform, we recommended using the jsonlines response type by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

**Common Request Formats for All Algorithms**

Most algorithms use several of the following inference request formats.

**JSON Request Format**

**Content type:** application/JSON

**Dense format**

```json
let request = {
  "instances": [
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    }
  ]
}
```

```json
let request = {
  "instances": [
    {
      "data": {
        "features": [1.5, 16.0, 14.0, 23.0]
      }
    }
  ]
}
```

**Sparse format**

```json
{
  "instances": [
    {
      "data": {
        "features": {
          "keys": [26, 182, 232, 243, 431],
          "shape": [2000],
          "values": [1, 1, 1, 4, 1]
        }
      }
    },
    {
      "data": {
        "features": {
          "keys": [0, 182, 232, 243, 431],
          "shape": [2000],
          "values": [13, 1, 1, 4, 1]
        }
      }
    }
  ]
}
```
JSONLINES Request Format

**Content type:** application/JSONLINES

**Dense format**

A single record in dense format can be represented as either:

```json
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```json
{ "data": { "features": [1.5, 16.0, 14.0, 23.0] } }
```

**Sparse Format**

A single record in sparse format is represented as:

```json
{"data": {"features": {"keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } }}
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```json
{"data": {"features": {"keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } }}
{"data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } } }
{"features": [1.5, 16.0, 14.0, 23.0] }
```

CSV Request Format

**Content type:** text/CSV; label_size=0

**Note**

CSV support is not available for factorization machines.

RECORDIO Request Format

**Content type:** application/x-recordio-protobuf

**Use Batch Transform with Built-in Algorithms**

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the `SplitType` must be set according to the `ContentType` of the input data. Similarly, depending on the `Accept` field in the `CreateTransformJobRequest`, `AssembleWith` must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th><strong>ContentType</strong></th>
<th><strong>Recommended SplitType</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
</tr>
<tr>

</tr>
</tbody>
</table>

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats (p. 2138)
- Factorization Machines Response Formats (p. 1995)
- IP Insights Inference Data Formats (p. 2149)
- K-Means Response Formats (p. 2158)
- k-NN Request and Response Formats (p. 2002)
- Linear learner response formats (p. 2029)
- NTM Response Formats (p. 2086)
- Data Formats for Object2Vec Inference (p. 2101)
- Encoder Embeddings for Object2Vec (p. 2102)
- PCA Response Formats (p. 2162)
- RCF Response Formats (p. 2169)

**Instance Types for Built-in Algorithms**

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.12xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. For most algorithm training, we support P2, P3, G4dn, and G5 GPU instances. Despite higher per-instance costs, GPUs train more quickly, making them more cost-effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost-effectiveness solution. To get an automatic instance recommendation or conduct custom load tests, use Amazon SageMaker Inference Recommender.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.
Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose **CloudWatch**, choose **Logs**, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

**Note**

If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```plaintext
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```plaintext
   AlgorithmError: u'abc' is not valid under any of the given schemas\n   Failed validating u'oneOf' in schema[u'properties'][u'feature_dim']:
   [u'oneOf':
    [u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'],
    {u'minimum': 1, u'type': u'integer'}]
   ```

3. Inaccurate protobuf file format.

   **From the CloudWatch log**

   ```plaintext
   [10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc'
   is not valid under any of the given schemas
   ```

   ```plaintext
   [10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
   ```
Built-in SageMaker Algorithms for Tabular Data

Amazon SageMaker provides built-in algorithms that are tailored to the analysis of tabular data. The built-in SageMaker algorithms for tabular data can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1971)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1978)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1986)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1996)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- **LightGBM (p. 2005)**—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
- **Linear Learner Algorithm (p. 2014)**—learns a linear function for regression or a linear threshold function for classification.
- **TabTransformer (p. 2031)**—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- **XGBoost Algorithm (p. 2038)**—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

### AutoGluon-Tabular

AutoGluon-Tabular is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers.

**How to use SageMaker AutoGluon-Tabular**

You can use AutoGluon-Tabular as an Amazon SageMaker built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-regression-ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(  
    region=None,  
    framework=None,  
    model_id=train_model_id,  
    model_version=train_model_version,  
    image_scope=train_scope,  
    instance_type=training_instance_type
```
# Retrieve the training script
train_source_uri = script_uri.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uri.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["auto_stack"] = "True"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance

# Create a SageMaker Estimator instance

# Launch a SageMaker Training job by passing the S3 path of the training data

For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm
- Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm
Input and Output interface for the AutoGluon-Tabular algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.
- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then a fraction of your training data is randomly sampled to serve as the validation data. This fraction is selected based on the number of rows in your training data. For more information see Tabular Prediction in the AutoGluon documentation.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AutoGluon-Tabular uses the `autogluon.tabular.TabularPredictor` module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker AutoGluon-Tabular with the AutoGluon framework**

- Use the following Python code:

```python
import tarfile
from autogluon.tabular import TabularPredictor
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = TabularPredictor.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names 'feature_0', 'feature_1', ..., 'feature_d'
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm

SageMaker AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage
of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AutoGluon-Tabular currently does not support multi-GPU training.

AutoGluon-Tabular sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AutoGluon-Tabular algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are assembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.
Use Built-in Algorithms

For more information, see *AutoGluon-Tabular: Robust and Accurate AutoML for Structured Data*.

### AutoGluon-Tabular hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AutoGluon-Tabular algorithm is an implementation of the open-source *AutoGluon-Tabular* package.

**Note**

The default hyperparameters are based on example datasets in the *AutoGluon-Tabular sample notebooks* (p. 1974).

By default, the SageMaker AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| eval_metric    | The evaluation metric for validation data. If `eval_metric` is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - "root_mean_squared_error" for regression  
  - "roc_auc" for binary classification  
  - "accuracy" for multi-class classification |

|                   | For more details, see AutoGluon Predictors.                                                                                                                                                                                                                                                                                                                    |
| Valid values:     | string, any of the following: ("best_quality", "high_quality", "good_quality", "medium_quality", "optimize_for_deployment", or "interpretable").                                                                                                                                                                                                                         |
| Default value:    | "medium_quality".                                                                                                                                                                                                                                                                                                                                                 |
| auto_stack        | Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set auto_stack to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the num_bag_folds and num_stack_levels arguments based on dataset properties.  
|                   | Valid values: string, "True" or "False".                                                                                                                                                                                                                                                                                                                        |
| Default value:    | "False".                                                                                                                                                                                                                                                                                                                                                         |
| num_bag_folds     | Number of folds used for bagging of models. When num_bag_folds is equal to k, training time is roughly increased by a factor of k. Set num_bag_folds to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing num_bag_folds results in models with lower bias, but that are more prone to overfitting. One is an invalid value for this parameter, and will raise a ValueError. Values greater than 10 may produce diminishing returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing num_bag_folds and instead increase num_bag_sets.  
<p>|                   | Valid values: string, any integer between (and including) &quot;0&quot; and &quot;10&quot;.                                                                                                                                                                                                                                                                                              |
| Default value:    | &quot;0&quot;.                                                                                                                                                                                                                                                                                                                                                             |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_bag_sets</td>
<td>Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to num_bag_folds * num_bag_sets. This parameter defaults to one if time_limit is not specified. This parameters is disabled if num_bag_folds is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [1, 20]. Default value: 1.</td>
</tr>
<tr>
<td>num_stack_levels</td>
<td>Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of num_stack_levels + 1. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a ValueError, num_bag_folds must be greater than or equal to 2. Valid values: float, range: [0, 3]. Default value: 0.</td>
</tr>
<tr>
<td>refit_full</td>
<td>Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>set_best_to_refit_full</td>
<td>Whether or not to change the default model that the predictor uses for prediction. If set_best_to_refit_full is set to &quot;True&quot;, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by refit_full). Only valid if refit_full is set. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>save_space</td>
<td>Whether or note to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting save_space to &quot;True&quot; if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if save_space is set to &quot;True&quot;. Refer to the predictor.save_space() documentation for more details. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>

### Tuning an AutoGluon-Tabular model

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see AutoGluon-Tabular hyperparameters (p. 1975).

### CatBoost

**CatBoost** is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

### How to use SageMaker CatBoost

You can use CatBoost as an Amazon SageMaker built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

**Use CatBoost as a built-in algorithm**

Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "catboost-classification-model", "*", "training"
```
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["iterations"] = "500"
print(hyperparameters)

from sagemaker import Estimator
from sagemaker import utils

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(train_dataset_s3_path)
For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples.
- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of CatBoost supports CSV for training and inference:
- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.
- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.
- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string “cat_index_list” and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker CatBoost uses the `catboost.CatBoostClassifier` and `catboost.CatBoostRegressor` modules to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker CatBoost with catboost**

- Use the following Python code:
import tarfile
from catboost import CatBoostClassifier

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)

Amazon EC2 instance recommendation for the CatBoost algorithm

SageMaker CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

CatBoost sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker CatBoost algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker CatBoost algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker CatBoost algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you
You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works (p. 2043). For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see CatBoost: unbiased boosting with categorical features.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker CatBoost algorithm is an implementation of the open-source CatBoost package.

**Note**
The default hyperparameters are based on example datasets in the CatBoost sample notebooks (p. 1981).

By default, the SageMaker CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iterations</td>
<td>The maximum number of trees that can be built. Valid values: integer, range: Positive integer. Default value: 500.</td>
</tr>
<tr>
<td>early_stopping_rounds</td>
<td>The training will stop if one metric of one validation data point does not improve in the last <code>early_stopping_rounds</code> round. If <code>early_stopping_rounds</code> is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: 5.</td>
</tr>
</tbody>
</table>
| eval_metric             | The evaluation metric for validation data. If `eval_metric` is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - "RMSE" for regression  
  - "AUC" for binary classification  
  - "MultiClass" for multi-class classification  
  Valid values: string, refer to the CatBoost documentation for valid values. Default value: "auto". |
<table>
<thead>

<td>The verbosity of print messages, with higher levels corresponding to more detailed print statements. Valid values: integer, range: Positive integer. Default value: 1.</td>
</tr>
</tbody>
</table>

**Tune a CatBoost model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

- A learning loss function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**

Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2436).

**Evaluation metrics computed by the CatBoost algorithm**

The SageMaker CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For a

### Tunable CatBoost hyperparameters

Tune the CatBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the CatBoost evaluation metrics are: learning_rate, depth, l2_leaf_reg, and random_strength. For a list of all the CatBoost hyperparameters, see CatBoost hyperparameters (p. 1982).

### Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.
Note
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics
- Input/Output Interface for the Factorization Machines Algorithm (p. 1987)
- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1987)
- Factorization Machines Sample Notebooks (p. 1987)
- How Factorization Machines Work (p. 1988)
- Factorization Machines Hyperparameters (p. 1988)
- Tune a Factorization Machines Model (p. 1993)
- Factorization Machines Response Formats (p. 1995)

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with Float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the binary classification problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the regression problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks (p. 1987) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.
How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function \( \hat{y} \) from a feature set \( x_i \) to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset \((x_i, y_j)\) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[
\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j > i} <v_i, v_j> x_i x_j
\]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w_0 \) term represents the global bias.
- The \( w_i \) linear terms model the strength of the \( i^{th} \) variable.
- The \( <v_i, v_j> \) factorization terms model the pairwise interaction between the \( i^{th} \) and \( j^{th} \) variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[
L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2
\]

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[
L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]
\]

where:

\[
\hat{p}_n = \frac{1}{1 + e^{-\hat{y}_n}}
\]

For more information about loss functions for classification, see Loss functions for classification.

Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

**Tune a Factorization Machines Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see *Perform Automatic Model Tuning with SageMaker* (p. 2436).

**Metrics Computed by the Factorization Machines Algorithm**

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

### Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if `bias_init_method==uniform`, then only `bias_init_scale`, `linear_init_scale`, and `factors_init_scale` are tunable. Similarly, if the initialization method is normal, then only `sigma` parameters are tunable. If the initialization method is constant, then only `value` parameters are tunable. These dependencies are listed in the following table.

#### Factorization Machines Response Formats

**JSON Response Format**

**Binary classification**

```json
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

**Regression**

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES Response Format**

**Binary classification**

```json
{"score": 0.4, "predicted_label": 0}
```

**Regression**

```json
{"score": 0.4}
```
**RECORDIO Response Format**

Binary classification

```
[ Record = {  
    features = {},  
    label = {  
        'score': {  
            keys: [],  
            values: [0.4]  # float32  
        },  
        'predicted_label': {  
            keys: [],  
            values: [0.0]  # float32  
        }  
    }  
}  
]
```

Regression

```
[ Record = {  
    features = {},  
    label = {  
        'score': {  
            keys: [],  
            values: [0.4]  # float32  
        }  
    }  
}  
]
```

**K-Nearest Neighbors (k-NN) Algorithm**

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the \( k \) points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the \( k \) closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (\( d >1000 \)) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN’s training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

**Topics**
- Input/Output Interface for the k-NN Algorithm (p. 1997)
- k-NN Sample Notebooks (p. 1997)
- How the k-NN Algorithm Works (p. 1998)
- EC2 Instance Recommendation for the k-NN Algorithm (p. 1998)
- k-NN Hyperparameters (p. 1999)
Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

- Use a **train channel** for data that you want to sample and construct into the k-NN index.
- Use a **test channel** to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports *text/csv* and *application/x-recordio-protobuf* data formats. For input type *text/csv*, the first *label_size* columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as *CSV*.

For inference inputs, k-NN supports the *application/json*, *application/x-recordio-protobuf*, and *text/csv* data formats. The *text/csv* format accepts a *label_size* and encoding parameter. It assumes a *label_size* of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the *application/json* and *application/x-recordio-protobuf* data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the *application/jsonlines* data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 2001) for training, k-NN Request and Response Formats (p. 2002) for inference, and the k-NN Sample Notebooks (p. 1997).

k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.
How the k-NN Algorithm Works

Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires $O(ndk)$ time to reduce the dimension of a batch of $n$ points of dimension $d$ into a target dimension $k$. The `fjlt` method requires $O(nd \log(d))$ time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.

Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- `model_algo-1`: Contains the serialized index for computing the nearest neighbors.
- `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the $k$ and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change $k$ to 10 or change `predictor_type` to `regressor`.

```json
{
    "k": 5,
    "predictor_type": "classifier",
    "dimension_reduction": {
        "type": "sign",
        "seed": 3,
        "target_dim": 10,
        "input_dim": 20,
        "normalize": false,
        "version": "1.0"
    }
}
```

EC2 Instance Recommendation for the k-NN Algorithm

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.
Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

</table>
Use Built-in Algorithms

Parameter Name | Description
--- | ---
faiss_index_pq_m | The FaceBook AI Similarity Search (FAISS) library requires that the value of `faiss_index_pq_m` is a divisor of the data dimension. If `faiss_index_pq_m` is not a divisor of the data dimension, we increase the data dimension to smallest integer divisible by `faiss_index_pq_m`. If no dimension reduction is applied, the algorithm adds a padding of zeros. If dimension reduction is applied, the algorithm increase the value of the `dimension_reduction_target` hyper-parameter.

**Optional**

Valid values: One of the following positive integers: 1, 2, 3, 4, 8, 12, 16, 20, 24, 28, 32, 40, 48, 56, 64, 96

index_metric | The metric to measure the distance between points when finding nearest neighbors. When training with `index_type` set to `faiss.IVFPQ`, the `INNER_PRODUCT` distance and `COSINE` similarity are not supported.

**Optional**

Valid values: `L2` for Euclidean-distance, `INNER_PRODUCT` for inner-product distance, `COSINE` for cosine similarity.

Default value: `L2`

index_type | The type of index.

**Optional**

Valid values: `faiss.Flat`, `faiss.IVFFlat`, `faiss.IVFPQ`.

Default values: `faiss.Flat`

mini_batch_size | The number of observations per mini-batch for the data iterator.

**Optional**

Valid values: positive integer

Default value: 5000

Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.
For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the predictor_type hyper-parameter.

- **classifier** specifies a classification task and computes test:accuracy
- **regressor** specifies a regression task and computes test:mse.

Choose the predictor_type value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:accuracy</td>
<td>When predictor_type is set to classifier, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:mse</td>
<td>When predictor_type is set to regressor, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.</td>
<td>Minimize</td>
</tr>

Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

**CSV Data Format**

content-type: text/csv; label_size=1

4,1.2,1.3,9.6,20.3

The first label_size columns are interpreted as the label vector for that row.
RECORDIO Data Format

content-type: application/x-recordio-protobuf

```
[  
  Record = {    
    features = {    
      'values': {    
        values: [1.2, 1.3, 9.6, 20.3]  # float32    
      },    
      label = {    
        'values': {    
          values: [4]  # float32    
        }    
      }    
    }  
  }  
]
```

**k-NN Request and Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

**INPUT: CSV Request Format**

content-type: text/csv

```
1.2,1.3,9.6,20.3
```

This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

**INPUT: JSON Request Format**

content-type: application/json

```
{  
  "instances": [  
    {"data": {"features": {"values": [-3, -1, -4, 2]}},  
     {"features": [3.0, 0.1, 0.04, 0.002]}]
  }
```

**INPUT: JSONLINES Request Format**

content-type: application/jsonlines

```
{"features": [1.5, 16.0, 14.0, 23.0]}  
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

**INPUT: RECORDIO Request Format**

content-type: application/x-recordio-protobuf

```
[  
  Record = {    
    features = {    
```

2002
'values': {'values': [-3, -1, -4, 2] # float32}, label = {}, Record = {
  'features': {
    'values': {'values': [3.0, 0.1, 0.04, 0.002] # float32},
    label = {}
  },
},

OUTPUT: JSON Response Format
accept: application/json

{
  "predictions": [
    {"predicted_label": 0.0},
    {"predicted_label": 2.0}
  ]
}

OUTPUT: JSONLINES Response Format
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}

OUTPUT: VERBOSE JSON Response Format
In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.
accept: application/json; verbose=true

{
  "predictions": [
    {
      "predicted_label": 0.0,
      "distances": [3.11792408, 3.89746071, 6.32548437],
      "labels": [0.0, 1.0, 0.0]
    },
    {
      "predicted_label": 2.0,
      "distances": [1.08470316, 3.04917915, 5.25393973],
      "labels": [2.0, 2.0, 0.0]
    }
  ]
}

OUTPUT: RECORDIO-PROTOBUF Response Format
content-type: application/x-recordio-protobuf

[ ]
OUTPUT: VERBOSERECORDIO-PROTOBUF Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/x-recordio-protobuf; verbose=true

```
[  
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0]  # float32
      },
      'distances': {
        values: [3.11792408, 3.89746071, 6.32548437]  # float32
      },
      'labels': {
        values: [0.0, 1.0, 0.0]  # float32
      }
    }
  },
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0]  # float32
      },
      'distances': {
        values: [1.08470316, 3.04917915, 5.25393973]  # float32
      },
      'labels': {
        values: [2.0, 2.0, 0.0]  # float32
      }
    }
  }
]
```

SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

```
[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse', 0.01333333333333334)
```
For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy', 0.9866666666666667)
```

**LightGBM**

**LightGBM** is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT.

**How to use SageMaker LightGBM**

You can use LightGBM as an Amazon SageMaker built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio UI, see [SageMaker JumpStart](p. 45).

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using [Amazon SageMaker Python SDK](version 2).

  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "lightgbm-classification-model", "+", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
```
output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(model_id=train_model_id, model_version=train_model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["num_boost_round"] = "500"

print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {"training": training_dataset_s3_path}, logs=True, job_name=training_job_name
)

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of LightGBM supports CSV for training and inference:

- For Training ContentType, valid inputs must be text/csv.
- For Inference ContentType, valid inputs must be text/csv.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.

- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker LightGBM with the JobLib module**

- Use the following Python code:

```python
import joblib
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = joblib.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

**Amazon EC2 instance recommendation for the LightGBM algorithm**

SageMaker LightGBM currently only trains using CPUs. LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

**LightGBM sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker LightGBM algorithm.
Notebook Title | Description
---|---
Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm | This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm | This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular regression model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

**How LightGBM works**

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works (p. 2043). For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see LightGBM: A Highly Efficient Gradient Boosting Decision Tree.

**LightGBM hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker LightGBM algorithm is an implementation of the open-source LightGBM package.

**Note**
The default hyperparameters are based on example datasets in the LightGBM sample notebooks (p. 2007).

By default, the SageMaker LightGBM algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The LightGBM algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error and the objective function is L2 loss. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric is multiclass cross entropy and the objective function is softmax. You can use the metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_boost_round</td>
<td>The maximum number of boosting iterations. <strong>Note:</strong> Internally, LightGBM constructs num_class * num_boost_round trees for multi-class classification problems.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>early_stopping_rounds</td>
<td>The training will stop if one metric of one validation data point does not improve in the last early_stopping_rounds round. If early_stopping_rounds is less than or equal to zero, this hyperparameter is ignored.</td>
</tr>
</tbody>
</table>
| metric                | The evaluation metric for validation data. If metric is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - \( \text{rmse} \) for regression  
  - \( \text{binary\_logloss} \) for binary classification  
  - \( \text{multi\_logloss} \) for multi-class classification  
  Valid values: string, any of the following: ("auto", "rmse", "l1", "l2", "huber", "fair", "binary\_logloss", "binary\_error", "auc", "average\_precision", "multi\_logloss", "multi\_error", "auc\_mu", or "cross\_entropy"). |
<p>| learning_rate         | The rate at which the model weights are updated after working through each batch of training examples.                                          |
| num_leaves            | The maximum number of leaves in one tree.                                                                                                    |
| feature_fraction      | A subset of features to be selected on each iteration (tree). Must be less than 1.0.                                                        |
| bagging_fraction      | A subset of features similar to feature_fraction, but bagging_fraction randomly selects part of the data without resampling.                |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bagging_freq</td>
<td>The frequency to perform bagging. At every bagging_freq iteration, LightGBM randomly selects a percentage of the data to use for the next bagging_freq iteration. This percentage is determined by the bagging_fraction hyperparameter. If bagging_freq is zero, then bagging is deactivated. Valid values: integer, range: Non-negative integer. Default value: 1.</td>
</tr>
<tr>
<td>max_depth</td>
<td>The maximum depth for a tree model. This is used to deal with overfitting when the amount of data is small. If max_depth is less than or equal to zero, this means there is no limit for maximum depth. Valid values: integer. Default value: 6.</td>
</tr>
<tr>
<td>min_data_in_leaf</td>
<td>The minimum amount of data in one leaf. Can be used to deal with overfitting. Valid values: integer, range: Non-negative integer. Default value: 3.</td>
</tr>
<tr>
<td>max_delta_step</td>
<td>Used to limit the max output of tree leaves. If max_delta_step is less than or equal to 0, then there is no constraint. The final max output of leaves is learning_rate * max_delta_step. Valid values: float. Default value: 0.0.</td>
</tr>
<tr>

<tr>
<td>lambda_l2</td>
<td>L2 regularization. Valid values: float, range: Non-negative float. Default value: 0.0.</td>
</tr>
<tr>
<td>boosting</td>
<td>Boosting type Valid values: string, any of the following: (&quot;gbdt&quot;, &quot;rf&quot;, &quot;dart&quot;, or &quot;goss&quot;). Default value: &quot;gbdt&quot;.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>min_gain_to_split</td>
<td>The minimum gain to perform a split. Can be used to speed up training. Valid values: integer, float: Non-negative float. Default value: 0.0.</td>
</tr>
<tr>
<td>scale_pos_weight</td>
<td>The weight of the labels with positive class. Used only for binary classification tasks. <code>scale_pos_weight</code> cannot be used if <code>is_unbalance</code> is set to &quot;True&quot;. Valid values: float, range: Positive float. Default value: 1.0.</td>
</tr>
<tr>
<td>tree_learner</td>
<td>Tree learner type. Valid values: string, any of the following: (&quot;serial&quot;, &quot;feature&quot;, &quot;data&quot;, or &quot;voting&quot;). Default value: &quot;serial&quot;.</td>
</tr>
<tr>
<td>feature_fraction_by_node</td>
<td>Selects a subset of random features on each tree node. For example, if <code>feature_fraction_by_node</code> is 0.8, then 80% of features are selected. Can be used to deal with overfitting. Valid values: integer, range: (0.0, 1.0]. Default value: 1.0.</td>
</tr>
<tr>
<td>is_unbalance</td>
<td>Set to &quot;True&quot; if training data is unbalanced. Used only for binary classification tasks. <code>is_unbalance</code> cannot be used with <code>scale_pos_weight</code>. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>max_bin</td>
<td>The maximum number of bins used to bucket feature values. A small number of bins may reduce training accuracy, but may increase general performance. Can be used to deal with overfitting. Valid values: integer, range: (1, ∞). Default value: 255.</td>
</tr>
<tr>
<td>tweedie_variance_power</td>
<td>Controls the variance of the Tweedie distribution. Set this closer to 2.0 to shift toward a gamma distribution. Set this closer to 1.0 to shift toward a Poisson distribution. Used only for regression tasks. Valid values: float, range: [1.0, 2.0]. Default value: 1.5.</td>
</tr>
</tbody>
</table>
## Parameter Name: `num_threads`

Number of parallel threads used to run LightGBM. Value 0 means default number of threads in OpenMP.

Valid values: integer, range: Non-negative integer.

Default value: 0.

## Parameter Name: `verbosity`

The verbosity of print messages. If the verbosity is less than 0, then print messages only show fatal errors. If verbosity is set to 0, then print messages include errors and warnings. If verbosity is 1, then print messages show more information. A verbosity greater than 1 shows the most information in print messages and can be used for debugging.

Valid values: integer.

Default value: 1.

---

### Tune a LightGBM model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**

Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2436).

### Evaluation metrics computed by the LightGBM algorithm

The SageMaker LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

<table>

### Tunable LightGBM hyperparameters

Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: `learning_rate`, `num_leaves`, `feature_fraction`, `bagging_fraction`, `bagging_freq`, `max_depth` and `min_data_in_leaf`. For a list of all the LightGBM hyperparameters, see LightGBM hyperparameters (p. 2008).

### Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(num\_classes - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see CreateTrainingJob. You can specify additional parameters in the HyperParameters string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

**Topics**

- Input/Output interface for the linear learner algorithm (p. 2015)
- EC2 instance recommendation for the linear learner algorithm (p. 2015)
- Linear learner sample notebooks (p. 2015)
- How linear learner works (p. 2016)
- Linear learner hyperparameters (p. 2017)
- Tune a linear learner model (p. 2025)
- Linear learner response formats (p. 2029)
Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don’t provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 2029). For more information on inference formats, and the Linear learner sample notebooks (p. 2015).

EC2 instance recommendation for the linear learner algorithm

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

**Step 1: Preprocess**

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

**Note**

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

**Step 2: Train**

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

**Step 3: Validate and set the threshold**

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the...
best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

**Note**
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

**Linear learner hyperparameters**

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>The number of classes for the response variable. The algorithm assumes that classes are labeled 0, ..., num_classes - 1. Required when predictor_type is multiclass_classifier. Otherwise, the algorithm ignores it. Valid values: Integers from 3 to 1,000,000</td>
</tr>
<tr>
<td>predictor_type</td>
<td>Specifies the type of target variable as a binary classification, multiclass classification, or regression. Required Valid values: binary_classifier, multiclass_classifier, or regressor</td>

**Tune a linear learner model**

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, num_models, to 1. The algorithm ignores any value that you set for num_models.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

**Metrics computed by the linear learner algorithm**

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>

**Linear learner response formats**

**JSON response formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). The following are the available output formats for the SageMaker linear learner algorithm.

**Binary Classification**

```json
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

**Multiclass Classification**

```json
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

**Regression**

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES response formats**

**Binary Classification**

```
```
Multiclass Classification

["score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2]

Regression

["score": 0.4]

RECORDIO response formats

Binary Classification

[    Record = {        features = {},        label = {            'score': {                keys: [],                values: [0.4]  # float32            },            'predicted_label': {                keys: [],                values: [0.0]  # float32            }        }    }]

Multiclass Classification

[    Record = {        "features": [],        "label": {            "score": {                "values": [0.1, 0.2, 0.3, 0.4]            },            "predicted_label": {                "values": [3]            }        },        "uid": "abc123",        "metadata": "{created_at: '2017-06-03'}"    }]

Regression

[    Record = {        features = {},        label = {            'score': {                keys: [],                values: [0.4]  # float32            }        }    }]
TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

How to use SageMaker TabTransformer

You can use TabTransformer as an Amazon SageMaker built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

• Use TabTransformer as a built-in algorithm

Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
output_bucket = sess.default_bucket()
```
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["n_epochs"] = "50"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance

tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data

tabular_estimator.fit(
    {"training": training_dataset_s3_path}, logs=True, job_name=training_job_name
)

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker TabTransformer algorithm
- Tabular regression with Amazon SageMaker TabTransformer algorithm

### Input and Output interface for the TabTransformer algorithm

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be text/csv.
- For **Inference ContentType**, valid inputs must be text/csv.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.
Be mindful of how to format your training data for input to the TabTransformer model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.

- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

**Amazon EC2 instance recommendation for the TabTransformer algorithm**

SageMaker TabTransformer supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker TabTransformer currently does not support multi-GPU training.

**TabTransformer sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker TabTransformer algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker TabTransformer algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker TabTransformer algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

**How TabTransformer works**

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform the
embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.
Figure 1: The architecture of TabTransformer.

For more information, see TabTransformer: Tabular Data Modeling Using Contextual Embeddings.
**TabTransformer hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker TabTransformer algorithm is an implementation of the open-source TabTransformer package.

**Note**
The default hyperparameters are based on example datasets in the TabTransformer sample notebooks (p. 2033).

The SageMaker TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is r square and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

**Note**
The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

**Tune a TabTransformer model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Note

The learning objective function and evaluation metric are both automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see TabTransformer hyperparameters (p. 2036).

Evaluation metrics computed by the TabTransformer algorithm

The SageMaker TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.
**Tunable TabTransformer hyperparameters**

Tune the TabTransformer model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the TabTransformer evaluation metrics are: `learning_rate`, `input_dim`, `n_blocks`, `attn_dropout`, `mlp_dropout`, and `frac_shared_embed`. For a list of all the TabTransformer hyperparameters, see [TabTransformer hyperparameters](p. 2036).

**XGBoost Algorithm**

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, and 1.5.
**Supported versions**

- Framework (open source) mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1
- Algorithm mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1

**Important**

When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the **Supported versions** (p. 2039) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see **Docker Registry Paths and Example Code**, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

**Warning**

The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. It is highly recommended to upgrade the XGBoost version to one of the newer versions.

**Note**

XGBoost v1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker XGBoost 1.2-2 or later.

**How to Use SageMaker XGBoost**

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK. For information on how to use XGBoost from the Amazon SageMaker Studio UI, see **SageMaker JumpStart** (p. 45).

**Use XGBoost as a framework**

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":"0.7",
    "verbosity":"1",
    "objective":"reg:squarederror",
    "num_round":"50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgboost-framework')
```
# construct a SageMaker XGBoost estimator

estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.5-1',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/*/*.format(bucket, prefix, 'train'),
                             content_type=content_type)
validation_input = TrainingInput("s3://{}/*/*.format(bucket, prefix, 'validation'),
                                content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

* Use XGBoost as a built-in algorithm

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

**Important**

When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 2039) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
                                content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm (default) or text/csv.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.
For v1.3-1 and later, SageMaker XGBoost saves the model in the XGBoost internal binary format, using `Booster.save_model`. Previous versions use the Python pickle module to serialize/deserialize the model.

**Note**
Be mindful of versions when using an SageMaker XGBoost model in open source XGBoost. Versions 1.3-1 and later use the XGBoost internal binary format while previous versions use the Python pickle module.

**To use a model trained with SageMaker XGBoost v1.3-1 or later in open source XGBoost**

- Use the following Python code:

```python
import xgboost as xgb
xgb_model = xgb.Booster()
xgb_model.load_model(model_file_path)
xgb_model.predict(dtest)
```

**To use a model trained with previous versions of SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))
# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For text/csv input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Algorithm**

SageMaker XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. SageMaker XGBoost version 1.2 or later supports P2 and P3 instances.

SageMaker XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.
To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker XGBoost currently does not support multi-GPU training.

SageMaker XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see [Amazon SageMaker ML Instance Types](#).

**XGBoost Sample Notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

<table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](#). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

**How XGBoost Works**

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the
regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.

\[
F_m(X) = F_{m-1}(X) + \alpha_m h_m(X, r_{m-1}),
\]

where \(\alpha_i\) and \(r_i\) are the regularization parameters and residuals computed with the \(i^{th}\) tree respectfully, and \(h_i\) is a function that is trained to predict residuals, \(r_i\) using \(X\) for the \(i^{th}\) tree. To compute \(\alpha_i\) we use the residuals computed, \(r_i\) and compute the following: 

\[
\arg \min_{\alpha} \sum_{i=1}^{m} L(Y_i, F_{i-1}(X_i) + \alpha h_i(X_i, r_{i-1})).
\]

\(L(Y, F(X))\) is a differentiable loss function.

For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

**XGBoost Hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2.2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

Tune an XGBoost Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**
Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

**Evaluation Metrics Computed by the XGBoost Algorithm**

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>validation:accuracy</code></td>
<td>Classification rate, calculated as #right/#all cases.</td>

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics
- Upgrade XGBoost Version 0.90 to Version 1.5 (p. 2053)
- XGBoost Version 0.72 (p. 2055)

Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost version and framework_version parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.
Topics

- Upgrade SageMaker Python SDK Version 1.x to Version 2.x (p. 2054)
- Change the image tag to 1.5-1 (p. 2054)
- Change Docker Image for Boto3 (p. 2054)
- Update Hyperparameters and Learning Objectives (p. 2055)

Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```python
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.5-1',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```python
content_type = "libsvm"
train_input = TrainingInput("s3:///{}/{}/*".format(bucket, prefix, 'train'),
                          content_type=content_type)
validation_input = TrainingInput("s3:///{}/{}/*".format(bucket, prefix, 'validation'),
                               content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.
Use Built-in Algorithms

```json
{
    "AlgorithmSpecification": {
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.5-1"
    }
}
```

If you using the SageMaker Python SDK to retrieve registry path, change the version parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

Update Hyperparameters and Learning Objectives

The silent parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use verbosity instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```python
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          ...
)
```

XGBoost Version 0.72

**Important**

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

SageMaker Python SDK v1

```python
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
                             repo_version="1")
```

SageMaker Python SDK v2

```python
import boto3
from sagemaker import image_uris
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 2039)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of
the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 2038). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm or (the default) text/csv.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```
To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight id_0:val_0 id_1:val_1.... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...).

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tbody>
</table>
| min_child_weight | Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than min_child_weight, the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is.  
Optional  
Valid values: Float. Range: \([0,\infty)\).  
Default value: 1  |
| normalize_type   | Type of normalization algorithm.  
Optional  
Valid values: Either tree or forest.  
Default value: tree  |
| nthread          | Number of parallel threads used to run xgboost.  
Optional  
Valid values: integer  
Default value: Maximum number of threads.  |
| objective        | Specifies the learning task and the corresponding learning objective. Examples: reg:logistic, reg:softmax, multi:squarederror. For a full list of valid inputs, refer to XGBoost Parameters.  
Optional  
Valid values: string  
Default value: reg:squarederror  |
| one_drop         | When this flag is enabled, at least one tree is always dropped during the dropout.  
Optional  
Valid values: 0 or 1  
Default value: 0  |
| process_type     | The type of boosting process to run.  
Optional  
Valid values: String. Either default or update.  
Default value: default  |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| rate_drop        | The dropout rate that specifies the fraction of previous trees to drop during the dropout.  
|                  | **Optional**  
|                  | Valid values: Float. Range: [0.0, 1.0].  
|                  | Default value: 0.0  |
| refresh_leaf     | This is a parameter of the 'refresh' updater plug-in. When set to true (1), tree leaves and tree node stats are updated. When set to false(0), only tree node stats are updated.  
|                  | **Optional**  
|                  | Valid values: 0/1  
|                  | Default value: 1  |
| sample_type      | Type of sampling algorithm.  
|                  | **Optional**  
|                  | Valid values: Either uniform or weighted.  
|                  | Default value: uniform  |
| scale_pos_weight | Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: sum(negative cases) / sum(positive cases).  
|                  | **Optional**  
|                  | Valid values: float  
|                  | Default value: 1  |
| seed             | Random number seed.  
|                  | **Optional**  
|                  | Valid values: integer  
|                  | Default value: 0  |
| silent           | 0 means print running messages, 1 means silent mode.  
|                  | **Optional**  
|                  | Valid values: 0 or 1  
<p>|                  | Default value: 0  |</p>

Tune an XGBoost Release 0.72 Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>

### Built-in SageMaker Algorithms for Text Data

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- **BlazingText algorithm (p. 2066)**—a highly optimized implementation of the Word2Vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- **Latent Dirichlet Allocation (LDA) Algorithm (p. 2076)**—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn’t use example data with answers during training.
- **Neural Topic Model (NTM) Algorithm (p. 2081)**—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- **Object2Vec Algorithm (p. 2087)**—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- **Sequence-to-Sequence Algorithm (p. 2103)**—a supervised algorithm commonly used for neural machine translation.
- **Text Classification - TensorFlow (p. 2116)**—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

**BlazingText algorithm**

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a word embedding. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's
implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>
<th>Word2Vec (Unsupervised Learning)</th>

</tbody>
</table>

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

Topics

- Input/Output Interface for the BlazingText Algorithm (p. 2067)
- EC2 Instance Recommendation for the BlazingText Algorithm (p. 2070)
- BlazingText Sample Notebooks (p. 2070)
- BlazingText Hyperparameters (p. 2071)
- Tune a BlazingText Model (p. 2074)

Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.
Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the train channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string __label__. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time , intel says , despite all the linux hype , the open-source movement has yet to make a huge splash in the desktop market . that may be about to change , thanks to chipmaking giant intel corp .
__label__2  bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived .
```

Note
The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the source tag and the label can be specified using the label tag. Both source and label tags should be provided under the AttributeNames parameter value as specified in the request.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label": [1, 3]}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly", "label": [2, 4, 5]}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2700).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores
the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesn't_match('breakfast cereal dinner lunch'.split())
```

If the evaluation parameter is set to `True`, an additional file, `eval.json`, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

**Sample JSON Request**

Mime-type: application/json

```json
{
  "instances": ["word1", "word2", "word3"]
}
```

**Model Artifacts for the Text Classification Algorithm**

Training with supervised outputs creates a `model.bin` file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

**Sample JSON Request**

Mime-type: application/json

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top \( k \) predictions, you can set \( k \) in the configuration, as follows:

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."],
  "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```json
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}

if you need to pass the value of \( k \) for top-\( k \), then you can do it in the following way:

```json
{"source": "source_0", "k": 2}
```
For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```bash
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks Text Classification with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the Word2Vec Algorithm.

EC2 Instance Recommendation for the BlazingText Algorithm

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the S3DataDistributionType field of the S3DataSource object that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.

BlazingText Sample Notebooks

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). After creating and opening a
notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

### BlazingText Hyperparameters

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

### Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

### Tune a BlazingText Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric
from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

**Metrics Computed by the BlazingText Algorithm**

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

<table>

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: eat, sleep, play, meow, and bark, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>eat</th>
<th>sleep</th>
<th>play</th>
<th>meow</th>
<th>bark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to meow and sleep), and documents that fall into Topic 2 are about dogs (who prefer to play and bark). These topics can be found even though the words dog and cat never appear in any of the texts.

Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

Topics

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to number of records * vocabulary size. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_mixture vector for each observation.

Please see the LDA Sample Notebooks (p. 2078) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.
LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

Note
Lemmatisation significantly increases algorithm performance and accuracy. Consider pre-processing any input text data.

An LDA model is defined by two parameters:

- \( \alpha \) — A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- \( \beta \) — A collection of k topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture \( \theta \sim \text{Dirichlet}(\alpha) \).

For each word in the document:

- Choose a topic \( z \sim \text{Multinomial}(\theta) \)
- Choose the corresponding topic-word distribution \( \beta_z \).
- Draw a word \( w \sim \text{Multinomial}(\beta_z) \).

When training the model, the goal is to find parameters \( \alpha \) and \( \beta \), which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
• **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a $V \times V \times V$ tensor, which summarizes the moments of the documents in our corpus. $V$ is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters $\alpha$ and $\beta$, which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this $V \times V \times V$ tensor is prohibitively large to store in memory.

2. Instead, it uses a $V \times V$ moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension $V \times k$. This matrix can be used to convert the $V \times V$ moment matrix into a $k \times k$ identity matrix. $k$ is the number of topics in the model.

3. This same whitening matrix can then be used to find a smaller $k \times k \times k$ tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the $V \times V \times V$ tensor.

4. **Alternating Least Squares** is used to decompose the smaller $k \times k \times k$ tensor. This provides a substantial improvement in memory consumption and speed. The parameters $\alpha$ and $\beta$ can be found by “unwhitening” these outputs in the spectral decomposition.

After the LDA model’s parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

**LDA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see *How LDA Works* (p. 2078).
<table>

Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2436).

**Metrics Computed by the LDA Algorithm**

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>test:pwll</code></td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable LDA Hyperparameters**

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

**Neural Topic Model (NTM) Algorithm**

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into topics that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on...
topic similarities. The topics from documents that NTM learns are characterized as a latent representation because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Topics

- Input/Output Interface for the NTM Algorithm (p. 2082)
- EC2 Instance Recommendation for the NTM Algorithm (p. 2083)
- NTM Sample Notebooks (p. 2083)
- NTM Hyperparameters (p. 2083)
- Tune an NTM Model (p. 2085)
- NTM Response Formats (p. 2086)

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only UTF-8 encoding is supported.

For inference, text/csv, application/json, application/jsonlines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.
See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats (p. 2086) for inference and the NTM Sample Notebooks (p. 2083).

**EC2 Instance Recommendation for the NTM Algorithm**

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference. NTM training supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

**NTM Sample Notebooks**

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 291). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**Tune an NTM Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. \textit{Training loss} measures how well the model fits the training data. \textit{Validation loss} measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see \href{https://docs.aws.amazon.com/sagemaker/latest/dg/perform-automatic-model-tuning-with-sagemaker.html}{Perform Automatic Model Tuning with SageMaker (p. 2436)}.

\textbf{Metrics Computed by the NTM Algorithm}

The NTM algorithm reports a single metric that is computed during training: \texttt{validation:total_loss}. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>

</tr>
</tbody>
</table>

\textbf{Tunable NTM Hyperparameters}

You can tune the following hyperparameters for the NTM algorithm. Usually setting low \texttt{mini_batch_size} and small \texttt{learning_rate} values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see \href{https://docs.aws.amazon.com/sagemaker/latest/dg/ntm-hyperparameters.html}{NTM Hyperparameters (p. 2083)}.

\textbf{NTM Response Formats}

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in \href{https://docs.aws.amazon.com/sagemaker/latest/dg/common-data-formats-inference.html}{Common Data Formats - Inference}. This topic contains a list of the available output formats for the SageMaker NTM algorithm.
**Object2Vec Algorithm**

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 2066). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

**Topics**

- How Object2Vec Works (p. 2089)
- Object2Vec Hyperparameters (p. 2091)
I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequences of discrete tokens, which is represented as a list of integer-ids. For example, [0,12,10,13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_{layer}` hyperparameter when you create the model training job.
EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INJECTION_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 2101) or the section called “GPU optimization: Encoder Embeddings” (p. 2102) inference network is loaded into GPU.

Object2Vec Sample Notebooks

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

Note

To run the notebooks on a notebook instance, see Example Notebooks (p. 306). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 133).

How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics

- Step 1: Process Data (p. 2089)
- Step 2: Train a Model (p. 2089)
- Step 3: Produce Inferences (p. 2090)

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 2101). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.
- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.
During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

![Architecture of the Object2Vec Algorithm from Data Inputs to Scores](image)

**Step 3: Produce Inferences**

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.
Object2Vec Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>

### Tune an Object2Vec Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2436).

### Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

#### Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:mean_squared_error</td>
<td>Mean Square Error</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mean_squared_error</td>
<td>Mean Square Error</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

#### Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:accuracy</td>
<td>Accuracy</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:cross_entropy</td>
<td>Cross-entropy</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:accuracy</td>
<td>Accuracy</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:cross_entropy</td>
<td>Cross-entropy</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

### Tunable Object2Vec Hyperparameters

You can tune the following hyperparameters for the Object2Vec algorithm.
<table>
<thead>
<tr>
<th>Hyperparameter Name</th>
<th>Hyperparameter Type</th>
<th>Recommended Ranges and Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>dropout</td>
<td>ContinuousParameterRange</td>
<td>MinValue: 0.0, MaxValue: 1.0</td>
</tr>
<tr>
<td>early_stopping_pat</td>
<td>IntegerParameterRange</td>
<td>MinValue: 1, MaxValue: 5</td>
</tr>
<tr>
<td>early_stopping_tol</td>
<td>ContinuousParameterRange</td>
<td>MinValue: 0.001, MaxValue: 0.1</td>
</tr>
<tr>
<td>enc_dim</td>
<td>IntegerParameterRange</td>
<td>MinValue: 4, MaxValue: 4096</td>
</tr>
<tr>
<td>enc0_cnn_filter_width</td>
<td>IntegerParameterRange</td>

Data Formats for Object2Vec Training

Input: JSON Lines Request Format

Content-type: application/jsonlines

```json
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The "in0" and "in1" are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field "label" can accept real valued inputs.
