A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson’s paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL) for each of the subgroups, with each subgroup disparity weighted
in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

\[
\text{CDDPL} = \frac{1}{n} \sum \text{n}_i \cdot \text{DDPL}_i
\]

Where:
- \( \sum \text{n}_i = n \) is the total number of observations and \( \text{n}_i \) is the number of observations for each subgroup.
- \( \text{DDPL}_i = \frac{\text{n}^{(0)}_i}{\text{n}^{(0)}} - \frac{\text{n}^{(1)}_i}{\text{n}^{(1)}} = p^{(d)}_i(y^{(0)}) - p^{(d)}_i(y^{(1)}) \) is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is \([-1, +1]\).
- +1: when there are no predicted rejection labels for facet \( a \) or subgroup and no predicted acceptances for facet \( d \) or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet \( d \) or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet \( a \) or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
- -1: when there are no predicted rejection lapels for facet \( d \) or subgroup and no predicted acceptances for facet \( a \) or subgroup.

**Counterfactual Flipped Test (FT)**

The flipped test is an approach that looks at each member of facet \( d \) and assesses whether similar members of facet \( a \) have different model predictions. The members of facet \( a \) are chosen to be k-nearest neighbors of the observation from facet \( d \). We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual flipped test is the difference in the cardinality of two sets divided by the number of members of facet \( d \):

\[
\text{FT} = \frac{(F^+ - F^-)}{n_d}
\]

Where:
- \( F^+ \) is the number of disfavored facet \( d \) members with an unfavorable outcome whose nearest neighbors in favored facet \( a \) received a favorable outcome.
- \( F^- \) is the number of disfavored facet \( d \) members with a favorable outcome whose nearest neighbors in favored facet \( a \) received an unfavorable outcome.
- \( n_d \) is the sample size of facet \( d \).

The range of values for the counterfactual flipped test for binary and multicategory facet labels is \([-1, +1]\). For continuous labels, we set a threshold to collapse the labels to binary.

- Positive values occur when the number of unfavorable counterfactual flipped test decisions for the disfavored facet \( d \) exceeds the favorable ones.
• Values near zero occur when the number of unfavorable and favorable counterfactual flitp test decisions balance out.
• Negative values occur when the number of unfavorable counterfactual flitp test decisions for the disfavored facet $d$ is less than the favorable ones.

Generalized entropy (GE)

The generalized entropy index (GE) measures the inequality in benefit $b$ for the predicted label compared to the observed label. A benefit occurs when a false positive is predicted. A false positive occurs when a negative observation ($y=0$) has a positive prediction ($y'=1$). A benefit also occurs when the observed and predicted labels are the same, also known as a true positive and true negative. No benefit occurs when a false negative is predicted. A false negative occurs when a positive observation ($y=1$) is predicted to have a negative outcome ($y'=0$). The benefit $b$ is defined, as follows:

$$b = y' - y + 1$$

Using this definition, a false positive receives a benefit $b$ of 2, and a false negative receives a benefit of 0. Both a true positive and a true negative receive a benefit of 1.

The GE metric is computed following the Generalized Entropy Index (GE) with the weight $\alpha$ set to 2. This weight controls the sensitivity to different benefit values. A smaller $\alpha$ means an increased sensitivity to smaller values.

$$GE = \frac{1}{2n} \sum_{i=1}^{n} \left( \frac{b_i}{b'} \right)^2 - 1$$

The following variables used to calculate GE are defined as follows:
• $b_i$ is the benefit received by the $i$th data point.
• $b'$ is the mean of all benefits.

GE can range from 0 to 0.5, where values of zero indicate no inequality in benefits across all data points. This occurs either when all inputs are correctly predicted or when all the predictions are false positives. GE is undefined when all predictions are false negatives.

Note
The metric GE does not depend on a facet value being either favored or disfavored.

Amazon SageMaker Clarify Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators. They need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach. You can use this to understand why a model made a prediction after training, and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value, from the field of cooperative game theory, that assigns each feature an importance value for a particular prediction.

Clarify produces partial dependence plots (PDPs) that show the marginal effect features have on the predicted outcome of a machine learning model. Partial dependence helps explain target response given a set of input features. It also supports both computer vision (CV) and natural language processing (NLP) explainability using the same Shapley Values (SHAP) algorithm as used for tabular data explanations.
What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- Why did the model predict a negative outcome such as a loan rejection for a given applicant?
- How does the model make predictions?
- Why did the model make an incorrect prediction?
- Which features have the largest influence on the behavior of the model?

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, for example in the case of ML modeling of images, the baseline might be implicit, where an image whose pixels are all the same color can serve as a baseline.

**Sample Notebooks**

Amazon SageMaker Clarify provides the following sample notebook for model explainability:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSONLines data formats, bringing your own container, and running processing jobs with Spark.
- **Explaining Image Classification with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models classify images.
- **Explaining object detection models with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models detect objects.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). If you're prompted to choose a kernel, choose Python 3 (Data Science).

**Topics**

- Feature Attributions that Use Shapley Values (p. 1885)
- SHAP Baselines for Explainability (p. 1886)
- Partial Dependence Plots: Analysis Configuration and Output (p. 1887)
- SageMaker Clarify Computer Vision (p. 1889)
- Create Feature Attribute Baselines and Explainability Reports (p. 1890)
- Explainability Reports for NLP Models (p. 1891)

**Feature Attributions that Use Shapley Values**

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These
attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model's predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the \textit{game} and the features included in the model as the \textit{players}. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either \textit{dropping} that feature from the model or \textit{dropping} all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given \( d \) features, there are \( 2^d \) such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature \( f \), consider the marginal contribution of including \( f \) in all feature combinations (and associated models) that do not contain \( f \), and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of \( d \), say 50 features, it is computationally prohibitive and impractical to train \( 2^d \) possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see A Unified Approach to Interpreting Model Predictions.

**SHAP Baselines for Explainability**

Explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines. Therefore, your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either \textit{uninformative} or \textit{informative}. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature, is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptances based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects
of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

**Partial Dependence Plots: Analysis Configuration and Output**

Partial dependence plots (PDP) show the dependence of the predicted target response on a set of input features of interest. These are marginalized over the values of all other input features and are referred to as the *complement features*. Intuitively, you can interpret the partial dependence as the target response, which is expected as a function of each input feature of interest.

**Topics**

- Partial dependence plots analysis configuration (p. 1887)
- Partial dependence plots analysis output (p. 1887)

**Partial dependence plots analysis configuration**

To create a partial dependence plot (PDP), Amazon SageMaker Clarify initially looks for the feature columns specified in a JSON array of the `analysis_config.json`. The other parameters that configure the analysis of a processing job must be provided in this JSON file. For more information about configuring PDPs and other aspects of an analysis, see *Configure the Analysis* (p. 1852).

The following code contains an example of a JSON "pdp" object in the "methods" object of an `analysis_config.json` configuration file.

```json
{
    "dataset_type":...
    "baseline": [[..]]
    ·
    "methods": {
        "shap": {
            "baseline": "..
            "num_samples": 100
        },
        "pdp": {
            "features": ["Age", "MaturityMonths"] // The features for which we need to plot PDP.
            "grid_resolution": 20, //Required for numerical columns only.
            //The number of buckets into which the range of values is divided.
            "top_k_features": 10, //Specifies how many of the top features must be used for PDP plots. The default is 10.
        },
        ·
    }
}
```

**Note**

If "features" is not mentioned in the "pdp" object but "shap" config is provided, SageMaker Clarify takes top ten features from the global SHAP results to plot the PDP visualizations.

**Partial dependence plots analysis output**

The following code shows an example of the partial dependence plot (PDP) schema returned in the `analysis.json` result file. The "pdp" section in this analysis output file contains the information required...
to generate the PDP plots. Each dictionary in the list contains the specification for the PDP of the feature specified by the feature_name.

The data_type indicates whether the data is numerical or categorical. The feature_values field contains the values present in the feature. If the data_type inferred by Clarify is categorical, feature_values contain all the unique values that the feature could assume. If the data_type inferred by Clarify is numerical, it contains a list of the central values of each of the grid_resolution number of buckets generated by Clarify.

If the partial dependence plots are computed for a particular feature, the feature_values, model_predictions, and data_distributions fields are replaced by the error field which contains an error message.

```json
{
    "version": "1.0",
    "explanations":{
        "kernel_shap":{
        ...
        },
        "pdp": [
            {
                "feature_name": "Age",
                "data_type": "numerical"
            }{
            "feature_values": [
                20.4,
                23.2,
                26.0,
                28.799999999999997,
                31.599999999999998,
                34.4,
                70.8,
                73.6
            ],
            "model_predictions": [
                [0.6830344458296895,
                 0.6812452118471265,
                 0.6908621763065458,
                 0.7008252082392573,
                 0.733054383918643,
                 0.7352442337572574,
                 0.7337257475035403,
                 0.7395857129991055],
            ],
            "data_distribution": [0.13, 0.25, 0.15, 0.35, 0.17]
        },
        {"feature_name": "text_column",
        "data_type": "free_text"
        "error": "Detected data type is not supported for PDP. PDP can only be computed for numerical or categorical columns"
        }
    }
}
```
This PDP schema generates the following partial dependence plot for the Age feature. The PDP plots the feature_values along the x-axis. The y-axis contains the values in model_predictions field. Each list in the model_predictions field corresponds to one class in the output from the model.

![Partial Dependence Plots](image)

You can view the plot in the report.pdf file in the analysis output path that you provided.

**SageMaker Clarify Computer Vision**

Amazon SageMaker Clarify generates heat maps for images that highlight features under analysis. In particular, the heat maps provide insights into how your computer vision models classify the images and how they detect objects in those images.

**Topics**

- Explain Image Classification with Amazon SageMaker Clarify (p. 1889)
- Explain Object Detection with Amazon SageMaker Clarify (p. 1890)

**Explain Image Classification with Amazon SageMaker Clarify**

SageMaker Clarify processing jobs provides support for explaining images using the KernelSHAP algorithm. This algorithm treats the image as a collection of super pixels. Given a dataset consisting of images, the processing job outputs a dataset of images where each image shows the heat map of the relevant super pixels.

For a sample notebook that uses SageMaker Clarify to classify images and explain its classification, see Explaining Image Classification with SageMaker Clarify.
Explain Object Detection with Amazon SageMaker Clarify

Amazon SageMaker Clarify can detect and classify objects in an image and then provide an explanation for the detection predicted. The objects are first categorized into one of the classes in a specified collection. SageMaker Clarify produces a confidence score for each object that it belongs to the class and the coordinates of a bounding box that delimits the object. For each detected object identified with sufficient probability, SageMaker Clarify extracts features using the Simple Linear Iterative Clustering (SLIC) method from scikit-learn library for image segmentation.

SageMaker Clarify can then provide an explanation for the detection of an object in the image scene. It uses Shapley values to determine the contribution that each feature has made to a model prediction. It produces a heat map that shows how important each of the features in the image scene were for its detection of the object. The context of an object is often very important for the correct identification of an object, so it is important not to just use the cropped image for classification.

For a sample notebook that uses SageMaker Clarify to detect objects in an image and explain its predictions, see Explaining object detection models with Amazon SageMaker Clarify.

Create Feature Attribute Baselines and Explainability Reports

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use SHAPConfig to create the baseline. In this example, the mean_abs is the mean of absolute SHAP values for all instances, specified as the baseline. You use DataConfig to configure the target variable, data input and output paths, and their formats.

```python
shap_config = clarify.SHAPConfig(baseline=[test_features.iloc[0].values.tolist()],
                                   num_samples=15,
                                   agg_method='mean_abs')

explainability_output_path = 's3://{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                                s3_output_path=explainability_output_path,
                                                label='Target',
                                                headers=training_data.columns.to_list(),
                                                dataset_type='text/csv')
```

**Note**
Kernel SHAP in SageMaker Clarify supports omitting the “baseline” parameter. In this case, a baseline based on clustering the input dataset is generated automatically.

Then run the explainability job.

```python
clarify_processor.run_explainability(data_config=explainability_data_config,
                                     model_config=model_config,
                                     explainability_config=shap_config)
```

To view Partial Dependence plots (PDP), use explainability_config=PDP_config.
You can select both types of reports with explainability_config=[PDP_config, shap_config].
View the results in Studio or download them from the explainability_output_path S3 bucket.
Explainability Reports for NLP Models

Amazon SageMaker Clarify supports explanations for natural language processing (NLP) models. NLP models help you understand which sections of text are most important for the predictions made by your model. This functionality can be used to explain either an individual local prediction or the model's expected predictions for overall global explanations. You can define the length of the text segment (tokens, phrases, sentences, paragraphs) to understand and visualize a model's behavior at multiple levels of granularity.

SageMaker Clarify NLP explainability is compatible with classification and regression models. You can also use Clarify to explain your model's behavior on multi-modal datasets that contain text, categorical, or numerical features. NLP explainability for multi-modal datasets can help you understand how important each feature is to the model's output. SageMaker Clarify supports 62 languages and can handle text which includes multiple languages.

To obtain feature importance for parts of an input text, create a `TextConfig` specifying the granularity of the parts of the text and the language. Clarify then breaks the text down into tokens, sentences, or paragraphs depending on your choice of granularity. It replaces subsets of these parts with the values from the baseline. The baseline defaults to empty strings, meaning SageMaker Clarify drops parts of the input text. SageMaker Clarify then replaces tokens (sentences and paragraphs, respectively) to determine how these replacements affect the model's prediction, in order to assess their importance.

```python
from sagemaker import clarify
text_config = clarify.TextConfig(
    # Specify the language of your text or use "multi-language" for multi-language.
    language="english",
    # Choose the granularity of your explanations as tokens, sentences or paragraphs.
    granularity="token"
)
shap_config = clarify.SHAPConfig(
    # For now, we don't support global aggregation,
    # so make sure you retrieve local explanations.
    save_local_shap_values=True,
    text_config=text_config,
    # Determine with what to replace tokens/sentences/paragraphs (based on your choice of granularity) with.
    baseline=["<UNK>"],
    # You can further specify num_samples and agg_method.
)
```

The remainder of the explainability job is coded as usual.

```python
explainability_output_path = 's3://{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=explainability_output_path,
    # With text data sometimes detection of headers fails,
    # so we recommend explicitly setting it in the config.
    headers=["text"],
    dataset_type="text/csv"
)
model_config = clarify.ModelConfig(
    model_name=model_name,
    # Specialized hardware is well-suited for NLP models.
    instance_type="ml.p2.xlarge",
    instance_count=1
)
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role, instance_count=1, instance_type="ml.m5.xlarge", sagemaker_session=session
)
View the local explanations in the explainability_output_path S3 bucket. SageMaker Clarify does not aggregate the importance of individual tokens/sentences/paragraphs.

Extensions:

- **Multi-modal data** - If your data contains more than text, such as categorical or numeric features, you can add more columns in your header and baseline to accommodate those features.
- **JSON** - If the model input or output data is in JSON Lines format, specify the dataset_type in the DataConfig or the accept_type and content_type in the ModelConfig.
- **Multi-class model output** - If your model does multi-class or multi-label predictions, SageMaker Clarify computes the importance for each class.
- **Model output** - Some model outputs contain more than a single score. A prediction of three examples returns a matrix of shape [3, 1] such as [[0.1], [-1.1], [10.2], [0.0], [3.2]]. You can specify model_scores in run_explainability. For example, if your model predicts probabilities of five classes and additionally outputs the winning class, ["c1", [0.1, 0.4, 0.3, 0.2]], then you can set model_scores=1.

Tips for fast results:

- During the development phase, work with a small subset of examples for quick iterations.
- To scale up for deployment, increase the instance_count for the processing job and the predictor. This instructs SageMaker Clarify to partition the data and work with multiple machines in parallel. For parallel processing, we recommend using the parquet data format because Spark can struggle with special characters in CSV files.
- Choose an appropriate instance_type for your model. GPU instances are often suitable for NLP models.
- To save unnecessary computation, consider truncating your text. Many models work with a maximum text length. By applying the truncation in a preprocessing step, SageMaker Clarify does not waste resources determining the feature importance for the parts of text that are disregarded by the model.

**Troubleshoot SageMaker Clarify Processing Jobs**

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

**Note**
The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

**Topics**

- Processing job fails to finish (p. 1893)
- Processing job finishes without results and you get a CloudWatch warning message (p. 1893)
- Error message for invalid analysis configuration (p. 1893)
- Bias metric computation fails for several or all metrics (p. 1893)
• Mismatch between analysis config and dataset/model input/output (p. 1894)
• Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error (p. 1894)
• Execution role is invalid (p. 1894)
• Failed to download data (p. 1894)
• Could not connect to SageMaker (p. 1894)

**Processing job fails to finish**

If the processing job fails to finish, you can try the following:

• Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
• Inspect the job logs in CloudWatch.
• Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
  clarify_processor.jobs[-1].describe()
  ```
• Execute the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

**Processing job finishes without results and you get a CloudWatch warning message**

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says “Signal 15 received, cleaning up”, this is an indication that the job was stopped either due to a customer request that called the StopProcessingJob API or that the job ran out of time allotted for its completion. In the later case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase it as needed.

**Error message for invalid analysis configuration**

• If you get the error message "Unable to load analysis configuration as JSON.", this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
• If you get the error message "Analysis configuration schema validation error.", this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the configuration specification file.

**Bias metric computation fails for several or all metrics**

If your receive one of the following error messages "No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values." or "Predicted Label Column series data type is not the same as Label Column series.", try the following:

• Check that the correct dataset is being used.
• Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
• Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the **DataType**. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
  • In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
  • For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

**Mismatch between analysis config and dataset/model input/output**

• Check that the baseline format in the analysis config is the same as dataset format.
• If you receive the error message "Could not convert string to float.", check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
• If you receive the error message "Unable to locate the facet." or "Headers must contain label." or "Headers in config do not match with the number of columns in the dataset." or "Feature names not found.", check that the headers match the columns.
• If you receive the error message "Data must contain features.", check the content template for JSON Lines and compare it with the dataset sample if available.

**Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error**

If you receive the error message "Fallback to per-record prediction because of model error.", this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

**Execution role is invalid**

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

**Failed to download data**

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

**Could not connect to SageMaker**

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify VPC configuration.

**Train Using a Heterogeneous Cluster**

Using the heterogeneous cluster feature of SageMaker Training, you can run a training job with multiple types of ML instances for a better resource scaling and utilization for different ML training tasks and
purposes. For example, if your training job on a cluster with GPU instances suffers low GPU utilization and CPU bottleneck problems due to CPU-intensive tasks, using a heterogeneous cluster can help offload CPU-intensive tasks by adding more cost-efficient CPU instance groups, resolve such bottleneck problems, and achieve a better GPU utilization.

**Note**
This feature is available in the SageMaker Python SDK v2.98.0 and later.

**Note**
This feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later.

**How to Configure a Heterogeneous Cluster**

This section provides instructions on how to run a training job using a heterogeneous cluster that consists of multiple instance types.

**Topics**
- How to Configure a Heterogeneous Cluster (p. 1895)
- Distributed Training with a Heterogeneous Cluster (p. 1898)
- Modify Your Training Script to Assign Instance Groups (p. 1900)
- Considerations (p. 1902)
- Examples, Blogs, and Case Studies (p. 1902)

**Using the SageMaker Python SDK**

Follow instructions on how to configure instance groups for a heterogeneous cluster using the SageMaker Python SDK.

1. To configure instance groups of a heterogeneous cluster for a training job, use the `sagemaker.instance_group.InstanceGroup` class. You can specify a custom name for each instance group, the instance type, and the number of instances for each instance group. For more information, see `sagemaker.instance_group.InstanceGroup` in the [SageMaker Python SDK documentation](#).

   **Note**
   For more information about available instance types and the maximum number of instance groups that you can configure in a heterogeneous cluster, see the InstanceGroup API reference.

   The following code example shows how to set up two instance groups that consists of two ml.c5.18xlarge CPU-only instances named `instance_group_1` and one ml.p3dn.24xlarge GPU instance named `instance_group_2`, as shown in the following diagram.
The preceding diagram shows a conceptual example of how pre-training processes, such as data preprocessing, can be assigned to the CPU instance group and stream the preprocessed data to the GPU instance group.

```
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 2
)

instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 1
)
```

2. Using the instance group objects, set up training input channels and assign instance groups to the channels through the instance_group_names argument of the sagemaker.inputs.TrainingInput class. The instance_group_names argument accepts a list of strings of instance group names.
The following example shows how to set two training input channels and assign the instance groups created in the example of the previous step. You can also specify Amazon S3 bucket paths to the `s3_data` argument for the instance groups to process data for your usage purposes.

```python
from sagemaker.inputs import TrainingInput

training_input_channel_1 = TrainingInput(
    s3_data_type='S3Prefix',  # Available Options: S3Prefix | ManifestFile | AugmentedManifestFile
    s3_data='s3://your-training-data-storage/folder1',
    distribution='FullyReplicated',  # Available Options: FullyReplicated | ShardedByS3Key
    input_mode='File',  # Available Options: File | Pipe | FastFile
    instance_groups=['instance_group_1']
)

training_input_channel_2 = TrainingInput(
    s3_data_type='S3Prefix',
    s3_data='s3://your-training-data-storage/folder2',
    distribution='FullyReplicated',
    input_mode='File',
    instance_groups=['instance_group_2']
)
```

For more information about the arguments of `TrainingInput`, see the following links.

- The `sagemaker.inputs.TrainingInput` class in the SageMaker Python SDK documentation
- The `S3DataSource` API in the SageMaker API Reference

3. Configure a SageMaker estimator with the `instance_groups` argument as shown in the following code example. The `instance_groups` argument accepts a list of `InstanceGroup` objects.

**PyTorch**

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z',  # 1.10.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=['instance_group_1', 'instance_group_2']
)
```

**TensorFlow**

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z',  # 2.6.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=['instance_group_1', 'instance_group_2']
)
```

**Note**

The `instance_type` and `instance_count` argument pair and the `instance_groups` argument of the SageMaker estimator class are mutually exclusive. For homogeneous cluster
training, use the instance_type and instance_count argument pair. For heterogeneous cluster training, use instance_groups.

**Note**
To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker Framework Containers in the AWS Deep Learning Container GitHub repository.

4. Configure the estimator.fit method with the training input channels configured with the instance groups and start the training job.

```python
estimator.fit(
    inputs={
        'training': training_input_channel_1,
        'dummy-input-channel': training_input_channel_2
    }
)
```

### Using the Low-Level SageMaker APIs

If you use the AWS Command Line Interface or AWS SDK for Python (Boto3) and want to use low-level SageMaker APIs for submitting a training job request with a heterogeneous cluster, see the following API references.

- `CreateTrainingJob`
- `ResourceConfig`
- `InstanceGroup`
- `S3DataSource`

### Distributed Training with a Heterogeneous Cluster

Through the distribution argument of the SageMaker estimator class, you can assign a specific instance group to run distributed training. For example, assume that you have the following two instance groups and want to run multi-GPU training on one of them.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup("instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup("instance_group_2", "ml.p3dn.24xlarge", 2)
```

You can set the distributed training configuration for one of the instance groups. For example, the following code examples show how to assign `training_group_2` with two `ml.p3dn.24xlarge` instances to the distributed training configuration.

**Note**
Currently, only one instance group of a heterogeneous cluster can be specified to the distribution configuration.

#### With MPI

PyTorch

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
```
instance_groups=["instance_group_1", "instance_group_2"],

distribution={
    "mpi": {
        "enabled": True, "processes_per_host": 8
    },
    "instance_groups": ["instance_group_2"]
}
)

TensorFlow

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=["instance_group_1", "instance_group_2"],
    distribution={
        "mpi": {
            "enabled": True, "processes_per_host": 8
        },
        "instance_groups": ["instance_group_2"]
    }
)

With the SageMaker data parallel library

PyTorch

from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=["instance_group_1", "instance_group_2"],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            },
        },
        "instance_groups": ["instance_group_2"]
    }
)

TensorFlow

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=["instance_group_1", "instance_group_2"],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            },
        },
        "instance_groups": ["instance_group_2"]
    }
)
Note
When using the SageMaker data parallel library, make sure the instance group consists of the supported instance types by the library.

For more information about the SageMaker data parallel library, see SageMaker Data Parallel Training.

With the SageMaker model parallel library

PyTorch

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ... # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

TensorFlow

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ... # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

For more information about the SageMaker model parallel library, see SageMaker Model Parallel Training.

Modify Your Training Script to Assign Instance Groups

With the heterogeneous cluster configuration in the previous sections, you have prepared the SageMaker training environment and instances for your training job. To further assign the instance groups to certain training and data processing tasks, the next step is to modify your training script. By default, the training job simply makes training script replicas for all nodes regardless the size of the instance, and this might lead to performance loss.
For example, if you mix CPU instances and GPU instances in a heterogeneous cluster while passing a deep neural network training script to the `entry_point` argument of the SageMaker estimator, the `entry_point` script is replicated to each instance. This means that, without proper task assignments, CPU instances also run the entire script and start the training job that's designed for distributed training on GPU instances. Therefore, you must make changes in specific processing functions that you want to offload and run on the CPU instances. You can use the SageMaker environment variables to retrieve the information of the heterogeneous cluster and let specific processes to run accordingly.

**Query instance group information during the initialization phase of a SageMaker training job**

When your training job starts, your training script reads SageMaker training environment information that includes heterogeneous cluster configuration. The configuration contains information such as the current instance groups, the current hosts in each group, and in which group the current host resides.

You can retrieve instance group information in the following ways.

*(Recommended) Reading instance group information with the SageMaker training toolkit*

Use the environment Python module that the [SageMaker training toolkit library](https://docs.aws.amazon.com/sagemaker/latest/dg/python-estimator-environment.html) provides. The toolkit library is preinstalled in the SageMaker framework containers for TensorFlow and PyTorch, so you don't need an additional installation step when using the prebuilt containers. This is the recommended way to retrieve the SageMaker environment variables with fewer code changes in your training script.

```python
from sagemaker_training import environment
env = environment.Environment()
```

Environment variables related to general SageMaker training and heterogeneous clusters:

- `env.is_hetero` – Returns a Boolean result whether a heterogeneous cluster is configured or not.
- `env.current_host` – Returns the current host.
- `env.current_instance_type` – Returns the type of instance of the current host.
- `env.current_instance_group` – Returns the name of the current instance group.
- `env.current_instance_group_hosts` – Returns a list of hosts in current instance group.
- `env.instance_groups` – Returns a list of instance group names used for training.
- `env.instance_groups_dict` – Returns the entire heterogeneous cluster configuration of the training job.
- `env.distribution_instance_groups` – Returns a list of instance groups assigned to the `distribution` parameter of the SageMaker estimator class.
- `env.distribution_hosts` – Returns a list of hosts belonging to the instance groups assigned to the `distribution` parameter of the SageMaker estimator class.

For example, consider the following example of a heterogeneous cluster that consists of two instance groups.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 2)
```
The output of `env.instance_groups_dict` of the example heterogeneous cluster should be similar to the following.

```json
{
    "instance_group_1": {
        "hosts": ["algo-2"],
        "instance_group_name": "instance_group_1",
        "instance_type": "ml.c5.18xlarge"
    },
    "instance_group_2": {
        "hosts": ["algo-3", "algo-1"],
        "instance_group_name": "instance_group_2",
        "instance_type": "ml.p3dn.24xlarge"
    }
}
```

(Optional) Reading instance group information from the resource configuration JSON file

If you prefer to retrieve the environment variables in JSON format, you can directly use the resource configuration JSON file. The JSON file in a SageMaker training instance is located at `/opt/ml/input/config/resourceconfig.json` by default.

```python
file_path = '/opt/ml/input/config/resourceconfig.json'
config = read_file_as_json(file_path)
print(json.dumps(config, indent=4, sort_keys=True))
```

Considerations

Consider the following items when using the heterogeneous cluster feature.

- All instance groups share the same Docker image and training script. Therefore, your training script should be modified to detect which instance group it belongs to and fork execution accordingly.
- The heterogeneous cluster feature is not supported in SageMaker local mode.
- The Amazon CloudWatch log streams of a heterogeneous cluster training job are not grouped by instance groups. You need to figure out from the logs which nodes are in which group.
- The heterogeneous cluster feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later. To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker Framework Containers in the AWS Deep Learning Container GitHub repository.
- A distributed training strategy can be applied only to one instance group.

Examples, Blogs, and Case Studies

The following blog discusses case studies about using the SageMaker heterogeneous cluster training.

- Improve price performance of your model training using Amazon SageMaker heterogeneous clusters (Oct 27, 2022)
Train Using SageMaker Managed Warm Pools

SageMaker Managed Warm Pools let you retain and reuse provisioned infrastructure after the completion of a training job to reduce latency for repetitive workloads, such as iterative experimentation or running many jobs consecutively. Subsequent training jobs that match specified parameters run on the retained warm pool infrastructure, which speeds up start times by reducing the time spent provisioning resources.

**Important**
SageMaker Managed Warm Pools are a billable resource. For more information, see Billing (p. 1905).

**Topics**
- How it works (p. 1903)
- Warm pool resource limits (p. 1905)
- How to use SageMaker Managed Warm Pools (p. 1905)
- Considerations (p. 1909)

How it works

To use SageMaker Managed Warm Pools and reduce latency between similar consecutive training jobs, create a training job that specifies a `KeepAlivePeriodInSeconds` value in its `ResourceConfig`. This value represents the duration of time in seconds to retain configured resources in a warm pool for subsequent training jobs.

**Topics**
- Warm pool lifecycle (p. 1903)
- Warm pool creation (p. 1904)
- Matching training jobs (p. 1904)
- Maximum warm pool duration (p. 1904)
- Billing (p. 1905)

Warm pool lifecycle

1. Create an initial training job with a `KeepAlivePeriodInSeconds` value greater than 0. When you run this first training job, this "cold-starts" a cluster with typical startup times.
2. When the first training job completes, the provisioned resources are kept alive in a warm pool for the period specified in the `KeepAlivePeriodInSeconds` value. As long as the cluster is healthy and the warm pool is within the specified `KeepAlivePeriodInSeconds`, then the warm pool status is Available.
3. The warm pool stays Available until it either identifies a matching training job for reuse or it exceeds the specified `KeepAlivePeriodInSeconds` and is terminated. The maximum length of time allowed for the `KeepAlivePeriodInSeconds` is 3600 seconds (60 minutes). If the warm pool status is Terminated, then this is the end of the warm pool lifecycle.
4. If the warm pool identifies a second training job with matching specifications such as instance count or instance type, then the warm pool moves from the first training job to the second training job for reuse. The status of the first training job warm pool becomes Reused. This is the end of the warm pool lifecycle for the first training job.
5. The status of the second training job that reused the warm pool becomes InUse. After the second training job completes, the warm pool is Available for the `KeepAlivePeriodInSeconds` duration
specified in the second training job. A warm pool can continue moving to subsequent matching training jobs for a maximum of 7 days.

6. If the warm pool is no longer available to reuse, the warm pool status is Terminated. Warm pools are no longer available if they are terminated by a user, for a patch update, or for exceeding the specified KeepAlivePeriodInSeconds.

For more information on warm pool status options, see WarmPoolStatus in the Amazon SageMaker API Reference.

**Warm pool creation**

If an initial training job successfully completes and has a KeepAlivePeriodInSeconds value greater than 0, this creates a warm pool. If you stop a training job after a cluster is already launched, a warm pool is still retained. If the training job fails due to an algorithm or client error, a warm pool is still retained. If the training job fails for any other reason that might compromise the health of the cluster, then the warm pool is not created.

To verify successful warm pool creation, check the warm pool status of your training job. If a warm pool successfully provisions, the warm pool status is Available. If a warm pool fails to provision, the warm pool status is Terminated.

**Matching training jobs**

For a warm pool to persist, it must find a matching training job within the time specified in the KeepAlivePeriodInSeconds value. The next training job is a match if the following values are identical:

- RoleArn
- ResourceConfig values:
  - InstanceCount
  - InstanceType
  - VolumeKmsKeyId
  - VolumeSizeInGB
- VpcConfig values:
  - SecurityGroupIds
  - Subnets
  - EnableInterContainerTrafficEncryption
  - EnableNetworkIsolation

All of these values must be the same for a warm pool to move to a subsequent training job for reuse.

**Maximum warm pool duration**

The maximum KeepAlivePeriodInSeconds for a single training job is 3600 seconds (60 minutes) and the maximum length of time that a warm pool cluster can continue running consecutive training jobs is 7 days.

Each subsequent training job must also specify a KeepAlivePeriodInSeconds value. When the warm pool moves to the next training job, it inherits the new KeepAlivePeriodInSeconds value specified in that training job's ResourceConfig. In this way, you can keep a warm pool moving from training job to training job for a maximum of 7 days.
If no `KeepAlivePeriodInSeconds` is specified, then the warm pool spins down after the training job completes.

**Billing**

SageMaker Managed Warm Pools are a billable resource. Retrieve the warm pool status for your training job to check the billable time for your warm pools. You can check the warm pool status either through the Using the Amazon SageMaker console (p. 1908) or directly through the `DescribeTrainingJob` API command. For more information, see `WarmPoolStatus` in the *Amazon SageMaker API Reference.*

**Warm pool resource limits**

To get started, you must first request a service limit increase for SageMaker Managed Warm Pools. The default resource limit for warm pools is 0.

If a training job is created with `KeepAlivePeriodInSeconds` specified, but you did not request a warm pool limit increase, then a warm pool is not retained after the completion of the training job. A warm pool is only created if your warm pool limit has sufficient resources. After a warm pool is created, the resources are released when they move to a matching training job or if the `KeepAlivePeriodInSeconds` expires (if the warm pool status is `Reused` or `Terminated`).

**Request a warm pool quota increase**

Request a warm pool quota increase using the AWS Service Quotas console.

**Note**

All warm pool instance usage counts toward your SageMaker training resource limit. Increasing your warm pool resource limit does not increase your instance limit, but allocates a subset of your resource limit to warm pool training.

1. Open the AWS Service Quotas console.
2. On the left-hand navigation panel, choose AWS services.
3. Search for and choose Amazon SageMaker.
4. Search for the keyword warm pool to see all available warm pool service quotas.
5. Find the instance type for which you want to increase your warm pool quota, select the warm pool service quota for that instance type, and choose Request quota increase.
6. Enter your requested instance limit number under Change quota value. The new value must be greater than the current Applied quota value.
7. Choose Request.

There is a limit on the number of instances that you can retain for each warm pool, which is determined by instance type. You can check your resource limits in the AWS Service Quotas console or directly using the list-service-quotas AWS CLI command. For more information on AWS Service Quotas, see Requesting a quota increase in the Service Quotas User Guide.

You can also use AWS Support Center to request a warm pool quota increase. For a list of available instance types according to Region, see Amazon SageMaker Pricing and choose Training in the On-Demand Pricing table.

**How to use SageMaker Managed Warm Pools**

You can use SageMaker Managed Warm Pools through the SageMaker Python SDK, the Amazon SageMaker console, or through the low-level APIs. Administrators can optionally use the sagemaker:KeepAlivePeriod condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups.
Using the SageMaker Python SDK

Create, update, or terminate warm pools using the SageMaker Python SDK.

**Note**
This feature is available in the SageMaker Python SDK v2.110.0 and later.

**Create a warm pool**

To create a warm pool, use the SageMaker Python SDK to create an estimator with a `keep_alive_period_in_seconds` value greater than 0 and call `fit()`. When the training job completes, a warm pool is retained. For more information on training scripts and estimators, see Train a Model with the SageMaker Python SDK. If your script does not create a warm pool, see Warm pool creation (p. 1904) for possible explanations.

```python
import sagemaker
from sagemaker import get_execution_role, tensorflow

# Creates a SageMaker session and gets execution role
session = sagemaker.Session()
role = get_execution_role()

# Creates an example estimator
estimator = tensorflow(  
    ...  
    entry_point='my-training-script.py',  
    source_dir='code',  
    role=role,  
    model_dir='model_dir',  
    framework_version='x.y.z',  
    py_version='pyxy',  
    job_name='my-training-job-1',  
    instance_type='instance_type',  
    instance_count=1,  
    volume_size=250,  
    hyperparameters={  
        "batch-size": 512,  
        "epochs": 1,  
        "learning-rate": 1e-3,  
        "beta_1": 0.9,  
        "beta_2": 0.999,  
    },  
    keep_alive_period_in_seconds=1800,  
)  

# Starts a SageMaker training job and waits until completion
```

Topics
- Using the SageMaker Python SDK (p. 1906)
- Using the Amazon SageMaker console (p. 1908)
- Using the low-level SageMaker APIs (p. 1908)
- IAM condition key (p. 1909)
Next, create a second matching training job. In this example, we create `my-training-job-2`, which has all of the necessary attributes to match with `my-training-job-1`, but has a different hyperparameter for experimentation. The second training job reuses the warm pool and starts up faster than the first training job. For more information on which attributes need to match, see Matching training jobs (p. 1904).

```python
# Creates an example estimator
estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='x.y.z',
    py_version='pyxy',
    job_name='my-training-job-2',
    instance_type='instance_type',
    instance_count=1,
    volume_size=250,
    hyperparameters={
        "batch-size": 512,
        "epochs": 2,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
    },
    keep_alive_period_in_seconds=1800,
)
# Starts a SageMaker training job and waits until completion
estimator.fit('s3://my_bucket/my_training_data/')
```

Check the warm pool status of both training jobs to confirm that the warm pool is Reused for `my-training-job-1` and InUse for `my-training-job-2`.

**Note**
Training job names have date/time suffixes. The example training job names `my-training-job-1` and `my-training-job-2` should be replaced with actual training job names. You can use the `estimator.latest_training_job.job_name` command to fetch the actual training job name.

```python
session.describe_training_job('my-training-job-1')
session.describe_training_job('my-training-job-2')
```

The result of `describe_training_job` provides all details about a given training job. Find the `WarmPoolStatus` attribute to check information about a training job's warm pool. Your output should look similar to the following example:

```json
# Warm pool status for training-job-1
...
'WarmPoolStatus': {'Status': 'Reused',
                    'ResourceRetainedBillableTimeInSeconds': 1000,
                    'ReusedByName': 'my-training-job-2'}
...

# Warm pool status for training-job-2
...
'WarmPoolStatus': {'Status': 'InUse'}
```
Amazon SageMaker Developer Guide
How to use SageMaker Managed Warm Pools
...

Update a warm pool
When the training job is complete and the warm pool status is Available, then you can update the
KeepAlivePeriodInSeconds value.
session.update_training_job(job_name, resource_config={"KeepAlivePeriodInSeconds":3600})

Terminate a warm pool
To manually terminate a warm pool, set the KeepAlivePeriodInSeconds value to 0.
session.update_training_job(job_name, resource_config={"KeepAlivePeriodInSeconds":0})

The warm pool automatically terminates when it exceeds the designated KeepAlivePeriodInSeconds
value or if there is a patch update for the cluster.

Using the Amazon SageMaker console
You cannot create or update a warm pool through the console, but you can use the console to check the
warm pool status and billable time of speciﬁc training jobs. You can also use the console to see which
matching training job reused the warm pool.
1.

2.
3.

Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/ and choose
Training jobs from the navigation pane. The warm pool status of each training job is visible in the
Warm pool status column.
Select a training job ID for more information.
Scroll down to the Warm pool status section to ﬁnd the warm pool status, the time left if the warm
pool status is Available, the warm pool billable seconds, and the name of the training job that
reused the warm pool if the warm pool status is Reused.

Using the low-level SageMaker APIs
Use SageMaker Managed Warm Pools with either the SageMaker API or the AWS CLI.

SageMaker API
Set up SageMaker Managed Warm Pools using the SageMaker API with the following commands:
•
•
•
•

CreateTrainingJob
UpdateTrainingJob
ListTrainingJobs
DescribeTrainingJob

AWS CLI
Set up SageMaker Managed Warm Pools using the AWS CLI with the following commands:
•
•
•
•

create-training-job
update-training-job
list-training-jobs
describe-training-job

1908


IAM condition key

Administrators can optionally use the `sagemaker:KeepAlivePeriod` condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups. SageMaker Managed Warm Pools are limited to a `KeepAlivePeriodInSeconds` value of 3600 seconds (60 minutes), but administrators can lower this limit if needed.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceKeepAlivePeriodLimit",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob"
      ],
      "Resource": "*",
      "Condition": {
        "NumericLessThanIfExists": {
          "sagemaker:KeepAlivePeriod": 1800
        }
      }
    }
  ]
}
```

For more information, see [Condition keys for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/service-authorization-reference.html) in the [Service Authorization Reference](https://docs.aws.amazon.com/sagemaker/latest/dg/service-authorization-reference.html).

Considerations

Consider the following items when using SageMaker Managed Warm Pools.

- SageMaker Managed Warm Pools cannot be used with heterogeneous cluster training.
- SageMaker Managed Warm Pools cannot be used with spot instances.
- SageMaker Managed Warm Pools are limited to a `KeepAlivePeriodInSeconds` value of 3600 seconds (60 minutes).
- If a warm pool continues to successfully match training jobs within the specified `KeepAlivePeriodInSeconds` value, the cluster can only continue running for a maximum of 7 days.

Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don't need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.
For more information about training jobs, see Train a Model with Amazon SageMaker (p. 10).

You can train incrementally using the SageMaker console or the Amazon SageMaker Python SDK.

**Important**

Only three built-in algorithms currently support incremental training: **Object Detection - MXNet** (p. 1420), **Image Classification - MXNet** (p. 1396), and **Semantic Segmentation Algorithm** (p. 1439).

**Topics**

- Perform Incremental Training (Console) (p. 1910)
- Perform Incremental Training (API) (p. 1912)

## Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code (p. 2396).
- The URL of the S3 bucket where you've stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose **Inference**, choose **Models**, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

**To perform incremental training (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and _ : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
   a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.
   b. For **Instance count**, use the default, 1.
   c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For **Channel name**, either leave the default (**train**) or enter a more meaningful name for the training dataset, such as **expanded-training-dataset**.
For **InputMode**, choose **File**. For incremental training, you need to use file input mode.

For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.

If the expanded dataset is uncompressed, set the **Compression type** to **None**. If the expanded dataset is compressed using Gzip, set it to **Gzip**.

(Optional) If you are using **File** input mode, leave **Content type** empty. For **Pipe** input mode, specify the appropriate MIME type. **Content type** is the multipurpose internet mail extension (MIME) type of the data.

For **Record wrapper**, if the dataset is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO formatted file, choose **None**.

For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose **Manifest**.

For **S3 location**, provide the URL to the path where you stored the expanded dataset.

Choose **Done**.

8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.

For **Input data configuration**, choose **Add channel**.

For **Channel name**, enter **model** to identify this channel as the source of the model artifacts.

For **InputMode**, choose **File**. Model artifacts are stored as files.

For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.

For **Compression type**, choose **None** because we are using a model for the channel.

Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.

Set **Record wrapper** to **None** because model artifacts are not stored in RecordIO format.

For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose **Manifest**.

For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name `model.tar.gz`. To find the URL for the model artifacts, in the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.

Choose **Done**.

9. For **Output data configuration**, provide the following information:

For **S3 location**, type the path to the S3 bucket where you want to store the output data.

(Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](https://docs.aws.amazon.com/kms/latest/developerguide/key-encryption-key-managed-via-kms.html).

(Optional) For **Tags**, add one or more tags to the training job. A tag is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value referring to a project that is related to the training job, such as **Home value forecasts**.

Choose **Create training job**. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2](p. 88).
Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the Caltech 256 Image Dataset, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the incremental training sample notebook for more details on using incremental training.

**Note**
In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the `data_channels` variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role
role = get_execution_role()
print(role)

sess = sagemaker.Session()
bucket=sess.default_bucket()
print(bucket)

prefix = 'ic-incr-training'
```

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(sess.boto_region_name, 'image-classification', repo_version="latest")
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split('/')[-1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}/train/'.format(bucket, prefix)
s3validation = 's3://{}/validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet
```
Define the training hyperparameters:

```python
# Define hyperparameters for the estimator
hyperparams = {
    "num_layers": "18",
    "resize": "32",
    "num_training_samples": "50000",
    "num_classes": "10",
    "image_shape": "3,28,28",
    "mini_batch_size": "128",
    "epochs": "3",
    "learning_rate": "0.1",
    "lr_scheduler_step": "2,3",
    "lr_scheduler_factor": "0.1",
    "augmentation_type": "crop_color",
    "optimizer": "sgd",
    "momentum": "0.9",
    "weight_decay": "0.0001",
    "beta_1": "0.9",
    "beta_2": "0.999",
    "gamma": "0.9",
    "eps": "1e-8",
    "top_k": "5",
    "checkpoint_frequency": "1",
    "use_pretrained_model": "0",
    "model_prefix": "" }
```

Create an estimator object and train the first model using the training and validation datasets:

```python
# Fit the base estimator
s3_output_location = 's3://{}/{}/output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    max_run=360000,
    input_mode='File',
    output_path=s3_output_location,
    sagemaker_session=sess,
    hyperparameters=hyperparams)
train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
    content_type='application/x-recordio',
    s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
    distribution='FullyReplicated',
    content_type='application/x-recordio',
    s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}
ic.fit(inputs=data_channels, logs=True)
```

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (ic.model_data, in this example) for the model_uri input argument:

```python
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    model_data=ic.model_data,
    model_uri=ic.model_uri)
```
After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in `output_path`. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 88).

Amazon SageMaker Training Storage Folders for Training Datasets, Checkpoints, Model Artifacts, and Outputs

This page provides a high-level summary of how the SageMaker training platform manages storage paths for training datasets, model artifacts, checkpoints, and outputs between AWS cloud storage and training jobs in SageMaker. Throughout this guide, you learn to identify the default paths set by the SageMaker platform and how the data channels can be streamlined with your data sources in Amazon S3, FSx for Lustre, and Amazon EFS. For more information about various data channel input modes and storage options, see Access Training Data (p. 1918).

Topics
- Overview (p. 1914)
- SageMaker Environment Variables and Default Paths for Training Storage Folders (p. 1916)
- Tips and Considerations for Setting Up Storage Paths (p. 1917)

Overview

The following diagram shows the simplest example of how SageMaker manages input and output folders when you run a training job using the SageMaker Python SDK Estimator class and its fit method. It's based on using file mode as the data access strategy and Amazon S3 as the data source for the training input channels.
This figure shows an overview of how SageMaker pairs storage paths between an Amazon S3 bucket as the data source and the SageMaker training instance based on how the paths are specified in a SageMaker estimator class. More information about the paths, how they read from or write to the paths, and purposes of the paths are described in the following section the section called “SageMaker Environment Variables and Default Paths for Training Storage Folders” (p. 1916).

For more information and examples of how SageMaker manages data source, input modes, and local paths in SageMaker training instances, see Access Training Data.

SageMaker Environment Variables and Default Paths for Training Storage Folders

The following table summarizes input and output paths for training datasets, checkpoints, model artifacts, and outputs, managed by the SageMaker training platform.

<table>
<thead>
<tr>
<th>Local path in SageMaker training instance</th>

\(^1\) channel\(_\)\_name is the place to specify user-defined channel names for training data inputs. Each training job can contain several data input channels. You can specify up to 20 training input channels per training job. Note that the data downloading time from the data channels is counted to the billable time. For more information about data input paths, see How Amazon SageMaker Provides Training Information. Also, there are three types of data input modes that SageMaker supports: file, FastFile, and pipe mode. To learn more about the data input modes for training in SageMaker, see Access Training Data.

\(^2\) SageMaker compresses and writes training artifacts to TAR files (\(\text{tar.gz}\)). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker Processes Training Output.

\(^3\) SageMaker compresses and writes the final model artifact to a TAR file (\(\text{tar.gz}\)). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker Processes Training Output.

\(^4\) Sync with Amazon S3 during training. Write as is without compressing to TAR files. For more information, see Use Checkpoints in Amazon SageMaker.

**Tips and Considerations for Setting Up Storage Paths**

Consider the following items when setting up storage paths for training jobs in SageMaker.

- If you want to store training artifacts for distributed training in the \(/opt/ml/output/\) directory, you must properly assign subfolders or unique file names for the artifacts through your model definition or training script. If the subfolders and file names are not properly configured, all of the distributed training workers might write outputs to the same file name in the same output folder in Amazon S3.

- If you use a custom training container, make sure you install the SageMaker Training Toolkit that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see Create a container with your own algorithms and models.
When using an ML instance with **NVMe SSD volumes**, SageMaker doesn’t provision Amazon EBS gp2 storage. Available storage is fixed to the NVMe-type instance's storage capacity. SageMaker configures storage paths for training datasets, checkpoints, model artifacts, and outputs to use the entire capacity of the instance storage. For example, ML instance families with the NVMe-type instance storage include `ml.p4d`, `ml.g4dn`, and `ml.g5`. When using an ML instance with the EBS-only storage option and without instance storage, you must define the size of EBS volume through the `volume_size` parameter in the SageMaker estimator class (or `VolumeSizeInGB` if you are using the ResourceConfig API). For example, ML instance families that use EBS volumes include `ml.c5` and `ml.p2`. To look up instance types and their instance storage types and volumes, see Amazon EC2 Instance Types.

- The default paths for SageMaker training jobs are mounted to Amazon EBS volumes or NVMe SSD volumes of the ML instance. When you adapt your training script to SageMaker, make sure that you use the default paths listed in the previous topic about the section called "SageMaker Environment Variables and Default Paths for Training Storage Folders" (p. 1916). We recommend that you use the `/tmp` directory as a scratch space for temporarily storing any large objects during training. This means that you must not use directories that are mounted to small disk space allocated for system, such as `/user` and `/home`, to avoid out-of-space errors.

To learn more, see the AWS machine learning blog [Choose the best data source for your Amazon SageMaker training job](https://aws.amazon.com/blogs/machine-learning/) that further discusses case studies and performance benchmarks of data sources and input modes.

## Access Training Data

When you create a training job, you specify the location of a training dataset and an input mode for accessing the dataset. For data location, Amazon SageMaker supports Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre. The input modes determine whether to stream data files of the dataset in real time or download the whole dataset at the start of the training job.

### SageMaker Input Modes and AWS Cloud Storage

This section summarizes SageMaker input modes for Amazon S3 and file systems in Amazon EFS and Amazon FSx for Lustre.
• **File mode** presents a file system view of the dataset to the training container. This is the default input mode if you don’t explicitly specify one of the other two options. If you use file mode, SageMaker downloads the training data from the storage location to a local directory in the Docker container. Training starts after the full dataset has been downloaded. In file mode, the training instance must have enough storage space to fit the entire dataset. File mode download speed depends on the size of dataset, the average size of files, and the number of files. You can configure the dataset for file mode by providing either an Amazon S3 prefix, manifest file, or augmented manifest file. You should use an S3 prefix when all your dataset files are located within a common S3 prefix. File mode is compatible with SageMaker local mode (starting a SageMaker training container interactively in seconds). For distributed training, you can shard the dataset across multiple instances with the `ShardedByS3Key` option.

• **Fast file mode** provides file system access to an Amazon S3 data source while leveraging the performance advantage of pipe mode. At the start of training, fast file mode identifies the data files but does not download them. Training can start without waiting for the entire dataset to download. This means that the training startup takes less time when there are fewer files in the Amazon S3 prefix provided.

In contrast to pipe mode, fast file mode works with random access to the data. However, it works best when data is read sequentially. Fast file mode doesn't support augmented manifest files.

Fast file mode exposes S3 objects using a POSIX-compliant file system interface, as if the files are available on the local disk of your training instance. It streams S3 content on demand as your training script consumes data. This means that your dataset no longer needs to fit into the training instance storage space as a whole, and you don’t need to wait for the entire dataset to be downloaded to the training instance before training starts. Fast file currently supports S3 prefixes only (it does not support manifest and augmented manifest). Fast file mode is compatible with SageMaker local mode.

• **Pipe mode** streams data directly from an Amazon S3 data source. Streaming can provide faster start times and better throughput than file mode.

When you stream the data directly, you can reduce the size of the Amazon EBS volumes used by the training instance. Pipe mode needs only enough disk space to store the final model artifacts.

It is another streaming mode that is largely replaced by the newer and simpler-to-use fast file mode. In pipe mode, data is pre-fetched from Amazon S3 at high concurrency and throughput, and streamed into a named pipe, which also known as a First-In-First-Out (FIFO) pipe for its behavior. Each pipe may only be read by a single process. A SageMaker specific extension to TensorFlow conveniently integrates Pipe mode into the native TensorFlow data loader for streaming text, TFRecords, or RecordIO file formats. Pipe mode also supports managed sharding and shuffling of data.

• **Amazon FSx for Lustre** – FSx for Lustre can scale to hundreds of gigabytes of throughput and millions of IOPS with low-latency file retrieval. When starting a training job, SageMaker mounts the FSx for Lustre file system to the training instance file system, then starts your training script. Mounting itself is a relatively fast operation that doesn’t depend on the size of the dataset stored in FSx for Lustre.

To access FSx for Lustre, your training job must connect to an Amazon Virtual Private Cloud (VPC), which requires DevOps setup and involvement. To avoid data transfer costs, the file system uses a single Availability Zone, and you need to specify a VPC subnet which maps to this Availability Zone ID when running the training job.

• **Amazon EFS** – To use Amazon EFS as a data source, the data must already reside in Amazon EFS prior to training. SageMaker mounts the specified Amazon EFS file system to the training instance, then starts your training script. Your training job must connect to a VPC to access Amazon EFS.

**Tip**
To learn more about how to specify your VPC configuration to SageMaker estimators, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.
Choosing Data Input Mode Using the SageMaker Python SDK

SageMaker Python SDK provides the generic `Estimator class` and its variations for ML frameworks for launching training jobs. You can specify one of the data input modes while configuring the SageMaker `Estimator` class or the `Estimator.fit` method. The following code templates show the two ways to specify input modes.

**To specify the input mode using the Estimator class**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/',
    base_job_name='job-name',
    input_mode='File'  # Available options: File | Pipe | FastFile
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(s3_data="s3://my-bucket/my-data/train")
)
```

For more information, see the `sagemaker.estimator.Estimator` class in the *SageMaker Python SDK documentation*.

**To specify the input mode through the Estimator fit method**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/',
    base_job_name='job-name',
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(s3_data="s3://my-bucket/my-data/train",
        input_mode='File'  # Available options: File | Pipe | FastFile
    )
)
```

For more information, see the `sagemaker.estimator.Estimator.fit` class method and the `sagemaker.inputs.TrainingInput` class in the *SageMaker Python SDK documentation*.

**Tip**

To learn more about how to configure Amazon FSx for Lustre or Amazon EFS with your VPC configuration using the SageMaker Python SDK estimators, see *Use File Systems as Training Inputs* in the *SageMaker Python SDK documentation*.

**Tip**

The data input mode integrations with Amazon S3, Amazon EFS, and FSx for Lustre are recommended ways to optimally configure data source for the best practices. You can
strategically improve data loading performance using the SageMaker managed storage options and input modes, but it's not strictly constrained. You can write your own data reading logic directly in your training container. For example, you can set to read from a different data source, write your own S3 data loader class, or use third-party frameworks' data loading functions within your training script. However, you must make sure that you specify the right paths that SageMaker can recognize.

**Tip**
If you use a custom training container, make sure you install the SageMaker training toolkit that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see Create a container with your own algorithms and models.

For more information about how to set the data input modes using the low-level SageMaker APIs, see How Amazon SageMaker Provides Training Information (p. 3287), the CreateTrainingJob API, and the TrainingInputMode in AlgorithmSpecification.

**Configure Data Input Channel to Use Amazon FSx for Lustre**

Learn how to use Amazon FSx for Lustre as your data source for higher throughput and faster training by reducing the time for data loading.

**Sync Amazon S3 and Amazon FSx for Lustre**

To link your Amazon S3 to Amazon FSx for Lustre and upload your training datasets, do the following.

1. Prepare your dataset and upload to an Amazon S3 bucket. For example, assume that the Amazon S3 paths for a train dataset and a test dataset are in the following format.

   ```
   s3://my-bucket/data/train
   s3://my-bucket/data/test
   ```

2. To create an FSx for Lustre file system linked with the Amazon S3 bucket with the training data, follow the steps at Linking your file system to an Amazon S3 bucket in the Amazon FSx for Lustre User Guide. Make sure that you add an endpoint to your VPC allowing Amazon S3 access. For more information, see the section called “Create an Amazon S3 VPC Endpoint” (p. 3777). When you specify Data repository path, provide the Amazon S3 bucket URI of the folder that contains your datasets. For example, based on the example S3 paths in step 1, the data repository path should be the following.

   ```
   s3://my-bucket/data
   ```

3. After the FSx for Lustre file system is created, check the configuration information by running the following commands.

   ```
   aws fsx describe-file-systems && \
   aws fsx describe-data-repository-association
   ```

   These commands return FileSystemId, MountName, FileSystemPath, and DataRepositoryPath. For example, the outputs should look like the following.

   ```
   # Output of aws fsx describe-file-systems
   "FileSystemId": "fs-0123456789abcdef0"
   "MountName": "1234abcd"
   ```

   ```
   # Output of aws fsx describe-data-repository-association
   ```
"FileSystemPath": "/ns1",
"DataRepositoryPath": "s3://my-bucket/data/"

After the sync between Amazon S3 and Amazon FSx has completed, your datasets are saved in Amazon FSx in the following directories.

/ns1/train  # synced with s3://my-bucket/data/train
/ns1/test   # synced with s3://my-bucket/data/test

Set the Amazon FSx file system path as the data input channel for SageMaker training

The following procedures walk you through the process of setting the Amazon FSx file system as the data source for SageMaker training jobs.

Using the SageMaker Python SDK

To properly set the Amazon FSx file system as the data source, configure the SageMaker estimator classes and FileSystemInput using the following instruction.

1. Configure a FileSystemInput class object.

```python
from sagemaker.inputs import FileSystemInput

train_fs = FileSystemInput(
    file_system_id="fs-0123456789abcdef0",
    file_system_type="FSxLustre",
    directory_path="/1234abcd/ns1/",
    file_system_access_mode="ro",
)
```

**Tip**
When you specify `directory_path`, make sure that you provide the Amazon FSx file system path starting with MountName.

2. Configure a SageMaker estimator with the VPC configuration used for the Amazon FSx file system.

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...,
    role="your-iam-role-with-access-to-your-fsx",
    subnets=["subnet-id"],  # Should be the same as the subnet used for Amazon FSx
    security_group_ids="security-group-id"
)
```

3. Launch the training job by running the estimator.fit method with the Amazon FSx file system.

```python
estimator.fit(train_fs)
```

To find more code examples, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.

Using the SageMaker CreateTrainingJob API

As part of the CreateTrainingJob request JSON, configure InputDataConfig as follows.
"InputDataConfig": [  {
    "ChannelName": "string",
    "DataSource": {
    "FileSystemDataSource": {
    "DirectoryPath": "/1234abcd/ns1/",
    "FileSystemAccessMode": "ro",
    "FileSystemId": "fs-0123456789abcdef0",
    "FileSystemType": "FSxLustre"
    }
    }
  }
],

Tip
When you specify DirectoryPath, make sure that you provide the Amazon FSx file system path starting with MountName.

Tips and Considerations When Configuring FSx for Lustre

1. When you use EFA-enabled instances such as P4d and P3dn, make sure that you set appropriate inbound and output rules in the security group. Specially, opening up these ports is necessary for SageMaker to access the Amazon FSx file system in the training job. To learn more, see File System Access Control with Amazon VPC.

2. Make sure the IAM Role used to launch the SageMaker training job has access to Amazon FSx.

Best Practices for Choosing Data Source and Input Mode

The best data source for your training job depends on workload characteristics such as the size of the dataset, the file format, the average size of files, the training duration, a sequential or random data loader read pattern, and how fast your model can consume the training data. The following best practices provide guidelines to get started with the most suitable input mode and data storage for your use case.
Best Practices for Choosing Data Source and Input Mode

1. **Where is the dataset stored?**
   - **EFS**
     - **Try Amazon EFS**
     - **Good enough performance?**
       - Yes
         - **Try Amazon FSx for Lustre**
       - No
         - **How big is the dataset?**
           - Less than 50GB-100GB
             - **Try File mode**
           - More than 50GB-100GB
             - **Can you concatenate files?**
               - Yes
                 - **Try FastFile mode**
               - No
                 - **Try Amazon FSx for Lustre**

2. **S3**
   - **How big is the dataset?**
     - Less than 50GB-100GB
       - **Try File mode**
     - More than 50GB-100GB
       - **How big are your files?**
         - More than 50MB
           - **Try FastFile mode**
         - Less than 50MB
           - **Try File mode**
This flowchart summarizes and visualizes best practices of choosing the best storage as the data source and input file mode. All of the cases in the flowchart are described in the following sections.

**When to use Amazon EFS**

If your dataset is stored in Amazon Elastic File System, you might have a preprocessing or annotations application that uses Amazon EFS for storage. You can run a training job configured with a data channel that points to the Amazon EFS file system. For more information, see [Speed up training on Amazon SageMaker using Amazon FSx for Lustre and Amazon EFS file systems](#). If you cannot achieve better performance, check your optimization options following the [Amazon Elastic File System performance guide](#) or consider using different input modes or data storage.

**Use file mode for small datasets**

If the dataset is stored in Amazon Simple Storage Service and its overall volume is relatively small (for example, less than 50-100 GB), try using file mode. The overhead of downloading a 50 GB dataset can vary based on the total number of files. For example, it takes about 5 minutes if a dataset is chunked into 100 MB shards. Whether this startup overhead is acceptable primarily depends on the overall duration of your training job, because a longer training phase means a proportionally smaller download phase.

**Serializing many small files**

If your dataset size is small (less than 50-100 GB), but is made up of many small files (less than 50 MB per file), the file mode download overhead grows, because each file needs to be downloaded individually from Amazon Simple Storage Service to the training instance volume. To reduce this overhead and data traversal time in general, consider serializing groups of such small files into fewer larger file containers (such as 150 MB per file) by using file formats, such as [TFRecord](#) for TensorFlow, [WebDataset](#) for PyTorch, and [RecordIO](#) for MXNet.

**When to use fast file mode**

For larger datasets with larger files (more than 50 MB per file), the first option is to try fast file mode, which is more straightforward to use than FSx for Lustre because it doesn’t require creating a file system, or connecting to a VPC. Fast file mode is ideal for large file containers (more than 150 MB), and might also do well with files more than 50 MB. Because fast file mode provides a POSIX interface, it supports random reads (reading non-sequential byte-ranges). However, this is not the ideal use case, and your throughput might be lower than with the sequential reads. However, if you have a relatively large and computationally intensive ML model, fast file mode might still be able to saturate the effective bandwidth of the training pipeline and not result in an IO bottleneck. You’ll need to experiment and see. To switch from file mode to fast file mode (and back), just add (or remove) the `input_mode='FastFile'` parameter while defining your input channel using the SageMaker Python SDK:

```python
sagemaker.inputs.TrainingInput(S3_INPUT_FOLDER, input_mode = 'FastFile')
```

**When to use Amazon FSx for Lustre**

If your dataset is too large for file mode, has many small files that you can’t serialize easily, or uses a random read access pattern, FSx for Lustre is a good option to consider. Its file system scales to hundreds of gigabytes per second (GB/s) of throughput and millions of IOPS, which is ideal when you have many small files. However, note that there might be the cold start issue due to lazy loading and the overhead of setting up and initializing the FSx for Lustre file system.
Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 1928).

Note
Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

Topics
- Using Managed Spot Training (p. 1927)
- Managed Spot Training Lifecycle (p. 1928)

Using Managed Spot Training

To use managed spot training, create a training job. Set EnableManagedSpotTraining to True and specify the MaxWaitTimeInSeconds. MaxWaitTimeInSeconds must be larger than MaxRuntimeInSeconds. For more information about creating a training job, see DescribeTrainingJob.

You can calculate the savings from using managed spot training using the formula \( \left(1 - \frac{\text{BillableTimeInSeconds}}{\text{TrainingTimeInSeconds}}\right) \times 100 \). For example, if BillableTimeInSeconds is 100 and TrainingTimeInSeconds is 500, the savings is 80%.

To learn how to run training jobs on Amazon SageMaker spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:

- Managed Spot Training with TensorFlow
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet
- Amazon SageMaker Managed Spot Training Examples GitHub repository
Managed Spot Training Lifecycle

You can monitor a training job using TrainingJobStatus and SecondaryStatus returned by DescribeTrainingJob. The list below shows how TrainingJobStatus and SecondaryStatus values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  
  1. InProgress: Starting ↠ Downloading ↠ Training ↠ Uploading

- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  
  1. InProgress: Starting ↠ Downloading ↠ Training ↠ Interrupted ↠ Starting ↠ Downloading ↠ Training ↠ Uploading

- **Spot instances interrupted twice and MaxWaitTimeInSeconds exceeded.**
  
  1. InProgress: Starting ↠ Downloading ↠ Training ↠ Interrupted ↠ Starting ↠ Downloading ↠ Training ↠ Interrupted ↠ Downloading ↠ Training
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded

- **Spot instances were never launched.**
  
  1. InProgress: Starting
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded

Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers (the default is /opt/ml/checkpoints). SageMaker provides the functionality to copy the checkpoints from the local path to Amazon S3 and automatically syncs the checkpoints in that directory with Amazon S3. Existing checkpoints in S3 are written to the SageMaker container at the start of the job, enabling jobs to resume from a checkpoint. Checkpoints added to the S3 folder after the job has started are not copied to the training container. SageMaker also writes new checkpoints from the container to S3 during training. If a checkpoint is deleted in the SageMaker container, it will also be deleted in the S3 folder.

Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Managed Spot Training in Amazon SageMaker (p. 1927).
Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for AWS Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path `'/opt/ml/checkpoints'` and copies them to Amazon S3.

- **Deep Learning Containers**: TensorFlow, PyTorch, MXNet, and HuggingFace

  **Note**
  If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker in the HuggingFace documentation.

- **Built-in algorithms**: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)

  **Note**
  If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`'/opt/ml/checkpoints'`) and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.
Enable Checkpointing

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see Docker Registry Paths and Example Code (p. 2396). You can also replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes, such as TensorFlow, PyTorch, MXNet, HuggingFace and XGBoost.

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...,
    image_uri="<ecr_path>/<algorithm-name>:<tag>" # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,

    # Parameters required to enable checkpointing
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path
)
```

The following two parameters specify paths for checkpointing:

- `checkpoint_local_path` – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to `'/opt/ml/checkpoints'`. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to `'/opt/ml/checkpoints'`.

**Note**

We recommend specifying the local paths as `'/opt/ml/checkpoints'` to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local...
Browse Checkpoint Files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

To find the checkpoint files programmatically

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

To find the checkpoint files from the Amazon S3 console

2. In the left navigation pane, choose Training jobs.
3. Choose the link to the training job with checkpointing enabled to open Job settings.
4. On the Job settings page of the training job, locate the Checkpoint configuration section.

   ![Checkpoint configuration table]

<table>
<thead>
<tr>
<th>S3 output path</th>
<th>Local path</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3://path-to-your-checkpoint</td>
<td>/opt/ml/checkpoints/</td>
</tr>
</tbody>
</table>

5. Use the link to the S3 bucket to access the checkpoint files.

Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the Enable Checkpointing (p. 1929) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to `checkpoint_local_path` in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.
Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Considerations for Amazon SageMaker Debugger (p. 1650)
  - Data Parallel Troubleshooting (p. 1725)
  - Model Parallel Troubleshooting (p. 1792)

Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3), and you must configure your training job to use the dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.
During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ["line", "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```json
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.

If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], the following example shows a valid augmented manifest file:

```json
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

In case of the first JSON line of this manifest file, SageMaker retrieves the image1.jpg file from s3://mybucket/sample01/ and the string representation of the is-a-cat attribute "1" for image classification.

**Tip**
To create an augmented manifest file, use Amazon SageMaker Ground Truth and create a labeling job. For more information about the output from a labeling job, see Output Data (p. 682).

**Stream Augmented Manifest File Data**

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a "-ref" suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying
RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.

Using the ["image-ref", "is-a-cat"] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding is-a-cat attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as S3DataDistributionType. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

### Use an Augmented Manifest File (Console)

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

#### To use an augmented manifest file in a training job (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For Resource configuration, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either accept the default (train) or enter a more meaningful name, such as training-augmented-manifest-file.
   b. For InputMode, choose Pipe.
Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
import sagemaker

# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(
    training_image,
    role,
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    volume_size = 50,
)
Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the `DescribeTrainingJob` operation.

**Note**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the *Amazon CloudWatch API Reference*.

**Tip**

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see *SageMaker Debugger Insights Dashboard Walkthrough*, *Debugger Profiling Report Walkthrough*, and *Analyze Data Using the SMDebug Client Library*.
Defining Training Metrics

SageMaker automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker sends system resource utilization metrics listed in SageMaker Jobs and Endpoint Metrics. If you want SageMaker to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker training job request.

You can specify the metrics that you want to track using the SageMaker console, the SageMaker Python SDK, or the low-level SageMaker API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318; Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
    {
        "Name": "train:error",
        "Regex": "Train_error=(.*?);"
    },
    {
        "Name": "validation:error",
        "Regex": "Valid_error=(.*?);"
    }
]
```

In the regex for the `train:error` metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=", and the expression `(.*?);` captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Define Metrics Using the SageMaker Python SDK

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an Estimator object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your Estimator initialization would look like the following example:

```
import sagemaker
```
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)

For more information about training by using Amazon SageMaker Python SDK estimators, see Sagemaker Python SDK on GitHub.

Define Metrics Using the SageMaker Console

If you choose the Your own algorithm container in ECR option as your algorithm source in the SageMaker console when you create a training job, add the metric definitions in the Metrics section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.

Define Metrics Using the Low-level SageMaker API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the MetricDefinitions field of the AlgorithmSpecification input parameter.
that you pass to the `CreateTrainingJob` operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following example:

```
"AlgorithmSpecification": {
   "TrainingImage": "your-own-image-uri",
   "TrainingInputMode": "File",
   "MetricDefinitions": [
      {
         "Name": "train:error",
         "Regex": "Train_error=(.*?);"
      },
      {
         "Name": "validation:error",
         "Regex": "Valid_error=(.*?);"
      }
   ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see `CreateTrainingJob`.

## Monitoring Training Job Metrics (CloudWatch Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

**To monitor training job metrics (CloudWatch console)**

2. Choose Metrics, then choose `/aws/sagemaker/TrainingJobs`.
3. Choose `TrainingJobName`.
4. On the All metrics tab, choose the names of the training metrics that you want to monitor.
5. On the Graphed metrics tab, configure the graph options. For more information about using CloudWatch graphs, see Graph Metrics in the Amazon CloudWatch User Guide.

## Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

**To monitor training job metrics (SageMaker console)**

2. Choose Training jobs, then choose the training job whose metrics you want to see.
3. Choose TrainingJobName.
4. In the Monitor section, you can review the graphs of instance utilization and algorithm metrics.
Monitor
Access logs for debugging and progress reporting. View metrics to set alarms, send notifications, or take actions. Learn more

Validation Cross Entropy

Train Cross Entropy
Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve. Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the `Image-classification-full-training` example in the `Example notebooks` section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at `Step 1: Create an Amazon SageMaker Notebook Instance` (p. 78). If you prefer, you can follow along with the `End-to-End Multiclass Image Classification Example` in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

2. Choose Notebooks, and then choose Notebook instances.
3. Choose the notebook instance that you want to use, and then choose Open.
4. On the dashboard for your notebook instance, choose SageMaker Examples.
5. Expand the Introduction to Amazon Algorithms section, and then choose Use next to `Image-classification-fulltraining.ipynb`.
7. Run all of the cells in the notebook up to the Inference section. You don’t need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
9. Choose Metrics, then choose `/aws/sagemaker/TrainingJobs`.
10. Choose TrainingJobName.
11. On the All metrics tab, choose the `train:accuracy` and `validation:accuracy` metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.
Example: Viewing a Training and Validation Curve

- DEMO-imageclassification-2018-10-27-00-05-40
Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

- To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an example of how to deploy a model to the SageMaker hosting service, see Create your endpoint and deploy your model (p. 1977).

  Or, if you prefer, watch the following video tutorial:

  Deploy Your ML Models to Production at Scale with Amazon SageMaker

- To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see Use Batch Transform (p. 2191).

  For an example of how to deploy a model with batch transform, see (Optional) Make Prediction with Batch Transform (p. 89).

  Or, if you prefer, watch the following video tutorial:

  Deploy Your ML Models to Production at Scale with Amazon SageMaker

**Prerequisites**

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the Get Started with Amazon SageMaker (p. 34) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models (p. 1170).

**What do you want to do?**

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

- To manage data processing and real-time predictions or to process batch transforms in a pipeline, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2021).

- If you want to deploy a model on inf1 instances, see Optimize model performance using Neo (p. 2305).

- To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see Optimize model performance using Neo (p. 2305).

- To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don't need a persistent endpoint, see Use Batch Transform (p. 2191).

- To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see Use Amazon SageMaker Elastic Inference (EI) (p. 2371).

- To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatically Scale Amazon SageMaker Models (p. 2035).
• To create an endpoint that can host multiple models using a shared serving container, see Host multiple models in one container behind one endpoint (p. 1987).
• To test multiple models in production, see Production variants (p. 2052).

Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

• For tools that can be used to monitor model deployments, see Monitor Amazon SageMaker (p. 3818).
• For troubleshooting model deployments, see Troubleshoot Amazon SageMaker model deployments (p. 2068).
• For model deployment best practices, see Best practices (p. 2062).
• For information about the size of storage volumes provided for different sizes of hosting instances, see Host instance storage volumes (p. 2051).

Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

• To run your own inference code hosting services, see Use Your Own Inference Code with Hosting Services (p. 3293).
• To run your own inference code for batch transforms, see Use Your Own Inference Code with Batch Transform (p. 3299).

Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender is a new capability of Amazon SageMaker that reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker ML instances. You can use Inference Recommender to deploy your model to a real-time inference endpoint that delivers the best performance at the lowest cost. Inference Recommender helps you select the best instance type and configuration (such as instance count, container parameters, and model optimizations) for your ML models and workloads.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you must first register a model to SageMaker model registry with your model artifact and container, use AWS SDK for Python (Boto3) to benchmark different SageMaker endpoint configurations, collect metrics, and visualize metrics across performance and resource utilization to help you decide on which instance type to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites (p. 1945) section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
Example notebooks

The following example Jupyter notebooks can help you with the workflows for multiple use cases in Inference Recommender:

- If you want an introductory notebook that benchmarks a TensorFlow model, see the SageMaker Inference Recommender TensorFlow notebook.
- If you want to benchmark a HuggingFace model, see the SageMaker Inference Recommender for HuggingFace notebook.
- If you want to benchmark an XGBoost model, see the SageMaker Inference Recommender XGBoost notebook.
- If you want to review CloudWatch metrics for your Inference Recommender jobs, see the SageMaker Inference Recommender CloudWatch metrics notebook.

Prerequisites

To use Amazon SageMaker Inference Recommender, first make sure you have met the prerequisites listed below. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs.

**Note**

- The following code examples use Python. Remove the ! prefix character if you run any of the following code samples in your terminal or AWS CLI.
- This example uses the conda_pytorch_p36_latest kernel within a Amazon SageMaker Notebook instance. This kernel is provided by SageMaker and uses Python 3.6 and PyTorch 1.7.1. For more information about SageMaker Notebooks, see Use Amazon SageMaker Notebook Instances (p. 358).

1. **Create an IAM role for Amazon SageMaker.**

   Create an IAM Role for Amazon SageMaker that has the AmazonSageMakerFullAccess IAM managed policy attached.

2. **(Optional) Review existing models benchmarked by Inference Recommender.**

   Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

   Use ListModelMetadata to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

   You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

   ```python
   import boto3
   aws_region="<INSERT>"
   sagemaker_client = boto3.client("sagemaker", aws_region)
   ```
Amazon SageMaker Developer Guide
Prerequisites

```
list_model_metadata_response = sagemaker_client.list_model_metadata()
```

The output includes model summaries (ModelMetadataSummaries) and response metadata (ResponseMetadata) similar to the following:

```
{
    'ModelMetadataSummaries': [
        {
            'Domain': 'NATURAL_LANGUAGE_PROCESSING',
            'Framework': 'PYTORCH:1.6.0',
            'Model': 'bert-base-cased',
            'Task': 'FILL_MASK'
        },
        {
            'Domain': 'NATURAL_LANGUAGE_PROCESSING',
            'Framework': 'PYTORCH:1.6.0',
            'Model': 'bert-base-uncased',
            'Task': 'FILL_MASK'
        },
        {
            'Domain': 'COMPUTER_VISION',
            'Framework': 'MXNET:1.8.0',
            'Model': 'resnet18v2-gluon',
            'Task': 'IMAGE_CLASSIFICATION'
        },
        {
            'Domain': 'COMPUTER_VISION',
            'Framework': 'PYTORCH:1.6.0',
            'Model': 'resnet152',
            'Task': 'IMAGE_CLASSIFICATION'
        }
    ],
    'ResponseMetadata': {
        'HTTPHeaders': {
            'content-length': '2345',
            'content-type': 'application/x-amz-json-1.1',
            'date': 'Tue, 19 Oct 2021 20:52:03 GMT',
            'x-amzn-requestid': 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx'
        },
        'HTTPStatusCode': 200,
        'RequestId': 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx',
        'RetryAttempts': 0
    }
}
```

For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```python
# ML framework details
framework = 'PYTORCH'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

3. **Upload your machine learning model to Amazon S3.**

Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```python
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets
```
# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)

# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is required for Inferentia compilation.
model.eval()
model_trace = torch.jit.trace(model, image)

# Save your traced model
model_trace.save('model.pth')

Download a sample inference script inference.py. Create a code directory and move the inference script to the code directory.

```bash
# Download the inference script
# move it into a code/ directory
!mkdir code
!mv inference.py code/
```

Amazon SageMaker requires pre-trained machine learning models be packaged as a compressed TAR file (*.tar.gz). Compress your model to satisfy this requirement:

```bash
!tar -czf test.tar.gz model.pth resnet18.py
```

When your endpoint is provisioned, the files in the archive are extracted to /opt/ml/model/ on the endpoint.

After you compress your model and model artifacts as a .tar.gz file, upload them to your Amazon S3 bucket. The following demonstrates how to upload your model to Amazon S3 using the AWS CLI:

```bash
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#).

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, create a new Docker image. See [Use Your Own Inference Code (p. 3293)](#) for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```python
from sagemaker import image_uris

aws_region="<aws_region>"

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
framework = 'PYTORCH'
```
# Prerequisites

```python
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework,
    region=aws_region,
    version=framework_version,
    py_version='py3',
    instance_type=instance_type,
    image_scope='inference')
```

For a list of available SageMaker Instances, see [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing/).

5. **Create a sample payload archive.**

Create an archive that contains individual files that the load testing tool can send to your SageMaker endpoints. Your inference code must be able to read the file formats from the sample payload.

The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.

```
!wget https://cdn.pixabay.com/photo/2020/12/18/05/56/flowers-5841251_1280.jpg
```

Compress the sample payload as a tarball:

```
!tar -cvzf payload.tar.gz flowers-5841251_1280.jpg
```

Upload the sample payload to Amazon S3 and note the Amazon S3 URI:

```
!aws s3 cp payload.tar.gz s3://{bucket}/models/
```

You need the Amazon S3 URI in a later step, so store it in a variable:

```python
bucket_prefix='models'
bucket = '<your-bucket-name>'  # Provide the name of your S3 bucket
payload_s3_key = f"{bucket_prefix}/payload.tar.gz"
sample_payload_url= f"s3://{bucket}/{payload_s3_key}"
```

6. **Register your model in the model registry**

With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the AWS SDK for Python (Boto3) or with Amazon SageMaker Studio. To create a versioned model package programmatically, first create a model package group with the `CreateModelPackageGroup` API. Next, create a model package using the `CreateModelPackage` API. Calling this method makes a versioned model package.
See *Create a Model Group* (p. 2234) and *Register a Model Version* (p. 2236) for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the AWS SDK for Python (Boto3) and Amazon SageMaker Studio.

The following code sample demonstrates how to create a versioned model package using the AWS SDK for Python (Boto3).

**Note**

Note: You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the `CreateModelPackageGroup` API. Provide a name to the model package group for the `ModelPackageName` and optionally provide a description of the model package in the `ModelPackageGroupDescription` field.

```python
model_package_group_name = '<INSERT>'
mmodel_package_group_description = '<INSERT>'

model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : model_package_group_description,
}

model_package_group_response = sagemaker_client.create_model_package_group(**model_package_group_input_dict)
```

See the *Amazon SageMaker API Reference Guide* for a full list of optional and required arguments you can pass to `CreateModelPackageGroup`.

Create a Model Package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for `InferenceSpecification`. `InferenceSpecification` should contain information about inference jobs that can be run with models based on this Model Package, including the following:

- The Amazon ECR paths of images that run your inference code.
- *(Optional)* The instance types that the Model Package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the Model Package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- **Domain**: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- **Task**: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification. Specify "OTHER" if none of the tasks listed in the API Reference Guide satisfy your use case. See the Task API field descriptions for a list of supported machine learning tasks.
- **SamplePayloadUrl**: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single gzip compressed tar archive (.tar.gz suffix).
- **Framework**: The machine learning framework of the model package container image.
- **FrameworkVersion**: The framework version of the Model Package Container Image.
If you provide an allow list of instance types to use to generate inferences in real-time for the `SupportedRealtimeInferenceInstanceTypes`, Inference Recommender will limit the search space for instance types during a Default job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. We use those variables in the following code sample where we define a dictionary used as input to the `CreateModelPackage` API.

```python
# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>'
model_s3_key = f'{bucket_prefix}/test.tar.gz'
model_url= f's3://{bucket}/{model_s3_key}"

# Similar open source model to the packaged model
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input.
input_content_type='image/jpeg'

# Optional - provide a description of your model.
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier
## step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version
## in a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo
PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating a model package group
model_package_input_dict = {
   "ModelPackageName" : model_package_group_name,
   "ModelPackageDescription" : model_package_description,
   "Domain": ml_domain,
   "Task": ml_task,
   "SamplePayloadUrl" : sample_payload_url,
   "InferenceSpecification": {
      "Containers": [
      {
         "Image": image_url,
         "ModelDataUrl": model_url,
         "Framework": framework.upper(),
         "FrameworkVersion": framework_version,
         "NearestModelName": nearest_model_name,
         "ModelInput": {"DataInputConfig": data_input_configuration}
      }
      ],
   }
}
```
Recommendation jobs

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. Instance recommendations (Default job type) run a set of load tests on recommended instance types. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Instance recommendation jobs complete within 45 minutes.

2. Endpoint recommendations (Advanced job type) are based on a custom load test where you select ML instances, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of instance configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Endpoint recommendations also provide an initial instance count which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, specify Default to create preliminary endpoint recommendations and Advanced for custom load testing and endpoint recommendations.

Note

- You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of each other.

Topics

- Get an instance recommendation (p. 1952)
- Get an instance recommendation for an existing endpoint (p. 1958)
- Get compiled recommendations with Neo (p. 1962)
- Interpret recommendation results (p. 1964)
- Run a custom load test (p. 1965)
- Troubleshoot Inference Recommender errors (p. 1974)
Get an instance recommendation

Instance recommendation jobs run a set of load tests on recommended instance types. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

Note
Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites (p. 1945).

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an instance recommendation based on your model type using the AWS SDK for Python (Boto3), AWS CLI, and Amazon SageMaker Studio.

Create an instance recommendation

Create an instance recommendation programmaticially using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. Specify a job name for your instance recommendation, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry.

AWS SDK for Python (Boto3)

Use the CreateInferenceRecommendationsJob API to get an instance endpoint recommendation. Set the JobType field to 'Default' for instance endpoint recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the RoleArn field.
- The ARN of the versioned model package you created when you registered your model with the model registry. Define this for ModelPackageVersionArn in the InputConfig field.
- Provide a name for your Inference Recommender recommendation job for the JobName field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the client class. If you followed the steps in the Prerequisites section, the model package group ARN was stored in a variable named model_package_arn.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = 'arn:aws:iam::<account>::role/*'

sagemaker_client.create_inference_recommendations_job(
```
JobName = job_name,
JobType = job_type,
RoleArn = role_arn,
InputConfig = {
    'ModelPackageVersionArn': model_package_arn
}
)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to get an instance endpoint recommendation. Set the job-type field to 'Default' for instance endpoint recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for ModelPackageVersionArn in the input-config field.
- Provide a name for your Inference Recommender recommendation job for the job-name field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

```
aws sagemaker create-inference-recommendations-job
    --region <region>\n    --job-name <job_name>\n    --job-type Default\n    --role-arn arn:aws:iam::<account:role/*>\n    --input-config "{
    }"
```

Amazon SageMaker Studio

Create an instance recommendation job in Studio.

1. In your Studio application, choose the home icon ( )
2. In the left sidebar of Studio, choose Models.
3. Choose Model Registry from the dropdown list to display models you have registered with the model registry.

   The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.

4. Select the name of your model group. When you select your model group, the right pane of Studio displays column heads such as Versions and Setting.

   If you have one or more model packages within your model group, you will see a list of those model packages within the Versions column.

5. Choose the Inference recommender column.
6. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the AmazonSageMakerFullAccess IAM managed policy to accomplish this. Or you can let Studio create a role for you.
7. Choose Get recommendations.
The instance recommendation can take up to 45 minutes.

**Warning**
Do not close this tab. If you close this tab, you cancel the instance recommendation job.

### Get Your Instance Recommendation Job Results

Collect the results of your instance recommendation job programmatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

**AWS SDK for Python (Boto3)**

Once an instance recommendation is complete, you can use `DescribeInferenceRecommendationsJob` to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

```python
job_name='<INSERT>'
response = sagemaker_client.describe_inference_recommendations_job(
    JobName=job_name)
```

Print the response object. The previous code sample stored the response in a variable name `response`.

```python
print(response['Status'])
```

This returns a JSON response similar to the following:

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 0
    },
    'InferenceRecommendations': [
        {
            'Metrics': {
                'CostPerHour': 0.20399999618530273,
                'CostPerInference': 5.246913588052848e-06,
                'MaximumInvocations': 648,
                'ModelLatency': 263596
            },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
                'InstanceType': 'ml.c5.xlarge',
                'InitialInstanceCount': 1
            },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
            }
        }
    ]
}
```
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference
(CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

**AWS CLI**

Once an instance recommendation is complete, you can use describe-inference-recommendations-job to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

```bash
aws sagemaker describe-inference-recommendations-job
    --job-name <job-name>
    --region <aws-region>
```

The JSON response similar should resemble the following:

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 0
    },
    'InferenceRecommendations': [{
        'Metrics': {
            'CostPerHour': 0.20399999618530273,
            'CostPerInference': 5.246913588052848e-06,
            'MaximumInvocations': 648,
            'ModelLatency': 263596
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5.xlarge',
            'InitialInstanceCount': 1
        },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
        }
    },
    'Metrics': {
        'CostPerHour': 0.11500000208616257,
        'CostPerInference': 2.92620870823157e-06,
        'MaximumInvocations': 655,
        'ModelLatency': 826019
    },
    'EndpointConfiguration': {
        'EndpointName': 'endpoint-name',
        'VariantName': 'variant-name'
    }
}
```
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

For more information about interpreting the results of your recommendation job, see Interpret recommendation results (p. 1964).
Amazon SageMaker Studio

The instance recommendations populate in a new Inference recommendations tab within Studio. It can take up to 45 minutes for the results to show up. This tab contains Results and Details column headings.

The Details column provides information about the instance recommendation job, such as the name of the instance recommendation, when the job was created (Creation time), and more. It also provides Settings information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The Results column provides a Deployment goals and SageMaker recommendations window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the Cost, Latency, and Throughput for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: Lowest Importance, Low Importance, Moderate importance, High importance, or Highest importance.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the SageMaker recommendation field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the All runs section.

Stop Your Instance Endpoint Recommendation

Stop your Inference Recommender instance recommendation jobs programmatically with the StopInferenceRecommendationsJob API or with Studio.

AWS SDK for Python (Boto3)

Specify the name of the instance recommendation job for the JobName field:

```python
sagemaker_client.stop_inference_recommendations_job(
    JobName='<INSERT>'
)
```

AWS CLI

Specify the job name of the instance recommendation job for the job-name flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio

Close the tab in which you initiated the instance recommendation to stop your Inference Recommender instance recommendation.

Get an instance recommendation for an existing endpoint

Inference recommendation jobs run a set of load tests on recommended instance types and existing endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

You can benchmark and get instance recommendations for an existing SageMaker Inference endpoint to help you improve the performance of your endpoint. The procedure of getting recommendations for an
existing SageMaker Inference endpoint is similar to the procedure for getting instance recommendations without an endpoint. There are several feature exclusions to take note of when benchmarking an existing endpoint:

- You can only use one existing endpoint per Inference Recommender job.
- You can only have one variant on your endpoint.
- You can’t use an endpoint that enables autoscaling.
- This functionality is only supported for Real-Time Inference.
- This functionality doesn’t support Real-Time Multi-Model Endpoints.

**Warning**

We strongly recommend that you don’t run an Inference Recommender job on a production endpoint that handles live traffic. The synthetic load during benchmarking can affect your production endpoint and cause throttling or provide inaccurate benchmark results. We recommend that you use a non-production or developer endpoint for comparison purposes.

The following sections demonstrate how to use Amazon SageMaker Inference Recommender to create an instance recommendation for an existing endpoint based on your model type using the AWS SDK for Python (Boto3) and the AWS CLI.

**Note**

Before you create an Inference Recommender recommendation job, make sure you have satisfied the [Prerequisites](p. 1945).

**Prerequisites**

If you don’t already have a SageMaker Inference endpoint, you can either get an instance recommendation without an endpoint, or you can create a Real-Time Inference endpoint by following the instructions in [Create your endpoint and deploy your model](Create your endpoint and deploy your model).

**Create an instance recommendation job for an existing endpoint**

Create an instance recommendation programmatically using AWS SDK for Python (Boto3), or the AWS CLI. Specify a job name for your instance recommendation, the name of an existing SageMaker Inference endpoint, an AWS IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry.

**AWS SDK for Python (Boto3)**

Use the `CreateInferenceRecommendationsJob` API to get an instance endpoint recommendation. Set the `JobType` field to 'Default' for instance endpoint recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
- Provide the name of an existing SageMaker Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `InputConfig` field.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the client class. If you followed the steps in the [Prerequisites](Prerequisites) section, the model package group ARN was stored in a variable named `model_package_arn`.

1959
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<model-package-arn>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<job-name>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = '<arn:aws:iam::<account>:role/*>'

# Provide endpoint name for your endpoint that want to benchmark in Inference
Recommender
endpoint_name = '<existing-endpoint-name>'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn,
        'Endpoints': [{'EndpointName': endpoint_name}]
    }
)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments
you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to get an instance endpoint
recommendation. Set the job-type field to `Default` for instance endpoint recommendation
jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the job-name field.
The Inference Recommender job name must be unique within the AWS Region and within your
AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference
Recommender to perform tasks on your behalf. Define this for the role-arn field.
- The ARN of the versioned model package you created when you registered your model with Model
Registry. Define this for ModelPackageVersionArn in the input-config field.
- Provide the name of an existing SageMaker Inference endpoint that you want to benchmark in
Inference Recommender for Endpoints in the input-config field.

aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job-name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account>:role/*>\
    --input-config "{\
        "Endpoints": [{"EndpointName": <endpoint_name>}]"}
Get your instance recommendation job results

You can collect the results of your instance recommendation job programmatically with the same procedure for standard instance recommendation jobs. For more information, see Get Your Instance Recommendation Job Results (p. 1954).

When you get instance recommendation job results for an existing endpoint, you should receive a JSON response similar to the following:

```json
{
  "JobName": "job-name",
  "JobType": "Default",
  "RoleArn": "iam-role-arn",
  "Status": "COMPLETED",
  "CreationTime": 1664922919.2,
  "LastModifiedTime": 1664924208.291,
  "InputConfig": {
    "Endpoints": [
      {
        "EndpointName": "endpoint-name"
      }
    ]
  },
  "InferenceRecommendations": [
    {
      "Metrics": {
        "CostPerHour": 0.7360000014305115,
        "CostPerInference": 7.456940238625975e-06,
        "MaxInvocations": 1645,
        "ModelLatency": 171
      },
      "EndpointConfiguration": {
        "EndpointName": "sm-endpoint-name",
        "VariantName": "variant-name",
        "InstanceType": "ml.g4dn.xlarge",
        "InitialInstanceCount": 1
      },
      "ModelConfiguration": {
        "EnvironmentParameters": [
          {
            "Key": "TS_DEFAULT_WORKERS_PER_MODEL",
            "ValueType": "string",
            "Value": "4"
          }
        ]
      }
    },
    {
      "Metrics": {
        "MaxInvocations": 184,
        "ModelLatency": 1312
      },
      "EndpointConfiguration": {
        "EndpointName": "endpoint-name"
      }
    }
  ],
  "EndpointPerformances": [
    {
      "Metrics": {
        "MaxInvocations": 184,
        "ModelLatency": 1312
      },
      "EndpointConfiguration": {
        "EndpointName": "endpoint-name"
      }
    }
  ]
}
```
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, and creation and latest modification times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job.

The `Metrics` nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The `EndpointPerformances` nested dictionary contains the name of your existing endpoint on which the recommendation job was run (EndpointName) and the performance metrics for your endpoint (MaxInvocations and ModelLatency).

Stop your instance endpoint recommendation

You can stop your Inference Recommender instance recommendation jobs programmatically with the same procedure for standard instance recommendation jobs. For more information, see Stop Your Instance Endpoint Recommendation (p. 1958).

Get compiled recommendations with Neo

In Inference Recommender, you can compile your model with Neo and get endpoint recommendations for your compiled model. SageMaker Neo is a service that can optimize your model for a target hardware platform (that is, a specific instance type or environment). Optimizing a model with Neo might improve the performance of your hosted model.

For Neo-supported frameworks and containers, Inference Recommender automatically suggests Neo-optimized recommendations. To be eligible for Neo compilation, your input must meet the following prerequisites:

- You are using a SageMaker owned DLC or XGBoost container.
- You are using a framework version supported by Neo. For the framework versions supported by Neo, see Cloud Instances (p. 2321) in the SageMaker Neo documentation.
- Neo requires that you provide a correct input data shape for your model. You can specify this data shape as the `DataInputConfig` in the `InferenceSpecification` when you create a model package. For information about the correct data shapes for each framework, see Prepare Model for Compilation in the SageMaker Neo documentation.

The following example shows how to specify the `DataInputConfig` field in the `InferenceSpecification`, where `data_input_configuration` is a variable that contains the data shape in dictionary format (for example, `{'input':[1,1024,1024,3]}`).

```
"InferenceSpecification": {
  "Containers": [
    {
      "Image": dlc_uri,
      "DataInputConfig": {
        "input": [1,1024,1024,3]
      }
    }
  ]
}
```

1962
If these conditions are met in your request, then Inference Recommender runs scenarios for both compiled and uncompiled versions of your model, giving you multiple recommendation combinations to choose from. You can compare the configurations for compiled and uncompiled versions of the same instance recommendation and determine which one best suits your use case. The recommendations are ranked by cost per inference.

To get the Neo compilation recommendations, you don't have to do any additional configuration besides making sure that your input meets the above requirements. Inference Recommender automatically runs Neo compilation on your model if your input meets the requirements, and you'll receive a response that includes Neo recommendations.

If you run into errors during your Neo compilation, see Troubleshoot Neo Compilation Errors (p. 2366).

The following table is an example of a response you might get from an Inference Recommender job that includes recommendations for compiled models. If the InferenceSpecificationName field is None, then the recommendation is an uncompiled model. The last row, where the value for the InferenceSpecificationName field is neo-00011122-2333-4445-5566-677788899900, is for a model compiled with Neo. The value in the field is the name of the Neo job used to compile and optimize your model.

Get started

The general steps for creating an Inference Recommender job that includes Neo-optimized recommendations are as follows:

- Prepare your ML model for compilation. For more information, see Prepare Model for Compilation in the Neo documentation.
- Package your model in a model archive (.tar.gz file).
- Create a sample payload archive.
- Register your model in Model Registry.
- Create an Inference Recommender job.
• View the results of the Inference Recommender job and choose a configuration.
• Debug compilation failures, if any. For more information, see Troubleshoot Neo Compilation Errors.

For an example that demonstrates the previous workflow and how to get Neo-optimized recommendations using XGBoost, see the following example notebook. For an example that show how to get Neo-optimized recommendations using TensorFlow, see the following example notebook.

**Interpret recommendation results**

Each Inference Recommender job result includes InstanceType, InitialInstanceCount, and EnvironmentParameters, which are tuned environment variable parameters for your container to improve its latency and throughput. The results also include performance and cost metrics such as MaxInvocations, ModelLatency, CostPerHour, and CostPerInference.

In the table below we provide a description of these metrics. These metrics can help you narrow down your search for the best endpoint configuration that suits your use case. For example, if your motivation is overall price performance with an emphasis on throughput, then you should focus on CostPerInference.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Use case</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelLatency</td>
<td>The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. Units: Milliseconds</td>
<td>Latency sensitive workloads such as ad serving and medical diagnosis</td>
</tr>
<tr>
<td>MaximumInvocations</td>
<td>The maximum number of InvokeEndpoint requests sent to a model endpoint in a minute. Units: None</td>
<td>Throughput-focused workloads such as video processing or batch inference</td>
</tr>
<tr>
<td>CostPerHour</td>
<td>The estimated cost per hour for your real-time endpoint. Units: US Dollars</td>
<td>Cost sensitive workloads with no latency deadlines</td>
</tr>
<tr>
<td>CostPerInference</td>
<td>The estimated cost per inference call for your real-time endpoint. Units: US Dollars</td>
<td>Maximize overall price performance with a focus on throughput</td>
</tr>
</tbody>
</table>

In some cases you might want to explore other SageMaker Endpoint Invocation metrics such as CPUUtilization. Every Inference Recommender job result includes the names of endpoints spun up during the load test. You can use CloudWatch to review the logs for these endpoints even after they've been deleted.

The following image is an example of CloudWatch metrics and charts you can review for a single endpoint from your recommendation result. This recommendation result is from a Default job. The way
to interpret the scalar values from the recommendation results is that they are based on the time point when the Invocations graph first begins to level out. For example, the ModelLatency value reported is at the beginning of the plateau around 03:00:31.

For full descriptions of the CloudWatch metrics used in the preceding charts, see SageMaker Endpoint Invocation metrics.

See the Amazon SageMaker Inference Recommender - CloudWatch Metrics Jupyter notebook in the amazon-sagemaker-examples Github repository for an example of how to use the AWS SDK for Python (Boto3) to explore CloudWatch metrics for your endpoints.

Run a custom load test

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programatically using AWS SDK for Python (Boto3) and the AWS CLI, and interactively using Amazon SageMaker Studio.

Create a Load Test Job

Create a load test programatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. As with Inference Recommender instance recommendations, specify a job name for your load test, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

AWS SDK for Python (Boto3)

Use the CreateInferenceRecommendationsJob API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:
• A job name for your load test (JobName). The job name must be unique within your AWS Region and within your AWS account.

• The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the RoleArn field.

• An endpoint configuration dictionary (InputConfig) where you specify the following:
  • For TrafficPattern, do the following:
    • For TrafficType, specify PHASES.
    • For Phases, specify the InitialNumberOfUsers (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), SpawnRate (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).

  Note
  A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an ml.c5.large instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.

  • For ResourceLimit, specify MaxNumberOfTests (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and MaxParallelNumberOfTests (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).

  • For EndpointConfigurations, specify the InstanceType, or the instance type on which you want to run your load tests.

• A stopping conditions dictionary (StoppingConditions), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:
  • For MaxInvocations, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
  • For ModelLatencyThresholds, specify Percentile (the model latency percentile threshold) and ValueInMilliseconds (the model latency percentile value in milliseconds).

```python
# Create a low-level SageMaker service client.
import boto3
aws_region=<INSERT>
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name=<INSERT>

# Provide the name of the sagemaker instance type
instance_type=<INSERT>

# Provide the IAM Role that gives SageMaker permission to access AWS services
role_arn='arn:aws:iam::<account>:role/*'

# Provide your model package ARN that was created when you registered your model with Model Registry
model_package_arn='arn:aws:sagemaker:<region>::<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName=load_test_job_name,
    JobType="Advanced",
    RoleArn=role_arn,
    InputConfig={
        'ModelPackageVersionArn': model_package_arn,
        "JobDurationInSeconds": 7200,
    }
)
```
Recommendation jobs

```json

'TrafficPattern' : {
    'TrafficType': 'PHASES',
    'Phases': [
        {
            'InitialNumberOfUsers': 1,
            'SpawnRate': 1,
            'DurationInSeconds': 120
        },
        {
            'InitialNumberOfUsers': 1,
            'SpawnRate': 1,
            'DurationInSeconds': 120
        }
    ],
    'ResourceLimit': {
        'MaxNumberOfTests': 10,
        'MaxParallelOfTests': 3
    },
    "EndpointConfigurations" : [[
        'InstanceType': 'ml.c5.xlarge'
    ],
    ['InstanceType': 'ml.m5.xlarge'
    ],
    ['InstanceType': 'ml.r5.xlarge'
    ]]},
StoppingConditions={
    'MaxInvocations': 1000,
    'ModelLatencyThresholds':[['
        'Percentile': 'P95',
        'ValueInMilliseconds': 100
    ]]
}
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:

- A job name for your load test (job-name). The job name must be unique within your AWS region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- An endpoint configuration dictionary (input-config) where you specify the following:
  - For TrafficPattern, do the following:
    - For TrafficType, specify PHASES.
    - For Phases, specify the InitialNumberOfUsers (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), SpawnRate (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).

  **Note**
  A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost
container running on an ml.c5.large instance, endpoints can reach 30,000
invocations per minute (500 tps) with just 15-20 users.

- For **ResourceLimit**, specify **MaxNumberOfTests** (the maximum number of benchmarking
load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10)
and **MaxParallelOfTests** (the maximum number of parallel benchmarking load tests for an
Inference Recommender job, with a minimum of 1 and a maximum of 10).

- For **EndpointConfigurations**, specify the **InstanceType**, or the instance type on which you
want to run your load tests.

- A stopping conditions dictionary (**stopping-conditions**), where if any of the conditions are
met, the Inference Recommender job stops. For this example, specify the following fields in the
dictionary:

  - For **MaxInvocations**, specify the maximum number of requests per minute expected for the
endpoint, with a minimum of 1 and a maximum of 30,000.

  - For **ModelLatencyThresholds**, specify **Percentile** (the model latency percentile threshold)
and **ValueInMilliseconds** (the model latency percentile value in milliseconds).

```
aws sagemaker create-inference-recommendations-job
  --region <region>
  --job-name <job-name>
  --job-type ADVANCED
  --role-arn arn:aws:iam::<account>:role/*
  --input-config "{
      "ModelPackageVersionArn": "arn:aws:sagemaker::<region>::<account>:role/*",
      "JobDurationInSeconds": 7200,
      "TrafficPattern": {
        "TrafficType": "PHASES",
        "Phases": [
          {
            "InitialNumberOfUsers": 1,
            "SpawnRate": 60,
            "DurationInSeconds": 300
          }
        ]
      },
      "ResourceLimit": {
        "MaxNumberOfTests": 10,
        "MaxParallelOfTests": 3
      },
      "EndpointConfigurations": [
        {
          "InstanceType": "ml.c5.xlarge"
        },
        {
          "InstanceType": "ml.m5.xlarge"
        },
        { 'InstanceType': 'ml.r5.xlarge' }
      ]
    }"
  --stopping-conditions "{
    "MaxInvocations": 1000,
    "ModelLatencyThresholds": [{
      "Percentile": "P95",
      "ValueInMilliseconds": 100
    }]
  }
```

Amazon SageMaker Studio

Create a load test with Studio.

1. In your Studio application, choose the home icon (🏠).
2. In the left sidebar of Studio, choose Deployments.
3. Choose Inference recommender from the dropdown list.
5. Select the name of your model group from the dropdown Model group field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
6. Select a model version from the dropdown Model version field.
7. Choose Continue.
8. Provide a name for the job in the Name field.
9. (Optional) Provide a description of your job in the Description field.
10. Choose Stop conditions to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.
   a. Specify the maximum number of requests per minute expected for the endpoint in the Max Invocations Per Minute field.
   b. Specify the model latency threshold in microseconds in the Model Latency Threshold field. The Model Latency Threshold depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.
12. Choose Traffic Pattern to expand the available input fields.
   a. Set the initial number of virtual users by specifying an integer in the Initial Number of Users field.
   b. Provide an integer number for the Spawn Rate field. The spawn rate sets the number of users created per second.
   c. Set the duration for the phase in seconds by specifying an integer in the Duration field.
   d. (Optional) Add additional traffic patterns. To do so, choose Add.
13. Choose the Additional setting to reveal the Max test duration field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.
15. Choose Selected Instances.
16. In the Instances for benchmarking field, choose Add instances to test. Select up to 10 instances for Inference Recommender to use for load testing.
17. Choose Additional settings.
   a. Provide an integer that sets an upper limit on the number of tests a job can make for the Max number of tests field. Note that each endpoint configuration results in a new load test.
b. Provide an integer for the **Max parallel** test field. This setting defines an upper limit on the number of load tests that can run in parallel.

18. Choose **Submit**.

The load test can take up to 2 hours.

**Warning**

Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

---

**Get Your Load Test Results**

You can collect metrics across all load tests once the load tests are done programmatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

**AWS SDK for Python (Boto3)**

Collect metrics with the `DescribeInferenceRecommendationsJob` API. Specify the job name of the load test for the `JobName` field:

```python
load_test_response = sagemaker_client.describe_inference_recommendations_job(
    JobName=load_test_job_name
)
```

Print the response object.

```python
load_test_response['Status']
```

This returns a JSON response similar to the following:

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 390000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }]
    },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818) for more information.

The EndpointConfiguration nested dictionary also contains the instance count (InitialInstanceCount) recommendation. This is the number of instances that you should provision in the endpoint to meet the MaxInvocations specified in the StoppingConditions. For example if the InstanceType is ml.m5.large and the InitialInstanceCount is 2, then you should provision 2 ml.m5.large instances for your endpoint so that it can handle the TPS specified in the MaxInvocations stopping condition.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) for your real-time endpoint, the maximum number of InvokeEndpoint requests sent to the endpoint, and the model latency (ModelLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

AWS CLI

Collect metrics with the describe-inference-recommendations-job API. Specify the job name of the load test for the job-name flag:
aws sagemaker describe-inference-recommendations-job --job-name <job-name>

This returns a response similar to the following:

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }]
    },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
        }]
    },
    'InferenceRecommendations': [{
        'Metrics': {
            'CostPerHour': 0.6899999976158142,
            'CostPerInference': 1.0332434612791985e-05,
            'MaximumInvocations': 1113,
            'ModelLatency': 100000
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5d.xlarge',
            'InitialInstanceCount': 3
        },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
        }
    }],
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {
            'x-amzn-requestid': 'x-amzn-requestid',
            'content-type': 'content-type',
            'content-length': '1199',
            'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
        }
    }
}
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

Amazon SageMaker Studio

The recommendations populate in a new tab called `Inference recommendations` within Studio. It can take up to 2 hours for the results to show up. This tab contains `Results` and `Details` columns.

The `Details` column provides information about the load test job, such as the name given to the load test job, when the job was created (`Creation time`), and more. It also contains `Settings` information, such as the maximum number of invocation that occurred per minute and information about the Amazon Resource Names used.

The `Results` column provides `Deployment goals` and `SageMaker recommendations` windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the `Cost`, `Latency`, and `Throughput` for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: `Lowest importance`, `Low importance`, `Moderate importance`, `High importance`, or `Highest importance`.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the `SageMaker recommendation` field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the `All runs` section.

**Stop Your Load Test**

Stop your load test jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio.

**AWS SDK for Python (Boto3)**

Specify the job name of the load test for the `JobName` field:

```python
sagemaker_client.stop_inference_recommendations_job()
```
**Amazon SageMaker Developer Guide**

**Recommendation jobs**

---

**AWS CLI**

Specify the job name of the load test for the `--job-name` flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

---

**Amazon SageMaker Studio**

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

---

**Troubleshoot Inference Recommender errors**

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors.

**How to troubleshoot**

You can attempt to resolve your error by going through the following steps:

- Check if you've covered all the prerequisites to use Inference Recommender. See the [Inference Recommender Prerequisites](#).
- Check that you are able to deploy your model from Model Registry to an endpoint and that it can process your payloads without errors. See [Deploy a Model from the Registry](#).
- When you kick off an Inference Recommender job, you should see endpoints being created in the console and you can review the CloudWatch logs.

**Common errors**

Review the following table for common Inference Recommender errors and their solutions.

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify Domain in the Model Package version 1. Domain is a mandatory parameter for the job.</td>
<td>Make sure you provide the ML Domain or OTHER if unknown.</td>
</tr>
<tr>
<td>Provided role ARN cannot be assumed and an AWSSecurityTokenServiceException error occurred.</td>
<td>Make sure the execution role provided has the necessary permissions specified in the prerequisites.</td>
</tr>
<tr>
<td>Specify Framework in the Model Package version 1. Framework is a mandatory parameter for the job.</td>
<td>Make sure you provide the ML Framework or OTHER if unknown.</td>
</tr>
<tr>
<td>Users at the end of prev phase is 0 while initial users of current phase is 1.</td>
<td>Users here refers to virtual users or threads used to send requests. Each phase starts with A users and ends with B users such that B &gt; A. Between sequential phases, x_1 and x_2, we require that abs(x_2.A - x_1.B) &lt;= 3 and &gt;= 0.</td>
</tr>
<tr>
<td>Total Traffic duration (across) should not be more than Job duration.</td>
<td>The total duration of all your Phases cannot exceed the Job duration.</td>
</tr>
</tbody>
</table>
## Error

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Burstable instance type ml.t2.medium is not allowed.</td>
<td>Inference Recommender doesn't support load testing on t2 instance family because burstable instances do not provide consistent performance.</td>
</tr>
<tr>
<td>ResourceLimitExceeded when calling CreateEndpoint operation</td>
<td>You have exceeded a SageMaker resource limit. For example, Inference Recommender might be unable to provision endpoints for benchmarking if the account has reached the endpoint quota. For more information about SageMaker limits and quotas, see <a href="https://docs.aws.amazon.com/sagemaker/latest/dg/limits-quota.html">Amazon SageMaker endpoints and quotas</a>.</td>
</tr>
</tbody>
</table>
| ModelError when calling InvokeEndpoint operation | A model error can happen for the following reasons:  
• The invocation timed out while waiting for a response from the model container.  
• The model couldn't process the input payload. |
| PayloadError when calling InvokeEndpoint operation | A payload error can happen for following reasons:  
• The payload source isn't in the Amazon S3 bucket.  
• The payload is in a non-file object format.  
• The payload is in an invalid file type. For example, a model expects an image type payload but is passed a text file.  
• The payload is empty. |

## Check CloudWatch

When you kick off an Inference Recommender job, you should see endpoints being created in the console. Select one of the endpoints and view the CloudWatch logs to monitor for any 4xx/5xx errors. If you have a successful Inference Recommender job, you will be able to see the endpoint names as part of the results. Even if your Inference Recommender job is unsuccessful, you can still check the CloudWatch logs for the deleted endpoints by following the steps below:

1. Open the Amazon CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/).
2. Select the Region in which you created the Inference Recommender job from the Region dropdown list in the top right.
3. In the navigation pane of CloudWatch, choose Logs, and then select Log groups.
4. Search for the log group called /aws/sagemaker/Endpoints/sm-epc-*. Select the log group based on your most recent Inference Recommender job.

## Check benchmarks

When you kick off an Inference Recommender job, Inference Recommender creates several benchmarks to evaluate the performance of your model on different instance types. You can use the ListInferenceRecommendationsJobSteps API to view the details for all the benchmarks. If you have a failed benchmark, you can see the failure reasons as part of the results.

To use the ListInferenceRecommendationsJobSteps API, provide the following values:
• For JobName, provide the name of the Inference Recommender job.
• For StepType, use BENCHMARK to return details about the job’s benchmarks.
• For Status, use FAILED to return details about only the failed benchmarks. For a list of the other
status types, see the Status field in the ListInferenceRecommendationsJobSteps API.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide the job name for the SageMaker Inference Recommender job
job_name = '<job-name>'

# Filter for benchmarks
step_type = 'BENCHMARK'

# Filter for benchmarks that have a FAILED status
status = 'FAILED'

response = sagemaker_client.list_inference_recommendations_job_steps(
    JobName = job_name,
    StepType = step_type,
    Status = status
)

You can print the response object to view the results. The preceding code example stored the response in
a variable called response:

print(response)
```

Real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency
requirements. You can deploy your model to SageMaker hosting services and get an endpoint that can be
used for inference. These endpoints are fully managed and support autoscaling (see Automatically Scale
Amazon SageMaker Models (p. 2035)).

Topics
• Hosting options (p. 1976)
• Automatically Scale Amazon SageMaker Models (p. 2035)
• Host instance storage volumes (p. 2051)
• Safely validate models in production (p. 2051)
• Best practices (p. 2062)
• Online Explainability with SageMaker Clarify (p. 2069)
• Invoke real-time endpoints (p. 2086)

Hosting options

The following topics describe available SageMaker realtime hosting options along with how to set up,
invoke, and delete each hosting option.
Topics

- Host a single model (p. 1977)
- Host multiple models in one container behind one endpoint (p. 1987)
- Host multiple models which use different containers behind one endpoint (p. 2014)
- Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2021)

Host a single model

Create, update, and delete real-time inference endpoints that host a single model with the AWS SDK for Python (Boto3), the SageMaker Python SDK, the SageMaker console, or the AWS CLI.

Topics

- Create your endpoint and deploy your model (p. 1977)
- Delete Endpoints and Resources (p. 1983)

Create your endpoint and deploy your model

There are several options to deploy a model using SageMaker hosting services. You can programmatically deploy a model using an AWS SDK (for example, the SDK for Python (Boto3)), the SageMaker Python SDK, the AWS CLI, or you can interactively deploy a model with the SageMaker console. The AWS SDK is a low-level API and supports Java, C++, Go, JavaScript, Node.js, PHP, Ruby, and Python whereas the SageMaker Python SDK is a high-level Python API. The following documentation demonstrates how to deploy a model using the AWS SDK for Python (Boto3) and the SageMaker Python SDK.

Deploying a model using SageMaker hosting services is a three-step process if you use AWS SDK for Python (Boto3), the AWS CLI, or the SageMaker console:

2. Create an endpoint configuration for an HTTPS endpoint.
3. Create an HTTPS endpoint.

Deploying a model using the SageMaker Python SDK does not require that you create an endpoint configuration. It is therefore a two-step process:

1. Create a model object from the Model Class that can be deployed to an HTTPS endpoint.
2. Create an HTTPS endpoint with the Model object's pre-built deploy() method.

To use the proceeding code snippets, replace the italicized placeholder text in the example code with your own information.

Note

- SageMaker supports running (a) multiple models, (b) multiple variants of a model, or (c) combinations of models and variants on the same endpoint. Model variants can reference the same model inference container (i.e. run the same algorithm), but use different model artifacts (e.g., different model weight values based on other hyper-parameter configurations). In contrast, two different models may use the same algorithm, but focus on different business problems or underlying goals and may operate on different data sets.
- When you create an endpoint, SageMaker attaches an Amazon EBS storage volume to each ML compute instance that hosts the endpoint. The size of the storage volume depends on the
Hosting options

instance type. For a list of instance types that SageMaker hosting service supports, see AWS Service Limits. For a list of the sizes of the storage volumes that SageMaker attaches to each instance, see Host instance storage volumes (p. 2051).

- Endpoints are scoped to an individual AWS account, and are not public. The URL does not contain the account ID, but SageMaker determines the account ID from the authentication token that is supplied by the caller.

For an example of how to use Amazon API Gateway and AWS Lambda to set up and deploy a web service that you can call from a client application that is not within the scope of your account, see Call a SageMaker model endpoint using Amazon API Gateway and AWS Lambda in the AWS Machine Learning Blog.

**Before you begin**

Before you create and deploy a SageMaker model, locate and make note of the:

- AWS region where your Amazon S3 bucket is located
- Amazon S3 URI path where the model artifacts are stored
- IAM role for SageMaker
- Docker Amazon ECR URI registry path for the custom image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by AWS.

For a list of AWS Services available in each AWS Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

**Important**
The Amazon S3 bucket where the model artifacts are stored must be in the same region as the model that you are creating.

The following demonstrates how to define the aforementioned parameters programmatically.

**AWS SDK for Python (Boto3)**

Import Boto3. Define your AWS region. Next, initialize a low-level SageMaker service client object using the Client class. This will make it easy to send and receive requests to AWS services. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>::<account>::role/*"
```

The first few lines define:

- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.
Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (framework field) along with the version of the framework or algorithm (version field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use Your Own Inference Code (p. 3293).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>'
# Example

# Version of the framework or algorithm
version = '<version-number>'
# Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region,
                               framework=framework,
                               version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK Model object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/{model_filename}

# Combine bucket name, model file name, and relative S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```

SageMaker Python SDK

Define your AWS region. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
# Specify your AWS Region
aws_region= '<aws_region>'

# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>:<account>::role/*"
```

The first few lines define:
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.
Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (framework field) along with the version of the framework or algorithm (version field). For a list of built-in Docker images provided by AWS, see `Available Deep Learning Containers Images`. For more information on how to bring your own image, see `Use Your Own Inference Code` (p. 3293).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>'  # Example

# Version of the framework or algorithm
version = '<version-number>'  # Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region,
                                framework=framework,
                                version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK Model object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/{model_filename}'

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```

### Create a Model

By creating a model, you tell SageMaker where it can find the model components.

**AWS SDK for Python (Boto3)**

Create a model in SageMaker with `CreateModel`. Specify the following:

- **ModelName**: A name for your model (in this example it is stored as a string variable called `model_name`).
- **ExecutionRoleArn**: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
Hosting options

- PrimaryContainer: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

For the primary container, specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

```py
model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })
```

**SageMaker Python SDK**

Create a model object from the SageMaker Python SDK `Model` Class. You will use this object to deploy your model to an endpoint in a later step.

```py
from sagemaker.model import Model

model = Model(image_uri=container,
               model_data=model_url,
               role=sagemaker_role)
```

**Create an Endpoint Configuration**

Create an endpoint configuration for an HTTPS endpoint. Specify the name of one or more models in production (variants) and the ML compute instances that you want SageMaker to launch to host each production variant.

**Note**
Skip this section if you are exclusively using the SageMaker Python SDK.

When hosting models in production, you can configure the endpoint to elastically scale the deployed ML compute instances. For each production variant, you specify the number of ML compute instances that you want to deploy. When you specify two or more instances, SageMaker launches them in multiple Availability Zones. This ensures continuous availability. SageMaker manages deploying the instances.

**AWS SDK for Python (Boto3)**

Create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```py
import datetime
```

1981
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = '<endpoint-config-name>'

# The name of the model that you want to host. This is the name that you specified when
# creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,  # You will specify this name in a
    CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at
    # this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1",  # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": instance_type,  # Specify the compute instance type.
            "InitialInstanceCount": 1  # Number of instances to launch initially.
        }
    ]
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")

In the aforementioned example, you specify the following keys for the ProductionVariants field:

- **VariantName**: The name of the production variant.
- **ModelName**: The name of the model that you want to host. This is the name that you specified when creating the model.
- **InstanceType**: The compute instance type. See the InstanceType field in https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html and SageMaker Pricing for a list of supported compute instance types and pricing for each instance type.

SageMaker Python SDK

You do not need to define an endpoint configuration for real-time endpoints if you use the SageMaker Python SDK Model Class.

**Deploy your model**

Deploy your model and create an HTTPS endpoint.

**AWS SDK for Python (Boto3)**

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the CreateEndpoint API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)

For more information, see the CreateEndpoint API.

## SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"
print("EndpointName = ", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object's built-in deploy() method. Provide the name of the Amazon EC2 instance type to deploy this model to in the instance_type field along with the initial number of instances to run the endpoint on for the initial_instance_count field:

```python
initial_instance_count=<integer>
# initial_instance_count=1 # Example

instance_type='<instance-type>'
# instance_type='ml.m4.xlarge' # Example

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name
)
```

---

### Delete Endpoints and Resources

Delete endpoints to stop incurring charges.

#### Delete Endpoint

Delete your endpoint programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console.

SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting an endpoint will not delete the endpoint configuration or the SageMaker model. See Delete Endpoint Configuration (p. 1984) and Delete Model (p. 1986) for information on how to delete your endpoint configuration and SageMaker model.

**AWS SDK for Python (Boto3)**

Use the DeleteEndpoint API to delete your endpoint. Specify the name of your endpoint for the EndpointName field.
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint
sagemaker_client.delete_endpoint(EndpointName=endpoint_name)

AWS CLI

Use the delete-endpoint command to delete your endpoint. Specify the name of your endpoint for the endpoint-name flag.

aws sagemaker delete-endpoint --endpoint-name <endpoint-name>

SageMaker Console

Delete your endpoint interactively with the SageMaker console.

2. Choose Endpoints from the drop down menu. A list of endpoints created in you AWS account will appear by name, Amazon Resource Name (ARN), creation time, status, and a time stamp of when the endpoint was last updated.
3. Select the endpoint you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Delete Endpoint Configuration

Delete your endpoint configuration programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting an endpoint configuration does not delete endpoints created using this configuration. See Delete Endpoint (p. 1983) for information on how to delete your endpoint.

Do not delete an endpoint configuration in use by an endpoint that is live or while the endpoint is being updated or created. You might lose visibility into the instance type the endpoint is using if you delete the endpoint configuration of an endpoint that is active or being created or updated.

AWS SDK for Python (Boto3)

Use the DeleteEndpointConfig API to delete your endpoint. Specify the name of your endpoint configuration for the EndpointConfigName field.

import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
endpoint_config_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

You can optionally use the `DescribeEndpointConfig` API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `EndpointConfigName` field.

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
endpoint_config_name = response['ProductionVariants'][0]['EndpointConfigName']

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

For more information about other response elements returned by `DescribeEndpointConfig`, see `DescribeEndpointConfig` in the SageMaker API Reference guide.

AWS CLI

Use the `delete-endpoint-config` command to delete your endpoint configuration. Specify the name of your endpoint configuration for the `endpoint-config-name` flag.

```bash
aws sagemaker delete-endpoint-config \
    --endpoint-config-name <endpoint-config-name>
```

You can optionally use the `describe-endpoint-config` command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```bash
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the endpoint configuration name associated with that endpoint.

SageMaker Console

Delete your endpoint configuration interactively with the SageMaker console.

1. In the SageMaker console at https://console.aws.amazon.com/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Endpoint configurations** from the dropdown menu. A list of endpoint configurations created in you AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the endpoint configuration you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

### Delete Model

Delete your SageMaker model programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting a SageMaker model only deletes the model entry that was created in SageMaker. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

#### AWS SDK for Python (Boto3)

Use the **DeleteModel** API to delete your SageMaker model. Specify the name of your model for the `ModelName` field.

```python
import boto3

# Specify your AWS Region
aws_region = '<aws_region>'

# Specify the name of your endpoint configuration
model_name = '<model_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete model
sagemaker_client.delete_model(ModelName=model_name)
```

You can optionally use the **DescribeEndpointConfig** API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `EndpointConfigName` field.

```python
# Specify the name of your endpoint
endpoint_name = '<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
model_name = response['ProductionVariants'][0]['ModelName']
sagemaker_client.delete_model(ModelName=model_name)
```

For more information about other response elements returned by `DescribeEndpointConfig`, see [DescribeEndpointConfig](https://docs.aws.amazon.com/sagemaker/latest/dg/API_DescribeEndpointConfig.html) in the SageMaker API Reference guide.

#### AWS CLI

Use the **delete-model** command to delete your SageMaker model. Specify the name of your model for the `model-name` flag.

```bash
aws sagemaker delete-model \
   --model-name <model-name>
```
You can optionally use the `describe-endpoint-config` command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```bash
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the name of the model associated with that endpoint.

**SageMaker Console**

Delete your SageMaker model interactively with the SageMaker console.

1. In the SageMaker console at [https://console.aws.amazon.com/sagemaker/](https://console.aws.amazon.com/sagemaker/) navigation menu, choose **Inference**.
2. Choose **Models** from the dropdown menu. A list of models created in your AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the model you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

**Host multiple models in one container behind one endpoint**

Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use the same fleet of resources and a shared serving container to host all of your models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to your endpoint.

The following diagram shows how multi-model endpoints work compared to single-model endpoints.

![Diagram showing multi-model endpoints vs. single-model endpoints](image-url)

Multi-model endpoints are ideal for hosting a large number of models that use the same ML framework on a shared serving container. If you have a mix of frequently and infrequently accessed models, a multi-
model endpoint can efficiently serve this traffic with fewer resources and higher cost savings. Your application should be tolerant of occasional cold start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support hosting both CPU and GPU backed models. By using GPU backed models, you can lower your model deployment costs through increased usage of the endpoint and its underlying accelerated compute instances.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints.

You can use multi-model endpoints with the following features:

- AWS PrivateLink and VPCs
- Auto scaling (p. 2012)
- Serial inference pipelines (but only one multi-model enabled container can be included in an inference pipeline)
- A/B testing

You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. For CPU backed multi-model endpoints, you can create your endpoint with custom-built containers by integrating the Multi Model Server library.

**Topics**

- Supported algorithms, frameworks, and instances (p. 1988)
- Sample notebooks for multi-model endpoints (p. 1989)
- How multi-model endpoints work (p. 1990)
- Setting SageMaker multi-model endpoint model caching behavior (p. 1991)
- Instance recommendations for multi-model endpoint deployments (p. 1991)
- Create a Multi-Model Endpoint (p. 1992)
- Invoke a Multi-Model Endpoint (p. 1999)
- Add or Remove Models (p. 2000)
- Build Your Own Container for SageMaker Multi-Model Endpoints (p. 2001)
- Multi-Model Endpoint Security (p. 2006)
- CloudWatch Metrics for Multi-Model Endpoint Deployments (p. 2007)
- Set Auto Scaling Policies for Multi-Model Endpoint Deployments (p. 2012)

**Supported algorithms, frameworks, and instances**

For information about the algorithms, frameworks, and instance types that you can use with multi-model endpoints, see the following sections.

**Supported algorithms, frameworks, and instances for multi-model endpoints using CPU backed instances**

The inference containers for the following algorithms and frameworks support multi-model endpoints:

- XGBoost Algorithm (p. 1262)
- K-Nearest Neighbors (k-NN) Algorithm (p. 1221)
Hosting options

- Linear Learner Algorithm (p. 1238)
- Random Cut Forest (RCF) Algorithm (p. 1387)
- Use TensorFlow with Amazon SageMaker (p. 31)
- Use Scikit-learn with Amazon SageMaker (p. 30)
- Use Apache MXNet with Amazon SageMaker (p. 15)
- Use PyTorch with Amazon SageMaker (p. 27)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container for SageMaker Multi-Model Endpoints (p. 2001).

Multi-model endpoints support all of the CPU instance types.

**Supported algorithms, frameworks, and instances for multi-model endpoints using GPU backed instances**

Hosting multiple GPU backed models on multi-model endpoints is supported through the SageMaker Triton Inference server. This supports all major inference frameworks such as NVIDIA® TensorRT™, PyTorch, MXNet, Python, ONNX, XGBoost, scikit-learn, RandomForest, OpenVINO, custom C++, and more.

To use any other framework or algorithm, you can use Triton backend for Python or C++ to write your model logic and serve any custom model. After you have the server ready, you can start deploying 100s of Deep Learning models behind one endpoint.

Multi-model endpoints support the following GPU instance types:

<table>
<thead>

**Sample notebooks for multi-model endpoints**

To learn more about how to use multi-model endpoints, you can try the following sample notebooks:
Hosting options

Examples for multi-model endpoints using CPU backed instances:

- **Multi-Model Endpoint XGBoost Sample Nootebook** – This notebook shows how to deploy multiple XGBoost models to an endpoint.
- **Multi-Model Endpoints BYOC Sample Notebook** – This notebook shows how to set up and deploy a customer container that supports multi-model endpoints in SageMaker.

Example for multi-model endpoints using GPU backed instances:

- **Run multiple deep learning models on GPUs with Amazon SageMaker Multi-model endpoints (MME)** – This notebook shows how to use an NVIDIA Triton Inference container to deploy ResNet-50 models to a multi-model endpoint.

For instructions on how to create and access Jupyter notebook instances that you can use to run the previous examples in SageMaker, see [Use Amazon SageMaker Notebook Instances](p. 358). After you've created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all the SageMaker samples. The multi-model endpoint notebooks are located in the **ADVANCED FUNCTIONALITY** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

For more information about use cases for multi-model endpoints, see the following blogs and resources:

- Video: [Hosting thousands of models on SageMaker](#)
- Video: [SageMaker ML for SaaS](#)
- Blog: [How to scale machine learning inference for multi-tenant SaaS use cases](#)
- Case study: [Veeva Systems](#)

**How multi-model endpoints work**

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container’s memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads and caches them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) on that accelerated compute instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don’t need code changes to use it.
**Note**
When you update a multi-model endpoint, initial invocation requests on the endpoint might experience higher latencies as Smart Routing in multi-model endpoints adapt to your traffic pattern. However, once it learns your traffic pattern, you can experience low latencies for most frequently used models. Less frequently used models may incur some cold start latencies since the models are dynamically loaded to an instance.

**Setting SageMaker multi-model endpoint model caching behavior**

By default, multi-model endpoints cache frequently used models in memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. For both CPU and GPU backed endpoints, the concurrency is a factor of the number of the vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see [Instance recommendations for multi-model endpoint deployments](#).

**Instance recommendations for multi-model endpoint deployments**

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint:

- Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served.
- Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see [Host instance storage volumes](#).
- For a container configured to run in MultiModel mode, the storage volume provisioned for its instances are larger than the default SingleModel mode. This allows more models to be cached on the instance storage volume than in SingleModel mode.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are currently supported for all CPU instances types and on single-GPU instance types.
- For the traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance), keep the following information in mind:
- Think of the amount of memory on an instance as the cache space for models to be loaded, and think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
- For CPU backed instances, the number of vCPUs impacts your maximum concurrent invocations per instance (assuming that invoking a model is bound to CPU). A higher amount of vCPUs enables you to invoke more unique models concurrently.
- For GPU backed instances, a higher amount of instance and GPU memory enables you to have more models loaded and ready to serve inference requests.
- For both CPU and GPU backed instances, have some "slack" memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Determine your tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) and g5s come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d and g5 instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

You can also use the following guidance to help you optimize model loading on your multi-model endpoints:

**Choosing an instance type that can't hold all of the targeted models in memory**

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you sacrifice dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for performance testing and analysis helps you to have successful production deployments.

**Evaluating your model cache hits**

Amazon CloudWatch metrics can help you evaluate your models. For more information about metrics you can use with multi-model endpoints, see CloudWatch Metrics for Multi-Model Endpoint Deployments (p. 2007).

You can use the Average statistic of the ModelCacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the ModelUnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

**Create a Multi-Model Endpoint**

You can use the SageMaker console or the AWS SDK for Python (Boto) to create a multi-model endpoint. To create either a CPU or GPU backed endpoint through the console, see the console procedure in the following sections. If you want to create a multi-model endpoint with the AWS SDK for Python (Boto), use either the CPU or GPU procedure in the following sections. The CPU and GPU workflows are similar but have several differences, such as the container requirements.
Topics

- Create a multi-model endpoint (console) (p. 1993)
- Create a multi-model endpoint using CPUs with the AWS SDK for Python (Boto3) (p. 1995)
- Create a multi-model endpoint using GPUs with the AWS SDK for Python (Boto3) (p. 1997)

Create a multi-model endpoint (console)

You can create both CPU and GPU backed multi-model endpoints through the console. Use the following procedure to create a multi-model endpoint through the SageMaker console.

To create a multi-model endpoint (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the Container definition section, for Provide model artifacts and inference image options, choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location of the inference code. See deploying a model on Amazon SageMaker Hosting Services [Learn More].

Model settings

Model name

mml-test-model

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique for your account in an AWS Region.

IAM role

Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let Amazon SageMaker create a role that has the AmazonSageMakerFullAccess IAM policy attached.

AmazonSageMaker-ExecutionRole-XXXXXXXXXXXXXXXXX

Container definition 1

Container input options

Provide model artifacts and inference image location

Provide model artifacts and inference image options

Use multiple models

Use this to host multiple models in this container.

Location of inference code image

Type the registry path where the inference code image is stored in Amazon ECR.

123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag

Location of model artifacts

Type the URL where model artifacts are stored in S3.

s3://my-bucket/path/to/artifacts/
6. For the Inference container image, enter the Amazon ECR path for your desired container image. For GPU models, you must use a container backed by the NVIDIA Triton Inference Server. For a list of container images that work with GPU backed endpoints, see the NVIDIA Triton Inference Containers (SM support only). For more information about the NVIDIA Triton Inference Server, see Use Triton Inference Server with SageMaker.

7. Choose Create model.

8. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see Deploy the Model to SageMaker Hosting Services (p. 88).

Create a multi-model endpoint using CPUs with the AWS SDK for Python (Boto3)

Use the following section to create a multi-model endpoint backed by CPU instances. You create a multi-model endpoint using the Amazon SageMaker create_model, create_endpoint_config, and create_endpoint APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new Mode parameter value, MultiModel. You also need to pass the ModelDataUrl field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see Multi-Model Endpoint XGBoost Sample Notebook.

The following procedure outlines the key steps used in that sample to create a CPU backed multi-model endpoint.

To deploy the model (AWS SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see Supported algorithms, frameworks, and instances (p. 1988). For this example, we use the K-Nearest Neighbors (k-NN) Algorithm (p. 1221) built-in algorithm. We call the SageMaker Python SDK utility function image_uris.retrieve() to get the address for the K-Nearest Neighbors built-in algorithm image.

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = sagemaker.image_uris.retrieve("knn", region=region)
   container = {
       'Image':        image,
       'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
       'Mode':         'MultiModel'
   }
   ```

2. Get an AWS SDK for Python (Boto3) SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sagemaker_client = boto3.client('sagemaker')
   response = sagemaker_client.create_model(
       ModelName        = '<MODEL_NAME>',
       ExecutionRoleArn = role,
       Containers       = [container])
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the Containers argument of CreateModel:

   ```python
   preprocessor_container = {
       'Image': '
          '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>':<TAG>'
   }
   ```
Hosting options

```
multi_model_container = {
    'Image':
        '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
}
```

response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [preprocessor_container, multi_model_container]
)

**Note**
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

```
container = {
    'Image': image,
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
    'MultiModelConfig': {
        // Default value is 'Enabled'
        'ModelCacheSetting': 'Disabled'
    }
}
```

response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [container]
)

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

```
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
    ProductionVariants=[
        {
            'InstanceType': 'ml.m4.xlarge',
            'InitialInstanceCount': 2,
            'InitialVariantWeight': 1,
            'ModelName': '<MODEL_NAME>',
            'VariantName': 'AllTraffic'
        }
    ]
)
```

**Note**
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.

```
response = sagemaker_client.create_endpoint(
```

1996
Create a multi-model endpoint using GPUs with the AWS SDK for Python (Boto3)

Use the following section to create a GPU backed multi-model endpoint. You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs similarly to creating single model endpoints, but there are several changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model. For GPU backed multi-model endpoints, you also must use a container with the NVIDIA Triton Inference Server that is optimized for running on GPU instances. For a list of container images that work with GPU backed endpoints, see the NVIDIA Triton Inference Containers (SM support only).

For an example notebook that demonstrates how to create a multi-model endpoint backed by GPUs, see Run multiple deep learning models on GPUs with Amazon SageMaker Multi-model endpoints (MME).

The following procedure outlines the key steps to create a GPU backed multi-model endpoint.

**To deploy the model (AWS SDK for Python (Boto 3))**

1. Define the container image. To create a multi-model endpoint with GPU support for ResNet models, define the container to use the **NVIDIA Triton Server image**. This container supports multi-model endpoints and is optimized for running on GPU instances. We call the `SageMaker Python SDK` utility function `image_uris.retrieve()` to get the address for the image. For example:

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = "<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-tritonserver:<TAG>".format(
     account_id=account_id_map[region], region=region
   )
   container = {
     'Image': image,
     'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
     'Mode': 'MultiModel',
     "Environment": {"SAGEMAKER_TRITON_DEFAULT_MODEL_NAME": "resnet"},
   }
   ```

2. Get an AWS SDK for Python (Boto3) SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sagemaker_client = boto3.client('sagemaker')
   response = sagemaker_client.create_model(
     ModelName = '<MODEL_NAME>',
     ExecutionRoleArn = role,
     Containers = [container]
   )
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:
Hosting options

```
preprocessor_container = {
    'Image':
    '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
}

multi_model_container = {
    'Image':
    '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
}

given a user-defined preprocessor

response = sagemaker_client.create_model(
    ModelName        = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers       = [preprocessor_container, multi_model_container]
)
```

**Note**

You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

```
container = {
    'Image': image,
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
    'MultiModelConfig': {
        // Default value is 'Enabled'
        'ModelCacheSetting': 'Disabled'
    }
}

response = sagemaker_client.create_model(
    ModelName        = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers       = [container]
)
```

5. Configure the multi-model endpoint with GPU backed instances for the model. We recommend configuring your endpoints with more than one instance to allow for high availability and higher cache hits.

```
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
    ProductionVariants=[
        {'InstanceType': 'ml.g4dn.4xlarge',
        'InitialInstanceCount': 2,
        'InitialVariantWeight': 1,
        'ModelName': '<MODEL_NAME>',
        'VariantName': 'AllTraffic'
        }
    ]
)
```

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.
Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

The following procedures are the same for both CPU and GPU-backed multi-model endpoints.

AWS SDK for Python (Boto 3)

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName = '<ENDPOINT_NAME>',
    ContentType = 'text/csv',
    TargetModel = '<MODEL_FILENAME>.tar.gz',
    Body = body)
```

AWS CLI

The following example shows how to make a CSV request with two rows using the AWS Command Line Interface (AWS CLI):

```bash
aws sagemaker-runtime invoke-endpoint \
--endpoint-name "<ENDPOINT_NAME>" \
--body "1.0,2.0,5.0\n2.0,3.0,4.0" \
--content-type "text/csv" \
--target-model "<MODEL_NAME>.tar.gz" \
output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the AWS CLI, see Making predictions with the AWS CLI in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. This is called a `cold start`, and it is expected on multi-model endpoints to optimize for better price performance for customers. Subsequent calls finish faster because there's no additional overhead after the model has loaded.

**Note**

For GPU backed instances, the HTTP response code with 507 from the GPU container indicates a lack of memory or other resources. This causes unused models to be unloaded from the container in order to load more frequently used models.
Retry Requests on ModelNotReadyException Errors

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code for an `invoke_endpoint` request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using `Legacy retry mode`) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for the AWS SDK for Python (Boto3), see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```python
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for up to 180 seconds: 1 origonal request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2  # This value can be adjusted to 5 to go up to the 360s max timeout
    }
)
runtime_sagemaker_client = boto3.client('sagemaker-runtime', config=config)
```

Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model. The process for adding and removing models is the same for CPU and GPU-backed multi-model endpoints.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```bash
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

Important

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don’t overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.
Client applications can request predictions from the additional target model as soon as it is stored in S3.

```
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName='<ENDPOINT_NAME>',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

**Build Your Own Container for SageMaker Multi-Model Endpoints**

Refer to the following sections for bringing your own container and dependencies to multi-model endpoints.

**Topics**

- Bring your own dependencies for multi-model endpoints on CPU backed instances (p. 2001)
- Bring your own dependencies for multi-model endpoints on GPU backed instances (p. 2002)
- Use the SageMaker Inference Toolkit (p. 2002)
- Custom Containers Contract for Multi-Model Endpoints (p. 2004)

**Bring your own dependencies for multi-model endpoints on CPU backed instances**

If none of the pre-built container images serve your needs, you can build your own container for use with CPU backed multi-model endpoints.

Custom Amazon Elastic Container Registry (Amazon ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 3293) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker also injects an environment variable into the container

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 2025).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.
• **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

**Bring your own dependencies for multi-model endpoints on GPU backed instances**

The bring your own container (BYOC) capability on multi-model endpoints with GPU backed instances is not currently supported by the Multi Model Server and SageMaker Inference Toolkit libraries.

For creating multi-model endpoints with GPU backed instances, you can use the SageMaker supported NVIDIA Triton Inference Server with the NVIDIA Triton Inference Containers. To bring your own dependencies, you can build your own container with the SageMaker supported NVIDIA Triton Inference Server as the base image to your Docker file:

```text
FROM 30121789009.dkr.ecr.us-west-2.amazonaws.com/sagemaker-tritonserver:22.07-py3
```

**Important**

Containers with the Triton Inference Server are the only supported containers you can use for GPU backed multi-model endpoints.

**Use the SageMaker Inference Toolkit**

**Note**

The SageMaker Inference Toolkit is only supported for CPU backed multi-model endpoints.

The SageMaker Inference Toolkit is not currently supported for GPU backed multi-model endpoints.

Pre-built containers that support multi-model endpoints are listed in *Supported algorithms, frameworks, and instances* (p. 1988). If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the SageMaker Inference Toolkit to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook.

**Note**

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see *Custom Containers Contract for Multi-Model Endpoints* (p. 2004).

**To extend a container by using the SageMaker inference toolkit**

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see `model_handler.py` from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
```
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through the
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

        # prevent docker exit
        subprocess.call(['tail', '-f', '/dev/null'])

main()

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile used in the sample notebook:

```bash
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]
```

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

```bash
%%sh

# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)

region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1

if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
```
You can now use this container to deploy multi-model endpoints in SageMaker.

Topics

• Custom Containers Contract for Multi-Model Endpoints (p. 2004)

Custom Containers Contract for Multi-Model Endpoints

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the `TargetModel` parameter passed into the `InvokeEndpoint` API. The original `TargetModel` value in the `InvokeEndpoint` request is passed to container in the APIs as a `X-Amzn-SageMaker-Target-Model` header that can be used for logging purposes.

**Note**

Multi-model endpoints for GPU backed instances are currently supported only with SageMaker's NVIDIA Triton Inference Server container. This container already implements the contract defined below. Customers can directly use this container with their multi-model GPU endpoints, without any additional work.

You can configure the following APIs on your containers for CPU backed multi-model endpoints.

Topics

• Load Model API (p. 2004)
• List Model API (p. 2005)
• Get Model API (p. 2005)
• Unload Model API (p. 2006)
• Invoke Model API (p. 2006)

Load Model API

Instructs the container to load a particular model present in the `url` field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
    "model_name": "model_name",
    "url": "/opt/ml/models/model_name/model",
}
```
Note
If model_name is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

List Model API
Returns the list of models loaded into the memory of the customer container.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
  "models": [
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    ....
  ]
}
```

This API also supports pagination.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
  "models": [
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    ....
  ]
}
```

SageMaker can initially call the List Models API without providing a value for next_page_token. If a nextPageToken field is returned as part of the response, it will be provided as the value for next_page_token in a subsequent List Models call. If a nextPageToken is not returned, it means that there are no more models to return.

Get Model API
This is a simple read API on the model_name entity.

```
GET /models/{model_name} HTTP/1.1
Accept: application/json

{
  "modelName" : "{model_name}",
}
```
Hosting options

```
"modelUrl" : "/opt/ml/models/{model_name}/model",
}
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```
DELETE /models/{model_name}
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime InvokeEndpoint request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

```
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: ContentType
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```

**Note**

If `model_name` is not loaded, this API should return 404.

Additionally, on GPU instances, if InvokeEndpoint fails due to a lack of memory or other resources, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

### Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with InvokeEndpoint permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the CreateModel operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict InvokeEndpoint access to a limited set of models in S3, you can do one of the following:

- Restrict InvokeEndpoint calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key. For example, the following policy allows InvokeEndpoint requests only when the value of the TargetModel field matches one of the specified regular expressions:

```

Hosting options

```json
"Version": "2012-10-17",
"Statement": [
  {
    "Action": [
      "sagemaker:InvokeEndpoint"
    ],
    "Effect": "Allow",
    "Resource":
      "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
    "Condition": {
      // TargetModel provided must be from this set of values
      "StringLike": {
        "sagemaker:TargetModel": ["company_a/*", "common/*"]
      }
    }
  }
]
```

For information about SageMaker condition keys, see [Condition Keys for Amazon SageMaker](aws.amazon.com/sagemaker) in the [AWS Identity and Access Management User Guide](aws.amazon.com/sagemaker).

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see [SageMaker Roles](aws.amazon.com/sagemaker) (p. 3646). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

### CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded and the model wait times for loading, downloading, and uploading at a multi-model endpoint. Some of the metrics are different for CPU and GPU backed multi-model endpoints, so the following sections describe the Amazon CloudWatch metrics that you can use for each type of multi-model endpoint.

For more information about the metrics, see [Multi-Model Endpoint Model Loading Metrics](aws.amazon.com/sagemaker) and [Multi-Model Endpoint Model Instance Metrics](aws.amazon.com/sagemaker) in [Monitor Amazon SageMaker with Amazon CloudWatch](aws.amazon.com/sagemaker) (p. 3818). Per-model metrics aren't supported.

#### CloudWatch metrics for CPU backed multi-model endpoints

You can monitor the following metrics on CPU backed multi-model endpoints.

The AWS/SageMaker namespace includes the following model loading metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see [GetMetricStatistics](aws.amazon.com/sagemaker) in the [Amazon CloudWatch API Reference](aws.amazon.com/sagemaker).

### Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>

Set Auto Scaling Policies for Multi-Model Endpoint Deployments

SageMaker multi-model endpoints fully support automatic scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances based on Instance recommendations for multi-model endpoint deployments (p. 1991) and also set up instance based auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event are based on the aggregate set of predictions across the full set of models served by the endpoint. For additional details on setting up endpoint auto scaling, see Automatically Scale Amazon SageMaker Models.

You can set up auto scaling policies with predefined and custom metrics on both CPU and GPU backed multi-model endpoints.

**Note**

SageMaker multi-model endpoint metrics are available at one-minute granularity.

Define a scaling policy

To specify the metrics and target values for a scaling policy, you can configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration.

**Use a predefined metric**

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the SageMakerVariantInvocationsPerInstance predefined metric to adjust the number of variant instances so that each instance has an InvocationsPerInstance metric of 70.

```json
{"TargetValue": 70.0,
 "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "InvocationsPerInstance"
  }
}
```

**Note**

We recommend that you use InvocationsPerInstance while using multi-model endpoints. The TargetValue for this metric depends on your application's latency requirements. We also recommend that you load test your endpoints to set up suitable scaling parameter values. To learn more about load testing and setting up autoscaling for your endpoints, see the blog Configuring autoscaling inference endpoints in Amazon SageMaker.
Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

**Important**

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example custom metric for a CPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named `my-model`, a custom metric of `CPUUtilization` adjusts the instance count on the endpoint based on an average CPU utilization of 50% across all instances.

```json
{"TargetValue": 50,
"CustomizedMetricSpecification":
{"MetricName": "CPUUtilization",
 "Namespace": "/aws/sagemaker/Endpoints",
 "Dimensions": [
  {"Name": "EndpointName", "Value": "my-endpoint" },
  {"Name": "ModelName","Value": "my-model"}
  ],
 "Statistic": "Average",
 "Unit": "Percent"
}
}
```

Example custom metric for a GPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named `my-model`, a custom metric of `GPUUtilization` adjusts the instance count on the endpoint based on an average GPU utilization of 50% across all instances.

```json
{"TargetValue": 50,
"CustomizedMetricSpecification":
{"MetricName": "GPUUtilization",
 "Namespace": "/aws/sagemaker/Endpoints",
 "Dimensions": [
  {"Name": "EndpointName", "Value": "my-endpoint" },
  {"Name": "ModelName","Value": "my-model"}
  ],
 "Statistic": "Average",
 "Unit": "Percent"
}
}
```

Add a cooldown period

To add a cooldown period for scaling out your endpoint, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.
The following is an example target-tracking configuration for a scaling policy. In this configuration, the SageMakerVariantInvocationsPerInstance predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{"TargetValue": 70.0, 
  "PredefinedMetricSpecification": 
    {"PredefinedMetricType": "SageMakerVariantInvocationsPerInstance" }, 
  "ScaleInCooldown": 600, 
  "ScaleOutCooldown": 300 } 
```

Host multiple models which use different containers behind one endpoint

SageMaker multi-container endpoints enable customers to deploy multiple containers, that use different models or frameworks, on a single SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2021).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 2015)

Topics

- Create a multi-container endpoint (Boto 3) (p. 2014)
- Update a multi-container endpoint (p. 2015)
- Delete a multi-container endpoint (p. 2015)
- Use a multi-container endpoint with direct invocation (p. 2015)

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.

Note
Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and InferenceExecutionConfig with direct invocation.
container1 = { 'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage1:mytag', 'ContainerHostname': 'firstContainer'}

container2 = { 'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage2:mytag', 'ContainerHostname': 'secondContainer'}
inferenceExecutionConfig = {'Mode': 'Direct'}

2. Create the model with the container elements and set the InferenceExecutionConfig field.

```python
import boto3
sm_client = boto3.Session().client('sagemaker')
response = sm_client.create_model(
    ModelName = 'my-direct-mode-model-name',
    InferenceExecutionConfig = inferenceExecutionConfig,
    ExecutionRoleArn = role,
    Containers = [container1, container2])
```

To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

**Update a multi-container endpoint**

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the Mode parameter in the InferenceExecutionConfig field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

**Delete a multi-container endpoint**

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the EndpointName parameter.

**Use a multi-container endpoint with direct invocation**

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

**Topics**

- Invoke a multi-container endpoint with direct invocation (p. 2016)
- Security with multi-container endpoints with direct invocation (p. 2016)
- Metrics for multi-container endpoints with direct invocation (p. 2017)
- Autoscale multi-container endpoints (p. 2020)
- Troubleshoot multi-container endpoints (p. 2020)
Invoke a multi-container endpoint with direct invocation

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```python
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(
    EndpointName='my-endpoint',
    ContentType='text/csv',
    TargetContainerHostname='secondContainer',
    Body=body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
        }
    ]
}
```
The following policy denies invoke_endpoint requests when the value of the TargetContainerHostname field matches one of the specified regular expressions in the Deny statement.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["*"]
                }
            }
        },
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Deny",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["special*"]
                }
            }
        }
    ]
}
```

For information about SageMaker condition keys, see Condition Keys for SageMaker in the AWS Identity and Access Management User Guide.

**Metrics for multi-container endpoints with direct invocation**

In addition to the endpoint metrics that are listed in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: AWS/SageMaker and aws/sagemaker/Endpoints. The AWS/SageMaker namespace includes invocation-related metrics, and the aws/sagemaker/Endpoints namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [EndpointName, VariantName, ContainerName] dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level [EndpointName, VariantName, ContainerName].

---

2017
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of InvokeEndpoint requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation4XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation5XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
</tbody>
</table>
request by SageMaker for overhead. 

OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, `Sample Count`.

| CPUUtilization | The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent | EndpointName, VariantName, ContainerName | aws/sagemaker/Endpoints |
MemoryUtilization | The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent

| EndpointName, VariantName, ContainerName | aws/sagemaker/Endpoints |

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table expect ContainerLatency.

**Autoscale multi-container endpoints**

If you want to configure automatic scaling for a multi-container endpoint using the InvocationsPerInstance metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a low CPU utilization model to a high CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see [Automatically Scale Amazon SageMaker Models](p. 2035).

**Troubleshoot multi-container endpoints**

The following sections can help you troubleshoot errors with multi-container endpoints.

**Ping Health Check Errors**

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

**Missing accept-bind-to-port=true Docker label**

The containers in a multi-container endpoints listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn’t present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, You will see an error message such as Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).
If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format `XXXX-YYYY`, where `XXXX` and `YYYY` are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

**Host models along with pre-processing logic as serial inference pipeline behind one endpoint**

An *inference pipeline* is a Amazon SageMaker model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker model registry, see Register and Deploy Models with Model Registry (p. 2232).

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

- Feature Processing with Spark ML and Scikit-learn (p. 2022)
- Create a Pipeline Model (p. 2022)
- Run Real-time Predictions with an Inference Pipeline (p. 2025)
- Run Batch Transforms with Inference Pipelines (p. 2027)
- Inference Pipeline Logs and Metrics (p. 2028)
- Troubleshoot Inference Pipelines (p. 2033)

**Sample Notebooks for Inference Pipelines**

For an example that shows how to create and deploy inference pipelines, see the Training using SparkML on EMR and hosting on SageMaker sample notebook. For instructions on creating and accessing Jupyter
notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create copy.

**Feature Processing with Spark ML and Scikit-learn**

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

**Feature Processing with Spark ML**

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to AWS Glue.

**Note**
To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

**Feature Processing with Scikit-Learn**

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher’s Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.

**Create a Pipeline Model**

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the CreateModel operation.

**To create an inference pipeline (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Models, and then choose Create models from the Inference group.
3. On the Create model page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.
4. To add information about the containers in the inference pipeline, choose **Add container**, then choose **Next**.

5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the **Container input options**, **Location of inference code image**, and, optionally, **Location of model artifacts**, **Container host name**, and **Environmental variables** fields.
Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.
MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format "XXXX-YYYY", where XXXX and YYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**

To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2033).

### Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}/{}{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge', endpoint_name=endpoint_name)
```

### Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
        {
            "name": "Pclass",
            "type": "float",
            "val": "1.0"
        },
        {
            "name": "Embarked",
            "type": "string",
```
The response you get from `predictor.predict(payload)` is the model's inference result.

**Realtime inference pipeline example**

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see "Section 2 - Preprocess the raw housing data using Scikit Learn" of the Amazon SageMaker Multi-Model Endpoints sample notebook. For information about Amazon SageMaker batch transforms, see Use Batch Transform (p. 2191).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2033).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK.
In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models.
(created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```python
import sagemaker
input_data_path = 's3://{}/{}{}'.format(default_bucket, 'key', 'file_name')
output_data_path = 's3://{}/{}'.format(default_bucket, 'key')
transform_job = sagemaker.transformer.Transformer(
    model_name = model_name,
    instance_count = 1,
    instance_type = 'ml.m4.xlarge',
    strategy = 'SingleRecord',
    assemble_with = 'Line',
    output_path = output_data_path,
    base_transform_job_name='inference-pipelines-batch',
    sagemaker_session=sagemaker.Session(),
    accept = CONTENT_TYPE_CSV
)
transform_job.transform(data = input_data_path,
    content_type = CONTENT_TYPE_CSV,
    split_type = 'Line')
```

### Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor Amazon SageMaker (p. 3818).

#### Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A *dimension* is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818).

#### Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
## Hosting options

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Invocation5XXErrors</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>Invocations</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
</tr>
<tr>
<td><strong>InvocationsPerInstance</strong></td>
<td>The number of endpoint invocations sent to a model, normalized by <code>InstanceCount</code> in each <code>ProductionVariant</code>. SageMaker sends <code>1/numberOfInstances</code> as the value for each request, where <code>numberOfInstances</code> is the number of active instances for the <code>ProductionVariant</code> at the endpoint at the time of the request. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td><strong>ModelLatency</strong></td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. <code>ModelLatency</code> is the total time taken by all containers in an inference pipeline. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>OverheadLatency</strong></td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. <code>OverheadLatency</code> is measured from the time that SageMaker receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. <code>Overhead latency</code> can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>ContainerLatency</strong></td>
<td>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. <code>ContainerLatency</code> includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

---

### Dimensions for Endpoint Invocation Metrics

2029
<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant at the specified endpoint and for the specified variant.</td>
</tr>
</tbody>
</table>

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The **ContainerLatency** metric appears only for inferences pipelines.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For training jobs, CPUUtilization is the CPU utilization of the algorithm container running on the instance. For batch transform jobs, CPUUtilization is the CPU utilization of the transform container running on the instance. For multi-container models, CPUUtilization is the sum of CPU utilization by all containers running on the instance. For endpoint variants, CPUUtilization is the sum of CPU utilization by all of the containers running on the instance. Units: Percent</td>
</tr>
</tbody>
</table>

Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces /aws/sagemaker/TrainingJobs, /aws/sagemaker/TransformJobs, and /aws/sagemaker/Endpoints include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.
<table>
<thead>
<tr>
<th><strong>Metric</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%.</td>
</tr>
<tr>
<td></td>

**Metric** | **Description**
--- | ---
DiskUtilization | The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs.

For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance.

For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance.

Units: Percent

**Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
</table>
| Host | For training jobs, Host has the format \([training-job-name]/algo-[instance-number-in-cluster]\). Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the \(/aws/sagemaker/TrainingJobs\) namespace.

For batch transform jobs, Host has the format \([transform-job-name]/[instance-id]\). Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the \(/aws/sagemaker/TransformJobs\) namespace.

For endpoints, Host has the format \([endpoint-name]/[production-variant-name]/[instance-id]\). Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the \(/aws/sagemaker/Endpoints\) namespace. |

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

**Use Logs to Monitor an Inference Pipeline**

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch:

A *log stream* is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

**Logs**

</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
</tbody>
</table>

**Note**

SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 366).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3830).

### Troubleshoot Inference Pipelines

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

### Topics

- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2033)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 2034)
- Use Error Messages to Troubleshoot Inference Pipelines (p. 2035)

### Troubleshoot Amazon ECR Permissions for Inference Pipelines

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            }
        }
    ]
}
```
Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.

/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}

For example, logs for this endpoint are published to the following log groups and streams:

```
EndpointName: MyInferencePipelinesEndpoint
Variant: MyInferencePipelinesVariant
InstanceId: i-0179208609ff7e488
ContainerHostname: MyContainerName1 and MyContainerName2
```

```
logGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2
```

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

To see the log groups and streams

2. In the navigation page, choose Logs.
3. In Log Groups, filter on MyInferencePipelinesEndpoint:

   ![CloudWatch Log Groups Screenshot]

4. To see the log streams, on the CloudWatch Log Groups page, choose MyInferencePipelinesEndpoint, and then Search Log Group.

   ![CloudWatch Search Log Group Screenshot]
Automatically Scale Amazon SageMaker Models

Amazon SageMaker supports automatic scaling (auto scaling) for your hosted models. Auto scaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, auto scaling brings more instances online. When the workload decreases, auto scaling removes unnecessary instances so that you don’t pay for provisioned instances that you aren’t using.

Prerequisites

Before you can use auto scaling, must have already created a Amazon SageMaker model deployment. Deployed models are referred to as a production variant. This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see Deploy the Model to SageMaker Hosting Services (p. 88).

To activate auto scaling for a model, you can use the console, the AWS CLI, or the Application Auto Scaling API. It is recommended to try to Configure model auto scaling with the console (p. 2038) to get familiar with the requirements and to test your first auto scaling configuration. When using the AWS CLI or Application Auto Scaling API, the flow is to register the model, define the scaling policy, then apply it. The
following overview provides further details on the prerequisites and components used with Application Auto Scaling.

**Auto scaling policy overview**

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Alternatively, you can use either the AWS Command Line Interface (AWS CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your auto scaling configuration. You configure the target-tracking scaling policy by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see Target Tracking Scaling Policies.

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see Step Scaling Policies.

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. SageMaker automatic scaling automatically generates this role, AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint, for you.

**Target metric for auto scaling**

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined InvocationsPerInstance metric with a target value of 70 can keep InvocationsPerInstance at, or close to 70.

**Minimum and maximum capacity**

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.
You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your auto scaling configuration with the expected rate of traffic to your model.

**Important**

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

**Cooldown period**

Tune the responsiveness of your scaling policy by adding a cooldown period. A *cooldown period* controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn't launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.

- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don't specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

**Permissions**

The SagemakerFullAccessPolicy IAM policy has all of the IAM permissions required to perform auto scaling. For more information about SageMaker IAM permissions, see [SageMaker Roles (p. 3646)](https://docs.aws.amazon.com/sagemaker/latest/dg/developer-guide-iam-permissions.html).

If you are using a custom permission policy, you must include the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "sagemaker:DescribeEndpoint",
    "sagemaker:DescribeEndpointConfig",
    "sagemaker:UpdateEndpointWeightsAndCapacities"
  ],
  "Resource": "*"
}
```
Service-linked role

Auto scaling uses the AWS_ServiceRoleForApplicationAutoScaling_SageMakerEndpoint service-linked role; it created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other AWS services on your behalf. For more information, see Service-Linked Roles.

Configure model auto scaling with the console

To configure auto scaling for a model using the console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, open Inference and choose Endpoints.
3. Choose the endpoint that you want to configure.
4. For Endpoint runtime settings, choose the model variant that you want to configure.
5. For Endpoint runtime settings, choose Configure auto scaling.

   The Configure variant automatic scaling page appears.
6. For Minimum capacity, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For Maximum capacity, type the maximum number of instances that you want the scaling policy to maintain.
8. For the target value, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing (p. 2049).

   Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.
9. For **Scale-in cool down (seconds)** and **Scale-out cool down (seconds)**, type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.

10. Select **Deactivate scale in** to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, deactivate scale-in activities.

    Scale-out activities are always activated so that the scaling policy can create endpoint instances as needed.

11. Choose **Save**.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

**Note**

SageMaker doesn't support auto scaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see [Amazon EC2 Instance Types](https://aws.amazon.com/ec2/instance-types/).

**Register a model**

You can add auto scaling for a model with the AWS CLI or the Application Auto Scaling API. You first must register the model, then you must define an auto scaling policy.

**Register a model with the AWS CLI**

With the AWS CLI, you can configure auto scaling based on either a predefined or a custom metric.

To register your endpoint, use the **register-scalable-target** AWS CLI command with the following parameters:

- **--service-namespace**—Set this value to sagemaker.
- **--resource-id**—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is endpoint and the unique identifier is the name of the production variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **--scalable-dimension**—Set this value to sagemaker:variant:DesiredInstanceCount.
- **--min-capacity**—The minimum number of instances that for this model. Set min-capacity to at least 1. It must be equal to or less than the value specified for max-capacity.
- **--max-capacity**—The maximum number of instances that Application Auto Scaling should manage. Set max-capacity to a minimum of 1, It must be equal to or greater than the value specified for min-capacity.

**Example**

The following example shows how to register a model named MyVariant that is dynamically scaled to have one to eight instances:

```bash
aws application-autoscaling register-scalable-target
--service-namespace sagemaker
```
Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the production variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant, for example `endpoint/MyEndPoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **MinCapacity**—The minimum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or less than the value specified for `MaxCapacity`.
- **MaxCapacity**—The maximum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or greater than the value specified for `MinCapacity`.

**Example**

The following example shows how to register a SageMaker production variant that is dynamically scaled to use one to eight instances:

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration.
Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the SageMakerVariantInvocationsPerInstance predefined metric to adjust the number of variant instances so that each instance has an InvocationsPerInstance metric of 70.

```
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
}
```

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

**Important**

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named my-variant, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```
{
    "TargetValue": 50,
    "CustomizedMetricSpecification": {
        "MetricName": "CPUUtilization",
        "Namespace": "/aws/sagemaker/Endpoints",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "VariantName","Value": "my-variant"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```
Use an online explainability metric

This guide shows how to use a metric to track the scaling of endpoints with online explainability. When an endpoint has online explainability activated, it emits a `ExplanationsPerInstance` metric that outputs the average number of records explained per minute, per instance, for a variant. The resource utilization of explaining records can be more different than that of predicting records. We strongly recommend using this metric for target-tracking scaling of endpoints with online explainability activated.

To use this online explainability metric inside a scaling policy, create a target tracking configuration. In the tracking configuration, include a `CustomizedMetricSpecification` for the custom metrics and a `TargetValue` for the target value.

The following is an example of a policy configuration that uses `ExplanationsPerInstance`. It is used to adjust the number of variant instances so that each instance has an `ExplanationsPerInstance` metric of 20.

```
{
    "TargetValue": 20,
    "CustomizedMetricSpecification": {
        "MetricName": "ExplanationsPerInstance",
        "Namespace": "AWS/SageMaker",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "VariantName","Value": "my-variant"}
        ],
        "Statistic": "Sum"
    }
}
```

**Application Auto Scaling** allows multiple target tracking scaling policies for a scalable target. Consider adding the `InvocationsPerInstance` policy from the predefined metric section (in addition to the `ExplanationsPerInstance` policy). For example, if most invocations don't return an explanation because of the threshold value set in the `EnableExplanations` parameter, then the endpoint can choose the `InvocationsPerInstance` policy. If there is a large number of explanations, the endpoint can use the `ExplanationsPerInstance` policy.

Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see `TargetTrackingScalingPolicyConfiguration` in the **Application Auto Scaling API Reference**.

Example

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{

}
```

2042
"TargetValue": 70.0,
"PredefinedMetricSpecification":
  "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
,"ScaleInCooldown": 600,
"ScaleOutCooldown": 300

Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the AWS CLI or the Application Auto Scaling API.

Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to your model, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to TargetTrackingScaling.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`.

```bash
aws application-autoscaling put-scaling-policy \
  --policy-name myscalablepolicy \
  --policy-type TargetTrackingScaling \
  --resource-id endpoint/MyEndpoint/variant/MyVariant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount \
  --target-tracking-scaling-policy-configuration file://config.json
```

Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:

- `PolicyName`—The name of the scaling policy.
- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceId`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

2043
• PolicyType—Set this value to TargetTrackingScaling.
• TargetTrackingScalingPolicyConfiguration—The target-tracking scaling policy configuration to use for the variant.

Example

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named myscalablepolicy to a variant named myscalablevariant. It uses a policy configuration based on the SageMakerVariantInvocationsPerInstance predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
  "PolicyName": "myscalablepolicy",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "PolicyType": "TargetTrackingScaling",
  "TargetTrackingScalingPolicyConfiguration": {
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
      "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
  }
}
```

Edit a scaling policy

You can edit a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Scale-in

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

Deactivate scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your variant by deactivating scale-in activity. Deactivating scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

To activate or deactivate scale-in activity for your model, specify a Boolean value for DisableScaleIn. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the SageMakerVariantInvocationsPerInstance predefined metric...
metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also deactivates scale-in activity for the scaling policy.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification": {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  },
  "DisableScaleIn": true
}
```

**Scale-out**

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--min-capacity` argument, or use the Application Auto Scaling API's `MinCapacity` parameter.

**Deactivate scale-out activity**

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--max-capacity` argument, or use the Application Auto Scaling API's `MaxCapacity` parameter.

**Edit a scaling policy (Console)**

To edit a scaling policy with the AWS Management Console, use the same procedure that you used to Configure model auto scaling with the console (p. 2038).

**Edit a scaling policy (AWS CLI or Application Auto Scaling API)**

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the AWS CLI, specify the name of the policy that you want to edit in the `--policy-name` parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the `PolicyName` parameter. Specify new values for the parameters that you want to change.

For more information, see Apply a scaling policy (p. 2043).

**Delete a scaling policy**

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

**Delete a scaling policy (Console)**

**To delete an automatic scaling policy (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Endpoints**.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For **Endpoint runtime settings**, choose the variant that you want to configure.
5. Choose **Configure auto scaling**.
6. Choose **Deregister auto scaling**.

**Delete a scaling policy (AWS CLI or Application Auto Scaling API)**

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

**Delete a scaling policy with AWS CLI or Application Auto Scaling API**

To delete a scaling policy from a variant, use the `delete-scaling-policy` AWS CLI command with the following parameters:

- **--policy-name**—The name of the scaling policy.
- **--resource-id**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **--service-namespace**—Set this value to `sagemaker`.
- **--scalable-dimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.

**Example**

The following example deletes a target-tracking scaling policy named `myscalablepolicy` from a variant named `myscalablevariant`.

```bash
aws application-autoscaling delete-scaling-policy
--policy-name myscalablepolicy
--resource-id endpoint/MyEndpoint/variant/MyVariant
--service-namespace sagemaker
--scalable-dimension sagemaker:variant:DesiredInstanceCount
```

**Delete a scaling policy (Application Auto Scaling API)**

To delete a scaling policy from your variant, use the `DeleteScalingPolicy` Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.

**Example**

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named `myscalablepolicy` from a variant named `myscalablevariant`.

```bash
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
```
Query Endpoint Auto scaling History

You can view the status of scaling activities from your endpoint using `DescribeScalingActivities`. `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

**How To Query Endpoint Auto Scaling Actions**

Query your auto scaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNamespace` parameter. `ServiceNamespace` is the name of the AWS service that provides the resource.

Valid service name values include the following:

- `ecs`
- `elasticmapreduce`
- `ec2`
- `appstream`
- `dynamodb`
- `rds`
- `sagemaker`
- `custom-resource`
- `comprehend`
- `lambda`
- `cassandra`

In this situation you need to set `ServiceNamespace` to `sagemaker`.

Use the following AWS CLI command to view details about all of your `sagemaker` endpoints that have a scaling policy:

```bash
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```bash
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

When you run this command, it returns the following output:

```json
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "string",
  "StartTime": timestamp,
  "EndTime": timestamp,
  "StatusCode": "string",
  "StatusMessage": "string"
}
```
**Identify blocked auto scaling from instance quotas**

When you scale out or add more instances, you might reach your account-level instance quota. You can use DescribeScalingActivities to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the AWS CLI command as shown in the proceeding example where you specified the ResourceId:

```bash
aws application-autoscaling describe-scaling-activities
  --service-namespace sagemaker
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

Within the return syntax, check the StatusCode and StatusMessage keys and their associated values. StatusCode returns Failed. Within StatusMessage there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```json
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "minimum capacity was set to 110",
  "StartTime": timestamp,
  "EndTime": timestamp,
  "StatusCode": "Failed",
  "StatusMessage": "Failed to set desired instance count to 110. Reason: The account-level service limit 'ml.xx.xxxxxx for endpoint usage' is 1000 Instances, with current utilization of 997 Instances and a request delta of 20 Instances. Please contact AWS support to request an increase for this limit. (Service: AmazonSageMaker; Status Code: 400; Error Code: ResourceLimitExceeded; Request ID: request-id)."
}
```

**Update or delete endpoints that use automatic scaling**

**Topics**

- Update endpoints that use automatic scaling (p. 2048)
- Delete endpoints configured for automatic scaling (p. 2049)

**Update endpoints that use automatic scaling**

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the AWS Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by calling the UpdateEndpoint API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the DeleteScalingPolicy Application Auto Scaling API action, then call DeregisterScalableTarget to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn't
typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn't significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

**To update an endpoint that has automatic scaling applied**

1. Deregister the endpoint as a scalable target by calling `DeregisterScalableTarget`.
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling `UpdateEndpointWeightsAndCapacities`.
3. Call `DescribeEndpoint` repeatedly until the value of the `EndpointStatus` field of the response is `InService`.
4. Call `DescribeEndpointConfig` to get the values of the current endpoint config.
5. Create a new endpoint config by calling `CreateEndpointConfig`. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to `DescribeEndpointConfig` in the previous step. For all other values, use the values that you got as the response when you called `DescribeEndpointConfig` in the previous step.
6. Update the endpoint by calling `UpdateEndpoint`. Specify the endpoint config you created in the previous step as the `EndpointConfig` field. If you want to retain the variant properties like instance count or weight, set the value of the `RetainAllVariantProperties` parameter to True. This specifies that production variants with the same name will be updated with the most recent `DesiredInstanceCount` from the response from the call to `DescribeEndpoint`, regardless of the values of the `InitialInstanceCount` field in the new `EndpointConfig`.
7. (Optional) Re-activating automatic scaling by calling `RegisterScalableTarget`.

**Note**
Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

- Changing the instance type for a production variant that has automatic scaling configured
- Removing a production variant that has automatic scaling configured.

**Delete endpoints configured for automatic scaling**

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn't provide permission for the `DeleteScalingPolicy` and `DeregisterScalableTarget` actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.

**Note**
You, as an IAM user, might not have sufficient permission to delete an endpoint if another IAM user configured automatic scaling for a variant on that endpoint.

**Load testing your auto scaling configuration**

Perform load tests to choose an automatic scaling configuration that works the way you want.
The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric `SageMakerVariantInvocationsPerInstance`.

**Topics**
- Determine the performance characteristics (p. 2050)
- Calculate the target load (p. 2050)

**Determine the performance characteristics**

Perform load testing to find the peak `InvocationsPerInstance` that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

**To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests**

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see *Deploy the Model to SageMaker Hosting Services* (p. 88).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

   **Note**
   You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate `SageMakerVariantInvocationsPerInstance` shown below.

   When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

**Calculate the target load**

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum value. Use the following equation in combination with load testing to determine the correct value for the `SageMakerVariantInvocationsPerInstance` target metric in your automatic scaling configuration.

\[
SageMakerVariantInvocationsPerInstance = (\text{MAX}_\text{RPS} \times \text{SAFETY}\_\text{FACTOR}) \times 60
\]

Where `MAX_RPS` is the maximum RPS that you determined previously, and `SAFETY_FACTOR` is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker uses to implement automatic scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

**Note**
SageMaker recommends that you start testing with a `SAFETY_FACTOR` of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

**Use AWS CloudFormation to update auto scaling policies**

The following example shows how to activate Application Auto Scaling on an endpoint using AWS CloudFormation.
**Host instance storage volumes**

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.

For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see [Host Instance Storage Volumes Table](#).

**Note**

Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances only when you create Asynchronous inference (p. 2175) or Real-time inference (p. 1976) endpoint types. For more information on customizing Amazon EBS storage volume, see [Deploying large models with Amazon SageMaker](#).

**Safely validate models in production**

With SageMaker, you can test multiple models or model versions behind the same endpoint using variants. A variant consists of an ML instance and the serving components specified in a SageMaker model. You can have multiple variants behind an endpoint. Each variant can have a different instance type or a SageMaker model that can be autoscaled independently of the others. The models within...
the variants can be trained using different datasets, different algorithms, different ML frameworks, or any combination of all of these. All the variants behind an endpoint share the same inference code. SageMaker supports two types of variants, production variants and shadow variants.

If you have multiple production variants behind an endpoint, then you can allocate a portion of your inference requests to each variant. Each request is routed to only one of the production variants. The production variant to which the request was routed provides the response to the caller. You can compare how the production variants perform relative to each other.

You can also have a shadow variant corresponding to a production variant behind an endpoint. A portion of the inference requests that goes to the production variant is replicated to the shadow variant. The responses of the shadow variant are logged for comparison and not returned to the caller. This lets you test the performance of the shadow variant without exposing the caller to the response produced by the shadow variant.

Topics
- Production variants (p. 2052)
- Shadow variants (p. 2060)

Production variants

In production ML workflows, data scientists and engineers frequently try to improve performance using various methods, such as Perform Automatic Model Tuning with SageMaker (p. 1654), training on additional or more-recent data, improving feature selection, using better updated instances and serving containers. You can use production variants to compare your models, instances and containers, and choose the best performing candidate to respond to inference requests.

With SageMaker multi-variant endpoints you can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

Topics
- Test models by specifying traffic distribution (p. 2052)
- Test models by invoking specific variants (p. 2053)
- Model A/B test example (p. 2054)

Test models by specifying traffic distribution

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see CreateEndpointConfig. The following diagram shows how this works in more detail.
Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the `TargetVariant` parameter when you call `InvokeEndpoint`. SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the `TargetVariant` parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.
Model A/B test example

Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously existing version, replace the old version of the model with the new version in production.

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production."

**Step 1: Create and deploy models**

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```python
model_url1 = f"s3://[path_to_model_1]"
model_url2 = f"s3://[path_to_model_2]"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:
from sagemaker.amazon.amazon_estimator import get_image_uri

model_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"
model_name2 = f"DEMO-xgb-churn-pred2-{datetime.now():%Y-%m-%d-%H-%M-%S}"
image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')
image_uri2 = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-2')

sm_session.create_model(
    name=model_name,
    role=role,
    container_defs=
    {
        'Image': image_uri,
        'ModelDataUrl': model_url
    }
)

sm_session.create_model(
    name=model_name2,
    role=role,
    container_defs=
    {
        'Image': image_uri2,
        'ModelDataUrl': model_url2
    }
)

We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial_weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

from sagemaker.session import production_variant

variant1 = production_variant(
    model_name=model_name,
    instance_type="ml.m5.xlarge",
    initial_instance_count=1,
    variant_name='Variant1',
    initial_weight=1,
)

variant2 = production_variant(
    model_name=model_name2,
    instance_type="ml.m5.xlarge",
    initial_instance_count=1,
    variant_name='Variant2',
    initial_weight=1,
)

Finally we're ready to deploy these production variants on a SageMaker endpoint.

endpoint_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"

print(f"EndpointName={endpoint_name}"

sm_session.endpoint_from_production_variants(
    name=endpoint_name,
    production_variants=[variant1, variant2]
)
Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.

```python
# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/test_sample_tail_input_cols.csv
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")

with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = row.rstrip('
')
        sm_runtime.invoke_endpoint(
            EndpointName=endpoint_name,
            ContentType="text/csv",
            Body=payload
        )
        time.sleep(0.5)

print("Done!")
```

SageMaker emits metrics such as Latency and Invocations for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818). Let's query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00+00:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00+00:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
</tbody>
</table>

Now let's invoke a specific version of the model by specifying Variant1 as the TargetVariant in the call to `invoke_endpoint`.

```python
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = row.rstrip('
')
```
To confirm that all new invocations were processed by Variant1, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by Variant1, as we had specified. There were no invocations made for Variant2.

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00+00:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00+00:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
<tr>
<td>2020-06-05 15:36:00+00:00</td>
<td>99.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**Step 3: Evaluate model performance**

To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let's look at these metrics for Variant1:

- Accuracy: 0.9583333333333334
- Precision: 0.941764705882353
- Recall: 0.8
- F1 Score: 0.8648648648648648
- AUC is 0.895

Now let's look at the metrics for Variant2:
For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

### Step 4: Increase traffic to the best model

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use TargetVariant to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling UpdateEndpointWeightsAndCapacities. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

```
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```
The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

![Graph showing CloudWatch metrics for Variant1 and Variant2]

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `update_endpoint_weights_and_capacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```python
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 0,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 1,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

![Graph showing CloudWatch metrics after traffic update]

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.
Shadow variants

You can use SageMaker Model Shadow Deployments to create long running shadow variants to validate any new candidate component of your model serving stack before promoting it to production. The following diagram shows how shadow variants work in more detail.

Deploy shadow variants

The following code example shows how you can programmatically deploy shadow variants. Replace the *user placeholder text* in the example with your own information.

1. Create two SageMaker models: one for your production variant, and one for your shadow variant.

```python
import boto3
from sagemaker import get_execution_role, Session

aws_region = "aws-region"

boto_session = boto3.Session(region_name=aws_region)
```
2. Create an endpoint configuration. Specify both your production and shadow variants in the configuration.

```python
endpoint_config_name = "name-of-your-endpoint-config"
create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": "name-of-your-production-variant",
            "ModelName": model_name1,
            "InstanceType": "ml.m5.xlarge",
            "InitialInstanceCount": 1,
            "InitialVariantWeight": 1,
        }
    ],
    ShadowProductionVariants=[
        {
            "VariantName": "name-of-your-shadow-variant",
            "ModelName": model_name2,
            "InstanceType": "ml.m5.xlarge",
            "InitialInstanceCount": 1,
            "InitialVariantWeight": 1,
        }
    ]
)
```
Best practices

This topic provides guidance on best practices for deploying machine learning models in Amazon SageMaker.

- Migrate inference workload from x86 to AWS Graviton (p. 2065)
- Troubleshoot Amazon SageMaker model deployments (p. 2068)

Best practices for deploying models on SageMaker Hosting Services

When hosting models using SageMaker hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.
- You can deploy a model trained with SageMaker to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training (p. 1184).
- You can deploy multiple variants of a model to the same SageMaker HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you've deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the ProductionVariant in your request to the CreateEndPointConfig. For more information, see ProductionVariant.
- You can configure a ProductionVariant to use Application Auto Scaling. For information about configuring automatic scaling, see Automatically Scale Amazon SageMaker Models (p. 2035).
- You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker implements the changes without any downtime. For more information see, UpdateEndpoint and UpdateEndpointWeightsAndCapacities.
- Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.
- If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Use Batch Transform (p. 2191)
Deploy Multiple Instances Across Availability Zones

Create robust endpoints when hosting your model. SageMaker endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommend that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two Subnets, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.

Low latency real-time inference with AWS PrivateLink

Amazon SageMaker provides low latency for real-time inferences while maintaining high availability and resiliency using multi-AZ deployment. The end-to-end application latency is made up of two primary components: infrastructure or overhead latency and model inference latency. Reduction of overhead latency opens up new possibilities such as deploying more complex, deep, and accurate models or splitting monolithic applications into scalable and maintainable microservice modules. You can reduce the latency for real-time inferences with SageMaker using an AWS PrivateLink deployment. With AWS PrivateLink, you can privately access all SageMaker API operations from your Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An interface VPC endpoint is an elastic network interface in your subnet with private IP addresses that serves as an entry point for all SageMaker API calls.

By default, a SageMaker endpoint with 2 or more instances is deployed in at least 2 AWS Availability Zones (AZs) and instances in any AZ can process invocations. This results in one or more AZ “hops” that contribute to the overhead latency. An AWS PrivateLink deployment with the privateDNSEnabled option set as true alleviates this by achieving two objectives:

- It keeps all inference traffic within your VPC.
- It keeps invocation traffic in the same AZ as the client that originated it when using SageMaker. This avoids the “hops” between AZs reducing the overhead latency.

The following sections of this guide demonstrate how you can reduce the latency for real-time inferences with AWS PrivateLink deployment.

Topics

- Deploy AWS PrivateLink (p. 2063)
- Deploy SageMaker endpoint in a VPC (p. 2064)
- Invoke the SageMaker endpoint (p. 2064)

Deploy AWS PrivateLink

To deploy AWS PrivateLink first create an interface endpoint for the VPC from which you connect to the SageMaker endpoints. Please follow the steps in Access an AWS service using an interface VPC endpoint to create the interface endpoint. While creating the endpoint select the following settings in the console interface:

- Select Enable DNS name checkbox under Additional Settings
- Select the appropriate security groups and the subnets to be used with the SageMaker endpoints.
Also make sure that the VPC has DNS hostnames turned on. For more information on how to change DNS attributes for your VPC, see View and update DNS attributes for your VPC.

### Deploy SageMaker endpoint in a VPC

To achieve low overhead latency, create a SageMaker endpoint using the same subnets that you specified when deploying AWS PrivateLink. These subnets should match the AZs of your client application, as shown in the following code snippet.

```python
model_name = '<the-name-of-your-model>'

vpc = 'vpc-0123456789abcdef0'
subnet_a = 'subnet-0123456789abcdef0'
subnet_b = 'subnet-0123456789abcdef1'
security_group = 'sg-0123456789abcdef0'

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    },
    VpcConfig = {
        'SecurityGroupIds': [security_group],
        'Subnets': [subnet_a, subnet_b],
    },
)
```

The aforementioned code snippet assumes that you have followed the steps in Before you begin (p. 1978).

### Invoke the SageMaker endpoint

Finally, specify the SageMaker client and invoke the SageMaker endpoint as shown in the following code snippet.

```python
endpoint_name = '<endpoint-name>'

runtime_client = boto3.client('sagemaker-runtime')
response = runtime_client.invoke_endpoint(EndpointName=endpoint_name,
    ContentType='text/csv',
    Body=payload)
```

For more information on endpoint configuration, see Create an Endpoint Configuration (p. 1981).

### Deploying large models with Amazon SageMaker

State-of-the-art natural language processing (NLP) models are large, typically with billions of parameters. Empirical demonstrations show that larger models are more accurate. But these models are often too large to fit on single accelerators, making low-latency inference with them difficult. With SageMaker Hosting you can customize the following parameters to facilitate low-latency real-time inference with large models:

- **Maximum Amazon EBS volume size on the instance (VolumeSizeInGB)** – If the size of the model is larger than 30 GB and you are using an instance without a local disk, you should increase this parameter to be slightly larger than the size of your model.
• **Health check timeout quota (ContainerStartupHealthCheckTimeoutInSeconds)** – If your container is correctly setup and the CloudWatch logs indicate a health check timeout, you should increase this quota so the container has enough time to respond to health checks.

• **Model download timeout quota (ModelDataDownloadTimeoutInSeconds)** – If the size of your model is larger than 40 GB, then you should increase this quota to provide sufficient time to download the model from Amazon S3 to the instance.

For more information on low latency inference with large models, see Deploy large models on Amazon SageMaker using DJServing and DeepSpeed model parallel inference. The following code snippet demonstrates how to programatically configure the aforementioned parameters. Replace the italicized placeholder text in the example with your own information.

```python
import boto3

aws_region = "aws-region"
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = "endpoint-name"

# Create an endpoint config name.
endpoint_config_name = "endpoint-config-name"

# The name of the model that you want to host.
model_name = "the-name-of-your-model"

instance_type = "instance-type"

sagemaker_client.create_endpoint_config(  
    EndpointConfigName = endpoint_config_name  
    ProductionVariants=[  
        {  
            "VariantName": "variant1", # The name of the production variant.  
            "ModelName": model_name,  
            "InstanceType": instance_type, # Specify the compute instance type.  
            "InitialInstanceCount": 1, # Number of instances to launch initially.  
            "VolumeSizeInGB": 256, # Specify the size of the Amazon EBS volume.  
            "ModelDataDownloadTimeoutInSeconds": 1800, # Specify the model download timeout in seconds.  
            "ContainerStartupHealthCheckTimeoutInSeconds": 1800, # Specify the health checkup timeout in seconds  
        },  
    ],
)

sagemaker_client.create_endpoint(EndpointName=endpoint_name,  
    EndpointConfigName=endpoint_config_name)

For more information on the keys for ProductionVariants, see ProductionVariant and Create an Endpoint Configuration (p. 1981).

### Migrate inference workload from x86 to AWS Graviton

**AWS Graviton** is a series of ARM-based processors designed by AWS. They are more energy efficient than x86-based processors and offer a compelling price-performance ratio. Amazon SageMaker offers Graviton-based instances so that you can take advantage of these advanced processors for your inference needs.
You can migrate your existing inference workloads from x86-based instances to Graviton-based instances, by using either ARM compatible container images or multi-architecture container images. This guide assumes that you are either using AWS Deep Learning container images, or your own ARM compatible container images. For more information on building your own images, check Building your image.

At a high level, migrating inference workload from x86-based instances to Graviton-based instances is a four-step process:

1. Push container images to Amazon Elastic Container Registry (Amazon ECR), an AWS managed container registry.
2. Create a SageMaker Model.
3. Create an endpoint configuration.
4. Create an endpoint.

This process is very similar to how you would deploy models to x86-based instances. Check Create your endpoint and deploy your model (p. 1977), and particularly Before you begin (p. 1978), for details on deploying to x86-based instances.

The following sections of this guide provide more details regarding the above steps. Replace the user placeholder text in the code examples with your own information.

Topics
- Push container images to Amazon ECR (p. 2066)
- Create a SageMaker Model (p. 2067)
- Create an endpoint configuration (p. 2067)
- Create an endpoint (p. 2068)

Push container images to Amazon ECR

You can push your container images to Amazon ECR with the AWS CLI. When using an ARM compatible image, verify that it supports ARM architecture:

```bash
docker inspect deep-learning-container-uri
```

The response "Architecture": "arm64" indicates that the image supports ARM architecture. You can push it to Amazon ECR with the `docker push` command. For more information, check Pushing a Docker image.

Multi-architecture container images are fundamentally a set of container images supporting different architectures or operating systems, that you can refer to by a common manifest name. If you are using multi-architecture container images, then in addition to pushing the images to Amazon ECR, you will also have to push a manifest list to Amazon ECR. A manifest list allows for the nested inclusion of other image manifests, where each included image is specified by architecture, operating system and other platform attributes. The following example creates a manifest list, and pushes it to Amazon ECR.

1. Create a manifest list.

```bash
docker manifest create aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository \
 aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:amd64 \
 aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:arm64 \
```
2. Annotate the manifest list, so that it correctly identifies which image is for which architecture.

```
docker manifest annotate --arch arm64 aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository \\
aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository:arm64
```

3. Push the manifest.

```
docker manifest push aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository
```

For more information on creating and pushing manifest lists to Amazon ECR, check Introducing multi-architecture container images for Amazon ECR, and Pushing a multi-architecture image.

Create a SageMaker Model

Create a SageMaker Model by calling the `CreateModel` API.

```
import boto3
import get_execution_role

aws_region = "aws-region"
sagemaker_client = boto3.client("sagemaker", region_name=aws_region)

role = get_execution_role()

sagemaker_client.create_model(
    ModelName = "model-name",
    PrimaryContainer = {
        "Image": "deep-learning-container-uri",
        "ModelDataUrl": "model-s3-location",
        "Environment": {
            "SAGEMAKER_PROGRAM": "inference.py",
            "SAGEMAKER_SUBMIT_DIRECTORY": "inference-script-s3-location",
            "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
            "SAGEMAKER_REGION": aws_region,
        }
    },
    ExecutionRoleArn = role
)
```

Create an endpoint configuration

Create an endpoint configuration by calling the `CreateEndpointConfig` API. For a list of Graviton-based instances, check Compute optimized instances.

```
sagemaker_client.create_endpoint_config(
    EndpointConfigName = "endpoint-config-name",
    ProductionVariants = [
    {
        "VariantName": "variant-name",
        "ModelName": "model-name",
        "InitialInstanceCount": 1,
        "InstanceType": "ml.c7g.xlarge", # Graviton-based instance
    }]
)
```
Create an endpoint

Create an endpoint by calling the `CreateEndpoint` API.

```python
sagemaker_client.create_endpoint(
    EndpointName = "endpoint-name",
    EndpointConfigName = "endpoint-config-name"
)
```

Troubleshoot Amazon SageMaker model deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

**Topics**

- Detection Errors in the Active CPU Count (p. 2068)
- Issues with deploying a model.tar.gz file (p. 2069)

Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux `taskset` commands or control groups (cgroups). SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn’t limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
```
Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the `-XX:-UseContainerSupport` parameter when starting Java applications. For example, run the `java` command to start your JVM as follows:

```
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Check whether the JVM used in your container supports the `-XX:-UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker containers. For example, when using a JVM to support SparkML Scala. The `-XX:-UseContainerSupport` parameter also affects the output returned by the Java `Runtime.getRuntime().availableProcessors()` API.

### Issues with deploying a model.tar.gz file

When you deploy a model using a `model.tar.gz` file, the model tarball should not include any symlinks. Symlinks cause the model creation to fail. Also, we recommend that you do not include any unnecessary files in the tarball.

### Online Explainability with SageMaker Clarify

This guide shows how to configure online explainability with SageMaker Clarify. With SageMaker real-time inference endpoints, you can analyze explainability in real time, continuously. The online explainability function fits into the Deploy to production part of the Amazon SageMaker Machine Learning workflow.

### How Clarify Online Explainability Works

The following graphic shows SageMaker architecture for hosting an endpoint that serves explainability requests. It includes interactions between an endpoint, the model container, and the SageMaker Clarify explainer.
Here’s how Clarify online explainability works. The application sends a REST-style InvokeEndpoint request to the SageMaker Runtime Service. The service routes this request to a SageMaker endpoint to obtain predictions and explanations. Then, the service receives the response from the endpoint. Lastly, the service sends the response back to the application.

To increase the endpoint availability, SageMaker automatically attempts to distribute endpoint instances in multiple Availability Zones, according to the instance count in the endpoint configuration. On an endpoint instance, upon a new explainability request, the SageMaker Clarify explainer calls the model container for predictions. Then it computes and returns the feature attributions.

Here are the four steps to create an endpoint that uses SageMaker Clarify online explainability:

1. Check if your pre-trained SageMaker model is compatible with online explainability by following the pre-check steps.
2. Create an endpoint configuration with the SageMaker Clarify explainer configuration using the CreateEndpointConfig API.
3. Create an endpoint and provide the endpoint configuration to SageMaker using the CreateEndpoint API. The service launches the ML compute instance and deploys the model as specified in the configuration.
4. Invoke the endpoint: After the endpoint is in service, call the SageMaker Runtime API InvokeEndpoint to send requests to the endpoint. The endpoint then returns explanations and predictions.
Pre-check the model container

This section shows how to pre-check the model container inputs and outputs for compatibility before configuring an endpoint. The SageMaker Clarify explainer is model agnostic, but it has requirements for model container input and output.

**Note**
You can increase efficiency by configuring your container to support batch requests, which support two or more records in a single request. A record is a single line of CSV data.

Model container input

The model container supports input in CSV (MIME type: "text/csv"). The following table shows example inputs that SageMaker Clarify supports:

<table>
<thead>
<tr>
<th>Model container input (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'1,2,3,4'</td>
<td>Single record (four numerical features).</td>
</tr>
<tr>
<td>'1,2,3,4\n5,6,7,8'</td>
<td>Two records, separated by line break '\n'.</td>
</tr>
<tr>
<td>&quot;This is a good product&quot;,5</td>
<td>Single record (a text feature and a numerical feature)</td>
</tr>
<tr>
<td>&quot;This is a good product&quot;,5\n&quot;Bad shopping experience&quot;,1</td>
<td>Two records</td>
</tr>
</tbody>
</table>

SageMaker also supports input in JSON Lines dense format (MIME type: "application/jsonlines"):

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}}'</td>
<td>Single record, a list of features can be extracted by JMESPath expression 'data.features'.</td>
</tr>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]\n&quot;data&quot;:{&quot;features&quot;:[5,6,7,8]}}'</td>
<td>Two records</td>
</tr>
<tr>
<td>'{&quot;features&quot;:[&quot;This is a good product&quot;,5]}'</td>
<td>Single record, a list of features can be extracted by JMESPath expression 'features'.</td>
</tr>
<tr>
<td>'{&quot;features&quot;:[&quot;This is a good product&quot;,5]\n{&quot;features&quot;:[&quot;Bad shopping experience&quot;,1]}'</td>
<td>Two records</td>
</tr>
</tbody>
</table>

Model container output

Like the input, your model container output should also be in either CSV or JSON Lines dense format. Additionally the model container should include the probabilities of the input records, which SageMaker Clarify requires to compute feature attributions.

The following data examples are for model container outputs in CSV format.

Probability only

For regression and binary classification problems, the model container outputs a single probability value (score) of the predicted label. These probabilities can be extracted using column index 0. For
multi-class problems, the model container outputs a list of probabilities (scores). For multi-class
problems, if no index is provided, all values are extracted.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'0.6'</td>
</tr>
<tr>
<td>Two records (results in one line)</td>
<td>'0.6,0.3'</td>
</tr>
<tr>
<td>Two records (results in two lines)</td>
<td>'0.6\n0.3'</td>
</tr>
<tr>
<td>Single record of a multi-class model (three classes)</td>
<td>'0.1,0.6,0.3'</td>
</tr>
<tr>
<td>Two records of a multi-class model (three classes)</td>
<td>'0.1,0.6,0.3\n0.2,0.5,0.3'</td>
</tr>
</tbody>
</table>

Predicted label and probabilities

The model container outputs the predicted label followed by its probability in CSV format. The probabilities can be extracted using index 1.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1,0.6'</td>
</tr>
<tr>
<td>Two records</td>
<td>'1,0.6\n0,0.3'</td>
</tr>
</tbody>
</table>

Predicted labels header and probabilities

A multi-class model container trained by Autopilot can be configured to output the string representation of the list of predicted labels and probabilities in CSV format. In the following example, the probabilities can be extracted by index 1 and the label headers can be extracted by index 1 and the label headers can be extracted using index 0.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;['cat','dog','fish'],[0.1,0.6,0.3]&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;['cat','dog','fish'],[0.1,0.6,0.3]\n['cat','dog','fish'],[0.2,0.5,0.3]&quot;</td>
</tr>
</tbody>
</table>

The following data examples are for model container outputs in JSON Lines format.

Probability only

In this example, the model container outputs the probability that can be extracted by be extracted by JMESPath expression 'score' in JSON Lines format.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;score&quot;:0.6}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;score&quot;:0.6}\n{&quot;score&quot;:0.3}'</td>
</tr>
</tbody>
</table>
Predicted label and probabilities

In this example, a multi-class model container outputs a list of label headers along with a list of probabilities in JSON Lines format. The probabilities can be extracted by JMESPath expression 'probability', and the label headers can be extracted by JMESPath expression 'predicted labels'.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.1,0.6,0.3]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.1,0.6,0.3]}, {&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.2,0.5,0.3]}'</td>
</tr>
</tbody>
</table>

Predicted labels header and probabilities

In this example, a multi-class model container outputs a list of label headers and probabilities in JSON Lines format. The probabilities can be extracted by JMESPath expression 'probability', and the label headers can be extracted by JMESPath expression 'predicted labels'.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.1,0.6,0.3]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.1,0.6,0.3]}, {&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;], &quot;probabilities&quot;: [0.2,0.5,0.3]}'</td>
</tr>
</tbody>
</table>

Model container validation

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests (model container inputs) and responses (model container outputs) to make sure that both are compliant with the requirements in the Model Container Input section and Model Container Output section. If your model container supports batch requests, you can start with a single record request, and then try two or more records.

The following commands show how to request a response using the AWS CLI. The AWS CLI is pre-installed in SageMaker Studio, and SageMaker Notebook instances. If you need to install the AWS CLI, follow this installation guide.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name $ENDPOINT_NAME \
   --content-type $CONTENT_TYPE \
   --accept $ACCEPT_TYPE \
   --body $REQUEST_DATA \
   $CLI_BINARY_FORMAT \
   /dev/stderr 1>/dev/null
```

The parameters are defined, as follows:
- **$ENDPOINT NAME**: The name of the endpoint.
- **$CONTENT_TYPE**: The MIME type of the request (model container input).
- **$ACCEPT_TYPE**: The MIME type of the response (model container output).
- **$REQUEST_DATA**: The requested payload string.
- **$CLI_BINARY_FORMAT**: The format of the command line interface (CLI) parameter. For AWS CLI v1, this parameter should remain blank. For v2, this parameter should be set to `-cli-binary-format raw-in-base64-out`.

**Note**
AWS CLI v2 passes binary parameters as base64-encoded strings [default].

The following examples use AWS CLI v1:

**Request and response in CSV format**

- The request consists of a single record and the response is its probability value.

  ```bash
  aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-xgboost-model \
  --content-type text/csv \
  --accept text/csv \
  --body '1,2,3,4' \
  /dev/stderr 1>/dev/null
  ```

  **Output:**

  0.6

- The request consists of two records, and the response includes their probabilities, and the model separates the probabilities by a comma. The `$content` expression in the `--body` tells the command to interpret `
` in the content as a line break.

  ```bash
  aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-xgboost-model \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
  ```

  **Output:**

  0.6,0.3

- The request consists of two records, the response includes their probabilities, and the model separates the probabilities with a line break.

  ```bash
  aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
  ```

  **Output:**

  0.6 0.3
• The request consists of a single record, and the response is probability values (multi-class model, three classes).

```bash
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name test-endpoint-csv-1 \
    --content-type text/csv \n    --accept text/csv \n    --body '1,2,3,4' \n/dev/stderr 1>/dev/null
```

Output:

0.1,0.6,0.3

• The request consists of two records, and the response includes their probability values (multi-class model, three classes).

```bash
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name test-endpoint-csv-1 \
    --content-type text/csv \n    --accept text/csv \n    --body "$'1,2,3,4\n5,6,7,8'" \n/dev/stderr 1>/dev/null
```

Output:

0.1,0.6,0.3
0.2,0.5,0.3

• The request consists of two records, and the response includes predicted label and probability.

```bash
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name test-endpoint-csv-2 \
    --content-type text/csv \n    --accept text/csv \n    --body "$'1,2,3,4\n5,6,7,8'" \n/dev/stderr 1>/dev/null
```

Output:

1,0.6
0,0.3

• The request consists of two records and the response includes label headers and probabilities.

```bash
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name test-endpoint-csv-3 \
    --content-type text/csv \n    --accept text/csv \n    --body "$'1,2,3,4\n5,6,7,8'" \n/dev/stderr 1>/dev/null
```

Output:

"['cat','dog','fish']","[0.1,0.6,0.3]"
"['cat','dog','fish']","[0.2,0.5,0.3]"

2075
Request and response in JSON Lines format

- The request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-jsonlines \
   --content-type application/jsonlines \
   --body '{"features":["This is a good product",5]}' \
   /dev/stderr 1>/dev/null
```

Output:

```
{"score":0.6}
```

- The request contains two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-jsonlines-2 \
   --content-type application/jsonlines \
   --accept application/jsonlines \
   --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
   /dev/stderr 1>/dev/null
```

Output:

```
{"predicted_label":1,"probability":0.6}
{"predicted_label":0,"probability":0.3}
```

- The request contains two records and the response includes label headers and probabilities.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-jsonlines-3 \
   --content-type application/jsonlines \
   --accept application/jsonlines \
   --body $'{"data":{"features":[1,2,3,4]}}\n{"data":{"features":[5,6,7,8]}}' \
   /dev/stderr 1>/dev/null
```

Output:

```
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}
```

Request and response in different formats

- The request is in CSV format and the response is in JSON Lines format:

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-in-jsonlines-out \
   --content-type text/csv \
   --accept application/jsonlines \
   --body $'1,2,3,4\n5,6,7,8' \
   /dev/stderr 1>/dev/null
```

Output:

```
{"probability":0.6}
```
The request is in JSON Lines format and the response is in CSV format:

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-in-csv-out \
  --content-type application/jsonlines \
  --accept text/csv \
  --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \n/dev/stderr 1>/dev/null
```

Output:

```
0.6
0.3
```

After the validations are complete, delete the testing endpoint.

**Configure and create an endpoint**

Create a new endpoint configuration to fit your model, and use this configuration to create the endpoint. You can use the model container validated in the pre-check step to create an endpoint and enable the SageMaker Clarify online explainability feature.

Use the `sagemaker_client` object to create an endpoint using the `CreateEndpointConfig` API. Set the member `ClarifyExplainerConfig` inside the `ExplainerConfig` parameter as follows:

```python
sagemaker_client.create_endpoint_config(
    EndpointConfigName='name-of-your-endpoint-config',
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'EnableExplanations': 'true',
            'InferenceConfig': {
                ...
            },
            'ShapConfig': {
                ...
            }
        }
    },
    ProductionVariants=[{
        'VariantName': 'AllTraffic',
        'ModelName': 'name-of-your-model',
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    }]
)
```

```
sagemaker_client.create_endpoint(
    EndpointName='name-of-your-endpoint',
    EndpointConfigName='name-of-your-endpoint-config'
)
```

The first call to the `sagemaker_client` object creates a new endpoint configuration with the explainability feature enabled. The second call uses the endpoint configuration to launch the endpoint.
The EnableExplanations expression

The EnableExplanations parameter is a JMESPath Boolean expression string. It is evaluated for each record in the explainability request. If this parameter is evaluated to be true, then the record will be explained. If this parameter is evaluated to be false, then explanations are not be generated.

SageMaker Clarify deserializes the model container output for each record into a JSON compatible data structure, and then uses the EnableExplanations parameter to evaluate the data.

**Notes**
There are two options for records depending on the format of the model container output.

- If the model container output is in CSV format, then a record is loaded as a JSON array.
- If the model container output is in JSON Lines format, then a record is loaded as a JSON object.

The EnableExplanations parameter is a JMESPath expression that can be passed either during the InvokeEndpoint or CreateEndpointConfig operations. If the JMESPath expression that you supplied is not valid, the endpoint creation will fail. If the expression is valid, but the expression evaluation result is unexpected, then the endpoint will be created successfully, but an error will be generated when the endpoint is invoked. Test your EnableExplanations expression by using the InvokeEndpoint API, and then apply it to the endpoint configuration.

The following are some examples of valid EnableExplanations expression. In the examples, a JMESPath expression encloses a literal using backtick characters. For example, `true` means true.

<table>
<thead>
<tr>
<th>Expression (string representation)</th>
<th>Model container output (string representation)</th>
<th>Evaluation result (Boolean)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>true</code></td>
<td>(N/A)</td>
<td>True</td>
<td>Activate online explainability unconditionally.</td>
</tr>
<tr>
<td><code>false</code></td>
<td>(N/A)</td>
<td>False</td>
<td>Deactivate online explainability unconditionally.</td>
</tr>
<tr>
<td><code>[1]&gt;</code>0.5`</td>
<td><code>1,0.6</code></td>
<td>True</td>
<td>For each record, the model container outputs its predicted label and probability. Explains a record if its probability (at index 1) is greater than 0.5.</td>
</tr>
<tr>

<tr>
<td><code>!contains(probabilities[-1],max(probabilities))</code></td>
<td><code>{&quot;probabilities&quot;: [0.4, 0.1, 0.4], &quot;labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;]}</code></td>
<td>False</td>
<td>For a multi-class model: Explains a record if its predicted label (the class that has the max probability value) is the</td>
</tr>
</tbody>
</table>
**Synthetic dataset**

SageMaker Clarify uses the Kernel SHAP algorithm. Given a record (also called a sample or an instance) and the SHAP configuration, the explainer first generates a synthetic dataset. SageMaker Clarify then queries the model container for the predictions of the dataset, and then computes and returns the feature attributions. The size of the synthetic dataset affects the runtime for the Clarify explainer. Larger synthetic datasets take more time to obtain model predictions than smaller ones.

The synthetic dataset size is determined by the following formula:

\[
\text{Synthetic dataset size} = \text{SHAP baseline size} \times \text{n_samples}
\]

The SHAP baseline size is the number of records in the SHAP baseline data. This information is taken from the ShapBaselineConfig.

The size of n_samples is set by the parameter NumberOfSamples in the explainer configuration and the number of features. If the number of features is n_features, then n_samples is the following:

\[
\text{n_samples} = \text{MIN(NumberOfSamples, } 2^n_{\text{features}} - 2)\]

The following shows n_samples if NumberOfSamples is not provided.

\[
\text{n_samples} = \text{MIN}(2^n_{\text{features}} + 2^{11}, 2^n_{\text{features}} - 2)\]

For example, a tabular record with 10 features has a SHAP baseline size of 1. If NumberOfSamples is not provided, the synthetic dataset contains 1022 records. If the record has 20 features, the synthetic dataset contains 2088 records.

For NLP problems, n_features is equal to the number of non-text features plus the number of text units.

**Note**

The InvokeEndpoint API has a request timeout limit. If the synthetic dataset is too large, the explainer may not be able to complete the computation within this limit. If necessary, use the previous information to understand and reduce the SHAP baseline size and NumberOfSamples. If your model container is set up to handle batch requests, then you can also adjust the value of MaxRecordCount.

**Invoke the endpoint**

After the endpoint is running, use the SageMaker Runtime InvokeEndpoint API in the SageMaker Runtime service to send requests to, or invoke the endpoint. In response, the requests are handled as explainability requests by the SageMaker Clarify explainer.

**Note**

To invoke an endpoint, choose one of the following options:
For instructions to use Boto3 or the AWS CLI to invoke an endpoint, see real-time endpoints. To use the SageMaker SDK for Python to invoke an endpoint, see the Predictor API.

Request

The InvokeEndpoint API has an optional parameter EnableExplanations, which is mapped to the HTTP header X-Amzn-SageMaker-Enable-Explanations. If this parameter is provided, it overrides the EnableExplanations parameter of the ClarifyExplainerConfig.

Note

The ContentType and Accept parameters of the InvokeEndpoint API are required. Supported formats include MIME type text/csv and application/jsonlines.

Use the sagemaker_runtime_client to send a request to the endpoint, as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName='name-of-your-endpoint',
    EnableExplanations='true',
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',  # single record (of four numerical features)
)
```

Response

If the endpoint is created with ExplainerConfig, then a new response schema is used. This new schema is different from, and is not compatible with, an endpoint that lacks the ExplainerConfig parameter provided.

The MIME type of the response is "application/json", and the response payload can be decoded from UTF-8 bytes to a JSON object. The following shows the members of this JSON object as follows:

- **version**: The version of the response schema in string format. For example, "1.0".
- **predictions**: The predictions that the request makes have the following:
  - **content_type**: The MIME type of the predictions, referring to the ContentType of the model container response.
  - **data**: The predictions data string delivered as the payload of the model container response for the request.
  - **label_headers**: The label headers from the LabelHeaders parameter. This is provided in either the explainer configuration or the model container output.
  - **explanations**: The explanations provided in the request payload. If no records are explained, then this member returns the empty object {}.
  - **kernel_shap**: A key that refers to an array of Kernel SHAP explanations for each record in the request. If a record is not explained, the corresponding explanation is null.

The kernel_shap element has the following members:

- **feature_header**: The header name of the features provided by the FeatureHeaders parameter in the explainer configuration ExplainerConfig.
- **feature_type**: The feature type inferred by explainer or provided in the FeatureTypes parameter in the ExplainerConfig. This element is only available for NLP explainability problems.
- **attributions**: An array of attribution objects. Text features can have multiple attribution objects, each for a unit. The attribution object has the following members:
  - **attribution**: A list of probability values, given for each class.
Code examples: SDK for Python

This section provides sample code to create and invoke an endpoint that uses SageMaker Clarify online explainability. These code examples use the AWS SDK for Python.

Tabular data

The following example uses tabular data and a SageMaker model called model_name. In this example, the model container accepts data in CSV format, and each record has four numerical features. In this minimal configuration, for demonstration purposes only, the SHAP baseline data is set to zero. Refer to the SHAP Baselines for Explainability to choose more appropriate values for ShapBaseline.

Configure the endpoint, as follows:

```python
endpoint_config_name = 'tabular_explainer_endpoint_config'
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'AllTraffic',
         'ModelName': model_name,
         'InitialInstanceCount': 1,
         'InstanceType': 'ml.m5.xlarge',
     },
    ],
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'ShapConfig': {
                'ShapBaselineConfig': {
                    'ShapBaseline': '0,0,0,0',
                },
            },
        },
    },
)
```

Use the endpoint configuration to create an endpoint, as follows:

```python
endpoint_name = 'tabular_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
```

Use the DescribeEndpoint API to inspect the progress of creating an endpoint, as follows:

```python
response = sagemaker_client.describe_endpoint(
    EndpointName=endpoint_name,
)
response['EndpointStatus']
```

After the endpoint status is "InService", invoke the endpoint with a test record, as follows:
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',
)

Assume that the response has a status code of 200 (no error), and load the response body, as follows:

```python
import codecs
import json
json.load(codecs.getreader('utf-8')(response['Body']))
```

The default action for the endpoint is to explain the record. The following shows example output in the returned JSON object.

```
{
    "version": "1.0",
    "predictions": {
        "content_type": "text/csv; charset=utf-8",
        "data": "0.0006380207487381"
    },
    "explanations": {
        "kernel_shap": [
            {
                "attributions": [
                    {
                        "attribution": [-0.00433456]
                    }
                ],
                "attributions": [
                    {
                        "attribution": [-0.005369821]
                    }
                ],
                "attributions": [
                    {
                        "attribution": [0.007917749]
                    }
                ],
                "attributions": [
                    {
                        "attribution": [-0.00261214]
                    }
                ]
            }
        ]
    }
}
```

Use the `EnableExplanations` parameter to enable on-demand explanations, as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(
```
In this example, the prediction value is less than the threshold value of 0.8, so the record is not explained:

```json
{
  "version": "1.0",
  "predictions": {
    "content_type": "text/csv; charset=utf-8",
    "data": "0.6380207487381995"
  },
  "explanations": {}
}
```

Use visualization tools to help interpret the returned explanations. The following image shows how SHAP plots can be used to understand how each feature contributes to the prediction. The base value on the diagram, also called the expected value, is the mean predictions of the training dataset. Features that push the expected value higher are red, and features that push the expected value lower are blue. See [SHAP additive force layout](#) for additional information.

See the [full example notebook](#) for tabular data.

**Text data**

This section provides a code example to create and invoke an online explainability endpoint for text data. The code example uses SDK for Python.

The following example uses text data and a SageMaker model called `model_name`. In this example, the model container accepts data in CSV format, and each record is a single string.

```python
endpoint_config_name = 'text_explainer_endpoint_config'
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'AllTraffic',
        'ModelName': model_name,
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    ],
}
ExplainerConfig={
    'ClarifyExplainerConfig': {
        'InferenceConfig': {
            'FeatureTypes': ['text'],
            'MaxRecordCount': 100,
        },
        'ShapConfig': {
            'ShapBaselineConfig': {
```
• **ShapBaseline**: A special token reserved for natural language processing (NLP) processing.
• **FeatureTypes**: Identifies the feature as text. If this parameter is not provided, the explainer will attempt to infer the feature type.
• **TextConfig**: Specifies the unit of granularity and language for the analysis of text features. In this example, the language is English, and granularity `'token'` means a word in English text.
• **NumberOfSamples**: A limit to set the upper bounds of the size of the synthetic dataset.
• **MaxRecordCount**: The maximum number of records in a request that the model container can handle. This parameter is set to stabilize performance.

Use the endpoint configuration to create the endpoint, as follows:

```python
endpoint_name = 'text_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
```

After the status of the endpoint becomes `InService`, invoke the endpoint. The following code sample uses a test record as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='"This is a good product"',
)
```

If the request completes successfully, the response body will return a valid JSON object that's similar to the following:

```json
{
    "version": "1.0",
    "predictions": {
        "content_type": "text/csv",
        "data": "0.9766594\n"
    },
    "explanations": {
        "kernel_shap": [
            {
                "attributions": [
                    {
                        "attribution": [
                            -0.007270948666666712
                        ],
                        "description": {
                            "mask": "This is a good product"
                        }
                    }]
                }]
            }
        }
    }
```
Use visualization tools to help interpret the returned text attributions. The following image shows how the captum visualization utility can be used to understand how each word contributes to the prediction. The higher the color saturation, the higher the importance given to the word. In this example, a highly saturated bright red color indicates a strong negative contribution. A highly saturated green color indicates a strong positive contribution. The color white indicates that the word has a neutral contribution. See the captum library for additional information on parsing and rendering the attributions.

See the full example notebook for text data.
Troubleshooting guide

If you encounter errors using SageMaker Clarify online explainability, consult the topics in this section.

InvokeEndpoint API fails with the error "ReadTimeoutError:Read timeout on endpoint..."

This error means that the request could not be completed within the 60-second time limit set by the request timeout.

To reduce the request latency, try the following:

- Tune the model's performance during inference. For example, SageMaker Neo can optimize models for inference.
- Allow the model container to handle batch requests.
- Use a larger MaxRecordCount to reduce the number of calls from the explainer to the model container. This will reduce network latency and overhead.
- Use an instance type that has more resources allocated to it. Alternately, assign more instances to the endpoint to help balance the load.
- Reduce the number of records inside a single InvokeEndpoint request.
- Reduce the number of records in the baseline data.
- Use a smaller NumberOfSamples value to reduce the size of the synthetic dataset. For more information, see the Synthetic dataset section in Configure and create an endpoint.

Invoke real-time endpoints

After you deploy your model using SageMaker hosting services, you can test your model on that endpoint by sending it test data. You can test your endpoints using Amazon SageMaker Studio, the AWS CLI, or AWS SDKs.

Test Your Endpoint Using Amazon SageMaker Studio

After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. 1977)) you can check that endpoint with Amazon SageMaker Studio.

Note
Note: SageMaker only supports endpoint testing with Amazon SageMaker Studio for real-time endpoints.

1. Launch Amazon SageMaker Studio.
2. Select the SageMaker Components and registries icon on the left sidebar.
3. From the dropdown, choose Endpoints.
4. Search for your endpoint by name and double-click on the name of your endpoint. The endpoint names listed within the SageMaker resources panel are defined when you deploy a model. You can deploy your model in several ways:
   - The SageMaker Python SDK Model Class sagemaker.model.Model.deploy.
   - The AWS SDK for Python (Boto3) SageMaker Service Client API CreateEndpoint.
   - The SageMaker console. Select Inference in the left panel and then select Endpoint configuration. Provide an endpoint name within the Endpoint name field.
5. (Optional) You can optionally provide a custom URL to send your request to. In the Configure endpoint URL and headers field provide the URL of where your model is hosted. Leave this field blank if you are using a SageMaker endpoint. You can also optionally add multiple key-value headers to pass additional information to the inference request.
6. A new tab will populate in the Studio workspace. Select the **Test inference** tab.
7. Send a request to your endpoint by providing sample data in JSON format. Use the JSON editor to submit a request to your endpoint.
8. Select **Send Request**.
9. When you send the request an *Inference output card* will appear on the right-hand side of the console.

The top of the card will display the type of request that was sent to the endpoint (currently only JSON is accepted). Within the card there are four main fields: Status, Execution Length, Request Time, and Result Time.

- **Status**: displays the request status. There are three types of statuses:
  - **Complete**: If the request is successful, the status will display Complete and the execution length will be calculated by tracking the request time.
  - **Failed**: If the request fails for any reason. A failure response will appear within the **Failure Reason** accordion.
  - **Pending**: A spinning, circular icon will appear while the inference request is pending.
- **Execution Length**: How long the invocation takes (end time minus the start time) in milliseconds.
- **Request Time**: How many minutes have passed since the request was sent.
- **Result Time**: How many minutes have passed since the result was returned.

**Test Your Endpoint Using AWS SDKs**

After you deploy your model to an endpoint (see [Create your endpoint and deploy your model](#)) you can check your endpoint with the `InvokeEndpoint` API using one of the AWS SDKs. If the invocation is successful, SageMaker will return an HTTP 200 response. You can index the returned response dictionary object to find out more about the response headers. For more information, see `InvokeEndpoint`.

The following demonstrates how to use `InvokeEndpoint` to check the status of your endpoint using the AWS SDK for Python (Boto3). Provide the name of your endpoint. This is the name you specified for `EndpointName` when you created your endpoint with `CreateEndpoint`.

Provide input data in the Body field for SageMaker to pass to the model. The data must be in the same format that was used for training.

```python
import boto3

# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=\<aws_region\>)

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name=\'\<endpoint-name\>\'

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    Body=bytes\(\{'\"features\": [\"This is great!\"]\}\', \'utf-8\'\) #
)

# Optional - Print the response body and decode it so it is human read-able.
print(response[\'Body\'].read().decode(\'utf-8\'))
```
Monitor models for data and model quality, bias, and explainability

Amazon SageMaker Model Monitor monitors the quality of Amazon SageMaker machine learning models in production. You can set up continuous monitoring with a real-time endpoint (or a batch transform job that runs regularly), or on-schedule monitoring for asynchronous batch transform jobs. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.
Model Monitor provides the following types of monitoring:

- **Monitor data quality (p. 2099)** - Monitor drift in data quality.
- **Monitor model quality (p. 2106)** - Monitor drift in model quality metrics, such as accuracy.
- **Monitor Bias Drift for Models in Production (p. 2114)** - Monitor bias in your model's predictions.
- **Monitor Feature Attribution Drift for Models in Production (p. 2123)** - Monitor drift in feature attribution.

**Topics**

- How Model Monitor Works (p. 2089)
- Capture data (p. 2091)
- Monitor data quality (p. 2099)
- Monitor model quality (p. 2106)

- Advanced topics (p. 2144)

**How Model Monitor Works**

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works in the case that your model is deployed to a real-time endpoint.

You can also use Model Monitor to monitor a batch transform job instead of a real-time endpoint. In this case, instead of receiving requests to an endpoint and tracking the predictions, Model Monitor will
monitor inference inputs and outputs. The following figure diagrams the process of monitoring a batch transform job.

To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- For a real-time endpoint, enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- For a batch transform job, enable data capture of the batch transform inputs and outputs.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time or batch predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.

**Notes**

- Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see [Host multiple models in one container behind one endpoint](p. 1987).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see [VPC endpoints](in the Amazon Virtual Private Cloud User Guide).
Capture data

To log the inputs to your endpoint and the inference outputs from your deployed model to Amazon S3, you can enable a feature called Data Capture. Data Capture is commonly used to record information that can be used for training, debugging, and monitoring. Amazon SageMaker Model Monitor automatically parses this captured data and compares metrics from this data with a baseline that you create for the model. For more information about Model Monitor see Monitor models for data and model quality, bias, and explainability (p. 2088).

You can implement Data Capture for both real-time and batch model-monitor modes using the AWS SDK for Python (Boto) or the SageMaker Python SDK. For a real-time endpoint, you will specify your Data Capture configuration when you create your endpoint. Due to the persistent nature of your real-time endpoint, you can configure additional options to turn data capturing on or off at certain times, or change the sampling frequency. You can also choose to encrypt your inference data.

For a batch transform job, you can enable Data Capture if you want to run on-schedule model monitoring or continuous model-monitoring for regular, periodic batch transform jobs. You will specify your Data Capture configuration when you create your batch transform job. Within this configuration, you have the option to turn on encryption or generate the inference ID with your output, which helps you match your captured data to Ground Truth data.

Capture data from real-time endpoint

Note
To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

To capture data for your real-time endpoint, you must deploy a model using SageMaker hosting services. This requires that you create a SageMaker model, define an endpoint configuration, and create an HTTPS endpoint.

The steps required to turn on data capture are similar whether you use the AWS SDK for Python (Boto) or the SageMaker Python SDK. If you use the AWS SDK, define the DataCaptureConfig dictionary, along with required fields, within the CreateEndpointConfig method to turn on data capture. If you use the SageMaker Python SDK, import the DataCaptureConfig Class and initialize an instance from this class. Then, pass this object to the DataCaptureConfig parameter in the sagemaker.model.Model.deploy() method.

To use the proceeding code snippets, replace the italicized placeholder text in the example code with your own information.
How to enable data capture

Specify a data capture configuration. You can capture the request payload, the response payload, or both with this configuration. The proceeding code snippet demonstrates how to enable data capture using the AWS SDK for Python (Boto) and the SageMaker Python SDK.

**Note**
You do not need to use Model Monitor to capture request or response payloads.

**AWS SDK for Python (Boto)**

Configure the data you want to capture with the `DataCaptureConfig` dictionary when you create an endpoint using the `CreateEndpointConfig` method. Set `EnableCapture` to the boolean value `True`. In addition, provide the following mandatory parameters:

- `EndpointConfigName`: the name of your endpoint configuration. You will use this name when you make a `CreateEndpoint` request.
- `ProductionVariants`: a list of models you want to host at this endpoint. Define a dictionary data type for each model.
- `DataCaptureConfig`: dictionary data type where you specify an integer value that corresponds to the initial percentage of data to sample (`InitialSamplingPercentage`), the Amazon S3 URI where you want captured data to be stored, and a capture options (`CaptureOptions`) list. Specify either `Input` or `Output` for `CaptureMode` within the `CaptureOptions` list.

You can optionally specify how SageMaker should encode captured data by passing key-value pair arguments to the `CaptureContentTypeHeader` dictionary.

```python
# Create an endpoint config name.
endpoint_config_name = '<endpoint-config-name>'

# The name of the production variant.
variant_name = '<name-of-production-variant>'

# The name of the model that you want to host.
# This is the name that you specified when creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'
#instance_type='ml.m5.xlarge' # Example

# Number of instances to launch initially.
initial_instance_count = <integer>

# Sampling percentage. Choose an integer value between 0 and 100
initial_sampling_percentage = <integer>

# The S3 URI containing the captured data
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output, or both
capture_modes = [ "Input", "Output" ]
#capture_mode = [ "Input"] # Example - If you want to capture input only

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {  
```
Capture data

```
    "VariantName": variant_name,
    "ModelName": model_name,
    "InstanceType": instance_type, # Specify the compute instance type.
    "InitialInstanceCount": initial_instance_count # Number of instances to
launch initially.

    DataCaptureConfig= {
        'EnableCapture': True, # Whether data should be captured or not.
        'InitialSamplingPercentage': initial_sampling_percentage,
        'DestinationS3Uri': s3_capture_upload_path,
        'CaptureOptions': [{"CaptureMode": capture_mode} for capture_mode in
                           capture_modes] # Example - Use list comprehension to capture both Input and Output
    }
```

For more information about other endpoint configuration options, see the CreateEndpointConfig API in the Amazon SageMaker Service API Reference Guide.

**SageMaker Python SDK**

Import the `DataCaptureConfig` Class from `sagemaker.model_monitor` module. Enable data capture by setting `EnableCapture` to the boolean value `True`.

Optionally provide arguments for the following parameters:

- **SamplingPercentage**: an integer value that corresponds to percentage of data to sample. If you do not provide a sampling percentage, SageMaker will sample a default of 20 (20%) of your data.
- **DestinationS3Uri**: the Amazon S3 URI SageMaker will use to store captured data. If you do not provide one, SageMaker will store captured data in "s3://<default-session-bucket>/model-monitor/data-capture".

```python
from sagemaker.model_monitor import DataCaptureConfig

# Set to True to enable data capture
enable_capture = True

# Optional - Sampling percentage. Choose an integer value between 0 and 100
sampling_percentage = <int>
# sampling_percentage = 30 # Example 30%

# Optional - The S3 URI of stored captured-data location
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>

# Specify either Input, Output or both.
capture_modes = ['REQUEST','RESPONSE'] # In this example, we specify both
# capture_mode = ['REQUEST'] # Example - If you want to only capture input.

data_capture_config = DataCaptureConfig(  
    enable_capture = enable_capture,  
    sampling_percentage = sampling_percentage, # Optional
    destination_s3_uri = s3_capture_upload_path, # Optional
    capture_options = [{"CaptureMode": capture_mode} for capture_mode in capture_modes]
)
```

**Deploy your model**

Deploy your model and create an HTTPS endpoint with DataCapture enabled.
Capture data

AWS SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

For more information, see the `CreateEndpoint` API.

SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"
print("EndpointName =", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object's built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```python
# initial_instance_count=<integer>  # Example
# instance_type='<instance-type>'  # Example
#
# Uncomment if you did not define this variable in the previous step
# data_capture_config = <name-of-data-capture-configuration>

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    data_capture_config=data_capture_config
)
```

View Captured Data

Create a predictor object from the SageMaker Python SDK `Predictor` Class. You will use the object returned by the `Predictor` Class to invoke your endpoint in a future step. Provide the name of your endpoint (defined earlier as `endpoint_name`), along with serializer and deserializer objects for the
serializer and deserializer, respectively. For information about serializer types, see the Serializers Class in the SageMaker Python SDK.

```python
from sagemaker.predictor import Predictor
from sagemaker.serializers import <Serializer>
from sagemaker.deserializers import <Deserializer>

predictor = Predictor(endpoint_name=endpoint_name,
                      serializer = <Serializer_Class>,
                      deserializer = <Deserializer_Class>)

# Example
#predictor = Predictor(endpoint_name=endpoint_name,
#                       serializer = CSVSerializer(),
#                       deserializer = JSONDeserializer())
```

In the proceeding code example scenario we invoke the endpoint with sample validation data that we have stored locally in a CSV file named validation_with_predictions. Our sample validation set contains labels for each input.

The first few lines of the with statement first opens the validation set CSV file, then splits each row within the file by the comma character ",", and then stores the two returned objects into a label and input_cols variables. For each row, the input (input_cols) is passed to the predictor variable's (predictor) objects built-in method Predictor.predict().

Suppose the model returns a probability. Probabilities range between integer values of 0 and 1.0. If the probability returned by the model is greater than 80% (0.8) we assign the prediction an integer value label of 1. Otherwise, we assign the prediction an integer value label of 0.

```python
from time import sleep
validate_dataset = "validation_with_predictions.csv"

cutoff = 0.8

i = 0
with open(f"test_data/{validate_dataset}", "w") as validation_file:
    validation_file.write("probability,prediction,label\n")  # CSV header
with open("test_data/validation.csv", "r") as f:
    for row in f:
        (label, input_cols) = row.split("," , 1)
        probability = float(predictor.predict(input_cols))
        prediction = "1" if probability > cutoff else "0"
        baseline_file.write(f"{probability},{prediction},{label}\n")
        i += 1
        if i > limit:
            break
    print(".", end="", flush=True)
    sleep(0.5)
print()
print("Done!"
```

Because you enabled the data capture in the previous steps, the request and response payload, along with some additional meta data, is saved in the Amazon S3 location that you specified in DataCaptureConfig. The delivery of capture data to Amazon S3 can require a couple of minutes.
Amazon SageMaker Developer Guide
Capture data

View captured data by listing the data capture ﬁles stored in Amazon S3. The format of the Amazon S3
path is: s3:///{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/filename.jsonl.
Expect to see diﬀerent ﬁles from diﬀerent time periods, organized based on the hour when the
invocation occurred. Run the following to print out the contents of a single capture ﬁle:
print("\n".join(capture_file[-3:-1]))

This will return a SageMaker speciﬁc JSON-line formatted ﬁle. The following is a response sample taken
from a real-time endpoint that we invoked using csv/text data:

{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT",
"data":"69,0,153.7,109,194.0,105,256.1,114,14.1,6,1,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0
"encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv;
charset=utf-8","mode":"OUTPUT","data":"0.0254181120544672","encoding":"CSV"}},
"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-ddddeeeeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"}
{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT",
"data":"94,23,197.1,125,214.5,136,282.2,103,9.5,5,4,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0
"encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv;
charset=utf-8","mode":"OUTPUT","data":"0.07675473392009735","encoding":"CSV"}},
"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-ddddeeeeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"}

In the proceeding example, the capture_file object is a list type. Index the ﬁrst element of the list to
view a single inference request.
# The capture_file object is a list. Index the first element to view a single inference
request
print(json.dumps(json.loads(capture_file[0]), indent=2))

This will return a response similar to the following. The values returned will diﬀer based on your
endpoint conﬁguration, SageMaker model, and captured data:
{

"captureData": {
"endpointInput": {
"observedContentType": "text/csv", # data MIME type
"mode": "INPUT",
"data":
"50,0,188.9,94,203.9,104,151.8,124,11.6,8,3,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,
"encoding": "CSV"
},
"endpointOutput": {
"observedContentType": "text/csv; charset=character-encoding",
"mode": "OUTPUT",
"data": "0.023190177977085114",
"encoding": "CSV"
}
},
"eventMetadata": {
"eventId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
"inferenceTime": "2022-02-14T17:25:06Z"
},
"eventVersion": "0"

}

2096


Capture data from batch transform job

The steps required to turn on data capture for your batch transform job are similar whether you use the AWS SDK for Python (Boto) or the SageMaker Python SDK. If you use the AWS SDK, define the `DataCaptureConfig` dictionary, along with required fields, within the `CreateTransformJob` method to turn on data capture. If you use the SageMaker Python SDK, import the `BatchDataCaptureConfig` class and initialize an instance from this class. Then, pass this object to the `batch_transform_data_capture_config` parameter of your transform job instance.

To use the proceeding code snippets, replace the italicized placeholder text in the example code with your own information.

How to enable data capture

Specify a data capture configuration when you launch a transform job. Whether you use the AWS SDK for Python (Boto3) or the SageMaker Python SDK, you must provide the `DestinationS3Uri` argument, which is the directory where you want the transform job to log the captured data. Optionally, you can also set the following parameters:

- `KmsKeyId`: The AWS KMS key used to encrypt the captured data.
- `GenerateInferenceId`: A Boolean flag that, when capturing the data, indicates if you want the transform job to append the inference ID and time to your output. This is useful for model quality monitoring, where you need to ingest the Ground Truth data. The inference ID and time help to match the captured data with your Ground Truth data.

AWS SDK for Python (Boto3)

Configure the data you want to capture with the `DataCaptureConfig` dictionary when you create a transform job using the `CreateTransformJob` method.

```python
input_data_s3_uri = "s3://<input_S3_uri>"
output_data_s3_uri = "s3://<output_S3_uri>"
data_capture_destination = "s3://<captured_data_S3_uri>"
model_name = "<model_name>"

sm_client.create_transform_job(
    TransformJobName="<transform_job_name>",
    MaxConcurrentTransforms=2,
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': "S3Prefix",
                'S3Uri': input_data_s3_uri,
            }
        },
        'ContentType': 'text/csv',
        'CompressionType': 'None',
        'SplitType': 'Line',
    },
    TransformOutput={
        'S3OutputPath': output_data_s3_uri,
        'Accept': 'text/csv',
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': "ml.m4.xlarge",
        'InstanceCount': 1,
    },
)
```

Capture data

```
DataCaptureConfig={
    "DestinationS3Uri": data_capture_destination,
    "KmsKeyId": "<kms_key>",
    "GenerateInferenceId": True,
}
)
```

SageMaker Python SDK

Import the BatchDataCaptureConfig class from the `sagemaker.model_monitor`.

```python
from sagemaker.transer import Transformer
from sagemaker.inputs import BatchDataCaptureConfig

# Optional - The S3 URI of where to store captured data in S3
data_capture_destination = 's3://<bucket_name>'

model_name = '<inference_model_name>'

transformer = Transformer(
    model_name=model_name,
    ...
    batch_transform_data_capture_config=BatchDataCaptureConfig(
        destination_s3_uri=data_capture_destination,
        kms_key_id="<kms_key>",
        generate_inference_id=True,
    ),
    ...
)

transformer.transform(...)
```

How to view data captured

Once the transform job completes, the captured data gets logged under the `DestinationS3Uri` you provided with the data capture configuration. There are two subdirectories under `DestinationS3Uri`, `input` and `output`. If `DestinationS3Uri` is `s3://my-data-capture`, then the transform job creates the following directories:

- `s3://my-data-capture/input`: The captured input data for the transform job.
- `s3://my-data-capture/output`: The captured output data for the transform job.

To avoid data duplication, the captured data under the preceding two directories are manifests. Each manifest is a JSONL file that contains the Amazon S3 locations of the source objects. A manifest file may look like the following example:

```json
// under "/input" directory
[
    {"prefix":"s3://<input_S3_uri>"},
    "dummy_0.csv",
    "dummy_1.csv",
    "dummy_2.csv",
    ...
]

// under "/output" directory
[
    {"prefix":"s3://<output_S3_uri>"},
    "dummy_0.csv.out",
    "dummy_1.csv.out",
    ...
]
```
The transform job organizes and labels these manifests with a `yyyy/mm/dd/hh` S3 prefix to indicate when they were captured. This helps the model monitor determine the appropriate portion of data to analyze. For example, if you start your transform job at 2022-08-26 13PM UTC, then the captured data is labeled with a `2022/08/26/13/` prefix string.

### InferenceId Generation

When you configure `DataCaptureConfig` for a transform job, you can turn on the Boolean flag `GenerateInferenceId`. This is particularly useful when you need to run model quality and model bias monitoring jobs, for which you need user-ingested Ground Truth data. Model monitor relies on an inference ID to match the captured data and the Ground Truth data. For additional details about Ground Truth ingestion, see *(Ingest Ground Truth Labels and Merge Them With Predictions)*. When `GenerateInferenceId` is on, the transform output appends an inference ID (a random UUID) as well as the transform job start time in UTC for each record. You need these two values to run model quality and model bias monitoring. When you construct the Ground Truth data, you need to provide the same inference ID to match the output data. Currently, this feature supports transform outputs in CSV, JSON, and JSONL formats.

If your transform output is in CSV format, the output file looks like the following example:

```
0, 1f1d57b1-2e6f-488c-8c30-db4e6d757861,2022-08-30T00:49:15Z
1, 22445434-0c67-45e9-bb4d-bd1bf26561e6,2022-08-30T00:49:15Z
...
```

The last two columns are inference ID and the transform job start time. Do not modify them. The remaining columns are your transform job outputs.

If your transform output is in JSON or JSONL format, the output file looks like the following example:

```
{"output": 0, "SageMakerInferenceId": "1f1d57b1-2e6f-488c-8c30-db4e6d757861", "SageMakerInferenceTime": "2022-08-30T00:49:15Z"}
{"output": 1, "SageMakerInferenceId": "22445434-0c67-45e9-bb4d-bd1bf26561e6", "SageMakerInferenceTime": "2022-08-30T00:49:15Z"}
...
```

There are two appended fields that are reserved, `SageMakerInferenceId` and `SageMakerInferenceTime`. Do not modify these fields if you need to run model quality or model bias monitoring — you need them for merge jobs.

### Monitor data quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint or batch transform job and stores the data in Amazon S3. For more information, see *(Capture data)*.
- Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an...
open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see Create a Baseline (p. 2100).

- Define and schedule data quality monitoring jobs. For specific information and code samples of data quality monitoring jobs, see Schedule data quality monitoring jobs (p. 2101). For general information about monitoring jobs, see Schedule monitoring jobs (p. 2132).
- Optionally use preprocessing and postprocessing scripts to transform the data coming out of your data quality analysis. For more information, see Preprocessing and Postprocessing (p. 2144).
- View data quality metrics. For more information, see Schema for Statistics (statistics.json file) (p. 2102).
- Integrate data quality monitoring with Amazon CloudWatch. For more information, see CloudWatch Metrics (p. 2104).
- Interpret the results of a monitoring job. For more information, see Interpret results (p. 2136).
- Use SageMaker Studio to enable data quality monitoring and visualize results if you are using a real-time endpoint. For more information, see Visualize results for real-time endpoints in Amazon SageMaker Studio (p. 2138).

Note
Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.

Topics
- Create a Baseline (p. 2100)
- Schedule data quality monitoring jobs (p. 2101)
- Schema for Statistics (statistics.json file) (p. 2102)
- CloudWatch Metrics (p. 2104)
- Schema for Violations (constraint_violations.json file) (p. 2104)

Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This sagemaker-model-monitor-analyzer container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with Deequ. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to train the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

To Create a baseline from a training dataset

When you have your training data ready and stored in Amazon S3, start a baseline processing job with DefaultModelMonitor.suggest_baseline(…) using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor prebuilt container (p. 2135) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the output_s3_uri location that you specify.
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)

Note
If you provide the feature/column names in the training dataset as the first row and set the header=True option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the statistics.json file and the suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri.

Output Files for Tabular Dataset Statistics and Constraints

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see Schema for Statistics (statistics.json file) (p. 2151).</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. For more information about the schema for this file, see Schema for Constraints (constraints.json file) (p. 2153).</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the Environment map as shown in the following example:

```json
"Environment": {
    "dataset_format": "{\"csv\": { \"header\": true}}",
    "dataset_source": "/opt/ml/processing/sm_input",
    "output_path": "/opt/ml/processing/sm_output",
    "publish_cloudwatch_metrics": "Disabled",
}
```

Schedule data quality monitoring jobs

After you create your baseline, you can call the create_monitoring_schedule() method of your DefaultModelMonitor class instance to schedule an hourly data quality monitor. The following sections show you how to create a data quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.
Data quality monitoring for models deployed to real-time endpoints

To schedule a data quality monitor for a real-time endpoint, pass your `EndpointInput` instance to the `endpoint_input` argument of your `DefaultModelMonitor` instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
data_quality_model_monitor = DefaultModelMonitor(    role=sagemaker.get_execution_role(),
    ...
)
schedule = data_quality_model_monitor.create_monitoring_schedule(    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    statistics=data_quality_model_monitor.baseline_statistics(),
    constraints=data_quality_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    endpoint_input=EndpointInput(        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
    )
)
```

Data quality monitoring for batch transform jobs

To schedule a data quality monitor for a batch transform job, pass your `BatchTransformInput` instance to the `batch_transform_input` argument of your `DefaultModelMonitor` instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
data_quality_model_monitor = DefaultModelMonitor(    role=sagemaker.get_execution_role(),
    ...
)
schedule = data_quality_model_monitor.create_monitoring_schedule(    monitor_schedule_name=mon_schedule_name,
    batch_transform_input=BatchTransformInput(        data_captured_destination_s3_uri=s3_capture_upload_path,
        destination="/opt/ml/processing/input",
        dataset_format=MonitoringDatasetFormat.csv(header=False),
    ),
    output_s3_uri=s3_report_path,
    statistics=statistics_path,
    constraints=constraints_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Schema for Statistics (statistics.json file)

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```json
{
```
"version": 0,
# dataset level stats
"dataset": {
    "item_count": number
},
# feature level stats
"features": [
    {
        "name": "feature-name",
        "inferred_type": "Fractional" | "Integral",
        "numerical_statistics": {
            "common": {
                "num_present": number,
                "num_missing": number
            },
            "mean": number,
            "sum": number,
            "std_dev": number,
            "min": number,
            "max": number,
            "distribution": {
                "kll": {
                    "buckets": [
                        {
                            "lower_bound": number,
                            "upper_bound": number,
                            "count": number
                        }
                    ],
                    "sketch": {
                        "parameters": {
                            "c": number,
                            "k": number
                        },
                        "data": [
                            [num, num, num, num],
                            [num, num]
                        ][num, num]
                    }
                }#sketch
            }#KLL
        }#distribution
    }
],
"num_stats",
{
    "name": "feature-name",
    "inferred_type": "String",
    "string_statistics": {
        "common": {
            "num_present": number,
            "num_missing": number
        },
        "distinct_count": number,
        "distribution": {
            "categorical": {
                "buckets": [
            
        
    }

}
Note the following:

- The prebuilt containers compute **KLL sketch**, which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

### CloudWatch Metrics

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the `emit_metrics` option is `Enabled` in the baseline constraints file, SageMaker emits these metrics for each feature/column observed in the dataset in the following namespace:

- For real-time endpoints: `/aws/sagemaker/Endpoints/data-metric` namespace with `EndpointName` and `ScheduleName` dimensions.
- For batch transform jobs: `/aws/sagemaker/ModelMonitoring/data-metric` namespace with `MonitoringSchedule` dimension.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: `Max` → query for `MetricName: feature_data_{feature_name}`, Stat: `Max`
- Metric: `Min` → query for `MetricName: feature_data_{feature_name}`, Stat: `Min`
- Metric: `Sum` → query for `MetricName: feature_data_{feature_name}`, Stat: `Sum`
- Metric: `SampleCount` → query for `MetricName: feature_data_{feature_name}`, Stat: `SampleCount`
- Metric: `Average` → query for `MetricName: feature_data_{feature_name}`, Stat: `Average`

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: `Completeness` → query for `MetricName: feature_non_null_{feature_name}`, Stat: `Sum`
- Metric: `Baseline Drift` → query for `MetricName: feature_baseline_drift_{feature_name}`, Stat: `Sum`

### Schema for Violations (constraint_violations.json file)

The violations file is generated as the output of a `MonitoringExecution`, which lists the results of evaluating the constraints (specified in the `constraints.json` file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```json
{
  "value": "string",
  "count": number
}
}]
#provision for custom stats
}
]
```
"violations": [{
  "feature_name": "string",
  "constraint_check_type":
    "data_type_check",
    "completeness_check",
    "baseline_drift_check",
    "missing_column_check",
    "extra_column_check",
    "categorical_values_check"
  "description": "string"
}]

### Types of Violations Monitored

<table>
<thead>
<tr>
<th>Violation Check Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_type_check</td>
<td>If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td></td>
<td>During the baseline step, the generated constraints suggest the inferred data type for each column. The monitoring_config.datatype_check_threshold parameter can be tuned to adjust the threshold on when it is flagged as a violation.</td>
</tr>
<tr>
<td>completeness_check</td>
<td>If the completeness (% of non-null items) observed in the current execution exceeds the threshold specified in completeness threshold specified per feature, this violation is flagged.</td>
</tr>
<tr>
<td></td>
<td>During the baseline step, the generated constraints suggest a completeness value.</td>
</tr>
<tr>
<td>baseline_drift_check</td>
<td>If the calculated distribution distance between the current and the baseline datasets is more than the threshold specified in monitoring_config.comparison_threshold, this violation is flagged.</td>
</tr>
<tr>
<td>missing_column_check</td>
<td>If the number of columns in the current dataset is less than the number in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td>extra_column_check</td>
<td>If the number of columns in the current dataset is more than the number in the baseline, this violation is flagged.</td>
</tr>
<tr>
<td>categorical_values_check</td>
<td>If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged. This value is dictated by the threshold in monitoring_config.domain_content_threshold.</td>
</tr>
</tbody>
</table>
Monitor model quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual Ground Truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time or batch inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model Quality Metrics (p. 2111).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint or batch transform job. To monitor model quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint or batch transform job and stores the data in Amazon S3. For more information, see Capture data (p. 2091).
- Create a baseline. In this step, you run a baseline job that compares predictions from the model with Ground Truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see Create a Model Quality Baseline (p. 2106).
- Define and schedule model quality monitoring jobs. For specific information and code samples of model quality monitoring jobs, see Schedule Model Quality Monitoring Jobs (p. 2108). For general information about monitoring jobs, see Schedule monitoring jobs (p. 2132).
- Ingest Ground Truth labels that model monitor merges with captured prediction data from a real-time inference endpoint or batch transform job. For more information, see Ingest Ground Truth Labels and Merge Them With Predictions (p. 2110).
- Integrate model quality monitoring with Amazon CloudWatch. For more information, see Model Quality CloudWatch Metrics (p. 2114).
- Interpret the results of a monitoring job. For more information, see Interpret results (p. 2136).
- Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see Visualize results for real-time endpoints in Amazon SageMaker Studio (p. 2138).

Topics

- Create a Model Quality Baseline (p. 2106)
- Schedule Model Quality Monitoring Jobs (p. 2108)
- Ingest Ground Truth Labels and Merge Them With Predictions (p. 2110)
- Model Quality Metrics (p. 2111)
- Model Quality CloudWatch Metrics (p. 2114)

Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the Ground Truth for your data.
To create a model quality baseline job

1. First, create an instance of the ModelQualityMonitor class. The following code snippet shows how to do this.

   ```python
   from sagemaker import get_execution_role, session, Session
   from sagemaker.model_monitor import ModelQualityMonitor

   role = get_execution_role()
   session = Session()

   model_quality_monitor = ModelQualityMonitor(
       role=role,
       instance_count=1,
       instance_type='ml.m5.xlarge',
       volume_size_in_gb=20,
       max_runtime_in_seconds=1800,
       sagemaker_session=session
   )
   ```

2. Now call the suggest_baseline method of the ModelQualityMonitor object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

   ```python
   baseline_job_name = "MyBaselineJob"
   job = model_quality_monitor.suggest_baseline(
       job_name=baseline_job_name,
       baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
       dataset_format=DatasetFormat.csv(header=True),
       output_s3_uri = baseline_results_uri, # The S3 location to store the results.
       problem_type='BinaryClassification',
       inference_attribute= "prediction", # The column in the dataset that contains predictions.
       probability_attribute= "probability", # The column in the dataset that contains probabilities.
       ground_truth_attribute= "label" # The column in the dataset that contains ground truth labels.
   )
   job.wait(logs=False)
   ```

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the latest_baselining_job method of the ModelQualityMonitor object.

   ```python
   baseline_job = model_quality_monitor.latest_baselining_job
   ```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the suggested_constraints method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

   ```python
   import pandas as pd
   pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"]).T
   ```
We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

If your constraint contains numbers expressed in scientific notation, you will need to convert them to float. The follow python preprocessing script example shows how to convert numbers in scientific notation to float.

```python
import csv

def fix_scientific_notation(col):
    try:
        return format(float(col), "f")
    except:
        return col

def preprocess_handler(csv_line):
    reader = csv.reader([csv_line])
    csv_record = next(reader)
    #skip baseline header, change HEADER_NAME to the first column's name
    if csv_record[0] == "HEADER_NAME":
        return []
    return {str(i).zfill(20) : fix_scientific_notation(d) for i, d in enumerate(csv_record)}
```

You can add your pre-processing script to a baseline or monitoring schedule as a record_preprocessor_script, as defined in the Model Monitor documentation.

5. When you are satisfied with the constraints, pass them as the constraints parameter when you create a monitoring schedule. For more information, see Schedule Model Quality Monitoring Jobs (p. 2108).

The suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri. For information about the schema for this file in the Schema for Constraints (constraints.json file) (p. 2153).

**Schedule Model Quality Monitoring Jobs**

After you create your baseline, you can call the create_monitoring_schedule() method of your ModelQualityMonitor class instance to schedule an hourly model quality monitor. The following sections show you how to create a model quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

Unlike data quality monitoring, you need to supply Ground Truth labels if you want to monitor model quality. However, Ground Truth labels could be delayed. To address this, specify offsets when you create your monitoring schedule.

**Model monitor offsets**

Model quality jobs include StartTimeOffset and EndTimeOffset, which are fields of the ModelQualityJobInput parameter of the create_model_quality_job_definition method that work as follows:

- **StartTimeOffset** - If specified, jobs subtract this time from the start time.
- **EndTimeOffset** - If specified, jobs subtract this time from the end time.
The format of the offsets are, for example, -PT7H, where 7H is 7 hours. You can use -PT#H or -P#D, where H=hours, D=days, and M=minutes, and # is the number. In addition, the offset should be in ISO 8601 duration format.

For example, if your Ground Truth starts coming in after 1 day, but is not complete for a week, set StartTimeOffset to -P8D and EndTimeOffset to -P1D. Then, if you schedule a job to run at 2020-01-09T13:00, it analyzes data from between 2020-01-01T13:00 and 2020-01-08T13:00.

Important
The schedule cadence should be such that one execution finishes before the next execution starts, which allows the Ground Truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of MaxRuntimeInSeconds specified as part of StoppingCondition should be no more than 1800.

Model quality monitoring for models deployed to real-time endpoints

To schedule a model quality monitor for a real-time endpoint, pass your EndpointInput instance to the endpoint_input argument of your ModelQualityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_quality_model_monitor = ModelQualityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=monitor_schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    statistics=model_quality_model_monitor.baseline_statistics(),
    constraints=model_quality_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT2D",
        end_time_offset="-PT1D",
    )
)
```

Model quality monitoring for batch transform jobs

To schedule a model quality monitor for a batch transform job, pass your BatchTransformInput instance to the batch_transform_input argument of your ModelQualityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_quality_model_monitor = ModelQualityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=monitor_schedule_name,
    batch_transform_input=BatchTransformInput(
    )
)
data_captured_destination_s3_uri=s3_capture_upload_path,
destination="/opt/ml/processing/input",
dataset_format=MonitoringDatasetFormat.csv(header=False),
# the column index of the output representing the inference probability
probability_attribute="0",
# the threshold to classify the inference probability to class 0 or 1 in
# binary classification problem
probability_threshold_attribute=0.5,
# look back 6 hour for transform job outputs.
start_time_offset="-PT6H",
end_time_offset="-PT0H"
),
ground_truth_input=gt_s3_uri,
output_s3_uri=s3_report_path,
problem_type="BinaryClassification",
constraints = constraints_path,
schedule_cron_expression=CronExpressionGenerator.hourly(),
enable_cloudwatch_metrics=True,

Ingest Ground Truth Labels and Merge Them With Predictions

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint or batch transform job and upload it to Amazon S3.

To match Ground Truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```
{
  "groundTruthData": {
    "data": "1",
    "encoding": "CSV" # only CSV supported at launch, we assume "data" only consists of label
  },
  "eventMetadata": {
    "eventId": "aaaa-bbbb-cccc"
  },
  "eventVersion": "0"
}
```

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with Ground Truth records. You are responsible for making sure that the `inferenceId` in the Ground Truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a Ground Truth record.

You must upload Ground Truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

```
s3://bucket/prefix/yyyy/mm/dd/hh
```

The date in this path is the date when the Ground Truth label is collected, and does not have to match the date when the inference was generated.
After you create and upload the Ground Truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using AWS SDK for Python (Boto3), do this by specifying the location of Ground Truth labels as the S3Uri field of the GroundTruthS3Input parameter in a call to the create_model_quality_job_definition method. If you are using the SageMaker Python SDK, specify the location of the Ground Truth labels as the ground_truth_input parameter in the call to the create_monitoring_schedule of the ModelQualityMonitor object.

**Model Quality Metrics**

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

**Note**

Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.

**Regression Metrics**

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```json
"regression_metrics" : {
  "mae" : {
    "value" : 0.3711832061068702,
    "standard_deviation" : 0.0037566388129940394
  },
  "mse" : {
    "value" : 0.3711832061068702,
    "standard_deviation" : 0.0037566388129940524
  },
  "rmse" : {
    "value" : 0.609248066149471,
    "standard_deviation" : 0.003079253267651125
  },

"standard_deviation" : "NaN"
},
"f1_best_constant_classifier" : {  
"value" : 0.4,  
"standard_deviation" : "NaN"
}
Multiclass Metrics

The following shows an example of the metrics that model quality monitor computes for a multiclass classification problem.

```json
"multiclass_classification_metrics": {
    "confusion_matrix": {
        "0": {
            "0": 1180,
            "1": 510
        },
        "1": {
            "0": 268,
            "1": 138
        }
    },
    "accuracy": {
        "value": 0.6288167938931297,
        "standard_deviation": 0.00375663881299405
    },
    "weighted_recall": {
        "value": 0.6288167938931297,
        "standard_deviation": 0.003756638812994008
    },
    "weighted_precision": {
        "value": 0.6983172269629505,
        "standard_deviation": 0.006195912915307507
    },
    "weighted_f0_5": {
        "value": 0.6803947317178771,
        "standard_deviation": 0.005328406973561699
    },
    "weighted_f1": {

    },
    "weighted_f0_5_best_constant_classifier": {
        "value": 0.0032049848450732355,
        "standard_deviation": 0.0032049848450732355
    },
    "weighted_f1_best_constant_classifier": {
        "value": 0.0032049848450732355,
        "standard_deviation": 0.0032049848450732355
    }
}
```
Model Quality CloudWatch Metrics

If you set the value of the `enable_cloudwatch_metrics` to `True` when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the following namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/model-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/model-metrics`

For a list of the metrics that are emitted, see Model Quality Metrics (p. 2111).

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see Create a CloudWatch Alarm Based on a Static Threshold in the Amazon CloudWatch User Guide.

Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates. With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=\langle a_{\text{min}}, a_{\text{max}} \rangle$, for instance an interval of (-0.1, 0.1), that DPPL should belong to during deployment. Any deviation from this range should raise a bias detected alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example, $D_{\text{win}}$ is the data that the model processed during last 2-day window. An alert is issued if the DPPL value $b_{\text{win}}$ computed on $D_{\text{win}}$ falls outside of an allowed range $A$. This approach to checking if $b_{\text{win}}$ is outside of $A$ can be somewhat noisy. $D_{\text{win}}$ might consist of very few samples and might not be representative of the live data.
distribution. The small sample size means that the value of bias $b_{\text{win}}$ computed over $D_{\text{win}}$ might not be a very robust estimate. In fact, very high (or low) values of $b_{\text{win}}$ may be observed purely due to chance. To ensure that the conclusions drawn from the observed data $D_{\text{win}}$ are statistically significant, SageMaker Clarify makes use of confidence intervals. Specifically, it uses the Normal Bootstrap Interval method to construct an interval $C=(c_{\text{min}},c_{\text{max}})$ such that SageMaker Clarify is confident that the true bias value computed over the full live data is contained in $C$ with high probability. Now, if the confidence interval $C$ overlaps with the allowed range $A$, SageMaker Clarify interprets it as “it is likely that the bias metric value of the live data distribution falls within the allowed range”. If $C$ and $A$ are disjoint, SageMaker Clarify is confident that the bias metric does not lie in $A$ and raises an alert.

**Model Monitor Sample Notebook**

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture inference data for a real-time endpoint, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

**Topics**

- Create a Bias Drift Baseline (p. 2115)
- Bias Drift Violations (p. 2116)
- Configure Parameters to Monitor Bias Drift (p. 2117)
- Schedule Bias Drift Monitoring Jobs (p. 2120)
- Inspect Reports for Data Bias Drift (p. 2122)
- CloudWatch Metrics for Bias Drift Analysis (p. 2122)

**Create a Bias Drift Baseline**

After you have configured your application to capture real-time or batch transform inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.

```python
model_bias_monitor = ModelBiasMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

`DataConfig` stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSON Lines), headers (if any) and label.

```python
model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"
```
BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the facet. For posttraining bias, you should also take the positive label into account.

```python
define_bias_config:
    model_bias_config = BiasConfig(
        label_values_or_threshold=[1],
        facet_name="Account Length",
        facet_values_or_threshold=[100],
    )
```

ModelPredictedLabelConfig specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JMESPath to locate predicted label in endpoint response payload.

```python
define_model_predicted_label_config:
    model_predicted_label_config = ModelPredictedLabelConfig(
        probability_threshold=0.8,
    )
```

ModelConfig is the configuration related to the model to be used for inferencing. In order to compute posttraining bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as shadow endpoint). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

```python
define_model_config:
    model_config = ModelConfig(
        model_name=model_name,
        instance_count=endpoint_instance_count,
        instance_type=endpoint_instance_type,
        content_type=dataset_type,
        accept_type=dataset_type,
    )
```

Now you can start the baselining job.

```python
run_baselining_job:
    model_config = model_config,
    data_config=model_bias_data_config,
    bias_config=model_bias_config,
    model_predicted_label_config=model_predicted_label_config,
) print(f"ModelBiasMonitor baselining job: {model_bias_monitor.latest_baselining_job_name}")
```

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

### Bias Drift Violations

Bias drift jobs evaluate the baseline constraints provided by the baseline configuration against the analysis results of current MonitoringExecution. If violations are detected, the job lists them to
the `constraint_violations.json` file in the execution output location, and marks the execution status as *Interpret results* (p. 2136).

Here is the schema of the bias drift violations file.

- **facet** – The name of the facet, provided by the monitoring job analysis configuration facet name_or_index.
- **facet_value** – The value of the facet, provided by the monitoring job analysis configuration facet value_or_threshold.
- **metric_name** – The short name of the bias metric. For example, "CI" for class imbalance. See *Measure Pretraining Bias* (p. 870) for the short names of each of the pretraining bias metrics and *Measure Posttraining Data and Model Bias* (p. 1863) for the short names of each of the posttraining bias metrics.
- **constraint_check_type** – The type of violation monitored. Currently only bias_drift_check is supported.
- **description** – A descriptive message to explain the violation.

```json
{
    "version": "1.0",
    "violations": [
        {
            "facet": "string",
            "facet_value": "string",
            "metric_name": "string",
            "constraint_check_type": "string",
            "description": "string"
        }
    ]
}
```

If the value of a bias metric in the baseline constraints file is different from its peer in the job analysis results file (`analysis.json`), the monitoring jobs log a violation. The following output provides an example of several logged violations.

```json
{
    "version": "1.0",
    "violations": [
        {
            "facet": "Age",
            "facet_value": "40",
            "metric_name": "CI",
            "constraint_check_type": "bias_drift_check",
            "description": "Value 0.0751544567666083 does not meet the constraint requirement"
        },
        {
            "facet": "Age",
            "facet_value": "40",
            "metric_name": "DPPL",
            "constraint_check_type": "bias_drift_check",
            "description": "Value -0.0791244970125596 does not meet the constraint requirement"
        }
    ]
}
```

**Configure Parameters to Monitor Bias Drift**

Amazon SageMaker Clarify bias monitoring reuses a subset of the parameters used in the analysis configuration of *Configure the Analysis* (p. 1852). After describing the configuration parameters, this topic provides examples of JSON files. These files are used to configure CSV and JSON Lines datasets to monitor them for bias drift when machine learning models are in production.

The following parameters must be provided in a JSON file. The path to this JSON file must be provided in the ConfigUri parameter of the `ModelBiasAppSpecification` API.
• "version" – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
• "headers" – (Optional) A list of column names in the dataset. If the dataset_type is "application/jsonlines" and "label" is specified, then the last header becomes the header of the label column.
• "label" – (Optional) Target attribute for the model to be used for bias metrics. Specified either as a column name, or an index (if dataset_format is CSV), or as a JMESPath (if dataset_format is JSON Lines).
• "label_values_or_threshold" – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.
• "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  • "name_or_index" – Facet column name or index.
  • "value_or_threshold" – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.
• "group_variable" – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.

The other parameters should be provided in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) of the ModelBiasJobInput API.

- FeaturesAttribute – This parameter is required if endpoint input data format is "application/jsonlines". It is the JMESPath used to locate the feature columns if the dataset format is JSON Lines.
- InferenceAttribute – Index or JMESPath location in the model output for the target attribute to be used for monitored for bias using bias metrics. If it is not provided in the CSV accept_type case, then it is assumed that the model output is a single numeric value corresponding to a score or probability.
- ProbabilityAttribute – Index or JMESPath location in the model output for probabilities. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations.
- ProbabilityThresholdAttribute – (Optional) A float value to indicate the threshold to select the binary label, in the case of binary classification. The default value is 0.5.

Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for bias drift.

Topics
• CSV Datasets (p. 2118)
• JSON Lines Datasets (p. 2119)

CSV Datasets

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

| 0, 0.5814568701544718, 0.6551538910132964, 0.3138080342665499, 0 |
| 1, 0.6711642728531724, 0.7466687034026017, 0.1215477472819713, 1 |
| 0, 0.0453256543008371, 0.6377430803264152, 0.3558625219713576, 1 |
Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697, 1

Then the following JSON configuration file shows an example of how this CSV dataset can be configured.

```json
{
    "headers": [
        "feature_0",
        "feature_1",
        "feature_2",
        "feature_3",
        "target"
    ],
    "label": "target",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "feature_1",
            "value_or_threshold": [1]
        }
    ]
}
```

The predicted label is selected by the "InferenceAttribute" parameter. Zero-based numbering is used, so 0 indicates the first column of the model output.

```
"EndpointInput": {
    ...
    "InferenceAttribute": 0
    ...
}
```

Alternatively, you can use different parameters to convert probability values to binary predicted labels. Zero-based numbering is used: 1 indicates the second column; the ProbabilityThresholdAttribute value of 0.6 indicates that a probability greater than 0.6 predicts the binary label as 1.

```
"EndpointInput": {
    ...
    "ProbabilityAttribute": 1,
    "ProbabilityThresholdAttribute": 0.6
    ...
}
```

**JSON Lines Datasets**

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

```json
[{
    "features": [0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499],
    "label": 0
},
{
    "features": [1, 0.6711642728531724, 0.7466687034026017, 0.1215477472819713],
    "label": 1
},
{
    "features": [0, 0.0453256543003371, 0.6377430803264152, 0.3558625219713576],
    "label": 1
},
{
    "features": [1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697],
    "label": 1
}]
```

Assume that the model output has two columns, where the first is a predicted label and the second is a probability.
The following JSON configuration file shows an example of how this JSON Lines dataset can be configured.

```json
{
  "headers": [
    "feature_0",
    "feature_1",
    "feature_2",
    "feature_3",
    "target"
  ],
  "label": "label",
  "label_values_or_threshold": [1],
  "facet": [
    {
      "name_or_index": "feature_1",
      "value_or_threshold": [1]
    }
  ]
}
```

Then, the "features" parameter value in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) is used to locate the features in the dataset, and the "predicted_label" parameter value selects the predicted label from the model output.

```
"EndpointInput": {
  ...
  "FeaturesAttribute": "features",
  "InferenceAttribute": "predicted_label"
  ...
}
```

Alternatively, you can convert probability values to predicted binary labels using the ProbabilityThresholdAttribute parameter value. A value of 0.6, for example, indicates that a probability greater than 0.6 predicts the binary label as 1.

```
"EndpointInput": {
  ...
  "FeaturesAttribute": "features",
  "ProbabilityAttribute": "probability",
  "ProbabilityThresholdAttribute": 0.6
  ...
}
```

**Schedule Bias Drift Monitoring Jobs**

After you create your baseline, you can call the `create_monitoring_schedule()` method of your `ModelBiasModelMonitor` class instance to schedule an hourly bias drift monitor. The following sections show you how to create bias drift monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

Unlike data quality monitoring, you need to supply Ground Truth labels if you want to monitor model quality. However, Ground Truth labels could be delayed. To address this, specify offsets when you create your monitoring schedule. For details about how to create time offsets, see ?? (p. 2108).

If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.
Bias drift monitoring for models deployed to real-time endpoint

To schedule a bias drift monitor for a real-time endpoint, pass your EndpointInput instance to the endpoint_input argument of your ModelBiasModelMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
model_bias_monitor = ModelBiasModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )

model_bias_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_bias_monitor.baseline_statistics(),
    constraints=model_bias_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    analysis_config=model_bias_analysis_config,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="PT1H",
        end_time_offset="PT0H",
        probability_threshold_attribute=0.8,
    ),
)
```

Bias drift monitoring for batch transform jobs

To schedule a bias drift monitor for a batch transform job, pass your BatchTransformInput instance to the batch_transform_input argument of your ModelBiasModelMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
model_bias_monitor = ModelBiasModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )
schedule = model_bias_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
)
post_analytics_processor_script=s3_code_postprocessor_uri,
output_s3_uri=s3_report_path,
statistics=model_bias_monitor.baseline_statistics(),
constraints=model_bias_monitor.suggested_constraints(),
schedule_cron_expression=CronExpressionGenerator.hourly(),
enable_cloudwatch_metrics=True,
analysis_config=model_bias_analysis_config,
batch_transform_input=BatchTransformInput(
    destination="opt/ml/processing/input",
data_captured_destination_s3_uri=s3_capture_path,
    start_time_offset="-PT1H",
    end_time_offset="-PT0H",
    probability_threshold_attribute=0.8
),
)

Inspect Reports for Data Bias Drift

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

```python
schedule_desc = model_bias_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[-1]
    last_model_bias_monitor_execution_report_uri = last_model_bias_monitor_execution.output.destination
    last_model_bias_monitor_execution_report_files = sorted(S3Downloader.list(last_model_bias_monitor_execution_report_uri))
    print("Found Report Files:")
    print\\n".join(last_model_bias_monitor_execution_report_files)
else:
    last_model_bias_monitor_execution = None
    print("====STOP==== \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures."")
```

If there are violations compared to the baseline, they are listed here:

```python
if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraint_violations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)
```

If your model is deployed to a real-time endpoint, you can see visualizations in SageMaker Studio of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

CloudWatch Metrics for Bias Drift Analysis

This guide shows CloudWatch metrics and their properties that you can use for bias drift analysis in SageMaker Clarify. Bias drift monitoring jobs compute both pretraining bias metrics and posttraining bias metrics, and publish them to the following CloudWatch namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/bias-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/bias-metrics`

The CloudWatch metric name appends the metric's short name to `bias_metric`.
For example, bias_metric_CI is the bias metric for class imbalance (CI).

**Note**

The bias metric for class imbalance (CI) is published as the floating point number \(+/- 2.348543e108\), and errors including null values are not published.

Each metric has the following properties:

- **Endpoint**: The name of the monitored endpoint, if applicable.
- **MonitoringSchedule**: The name of the schedule for the monitoring job.
- **BiasStage**: The name of the stage of the bias drift monitoring job. Choose either Pre-training or Post-Training.
- **Label**: The name of the target feature, provided by the monitoring job analysis configuration label.
- **LabelValue**: The value of the target feature, provided by the monitoring job analysis configuration label_values_or_threshold.
- **Facet**: The name of the facet, provided by the monitoring job analysis configuration facet name_of_index.
- **FacetValue**: The value of the facet, provided by the monitoring job analysis configuration facet nvalue_or_threshold.

To stop the monitoring jobs from publishing metrics, set publish_cloudwatch_metrics to Disabled in the Environment map of model bias job definition.

## Monitor Feature Attribution Drift for Models in Production

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:

### College Admission Hypothetical Scenario

<table>
<thead>
<tr>
<th>Feature</th>
<th>Attribution in training data</th>
<th>Attribution in live data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAT score</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>GPA</td>
<td>0.50</td>
<td>0.20</td>
</tr>
<tr>
<td>Class rank</td>
<td>0.05</td>
<td>0.70</td>
</tr>
</tbody>
</table>

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive
Monitor Feature Attribution Drift

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.

Model Monitor Example Notebook

SageMaker Clarify provides the following example notebook that shows how to capture inference data for a real-time endpoint, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in SageMaker Studio only. If you need instructions on how to open a notebook in SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). If you’re prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics
- Create a SHAP Baseline for Models in Production (p. 2125)
- Model Feature Attribution Drift Violations (p. 2126)
- Configure Parameters to Monitor Attribution Drift (p. 2127)
- Schedule Feature Attribute Drift Monitoring Jobs (p. 2130)
- Inspect Reports for Feature Attribute Drift in Production Models (p. 2131)
- CloudWatch Metrics for Feature Drift Analysis (p. 2132)
Create a SHAP Baseline for Models in Production

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see SHAP Baselines for Explainability (p. 1886).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- mean_abs – Mean of absolute SHAP values for all instances.
- median – Median of SHAP values for all instances.
- mean_sq – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time or batch transform inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can explain the predictions of a deployed model that's producing inferences and detect feature attribution drift on a regular basis.

```python
model_explainability_monitor = ModelExplainabilityMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it uses the same DataConfig, and the only difference is the job output URI.

```python
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/model_explainability"
model_explainability_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_explainability_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)
```

Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the explainability config is SHAPConfig, including the following:

- baseline – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values.
- num_samples – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
- agg_method – Aggregation method for global SHAP values. Following are valid values:
  - mean_abs – Mean of absolute SHAP values for all instances.
  - median – Median of SHAP values for all instances.
  - mean_sq – Mean of squared SHAP values for all instances.

2125
• `use_logit` – Indicator of whether the logit function is to be applied to the model predictions. Default is `False`. If `use_logit` is `True`, the SHAP values will have log-odds units.
• `save_local_shap_values` (bool) – Indicator of whether to save the local SHAP values in the output location. Default is `False`.

```python
# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]

shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)
```

Start a baselining job. The same `model_config` is required because the explainability baselining job needs to create a shadow endpoint to get predictions for the generated synthetic dataset.

```python
model_explainability_monitor.suggest_baseline(
    data_config=model_explainability_data_config,
    model_config=model_config,
    explainability_config=shap_config,
)
print(f"ModelExplainabilityMonitor baselining job:
{model_explainability_monitor.latest_baselining_job_name}"
)
```

## Model Feature Attribution Drift Violations

Feature attribution drift jobs evaluate the baseline constraints provided by the `baseline configuration` against the analysis results of current `MonitoringExecution`. If violations are detected, the job lists them to the `constraint_violations.json` file in the execution output location, and marks the execution status as `Interpret results` (p. 2136).

Here is the schema of the feature attribution drift violations file.

- `label` – The name of the label, job analysis configuration `label_headers` or a placeholder such as "label0".
- `metric_name` – The name of the explainability analysis method. Currently only `shap` is supported.
- `constraint_check_type` – The type of violation monitored. Currently only `feature_attribution_drift_check` is supported.
- `description` – A descriptive message to explain the violation.

```json
{
    "version": "1.0",
    "violations": [{
        "label": "string",
        "metric_name": "string",
        "constraint_check_type": "string",
        "description": "string"
    }]
}
```

For each label in the `explanations` section, the monitoring jobs calculate the nDCG score of its global SHAP values in the baseline constraints file and in the job analysis results file (`analysis.json`). If the score is less than 0.9, then a violation is logged. The combined global SHAP value is evaluated, so there are
no “feature” fields in the violation entry. The following output provides an example of several logged violations.

```
{
  "version": "1.0",
  "violations": [
    {
      "label": "label0",
      "metric_name": "shap",
      "constraint_check_type": "feature_attribution_drift_check",
      "description": "Feature attribution drift 0.7639720923277322 exceeds threshold 0.9"
    },
    {
      "label": "label1",
      "metric_name": "shap",
      "constraint_check_type": "feature_attribution_drift_check",
      "description": "Feature attribution drift 0.7323763972092327 exceeds threshold 0.9"
    }
  ]
}
```

### Configure Parameters to Monitor Attribution Drift

Amazon SageMaker Clarify explainability monitor reuses a subset of the parameters used in the analysis configuration of Configure the Analysis (p. 1852). The following parameters must be provided in a JSON file and the path must be provided in the ConfigUri parameter of ModelExplainabilityAppSpecification.

- **"version"** – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- **"headers"** – (Optional) A list of feature names in the dataset. Explainability analysis does not require labels.
- **"methods"** – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.
  - **"shap"** – (Optional) Section on SHAP value computation.
    - "baseline" – (Optional) A list of rows (at least one), or an Amazon Simple Storage Service Amazon S3 object URI. To be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values). Before you send each row to the model, omit any column that must be excluded.
    - "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values. If not provided, then a SageMaker Clarify job chooses the value based on a count of features.
    - "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
      - "mean_abs" – Mean of absolute SHAP values for all instances.
      - "median" – Median of SHAP values for all instances.
      - "mean_sq" – Mean of squared SHAP values for all instances.
      - "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The default value is false.
      - "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Use true to save them. Use false to not save them. The default is false.
  - **"predictor"** – (Optional for real-time endpoint, required for batch transform) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
    - "model_name" – Model name created by CreateModel API, with container mode as SingleModel.
• "instance_type" – Instance type for the shadow endpoint.
• "initial_instance_count" – Instance count for the shadow endpoint.
• "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as the dataset_type format.
• "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines. If omitted, SageMaker Clarify uses the response data type of the captured data.
• "content_template" – (Optional) A template string used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have only one placeholder, $features, which is replaced by the features list at runtime. For example, given "content_template":"{"myfeatures":$features}", if an instance (no label) is 1,2,3, then model input becomes JSON Lines '{"myfeatures":[1,2,3]}'.
• "label_headers" – (Optional) A list of values that the "label" takes in the dataset. Associates the scores returned by the model endpoint or batch transform job with their corresponding label values. If it is provided, then the analysis report uses the headers instead of placeholders like "label0".

The other parameters should be provided in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) of the ModelExplainabilityJobInput API.

• FeaturesAttribute – This parameter is required if endpoint or batch job input data format is "application/jsonlines". It is the JMESPath used to locate the feature columns if the dataset format is JSON Lines.
• ProbabilityAttribute – Index or JMESPath location in the model output for probabilities. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations.

Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for feature attribution drift.

Topics
• CSV Datasets (p. 2128)
• JSON Lines Datasets (p. 2129)

CSV Datasets

Consider a dataset that has three numerical feature columns, as in the following example.

0.5814568701544718, 0.6651538910132964, 0.3138080342665499
0.6711642728531724, 0.7466687034026017, 0.1215477472819713
0.0453256543003371, 0.6377430803264152, 0.3558625219713576
0.4785191813363956, 0.0265841045263860, 0.0376935084990697

Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

1, 0.5385257417814224

The following example JSON configuration file shows how this CSV dataset can be configured.
The predicted label is selected by the "ProbabilityAttribute" parameter. Zero-based numbering is used, so 1 indicates the second column of the model output.

```json
"EndpointInput": {
  "..."
  "ProbabilityAttribute": 1
  "..."
}
```

**JSON Lines Datasets**

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

```json
["features": [0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499], "label": 0]
["features": [1, 0.6711642728531724, 0.7466687034026017, 0.1215477472819713], "label": 1]
["features": [0, 0.0453256543003371, 0.6377430803264152, 0.3558625219713576], "label": 1]
["features": [1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697], "label": 1]
```

The model input is the same as the dataset format, and the model output are JSON Lines, as in the following example.

```json
{"predicted_label": 1, "probability": 0.5385257417814224}
```

In the following example, the JSON configuration file shows how this JSON Lines dataset can be configured.

```json
{
  "headers": [
    "feature_1",
    "feature_2",
    "feature_3"
  ],
  "methods": {
    "shap": {
      "baseline": [
        0.44411649646610942, 0.5190374448171748, 0.20722795300473712
      ],
      "num_samples": 100,
      "agg_method": "mean_abs"
    }
  },
  "predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1
  }
}
```
Then the "features" parameter value in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) is used to locate the features in the dataset, and the "probability" parameter value selects the probability value from model output.

Schedule Feature Attribute Drift Monitoring Jobs

After you create your SHAP baseline, you can call the create_monitoring_schedule() method of your ModelExplainabilityMonitor class instance to schedule an hourly model explainability monitor. The following sections show you how to create a model explainability monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. ModelConfig is required by ExplainabilityAnalysisConfig for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude Ground Truth labeling.

Feature attribution drift monitoring for models deployed to real-time endpoint

To schedule a model explainability monitor for a real-time endpoint, pass your EndpointInput instance to the endpoint_input argument of your ModelExplainabilityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_exp_model_monitor = ModelExplainabilityMonitor(  
    role=sagemaker.get_execution_role(),
    ...
)

schedule = model_exp_model_monitor.create_monitoring_schedule(  
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_exp_model_monitor.baseline_statistics(),
    constraints=model_exp_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    ...
)
```
enable_cloudwatch_metrics=True,
endpoint_input=EndpointInput(
    endpoint_name=endpoint_name,
    destination="/opt/ml/processing/input/endpoint",
)  
}

Feature attribution drift monitoring for batch transform jobs

To schedule a model explainability monitor for a batch transform job, pass your 
BatchTransformInput instance to the batch_transform_input argument of your 
ModelExplainabilityMonitor instance, as shown in the following code sample:

from sagemaker.model_monitor import CronExpressionGenerator
model_exp_model_monitor = ModelExplainabilityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
schedule = model_exp_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_exp_model_monitor.baseline_statistics(),
    constraints=model_exp_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    batch_transform_input=BatchTransformInput(
        destination="opt/ml/processing/data",
        model_name="batch-fraud-detection-model",
        input_manifests_s3_uri="s3://my-bucket/batch-fraud-detection/on-schedule-
        monitoring/in/",
        excludeFeatures="0",
    )
)

Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for the its first execution to 
start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

schedule_desc = model_explainability_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_explainability_monitor_execution =
    model_explainability_monitor.list_executions()[-1]
    last_model_explainability_monitor_execution_report_uri =
    last_model_explainability_monitor_execution.output.destination
    print(f"Report URI: {last_model_explainability_monitor_execution_report_uri}")
    last_model_explainability_monitor_execution_report_files =
    sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("====STOP==== \n No completed executions to inspect further. Please wait till an 
 execution completes or investigate previously reported failures.")

If there are any violations compared to the baseline, they are listed here:

```python
if last_model_explainability_monitor_execution:
    model_explainability_violations = last_model_explainability_monitor_execution.constraint_violations()
    if model_explainability_violations:
        print(model_explainability_violations.body_dict)
```

If your model is deployed to a real-time endpoint, you can see visualizations in SageMaker Studio of the analysis results and CloudWatch metrics by choosing the Endpoints tab, and then double-clicking the endpoint.

**CloudWatch Metrics for Feature Drift Analysis**

This guide shows CloudWatch metrics and their properties that you can use for feature attribute drift analysis in SageMaker Clarify. Feature attribute drift monitoring jobs compute and publish two types of metrics:

- The global SHAP value of each feature.

  **Note**
  The name of this metric appends the feature name provided by the job analysis configuration to `feature_`. For example, `feature_X` is the global SHAP value for feature `X`.

- The `ExpectedValue` of the metric.

These metrics are published to the following CloudWatch namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/explainability-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/explainability-metrics`

Each metric has the following properties:

- **Endpoint**: The name of the monitored endpoint, if applicable.
- **MonitoringSchedule**: The name of the schedule for the monitoring job.
- **ExplainabilityMethod**: The method used to compute Shapley values. Choose KernelShap.
- **Label**: The name provided by job analysis configuration `label_headers`, or a placeholder like `label0`.
- **ValueType**: The type of the value returned by the metric. Choose either `GlobalShapValues` or `ExpectedValue`.

To stop the monitoring jobs from publishing metrics, set `publish_cloudwatch_metrics` to `Disabled` in the Environment map of `model explainability job` definition.

**Schedule monitoring jobs**

Amazon SageMaker Model Monitor provides you the ability to monitor the data collected from your real-time endpoints on a continuous schedule or from your batch transform jobs on a specific schedule. You can create a monitoring schedule with the `CreateMonitoringSchedule` API with a predefined periodic interval. For example, every x hours (x can range from 1 to 23).

With a monitoring schedule, SageMaker can kick off processing jobs at a specified frequency to analyze the data collected during a given period. SageMaker provides a prebuilt container for performing analysis on tabular datasets. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics, constraints provided and generate a violations report. In addition,
CloudWatch metrics are emitted for each feature under analysis. Alternatively, you could choose to bring your own container as outlined in the Bring Your Own Containers (p. 2148) topic.

You can create a model monitoring schedule for your real-time endpoint or batch transform job. Use the baseline resources (constraints and statistics) to compare against the real-time traffic or batch job inputs. In the following example, the training dataset used to train the model was uploaded to Amazon S3. If you already have it in Amazon S3, you can point to it directly.

```python
# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'

baseline_data_uri = 's3://{}/{}'.format(bucket, baseline_data_prefix)
baseline_results_uri = 's3://{}/{}'.format(bucket, baseline_results_prefix)
print('Baseline data uri: {}'.format(baseline_data_uri))
print('Baseline results uri: {}'.format(baseline_results_uri))

training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
s3_key = os.path.join(baseline_prefix, 'data', 'training-dataset-with-header.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(training_data_file)
```

If you are scheduling a model monitor for a real-time endpoint, use the baseline constraints and statistics to compare against real-time traffic. The following code snippet shows the general format you use to schedule a model monitor for a real-time endpoint.

```python
from sagemaker.model_monitor import CronExpressionGenerator
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    endpoint_input=EndpointInput(  
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint"
    ),
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

The following code snippet shows the general format you use to schedule a model monitor for a batch transform job.

```python
from sagemaker.model_monitor import (  
    CronExpressionGenerator,
    BatchTransformInput,
    MonitoringDatasetFormat,
)
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    input=BatchTransformInput(
        source=TrainingDatasetFormat(input='s3://boston-housing-house-prices-dataset-training-data'),
    ),
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```
batch_transform_input=BatchTransformInput(
    destination="opt/ml/processing/input",
    data_captured_destination_s3_uri=s3_capture_upload_path,
    dataset_format=MonitoringDatasetFormat.csv(header=False),
)
post_analytics_processor_script=s3_code_postprocessor_uri,
output_s3_uri=s3_report_path,
statistics=my_default_monitor.baseline_statistics(),
constraints=my_default_monitor.suggested_constraints(),
schedule_cron_expression=CronExpressionGenerator.hourly(),
enable_cloudwatch_metrics=True,
)
```

Describe and inspect the schedule: After you describe it, observe that the
MonitoringScheduleStatus in MonitoringScheduleSummary returned by the
ListMonitoringSchedules API changes to Scheduled.

```
desc_schedule_result = my_default_monitor.describe_schedule()
print('Schedule status: {}'.format(desc_schedule_result['MonitoringScheduleStatus']))
```

The cron expression for monitoring schedule

To provide details for the monitoring schedule, use ScheduleConfig, which is a cron expression that
describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following cron expressions:

- To set the job to start every hour, use the following:
  
  Hourly: `cron(0 * ? * *)`

- To run the job daily, use the following:
  
  `cron(0 [00-23] ? * *)`

For example, the following are valid cron expressions:

- Daily at 12 PM UTC: `cron(0 12 ? * *)`
- Daily at 12 AM UTC: `cron(0 0 ? * *)`

To support running every 6, 12 hours, Model Monitor supports the following expression:

`cron(0 [00-23]/[01-24] ? * *)`

For example, the following are valid cron expressions:

- Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * *)`
- Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * *)`

Notes

- Although the cron expression is set to start at 5 PM UTC, note that there could be a delay of
  0-20 minutes from the actual requested time to run the execution.
- If you want to run on a daily schedule, don't provide this parameter. SageMaker picks a time
to run every day.
- Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.
Amazon SageMaker Model Monitor prebuilt container

SageMaker provides a built-in image called sagemaker-model-monitor-analyzer that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This image is based on Spark and is built with Deequ.

**Note**

You cannot pull the built-in sagemaker-model-monitor-analyzer image directly. You can use the sagemaker-model-monitor-analyzer image when you submit a baseline processing or monitoring job using one of the AWS SDKs.

Use the SageMaker Python SDK (see `image_uris.retrieve` in the SageMaker Python SDK reference guide) to generate the ECR image URI for you, or specify the ECR image URI directly. The prebuilt image for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer`

For example: `159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer`

If you are in an AWS region in China, the prebuilt images for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com.cn/sagemaker-model-monitor-analyzer`

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>

</tbody>
</table>
To write your own analysis container, see the container contract described in Customize monitoring (p. 2144).

### Interpret results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see Visualize results for real-time endpoints in Amazon SageMaker Studio (p. 2138).

### List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```python
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus 0 - 20 min buffer.
We will have to wait till we hit the hour...")

while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()
```

### Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
Failed – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the FailureReason and ExitMessage.

```python
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and so on..
time.sleep(60)
latest_execution.wait(logs=False)
print("Latest execution status: {}".format(latest_execution.describe()['ProcessingJobStatus']))
print("Latest execution result: {}".format(latest_execution.describe()['ExitMessage']))

latest_job = latest_execution.describe()
if (latest_job['ProcessingJobStatus'] != 'Completed'):
    print("====STOP==== \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")

report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))
```

### List Generated Reports

List the generated reports.

```python
from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/')
print('Report bucket: {}'.format(report_bucket))
print('Report key: {}'.format(report_key))

s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get('Key') for report_file in result.get('Contents')]
print("\n Found Report Files:")
print("\n ".join(report_files))
```

### Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

```python
violations = my_default_monitor.latest_monitoring_constraint_violations()
pd.set_option('display.max_colwidth', -1)
constraints_df = pd.io.json.json_normalize(violations.body_dict['violations'])
constraints_df.head(10)
```

This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

### Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic.</td>
</tr>
</tbody>
</table>
### File Name and Description

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>This file is created only for data quality monitoring.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics paths.</td>
</tr>
</tbody>
</table>

The **Amazon SageMaker Model Monitor** prebuilt container (p. 2135) saves a set of Amazon CloudWatch metrics for each feature by default.

The container code can emit CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

#### Visualize results for real-time endpoints in Amazon SageMaker Studio

If you are monitoring a real-time endpoint, you can also visualize the results in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

**To view the detailed results of a monitoring job**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. Choose **Endpoints** in the drop-down menu.
4. On the endpoint tab, choose the monitoring type for which you want to see job details.

5. Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.
6. The **MONITORING JOB DETAILS** tab opens with a detailed report of the monitoring job.

You can create a chart that displays the baseline and captured metrics for a time period.
To create a chart in SageMaker Studio to visualize monitoring results

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Components and registries icon (✓).
3. Choose Endpoints in the drop-down menu.

   ![Endpoints](image)

4. On the Endpoint tab, choose the monitoring type you want to create a chart for. This example shows a chart for the Model quality monitoring type.
5. Choose Add chart.

6. On the **CHART PROPERTIES** tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a **Timeline** of 1 week, the **Average Statistic** of, and the **F1 Metric**.
7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.
Advanced topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use AWS CloudFormation to create a monitoring schedule.

Topics
- Customize monitoring (p. 2144)
- Create a Monitoring Schedule for a Real-time Endpoint with an AWS CloudFormation Custom Resource (p. 2156)

Customize monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

Topics
- Preprocessing and Postprocessing (p. 2144)
- Bring Your Own Containers (p. 2148)

Preprocessing and Postprocessing

You can use custom preprocessing and postprocessing Python scripts to transform the input to your model monitor or extend the code after a successful monitoring run. Upload these scripts to Amazon S3 and reference them when creating your model monitor.

The following example shows how you can customize monitoring schedules with preprocessing and postprocessing scripts. Replace user placeholder text with your own information.

```python
import boto3, os
from sagemaker import get_execution_role, Session
from sagemaker.model_monitor import CronExpressionGenerator, DefaultModelMonitor

# Upload pre and postprocessor scripts
```
Amazon SageMaker Developer Guide
Advanced topics

```python
session = Session()
bucket = boto3.Session().resource("s3").Bucket(session.default_bucket())
prefix = "demo-sagemaker-model-monitor"
pre_processor_script = bucket.Object(os.path.join(prefix, "preprocessor.py")).upload_file("preprocessor.py")
post_processor_script = bucket.Object(os.path.join(prefix, "postprocessor.py")).upload_file("postprocessor.py")

# Get execution role
role = get_execution_role() # can be an empty string

# Instance type
instance_type = "instance-type"
# instance_type = "ml.m5.xlarge" # Example

# Create a monitoring schedule with pre and postprocessing
my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type=instance_type,
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

s3_report_path = "s3://{}/{}".format(bucket, "reports")
monitor_schedule_name = "monitor-schedule-name"
endpoint_name = "endpoint-name"
my_default_monitor.create_monitoring_schedule(
    post_analytics_processor_script=post_processor_script,
    record_preprocessor_script=pre_processor_script,
    monitor_schedule_name=monitor_schedule_name,
    # use endpoint_input for real-time endpoint
    endpoint_input=endpoint_name,
    # or use batch_transform_input for batch transform jobs
    # batch_transform_input=batch_transform_name,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Topics

- Preprocessing Script (p. 2145)
- Custom Sampling (p. 2148)
- Postprocessing Script (p. 2148)

### Preprocessing Script

Use preprocessing scripts when you need to transform the inputs to your model monitor.

For example, suppose the output of your model is an array \([1.0, 2.1]\). The Amazon SageMaker Model Monitor container only works with tabular or flattened JSON structures, like \{"prediction0": 1.0, "prediction1": 2.1\}. You could use a preprocessing script like the following to transform the array into the correct JSON structure.

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data.rstrip("\n")
    data = output_data + "," + input_data
    return { str(i).zfill(20) : d for i, d in enumerate(data.split(\",")) }
```
In another example, suppose your model has optional features and you use -1 to denote that the optional feature has a missing value. If you have a data quality monitor, you may want to remove the -1 from the input value array so that it isn’t included in the monitor’s metric calculations. You could use a script like the following to remove those values.

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    return {i : None if x == -1 else x for i, x in enumerate(input_data.split(","))}
```

Your preprocessing script receives an `inference_record` as its only input. The following code snippet shows an example of an `inference_record`.

```json
{
    "captureData": {
        "endpointInput": {
            "observedContentType": "text/csv",
            "mode": "INPUT",
            "data": "132,25,113.2,96,269.9,107,,0,0,0,0,0,0,1,0,1,0,0,1",
            "encoding": "CSV"
        },
        "endpointOutput": {
            "observedContentType": "text/csv; charset=utf-8",
            "mode": "OUTPUT",
            "data": "0.01076381653547287",
            "encoding": "CSV"
        }
    },
    "eventMetadata": {
        "eventId": "feca1ab1-8025-47e3-8f6a-99e3fdd7b8d9",
        "inferenceTime": "2019-11-20T23:33:12Z"
    },
    "eventVersion": "0"
}
```

The following code snippet shows the full class structure for an `inference_record`.

```python
KEY_EVENT_METADATA = "eventMetadata"
KEY_EVENT_METADATA_EVENT_ID = "eventId"
KEY_EVENT_METADATA_EVENT_TIME = "inferenceTime"
KEY_EVENT_METADATA_CUSTOM_ATTR = "customAttributes"

KEY_EVENTDATA_ENCODING = "encoding"
KEY_EVENTDATA_DATA = "data"

KEY_GROUND_TRUTH_DATA = "groundTruthData"

class EventConfig:
    def __init__(self, endpoint, variant, start_time, end_time):
```
self.endpoint = endpoint
self.variant = variant
self.start_time = start_time
self.end_time = end_time

class EventMetadata:
    def __init__(self, event_metadata_dict):
        self.event_id = event_metadata_dict.get(KEY_EVENT_METADATA_EVENT_ID, None)
        self.event_time = event_metadata_dict.get(KEY_EVENT_METADATA_EVENT_TIME, None)
        self.custom_attribute = event_metadata_dict.get(KEY_EVENT_METADATA_CUSTOM_ATTR, None)

class EventData:
    def __init__(self, data_dict):
        self.encoding = data_dict.get(KEY_EVENTDATA_ENCODING, None)
        self.data = data_dict.get(KEY_EVENTDATA_DATA, None)
        self.observedContentType = data_dict.get(KEY_EVENTDATA_OBSERVED_CONTENT_TYPE, None)
        self.mode = data_dict.get(KEY_EVENTDATA_MODE, None)

    def as_dict(self):
        ret = {
            KEY_EVENTDATA_ENCODING: self.encoding,
            KEY_EVENTDATA_DATA: self.data,
            KEY_EVENTDATA_OBSERVED_CONTENT_TYPE: self.observedContentType,
        }
        return ret

class CapturedData:
    def __init__(self, event_dict):
        self.event_metadata = None
        self.endpoint_input = None
        self.endpoint_output = None
        self.batch_transform_output = None
        self.ground_truth = None
        self.event_version = None
        self.event_dict = event_dict
        self._event_dict_postprocessed = False

        if KEY_EVENT_METADATA in event_dict:
            self.event_metadata = EventMetadata(event_dict[KEY_EVENT_METADATA])
        if KEY_EVENTDATA in event_dict:
            if KEY_EVENTDATA_ENDPOINT_INPUT in event_dict[KEY_EVENTDATA]:
                self.endpoint_input = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_INPUT])
            if KEY_EVENTDATA_ENDPOINT_OUTPUT in event_dict[KEY_EVENTDATA]:
                self.endpoint_output = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_OUTPUT])
            if KEY_EVENTDATA_BATCH_OUTPUT in event_dict[KEY_EVENTDATA]:
                self.batch_transform_output = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_BATCH_OUTPUT])
            if KEY_GROUND_TRUTH_DATA in event_dict:
                self.ground_truth = EventData(event_dict[KEY_GROUND_TRUTH_DATA])
            if KEY_EVENT_VERSION in event_dict:
                self.event_version = event_dict[KEY_EVENT_VERSION]

    def as_dict(self):
        if self._event_dict_postprocessed is True:
            return self.event_dict
        if KEY_EVENTDATA in self.event_dict:
            if KEY_EVENTDATA_ENDPOINT_INPUT in self.event_dict[KEY_EVENTDATA]:
                self.event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_INPUT] =
                self.endpoint_input.as_dict()
if KEY_EVENTDATA_ENDPOINT_OUTPUT in self.event_dict[KEY_EVENTDATA]:
    self.event_dict[KEY_EVENTDATA][
        KEY_EVENTDATA_ENDPOINT_OUTPUT
    ] = self.endpoint_output.as_dict()
if KEY_EVENTDATA_BATCH_OUTPUT in self.event_dict[KEY_EVENTDATA]:
    self.event_dict[KEY_EVENTDATA][KEY_EVENTDATA_BATCH_OUTPUT] =
    self.batch_transform_output.as_dict()

self._event_dict_postprocessed = True
return self.event_dict

def __str__(self):
    return str(self.as_dict())

## Custom Sampling

You can also apply a custom sampling strategy in your preprocessing script. To do this, configure Model Monitor's first-party, pre-built container to ignore a percentage of the records according to your specified sampling rate. In the following example, the handler samples 10 percent of the records by returning the record in 10 percent of handler calls and an empty list otherwise.

```python
import random

def preprocess_handler(inference_record):
    # we set up a sampling rate of 0.1
    if random.random() > 0.1:
        # return an empty list
        return []
    input_data = inference_record.endpoint_input.data
    return {i : None if x == -1 else x for i, x in enumerate(input_data.split(","))}
```

## Postprocessing Script

Use a postprocessing script when you want to extend the code following a successful monitoring run.

```python
def postprocess_handler():
    print("Hello from post-proc script!")
```

## Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints or batch transform jobs for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a MonitoringSchedule, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the Build Your Own Processing Container (Advanced Scenario) (p. 1108) topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the Container Contract Inputs (p. 2149).

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can chose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in Container Contract Outputs (p. 2151). If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.
You also emit CloudWatch metrics from the container by following the instructions in CloudWatch Metrics for Bring Your Own Containers (p. 2155).

Topics
- Container Contract Inputs (p. 2149)
- Container Contract Outputs (p. 2151)
- CloudWatch Metrics for Bring Your Own Containers (p. 2155)

Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you choose to write your own container code, the following environment variables are available. In this context, you can analyze the current dataset or evaluate the constraints if you choose and emit metrics, if applicable.

The available environment variables are the same for real-time endpoints and batch transform jobs, except for the dataset_format variable. If you are using a real-time endpoint, the dataset_format variable supports the following options:

```
{"sagemakerCaptureJson": {"captureIndexNames": ["endpointInput","endpointOutput"]}}
```

If you are using a batch transform job, the dataset_format supports the following options:

```
{"csv": {"header": ["true","false"]}}
```

```
{"json": {"line": ["true","false"]}}
```

```
{"parquet": {}}
```

The following code sample shows the complete set of environment variables available for your container code (and uses the dataset_format format for a real-time endpoint).

```
"Environment": {
  "dataset_format": "{"sagemakerCaptureJson": {"captureIndexNames": ["endpointInput","endpointOutput"]}}",
  "dataset_source": "/opt/ml/processing/endpointdata",
  "end_time": "2019-12-01T16:00:00Z",
  "output_path": "/opt/ml/processing/resultdata",
  "publish_cloudwatch_metrics": "Disabled",
  "sagemaker_endpoint_name": "endpoint-name",
  "sagemaker_monitoring_schedule_name": "schedule-name",
  "start_time": "2019-12-01T15:00:00Z"
}
```

Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset_format</td>
<td>For a job started from a MonitoringSchedule backed by an Endpoint, this is sagemakerCaptureJson with the capture indices endpointInput, or endpointOutput, or both. For a batch transform job, this specifies the data format, whether CSV, JSON, or Parquet.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>dataset_source</td>
<td>If you are using a real-time endpoint, the local path in which the data corresponding to the monitoring period, as specified by start_time and end_time, are available. At this path, the data is available in /{endpoint-name}/{variant-name}/yyyy/mm/dd/hh. We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.</td>
</tr>
<tr>
<td>output_path</td>
<td>The local path to write output reports and other files. You specify this parameter in the CreateMonitoringSchedule request as MonitoringOutputConfig.MonitoringOutput[0].LocalPath. It is uploaded to the S3Uri path specified in MonitoringOutputConfig.MonitoringOutput[0].S3Uri.</td>
</tr>
<tr>
<td>publish_cloudwatch_metrics</td>
<td>For a job launched by CreateMonitoringSchedule, this parameter is set to Enabled. The container can choose to write the Amazon CloudWatch output file at [filepath].</td>
</tr>
<tr>
<td>sagemaker_endpoint_name</td>
<td>If you are using a real-time endpoint, the name of the Endpoint that this scheduled job was launched for.</td>
</tr>
<tr>
<td>sagemaker_monitoring_schedule_name</td>
<td>The name of the MonitoringSchedule that launched this job.</td>
</tr>
<tr>
<td><em>sagemaker_endpoint_datacapture_prefix</em></td>
<td>If you are using a real-time endpoint, the prefix specified in the DataCaptureConfig parameter of the Endpoint. The container can use this if it needs to directly access more data than already downloaded by SageMaker at the dataset_source path.</td>
</tr>
<tr>
<td>start_time, end_time</td>
<td>The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, start_time: is 2020-02-19T06:00:00Z and end_time: is 2020-02-20T05:00:00Z</td>
</tr>
<tr>
<td>baseline_constraints:</td>
<td>The local path of the baseline constraint file specified in BaselineConfig.ConstraintResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
--- | ---
baseline_statistics | The local path to the baseline statistics file specified in \BaselineConfig.StatisticsResource.S3Uri. This is available only if this parameter was specified in the \CreateMonitoringSchedule request.:

---

**Container Contract Outputs**

The container can analyze the data available in the *dataset_source* path and write reports to the path in *output_path*. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API. This applies only to tabular datasets.

**Output Files for Tabular Datasets**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics path.</td>
</tr>
</tbody>
</table>

In addition, if the `publish_cloudwatch_metrics` value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`. The schema for these files is described in the following sections.

**Topics**

- Schema for Statistics (statistics.json file) (p. 2151)
- Schema for Constraints (constraints.json file) (p. 2153)

**Schema for Statistics (statistics.json file)**

The schema defined in the statistics.json file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by KLL, a very compact quantiles sketch with lazy compaction scheme.

```json
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
```
"features": [

    {
    "name": "feature-name",
    "inferred_type": "Fractional" | "Integral",
    "numerical_statistics": {
        "common": {
            "num_present": number,
            "num_missing": number
        },

                    },
                    "data": [
                        [num, num, num, num],
                        [num, num]
                ]
            }
        }
    }
    },

    {
    "name": "feature-name",
    "inferred_type": "String",
    "string_statistics": {
        "common": {
            "num_present": number,
            "num_missing": number
        },
        "distinct_count": number,
        "distribution": {
            "categorical": {
                "buckets": [
                    {
                        "value": "string",
                        "count": number
                    }
                ]
            }
        }
    }
    }
]}
Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- KLL sketch is the recognized sketch. Custom containers can write their own representation, but it won't be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can't change this.

Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```json
{
    "version": 0,
    "features": [
        {
            "name": "string",
            "inferred_type": "Integral" | "Fractional" | "String" | "Unknown",
            "completeness": number, # denotes observed non-null value percentage
            "num_constraints": {
                "is_non_negative": boolean,
            },
            "string_constraints": {
                "domains": [
                    "list of",
                    "observed values",
                    "for small cardinality"
                ],
            },
            "monitoringConfigOverrides": {
            }
        }
    ]
}
```

# features

# options to control monitoring for this feature with monitoring jobs
# See the following table for notes on what each constraint is doing.
"monitoring_config": {
    "evaluate_constraints": "Enabled",
    "emit_metrics": "Enabled",
    "datatype_check_threshold": 0.1,
    "domain_content_threshold": 0.1,

<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>comparison_threshold</td>
<td>If the threshold is above the value set for the <code>comparison_threshold</code>, this causes a failure that is treated as a violation in the violation report. The distance is calculated by getting the maximum absolute difference between the cumulative distribution functions of two distributions.</td>
</tr>
<tr>
<td></td>
<td>Default: 0.1</td>
</tr>
<tr>
<td>comparison_method</td>
<td>Whether to calculate <code>linf_simple</code> or <code>linf_robust</code>. The <code>linf_simple</code> is based on the maximum absolute difference between the cumulative distribution functions of two distributions. Calculating <code>linf_robust</code> is based on <code>linf_simple</code>, but is used when there are not enough samples. The <code>linf_robust</code> formula is based on the Two-sample Kolmogorov–Smirnov test.</td>
</tr>
</tbody>
</table>

**CloudWatch Metrics for Bring Your Own Containers**

If the `publish_cloudwatch_metrics` value is Enabled in the Environment map in the `/opt/ml/processing/processingjobconfig.json` file, the container code emits Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`

The schema for this file is closely based on the CloudWatch PutMetrics API. The namespace is not specified here. It defaults to the following:

- For real-time endpoints: `/aws/sagemaker/Endpoint/data-metrics`
- For batch transform jobs: `/aws/sagemaker/ModelMonitoring/data-metrics`

However, you can specify dimensions. We recommend you add the following dimensions at minimum:

- Endpoint and MonitoringSchedule for real-time endpoints
- MonitoringSchedule for batch transform jobs

The following JSON snippets show how to set your dimensions.

For a real-time endpoint, see the following JSON snippet which includes the Endpoint and MonitoringSchedule dimensions:

```json
{
    "MetricName": "", # Required
    "Timestamp": "2019-11-26T03:00:00Z", # Required
```
For a batch transform job, see the following JSON snippet which includes the MonitoringSchedule dimension:

```
{
    "MetricName": "", # Required
    "Timestamp": "2019-11-26T03:00:00Z", # Required
    "Dimensions": [{"Name":"MonitoringSchedule","Value":"schedule_0"}]
    "Value": Float,
    # Either the Value or the StatisticValues field can be populated and not both.
    "StatisticValues": {
        "SampleCount": Float,
        "Sum": Float,
        "Minimum": Float,
        "Maximum": Float
    },
    "Unit": "Count", # Optional
}
```

Create a Monitoring Schedule for a Real-time Endpoint with an AWS CloudFormation Custom Resource

If you are using a real-time endpoint, you can use a AWS CloudFormation custom resource to create a monitoring schedule. The custom resource is in Python. To deploy it, see Python Lambda deployment.

**Custom Resource**

Start by adding a custom resource to your AWS CloudFormation template. This points to a AWS Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule. You can add or remove more parameters by modifying the AWS CloudFormation resource and the Lambda function in the following example resource.

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "MonitoringSchedule": {
            "Type": "Custom::MonitoringSchedule",
            "Version": "1.0",
            "Properties": {
                "ScheduleName": "YourScheduleName",
                "EndpointName": "YourEndpointName",
                "BaselineConstraintsUri": "s3://your-baseline-constraints/constraints.json",
```
Lambda Custom Resource Code

This AWS CloudFormation custom resource uses the Custom Resource Helper AWS library, which you can install with pip using `pip install crhelper`.

This Lambda function is invoked by AWS CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```python
import boto3
import botocore
import logging
from crhelper import CfnResource
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')

# cfhelper makes it easier to implement a CloudFormation custom resource
helper = CfnResource()

# CFN Handlers

def handler(event, context):
    helper(event, context)

@helper.create
def create_handler(event, context):
    '''
    Called when CloudFormation custom resource sends the create event
    '''
    create_monitoring_schedule(event)

@helper.delete
def delete_handler(event, context):
    '''
    Called when CloudFormation custom resource sends the delete event
    '''
    schedule_name = get_schedule_name(event)
    delete_monitoring_schedule(schedule_name)

@helper.poll_create
```

Serverless Inference

Amazon SageMaker Serverless Inference is a purpose-built inference option that makes it easy for you to deploy and scale ML models. Serverless Inference is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies. This takes away the undifferentiated heavy lifting of selecting and managing servers. Serverless Inference integrates with AWS Lambda to offer you high availability, built-in fault tolerance and automatic scaling.

With a pay-per-use model, Serverless Inference is a cost-effective option if you have an infrequent or unpredictable traffic pattern. During times when there are no requests, Serverless Inference scales
your endpoint down to 0, helping you to minimize your costs. For more information about pricing for Serverless Inference, see Amazon SageMaker Pricing.

You can integrate Serverless Inference with your MLOps Pipelines to streamline your ML workflow, and you can use a serverless endpoint to host a model registered with Model Registry (p. 2232).

Serverless Inference is generally available in all AWS commercial Regions where SageMaker is available (except the AWS China Regions). For more information about Amazon SageMaker regional availability, see the AWS Regional Services List.

How it works

The following diagram shows the workflow of Serverless Inference and the benefits of using a serverless endpoint.

When you create a serverless endpoint, SageMaker provisions and manages the compute resources for you. Then, you can make inference requests to the endpoint and receive model predictions in response. SageMaker scales the compute resources up and down as needed to handle your request traffic, and you only pay for what you use.

The following sections provide additional details about Serverless Inference and how it works.

Topics
- Container support (p. 2160)
- Memory size (p. 2161)
- Concurrent invocations (p. 2161)
- Cold starts (p. 2161)
- Feature exclusions (p. 2162)

Container support

For your endpoint container, you can choose either a SageMaker-provided container or bring your own. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a list of available SageMaker images, see Available Deep Learning Containers Images. If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see Adapting Your Own Inference Container (p. 3279).

The maximum size of the container image you can use is 10 GB. For serverless endpoints, we recommend creating only one worker in the container and only loading one copy of the model. Note that this is unlike real-time endpoints, where some SageMaker containers may create a worker for each vCPU to process inference requests and load the model in each worker.
If you already have a container for a real-time endpoint, you can use the same container for your serverless endpoint, though some capabilities are excluded. To learn more about the container capabilities that are not supported in Serverless Inference, see Feature exclusions (p. 2162). If you choose to use the same container, SageMaker escrows (retains) a copy of your container image until you delete all endpoints that use the image. SageMaker encrypts the copied image at rest with a SageMaker-owned AWS KMS key.

**Memory size**

Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs. Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Regardless of the memory size you choose, your serverless endpoint has 5 GB of ephemeral disk storage available. For help with container permissions issues when working with storage, see Troubleshooting (p. 2174).

**Concurrent invocations**

Serverless Inference manages predefined scaling policies and quotas for the capacity of your endpoint. Serverless endpoints have a quota for how many concurrent invocations can be processed at the same time. If the endpoint is invoked before it finishes processing the first request, then it handles the second request concurrently. For the US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), and Europe (Ireland) Regions, the total concurrency you can share between all serverless endpoints per Region in your account is 1000. For the US West (N. California), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Osaka), Asia Pacific (Seoul), Canada (Central), Europe (London), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo) Regions, the total concurrency per Region is 500. You can set the maximum concurrency for a single endpoint up to 200, and the total number of serverless endpoints you can host in a Region is 50. The maximum concurrency for an individual endpoint prevents that endpoint from taking up all of the invocations allowed for your account, and any endpoint invocations beyond the maximum are throttled.

To learn how to set the maximum concurrency for your endpoint, see Create an endpoint configuration (p. 2166). For more information about quotas and limits, see Amazon SageMaker endpoints and quotas in the AWS General Reference. To request a service limit increase, contact AWS Support. For instructions on how to request a service limit increase, see Supported Regions and Quotas (p. 33).

**Cold starts**

If your endpoint does not receive traffic for a while and then your endpoint suddenly receives new requests, it can take some time for your endpoint to spin up the compute resources to process the requests. This is called a cold start. Since serverless endpoints provision compute resources on demand, your endpoint may experience cold starts. A cold start can also occur if your concurrent requests exceed the current concurrent request usage. The cold start time depends on your model size, how long it takes to download your model, and the start-up time of your container.

To monitor how long your cold start time is, you can use the Amazon CloudWatch metric ModelSetupTime to monitor your serverless endpoint. This metric tracks the time it takes to launch new compute resources for your endpoint. To learn more about using CloudWatch metrics with serverless endpoints, see Monitor a Serverless Endpoint (p. 2174).
Feature exclusions

Some of the features currently available for SageMaker Real-time Inference are not supported for Serverless Inference, including GPUs, AWS marketplace model packages, private Docker registries, Multi-Model Endpoints, VPC configuration, network isolation, data capture, multiple production variants, Model Monitor, and inference pipelines.

You cannot convert your instance-based, real-time endpoint to a serverless endpoint. If you try to update your real-time endpoint to serverless, you receive a `ValidationError` message. You can convert a serverless endpoint to real-time, but once you make the update, you cannot roll it back to serverless.

Getting started

You can create, update, describe, and delete a serverless endpoint using the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. You can invoke your endpoint using the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. For more information about how to set up and use a serverless endpoint, read the guide Create, Invoke, Update, and Delete an Endpoint (p. 2162).

Example notebooks and blogs

For Jupyter notebook examples that show end-to-end serverless endpoint workflows, see the Serverless Inference example notebooks.

Create, Invoke, Update, and Delete an Endpoint

Unlike other SageMaker real-time endpoints, Serverless Inference manages compute resources and scaling policies for you, reducing complexity so you can focus on your ML model instead of on managing infrastructure. The following guide highlights the key capabilities of serverless endpoints: how to create, invoke, update, describe, or delete an endpoint. You can use the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, or the AWS CLI to manage your serverless endpoints.

Topics

- Prerequisites (p. 2162)
- Create a serverless endpoint (p. 2164)
- Invoke a serverless endpoint (p. 2172)
- Update a serverless endpoint (p. 2172)
- Describe a serverless endpoint (p. 2173)
- Delete a serverless endpoint (p. 2174)

Prerequisites

Before you can create a serverless endpoint, complete the following prerequisites.

1. **Set up an AWS account.** You first need an AWS account and an AWS Identity and Access Management administrator user. For instructions on how to set up an AWS account, see How do I create and activate a new AWS account?. For instructions on how to secure your account with an IAM administrator user, see Creating your first IAM admin user and user group in the IAM User Guide.

2. **Create an Amazon S3 bucket.** You use an Amazon S3 bucket to store your model artifacts. To learn how to create a bucket, see Create your first S3 bucket in the Amazon S3 User Guide.

3. **Upload your model artifacts to your S3 bucket.** For instructions on how to upload your model to your bucket, see Upload an object to your bucket in the Amazon S3 User Guide.
4. **Create an IAM role for Amazon SageMaker.** Amazon SageMaker needs access to the S3 bucket that stores your model. Create an IAM role with a policy that gives SageMaker read access to your bucket. The following procedure shows how to create a role in the console, but you can also use the `CreateRole` API from the *IAM User Guide*. For information on giving your role more granular permissions based on your use case, see *SageMaker Roles* (p. 3662).

   a. Sign in to the **IAM console**.
   b. In the navigation tab, choose **Roles**.
   c. Choose **Create Role**.
   d. For **Select type of trusted entity**, choose **AWS service** and then choose **SageMaker**.
   e. Choose **Next: Permissions** and then choose **Next: Tags**.
   f. (Optional) Add tags as key-value pairs if you want to have metadata for the role.
   g. Choose **Next: Review**.
   h. For **Role name**, enter a name for the new role that is unique within your AWS account. You cannot edit the role name after creating the role.
   i. (Optional) For **Role description**, enter a description for the new role.
   j. Choose **Create role**.

5. **Attach S3 bucket permissions to your SageMaker role.** After creating an IAM role, attach a policy that gives SageMaker permission to access the S3 bucket containing your model artifacts.

   a. In the IAM console navigation tab, choose **Roles**.
   b. From the list of roles, search for the role you created in the previous step by name.
   c. Choose your role, and then choose **Attach policies**.
   d. For **Attach permissions**, choose **Create policy**.
   e. In the **Create policy** view, select the **JSON** tab.
   f. Add the following policy statement into the JSON editor. Make sure to replace `<your-bucket-name>` with the name of the S3 bucket that stores your model artifacts. If you want to restrict the access to a specific folder or file in your bucket, you can also specify the Amazon S3 folder path, for example, `<your-bucket-name>/<model-folder>`.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "s3:GetObject",
         "Resource": "arn:aws:s3:::<your-bucket-name>/*"
       }
     ]
   }
   ```

   g. Choose **Next: Tags**.
   h. (Optional) Add tags in key-value pairs to the policy.
   i. Choose **Next: Review**.
   j. For **Name**, enter a name for the new policy.
   k. (Optional) Add a **Description** for the policy.
   l. Choose **Create policy**.
   m. After creating the policy, return to **Roles** in the **IAM console** and select your SageMaker role.
   n. Choose **Attach policies**.
   o. For **Attach permissions**, search for the policy you created by name. Select it and choose **Attach policy**.
6. **Select a prebuilt Docker container image or bring your own.** The container you choose serves inference on your endpoint. SageMaker provides containers for built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [*Available Deep Learning Containers Images*](#).

If none of the existing SageMaker containers meet your needs, you may need to create your own Docker container. For information about how to create your Docker image and make it compatible with SageMaker, see [*Use Your Own Inference Code*](#). To use your container with a serverless endpoint, the container image must reside in an Amazon ECR repository within the same AWS account that creates the endpoint.

7. *(Optional) Register your model with Model Registry.* SageMaker Model Registry (p. 2232) helps you catalog and manage versions of your models for use in ML pipelines. For more information about registering a version of your model, see [*Create a Model Group*](#) and [*Register a Model Version*](#). For an example of a Model Registry and Serverless Inference workflow, see the following example notebook.

8. *(Optional) Bring an AWS KMS key.* When setting up a serverless endpoint, you have the option to specify a KMS key that SageMaker uses to encrypt your Amazon ECR image. Note that the key policy for the KMS key must grant access to the IAM role you specify when setting up your endpoint. To learn more about KMS keys, see the [*AWS Key Management Service Developer Guide*](#).

### Create a serverless endpoint

To create a serverless endpoint, you can use the Amazon SageMaker console, the APIs, or the AWS CLI. You can create a serverless endpoint using a similar process as a real-time endpoint (p. 1976).

**Topics**

- Create a model (p. 2164)
- Create an endpoint configuration (p. 2166)
- Create an endpoint (p. 2169)

### Create a model

To create your model, you must provide the location of your model artifacts and container image. You can also use a model version from SageMaker Model Registry (p. 2232). The examples in the following sections show you how to create a model using the CreateModel API, Model Registry, and the Amazon SageMaker console.

**To create a model (using Model Registry)**

Model Registry (p. 2232) is a feature of SageMaker that helps you catalog and manage versions of your model for use in ML pipelines. To use Model Registry with Serverless Inference, you must first register a model version in a Model Registry model group. To learn how to register a model in Model Registry, follow the procedures in [*Create a Model Group*](#) and [*Register a Model Version*](#).

The following example requires you to have the ARN of a registered model version and uses the AWS SDK for Python (Boto3) to call the CreateModel API. For Serverless Inference, Model Registry is currently only supported by the AWS SDK for Python (Boto3). For the example, specify the following values:

- For **model_name**, enter a name for the model.
- For **sagemaker_role**, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the [*Prerequisites*](#) section.
- For **ModelPackageName**, specify the ARN for your model version, which must be registered to a model group in Model Registry.
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Specify a name for the model
model_name = "<name-for-model>"

#Specify a Model Registry model version
container_list = [
    
    "ModelPackageName": <model-version-arn>

]

#Create the model
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    container_list
)

To create a model (using API)
The following example uses the AWS SDK for Python (Boto3) to call the CreateModel API. Specify the following values:

- For sagemaker_role, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2162) section.
- For model_url, specify the Amazon S3 URI to your model.
- For container, retrieve the container you want to use by its Amazon ECR path. This example uses a SageMaker-provided XGBoost container. If you have not selected a SageMaker container or brought your own, see Step 6 of the Prerequisites (p. 2162) section for more information.
- For model_name, enter a name for the model.

#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Get model from S3
model_url = "s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz"

#Get container image (prebuilt example)
from sagemaker import image_uris
container = image_uris.retrieve("xgboost", region, "0.90-1")

#Create model
model_name = "<name-for-model>"
response = client.create_model(
    ModelName = model_name,
To create a model (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Models.
4. Choose Create model.
5. For Model name, enter a name for the model that is unique to your account and AWS Region.
6. For IAM role, either select an IAM role you have already created (see Prerequisites (p. 2162)) or allow SageMaker to create one for you.
7. In Container definition 1, for Container input options, select Provide model artifacts and input location.
8. For Provide model artifacts and inference image options, select Use a single model.
9. For Location of inference code image, enter an Amazon ECR path to a container. The image must either be a SageMaker-provided first party image (e.g. TensorFlow, XGBoost) or an image that resides in an Amazon ECR repository within the same account in which you are creating the endpoint. If you do not have a container, go back to Step 6 of the Prerequisites (p. 2162) section for more information.
10. For Location of model artifacts, enter the Amazon S3 URI to your ML model. For example, s3:// DOC-EXAMPLE-BUCKET/models/model.tar.gz.
11. (Optional) For Tags, add key-value pairs to create metadata for your model.
12. Choose Create model.

Create an endpoint configuration

After you create a model, create an endpoint configuration. You can then deploy your model using the specifications in your endpoint configuration. In the configuration, you specify whether you want a real-time or serverless endpoint. To create a serverless endpoint configuration, you can use the Amazon SageMaker console, the CreateEndpointConfig API, or the AWS CLI. The API and console approaches are outlined in the following sections.

To create an endpoint configuration (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpointConfig API. Specify the following values:

• For EndpointConfigName, choose a name for the endpoint configuration. The name should be unique within your account in a Region.
• (Optional) For KmsKeyId, use the key ID, key ARN, alias name, or alias ARN for an AWS KMS key that you want to use. SageMaker uses this key to encrypt your Amazon ECR image.
• For ModelName, use the name of the model you want to deploy. It should be the same model that you used in the Create a model (p. 2164) step.
• For ServerlessConfig:
  • Set MemorySizeInMB to 2048. For this example, we set the memory size to 2048 MB, but you can choose any of the following values for your memory size: 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB.
- Set MaxConcurrency to 20. For this example, we set the maximum concurrency to 20. The maximum number of concurrent invocations you can set for a serverless endpoint is 200, and the minimum value you can choose is 1.

```python
response = client.create_endpoint_config(
    EndpointConfigName="<your-endpoint-configuration>",
    KmsKeyId="arn:aws:kms:us-east-1:123456789012:key/143ef68f-76fd-45e3-abba-ed28fc8d3d5e",
    ProductionVariants=[[
        {
            "ModelName": "<your-model-name>",
            "VariantName": "AllTraffic",
            "ServerlessConfig": {
                "MemorySizeInMB": 2048,
                "MaxConcurrency": 20
            }
        }
    ]]
)
```

To create an endpoint configuration (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoint configurations.
4. Choose Create endpoint configuration.
5. For Endpoint configuration name, enter a name that is unique within your account in a Region.
6. For Type of endpoint, select Serverless.
7. For **Production variants**, choose **Add model**.
8. Under **Add model**, select the model you want to use from the list of models and then choose **Save**.
9. After adding your model, under **Actions**, choose **Edit**.
10. For **Memory size**, choose the memory size you want in GB.
11. For **Max Concurrency**, enter your desired maximum concurrent invocations for the endpoint. The maximum value you can enter is 200 and the minimum is 1.

12. Choose **Save**.

13. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint configuration.

14. Choose **Create endpoint configuration**.

**Create an endpoint**

To create a serverless endpoint, you can use the Amazon SageMaker console, the `CreateEndpoint` API, or the AWS CLI. The API and console approaches are outlined in the following sections. Once you create your endpoint, it can take a few minutes for the endpoint to become available.

**To create an endpoint (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the `CreateEndpoint` API. Specify the following values:

- For **EndpointName**, enter a name for the endpoint that is unique within a Region in your account.
- For **EndpointConfigName**, use the name of the endpoint configuration that you created in the previous section.

```python
response = client.create_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-endpoint-config>"
)```
To create an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. Choose Create endpoint.
5. For Endpoint name, enter a name than is unique within a Region in your account.
6. For Attach endpoint configuration, select Use an existing endpoint configuration.
7. For Endpoint configuration, select the name of the endpoint configuration you created in the previous section and then choose Select endpoint configuration.
8. (Optional) For Tags, enter key-value pairs if you want to create metadata for your endpoint.
9. Choose Create endpoint.
Create and configure endpoint

To deploy models to Amazon SageMaker, first create an endpoint. Provide an endpoint configuration to specify which models to deploy and the hardware requirements for each. See Deploying a Model on Amazon SageMaker Hosting Services. Learn more about the API.

**Endpoint**

- **Endpoint name**: Your application uses this name to access this endpoint.
  - **example-endpoint**

  Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

**Attach endpoint configuration**

- **Use an existing endpoint configuration**
  - Use an existing endpoint configuration or clone an endpoint configuration.

- **Create a new endpoint configuration**
  - Add models and configure the instance and initial weight for each model.

**New endpoint configuration**

- **Endpoint configuration name**: example-epc
  - **Encryption key**: -

- **Production variants**

<table>
<thead>
<tr>
<th>Model name</th>
<th>Training job</th>
<th>Variant name</th>
<th>Memory Size</th>
<th>Max Concurrency</th>
</tr>
</thead>
<tbody>
<tr>
<td>example-model</td>
<td>-</td>
<td>variant-name-1</td>
<td>1 GB</td>
<td>20</td>
</tr>
</tbody>
</table>

**Tags - optional**

- **Key**: 
  - **Value**: 
  - **Remove**

**Add tag**

[Create endpoint]
Invoke a serverless endpoint

In order to perform inference using a serverless endpoint, you must send an HTTP request to the endpoint. You can use the `InvokeEndpoint` API or the AWS CLI, which make a POST request to invoke your endpoint. The maximum request and response payload size for serverless invocations is 4 MB. Note that a cold start (or a delay in spinning up compute resources) on the endpoint may delay the response time to up to 4 minutes:

- The model must download and the server must respond successfully to `/ping` within 3 minutes.
- The timeout for the container to respond to inference requests to `/invocations` is 1 minute.

For more information on cold starts for serverless endpoints, see Cold starts (p. 2161).

To invoke an endpoint

The following example uses the AWS SDK for Python (Boto3) to call the `InvokeEndpoint` API. Note that unlike the other API calls in this guide, for `InvokeEndpoint`, you must use SageMaker Runtime as the client. Specify the following values:

- For `endpoint_name`, use the name of the in-service serverless endpoint you want to invoke.
- For `content_type`, specify the MIME type of your input data in the request body (for example, `application/json`).
- For `payload`, use your request payload for inference. Your payload should be in bytes or a file-like object.

```python
runtime = boto3.client("sagemaker-runtime")
endpoint_name = "<your-endpoint-name>"
content_type = "<request-mime-type>"
payload = <your-request-body>
response = runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType=content_type,
    Body=payload
)
```

Update a serverless endpoint

Before updating your endpoint, create a new endpoint configuration or use an existing endpoint configuration. The endpoint configuration is where you specify the changes for your update. Then, you can update your endpoint with the SageMaker console, the `UpdateEndpoint` API, or the AWS CLI. The process for updating a serverless endpoint is the same as the process for updating a real-time endpoint (p. 1976). Note that when updating your endpoint, you can experience cold starts when making requests to the endpoint because SageMaker must re-initialize your container and model.

Create a new endpoint configuration

To create a new serverless endpoint configuration, see the previous procedure in Create an endpoint configuration (p. 2166). You can also create a real-time endpoint configuration to switch from serverless to instance-based capacity.

Update the endpoint

Examples of how to update your endpoint using the `UpdateEndpoint` API and the SageMaker console are outlined in the following sections.
To update the endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the `UpdateEndpoint` API. Specify the following values:

- For `EndpointName`, use the name of the endpoint you're updating.
- For `EndpointConfigName`, use the name of the endpoint configuration that you want to use for the update.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<new-endpoint-config>",
)
```

To update the endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to update.
5. Choose Update endpoint.
6. For Change the Endpoint configuration, choose Use an existing endpoint configuration.
7. From the list of endpoint configurations, select the one you want to use for your update.
8. Choose Select endpoint configuration.
9. Choose Update endpoint.

Describe a serverless endpoint

You might want to retrieve information about your endpoint, including details such as the endpoint's ARN, current status, deployment configuration, and failure reasons. You can find information about your endpoint using the SageMaker console, the DescribeEndpoint API, or the AWS CLI.

To describe an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the `DescribeEndpoint` API. For `EndpointName`, use the name of the endpoint you want to check.

```python
response = client.describe_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To describe an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, choose the endpoint you want to check.

The endpoint page contains the information about your endpoint.
Delete a serverless endpoint

You can delete your serverless endpoint using the SageMaker console, the DeleteEndpoint API, or the AWS CLI. The following examples show you how to delete your endpoint through the API and the SageMaker console.

To delete an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the DeleteEndpoint API. For EndpointName, use the name of the serverless endpoint you want to delete.

```python
response = client.delete_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To delete an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to delete.
5. Choose the Actions drop-down list, and then choose Delete.
6. When prompted again, choose Delete.

Your endpoint should now begin the deletion process.

Monitor a Serverless Endpoint

To monitor your serverless endpoint, you can use Amazon CloudWatch alarms. CloudWatch is a service that collects metrics in real time from your AWS applications and resources. An alarm watches metrics as they are collected and gives you the ability to pre-specify a threshold and the actions to take if that threshold is breached. For example, your CloudWatch alarm can send you a notification if your endpoint breaches an error threshold. By setting up CloudWatch alarms, you gain visibility into the performance and functionality of your endpoint.

To learn more about CloudWatch metrics you can use to monitor your endpoints in SageMaker, see SageMaker Endpoint Invocation Metrics (p. 3819). The ModelSetupTime metric tracks the cold start time for your endpoint, or the time it takes to launch new compute resources for your serverless endpoint. This metric depends on your model size and the container's start-up time. Serverless endpoints can also use the Invocations4XXErrors, Invocations5XXErrors, and Invocations metrics in the AWS/SageMaker namespace. In the aws/sagemaker/Endpoints namespace, they can use the MemoryUtilization metric. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

If you want to monitor the logs from your endpoint for debugging or progress analysis, you can use Amazon CloudWatch Logs. The SageMaker-provided log group that you can use for serverless endpoints is /aws/sagemaker/Endpoints/[EndpointName]. For more information about using CloudWatch Logs in SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3830). To learn more about CloudWatch Logs, see What is Amazon CloudWatch Logs? in the Amazon CloudWatch Logs User Guide.

Troubleshooting

If you are having trouble with Serverless Inference, refer to the following troubleshooting tips.
Container issues

If the container you use for a serverless endpoint is the same one you used on an instance-based endpoint, your container may not have permissions to write files. This can happen for the following reasons:

- Your serverless endpoint fails to create or update due to a ping health check failure.
- The Amazon CloudWatch logs for the endpoint show that the container is failing to write to some file or directory due to a permissions error.

To fix this issue, you can try to add read, write, and execute permissions for other on the file or directory and then rebuild the container. You can perform the following steps to complete this process:

1. In the Dockerfile you used to build your container, add the following command: `RUN chmod o+rwX <file or directory name>
2. Rebuild the container.
3. Upload the new container image to Amazon ECR.
4. Try to create or update the serverless endpoint again.

Asynchronous inference

Amazon SageMaker Asynchronous Inference is a new capability in SageMaker that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to 15 minutes), and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker models and only need to specify the AsyncInferenceConfig object while creating your endpoint configuration with the EndpointConfig field in the CreateEndpointConfig API. The following diagram shows the architecture and workflow of Asynchronous Inference.
To invoke the endpoint, you need to place the request payload in Amazon S3 and provide a pointer to this payload as a part of the `InvokeEndpointAsync` request. Upon invocation, SageMaker queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check prediction results (p. 2187).

**Note**
The presence of an asynchronous inference configuration (`AsyncInferenceConfig`) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

**How Do I Get Started?**

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Create, invoke, and update an Asynchronous Endpoint (p. 2176) for information on how to create, invoke, update, and delete an asynchronous endpoint.
- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Note that if your endpoint uses any of the features listed in this Exclusions (p. 2216) page, you cannot use Asynchronous Inference.

**Create, invoke, and update an Asynchronous Endpoint**

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with the AWS SDKs and the Amazon SageMaker Python SDK.

**Topics**
- Prerequisites (p. 2177)
Create, invoke, and update an Asynchronous Endpoint

- Create an Asynchronous Inference Endpoint (p. 2179)
- Invoke an Asynchronous Endpoint (p. 2183)
- Update an Asynchronous Endpoint (p. 2184)
- Delete an Asynchronous Endpoint (p. 2184)

Prerequisites

To use asynchronous endpoints, first make sure you have met these prerequisites.

1. **Create an IAM role for Amazon SageMaker.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3 and Amazon SNS. Using this role, SageMaker can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
   b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
   c. For Select type of trusted entity, choose AWS service.
   d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.
      - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose Next: Tags.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
   g. Choose Next: Review.
   h. Type in a Role name.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For Role description, type a description for the new role.
   k. Review the role and then choose Create role.

   Note the SageMaker role ARN. To find the role ARN using the console, do the following:
   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Select Roles.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the Summary page.

2. **Add Amazon SageMaker, Amazon S3 and Amazon SNS Permissions to your IAM Role.**

   Once the role is created, grant SageMaker, Amazon S3, and optionally Amazon SNS permissions to your IAM role.
Choose Roles in the IAM console. Search for the role you created by typing in your role name in the Search field.

a. Choose your role.
b. Next, choose Attach Policies.
c. Amazon SageMaker Asynchronous Inference needs permission to perform the following actions: "sagemaker:CreateModel", "sagemaker:CreateEndpointConfig", "sagemaker:CreateEndpoint", and "sagemaker:InvokeEndpointAsync".

These actions are included in the AmazonSageMakerFullAccess policy. Add this policy to your IAM role. Search for AmazonSageMakerFullAccess in the Search field. Select AmazonSageMakerFullAccess.
d. Choose Attach policy.
e. Next, choose Attach Policies to add Amazon S3 permissions.
f. Select Create policy.
g. Select the JSON tab.
h. Add the following policy statement:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:AbortMultipartUpload",
                "s3:ListBucket"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:s3:::bucket_name/*"
        }
    ]
}
```
i. Choose Next: Tags.
j. Type in a Policy name.
k. Choose Create policy.
l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": ["sns:Publish"],
            "Effect": "Allow",
            "Resource": "arn:aws:sns:<region>:<Account_ID>::SNS_Topic"
        }
    ]
}
```

3. Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.
4. Select a prebuilt Docker inference image or create your own Inference Docker Image.
SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#). If you choose to use a SageMaker provided container, you can increase the endpoint timeout and payload sizes from the default by setting the environment variables in the container. To learn how to set the different environment variables for each framework, see the Create a Model step of creating an asynchronous endpoint.

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See [Use Your Own Inference Code](#) for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an `EndpointConfig` object when you specify `AsyncInferenceConfig` using the `EndpointConfig` API.

Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see [Creating an Amazon SNS topic](#) in the [Amazon Simple Notification Service Developer Guide](#).

b. Subscribe to the topic. For instructions, see [Subscribing to an Amazon SNS topic](#) in the [Amazon Simple Notification Service Developer Guide](#).

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your AWS account, and it has a unique ARN. The ARN is in the following format:

```
arn:aws:sns::aws-region:account-id:topic-name
```

For more information about Amazon SNS, see the [Amazon SNS Developer Guide](#).

## Create an Asynchronous Inference Endpoint

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker hosting services:

- Create a model in SageMaker with `CreateModel`.
- Create an endpoint configuration with `CreateEndpointConfig`.
- Create an HTTPS endpoint with `CreateEndpoint`.

To create an endpoint, you first create a model with `CreateModel`, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using `CreateEndpointConfig` where you specify one or more models that were created using the `CreateModel` API to deploy and the resources that you want SageMaker to provision. Create your endpoint with `CreateEndpoint` using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the `UpdateEndpoint` API. Send and receive inference requests from the model hosted at the endpoint with `InvokeEndpointAsync`. You can delete your endpoints with the `DeleteEndpoint` API.
For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Use Your Own Inference Code (p. 3293) for information on how to create your Docker image.

**Create a Model**

The following example shows how to create a model using the AWS SDK for Python (Boto3). The first few lines define:

- **sagemaker_client**: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- **sagemaker_role**: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- **aws_region**: A string variable with the name of your AWS region.

```python
import boto3

aws_region = '<aws_region>'

sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

sagemaker_role = 'arn:aws:iam::<account>:role/*'
```

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named `demo-xgboost-model.tar.gz`. The full Amazon S3 URI is stored in a string variable `model_url`:

```python
s3_bucket = '<your-bucket-name>'

model_s3_key = f'{bucket_prefix}/demo-xgboost-model.tar.gz'

model_url = f's3://{s3_bucket}/{model_s3_key}'
```

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

```python
from sagemaker import image_uris

container = image_uris.retrieve(region=aws_region, framework='xgboost', version='0.90-1')
```

Create a model in Amazon SageMaker with `CreateModel`. Specify the following:

- **ModelName**: A name for your model (in this example it is stored as a string variable called `model_name`).
- **ExecutionRoleArn**: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- **PrimaryContainer**: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.
model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    }
)

If you're using a SageMaker provided container, you can increase the model server timeout and payload sizes from the default values to the framework-supported maximums by setting environment variables in this step. You might not be able to leverage the maximum timeout and payload sizes that Asynchronous Inference supports if you don't explicitly set these variables. The following example shows how you can set the environment variables for a PyTorch Inference container based on TorchServe.

model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
        'Environment': {
            'TS_MAX_REQUEST_SIZE': '100000000',
            'TS_MAX_RESPONSE_SIZE': '100000000',
            'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
        }
    }
)

After you finish creating your endpoint, you should test that you've set the environment variables correctly by printing them out from your inference.py script. The following table lists the environment variables for several frameworks that you can set to change the default values.

<table>
<thead>
<tr>
<th>Framework</th>
<th>Environment variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyTorch 1.8 (based on TorchServe)</td>
<td>'TS_MAX_REQUEST_SIZE': '100000000'</td>
</tr>
<tr>
<td></td>
<td>'TS_MAX_RESPONSE_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'</td>
</tr>
<tr>
<td>PyTorch 1.4 (based on MMS)</td>
<td>'MMS_MAX_REQUEST_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_MAX_RESPONSE_SIZE': '10000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'</td>
</tr>
<tr>
<td>HuggingFace Inference Container (based on MMS)</td>
<td>'MMS_MAX_REQUEST_SIZE': '20000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_MAX_RESPONSE_SIZE': '20000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'</td>
</tr>
</tbody>
</table>
Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision. Specify the AsyncInferenceConfig object and provide an output Amazon S3 location for OutputConfig. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S', gmtime())}"

# The name of the model that you want to host. This is the name that you specified when
# creating the model.
model_name='<The_name_of_your_model>'

create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a
    CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at this
    endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name, # Specify the compute instance type.
            "InstanceType": "ml.m5.xlarge", # The name of the model that you want to host.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            "S3OutputPath": f"s3://{s3_bucket}/{bucket_prefix}/output" # Location to upload response outputs when no location is provided in the request.
        },
        "NotificationConfig": {
            "SuccessTopic": "arn:aws:sns:aws-region:account-id:topic-name", # (Optional) specify Amazon SNS topics
        },
    },
    "ClientConfig": {
        "MaxConcurrentInvocationsPerInstance": 4 # (Optional) Specify the max number of inflight invocations per instance
    }
)

print(f"Created EndpointConfig: {create_endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for OutputConfig for the AsyncInferenceConfig field:

- **S3OutputPath**: Location to upload response outputs when no location is provided in the request.
• NotificationConfig: (Optional) SNS topics that post notifications to you when an inference request is successful (SuccessTopic) or if it fails (ErrorTopic).

You can also specify the following optional argument for ClientConfig in the AsyncInferenceConfig field:

• MaxConcurrentInvocationsPerInstance: (Optional) The maximum number of concurrent requests sent by the SageMaker client to the model container.

Create Endpoint

Once you have your model and endpoint configuration, use the CreateEndpoint API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

When you call the CreateEndpoint API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. Amazon SageMaker Asynchronous Inference also sends test notifications after calls to UpdateEndpoint and UpdateEndpointWeightsAndCapacities. This lets SageMaker check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```json
{
    "eventVersion":"1.0",
    "eventSource":"aws:sagemaker",
    "eventName":"TestNotification"
}
```

Invoke an Asynchronous Endpoint

Get inferences from the model hosted at your asynchronous endpoint with InvokeEndpointAsync.

**Note**
If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

Specify the location of your inference data in the InputLocation field and the name of your endpoint for EndpointName:

```python
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"
```
Create, invoke, and update an Asynchronous Endpoint

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(EndpointName=endpoint_name, InputLocation=input_location)

You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

## Update an Asynchronous Endpoint

Update an asynchronous endpoint with the `UpdateEndpoint` API. When you update an endpoint, SageMaker first provisions and switches to the new endpoint configuration you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an `EndpointConfig` with an endpoint that is live or while the `UpdateEndpoint` or `CreateEndpoint` operations are being performed on the endpoint.

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>

sagemaker_client.update_endpoint(EndpointConfigName=endpoint_config_name, EndpointName=endpoint_name)

When Amazon SageMaker receives the request, it sets the endpoint status to **Updating**. After updating the asynchronous endpoint, it sets the status to **InService**. To check the status of an endpoint, use the `DescribeEndpoint` API. For a full list of parameters you can specify when updating an endpoint, see the `UpdateEndpoint` API.

## Delete an Asynchronous Endpoint

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker hosted endpoint with the `DeleteEndpoint` API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Delete your SageMaker model with the `DeleteModel` API or with the SageMaker console.

**Boto3**

```python
import boto3

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')
```

**SageMaker console**

2. Expand the **Inference** dropdown list.
3. Select **Endpoints**.
4. Search for endpoint in the **Search endpoints** search bar.
5. Select your endpoint.
6. Choose **Delete**.

In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker model, and the asynchronous endpoint configuration itself.

### Monitor asynchronous endpoint

You can monitor SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see [What is Amazon CloudWatch?](#).

### Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- **OverheadLatency**
- **Invocations**
- **InvocationsPerInstance**

### Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see [Monitor SageMaker with Amazon CloudWatch](#).

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Invocation4XXErrors</strong></td>
<td>The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.</td>
<td>Units: None&lt;br&gt;Valid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>Invocation5XXErrors</strong></td>
<td>The number of InvokeEndpoint requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent.</td>
<td>Units: None&lt;br&gt;Valid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>ModelLatency</strong></td>
<td>The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container</td>
<td>Units: Microseconds&lt;br&gt;Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Description</td>
<td>Unit/Stats</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>ApproximateBacklogSize</td>
<td>The number of items in the queue for an endpoint that are currently being processed or yet to be processed.</td>
<td>Units: Count, Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateBacklogSizePerInstance</td>
<td>Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint.</td>
<td>Units: Count, Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateAgeOfOldestRequest</td>
<td>Age of the oldest request in the queue.</td>
<td>Units: Seconds, Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestDownloadFailures</td>
<td>When an inference failure occurs due to an issue downloading the request from Amazon S3.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>ResponseUploadFailures</td>
<td>When an inference failure occurs due to an issue uploading the response to Amazon S3.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>NotificationFailures</td>
<td>When an issue occurs publishing notifications.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>RequestDownloadLatency</td>
<td>Total time to download the request payload.</td>
<td>Units: Microseconds, Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ResponseUploadLatency</td>
<td>Total time to upload the response payload.</td>
<td>Units: Microseconds, Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

**Asynchronous Inference Endpoint Metrics**

These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the EndpointName dimension:
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExpiredRequests</td>
<td>Number of requests in the queue that fail due to reaching their specified request TTL.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationFailures</td>
<td>If an invocation fails for any reason.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationsProcessed</td>
<td>Number of async invocations processed by the endpoint.</td>
<td>Units: Count, Valid statistics: Sum</td>
</tr>
<tr>
<td>TimeInBacklog</td>
<td>Total time the request was queued before being processed. This does not include the actual processing time (i.e. downloading time, uploading time, model latency).</td>
<td>Units: Milliseconds, Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>TotalProcessingTime</td>
<td>Time the inference request was recieved by SageMaker to the time the request finished processing. This includes time in backlog and time to upload and send response notifications, if any.</td>
<td>Units: Milliseconds, Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see SageMaker Jobs and Endpoint Metrics.

### Logs

In addition to the Model container logs that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

```
/aws/sagemaker/Endpoints/[EndpointName]
```

The log stream name consists of:

```
[production-variant-name]/[instance-id]/data-log.
```

Log lines contain the request’s inference ID so that errors can be easily mapped to a particular request.

### Check prediction results

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.
Amazon SNS Topics

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts notifications when you create an endpoint with CreateEndpointConfig and specify an Amazon SNS topic.

**Note**

In order to receive Amazon SNS notifications, your IAM role must have sns:Publish permissions. See the Prerequisites (p. 2177) for information on requirements you must satisfy to use Asynchronous Inference.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the AsyncInferenceConfig field when you create an endpoint configuration with CreateEndpointConfig. You can specify both an Amazon SNS ErrorTopic and an SuccessTopic.

```python
import boto3
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.create_endpoint_config(
    EndpointConfigName=<endpoint_config_name>, # You specify this name in a CreateEndpoint request.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": "model_name",
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the request.
            "S3OutputPath": "s3://<bucket>/<output_directory>"
        }"
    }
)
```

After creating your endpoint and invoking it, you receive a notification from your Amazon SNS topic. For example, if you subscribed to receive email notifications from your topic, you receive an email notification every time you invoke your endpoint. The following example shows the JSON content of a successful invocation email notification.

```json
{
    "awsRegion": "us-east-1",
    "eventTime": "2022-01-25T22:46:00.608Z",
    "receivedTime": "2022-01-25T22:46:00.455Z",
}
```
Check prediction results

"invocationStatus": "Completed",
"requestParameters": {
    "contentType": "text/csv",
    "endpointName": "<example-endpoint>",
    "inputLocation": "s3://<bucket>/<input-directory>/input-data.csv"
},
"responseParameters": {
    "contentType": "text/csv; charset=utf-8",
    "outputLocation": "s3://<bucket>/<output_directory>/prediction.out"
},
"inferenceId": "11111111-2222-3333-4444-555555555555",
"eventVersion": "1.0",
"eventSource": "aws:sagemaker",
"eventName": "InferenceResult"
}

Check Your S3 Bucket

When you invoke an endpoint with `InvokeEndpointAsync`, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker session class to programmatically check for on an output.

The following stores the output dictionary of `InvokeEndpointAsync` as a variable named `response`. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called `output_location`.

```python
import uuid
import boto3

sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
    ContentType="text/libsvm"  # Specify the content type of your data
)

output_location = response['OutputLocation']
print(f"OutputLocation: {output_location}"

For information about supported content types, see Common Data Formats for Inference (p. 1188).

With the Amazon S3 output location, you can then use a SageMaker Python SDK SageMaker Session Class to read in Amazon S3 files. The following code example shows how to create a function (get_output) that repeatedly attempts to read a file from the Amazon S3 output location:

```python
import sagemaker
import urllib, time
from botocore.exceptions import ClientError

sagemaker_session = sagemaker.session.Session()

def get_output(output_location):
    output_url = urllib.parse.urlparse(output_location)
    bucket = output_url.netloc
    key = output_url.path[1:]
    while True:
        try:
```
return sagemaker_session.read_s3_file(
    bucket=output_url.netloc,
    key_prefix=output_url.path[1:]
)
except ClientError as e:
    if e.response['Error']['Code'] == 'NoSuchKey':
        print("waiting for output...")
        time.sleep(2)
    continue
    raise
output = get_output(output_location)
print(f"Output: {output}"

Autoscale an asynchronous endpoint

Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already created a SageMaker model deployment. Deployed models are referred to as a production variant. See Deploy the Model to SageMaker Hosting Services for more information about deploying a model endpoint. To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. For information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.

For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker autoscaling documentation.

**Note**
If you attach multiple scaling policies to the same autoscaling group, you might have scaling conflicts. When a conflict occurs, Amazon EC2 Auto Scaling chooses the policy that provisions the largest capacity for both scale out and scale in. For more information about this behavior, see Multiple dynamic scaling policies in the Amazon EC2 Auto Scaling documentation.

Define a Scaling Policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

For asynchronous endpoints SageMaker strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, CustomizedMetricSpecification, called ApproximateBacklogSizePerInstance.

```
TargetTrackingScalingPolicyConfiguration=
    'TargetValue': 5.0, # The target value for the metric. Here the metric is:
    SageMakerVariantInvocationsPerInstance
```
Define a Scaling Policy that Scales to 0

The following shows you how to both define and register your endpoint variant with application autoscaling using the AWS SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the `RegisterScalableTarget` method to register the production variant. We set `MinCapacity` to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```python
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + <endpoint_name> + '/variant/' + '<variant1>

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.

Use Batch Transform

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records (p. 2194). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

Topics

- Use Batch Transform to Get Inferences from Large Datasets (p. 2192)
- Speed up a Batch Transform Job (p. 2193)
- Use Batch Transform to Test Production Variants (p. 2193)
Use Batch Transform to Get Inferences from Large Datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following example.

| Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM |
| Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM |
| Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM |
| ... |
| RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM |

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiple files, one instance might process input1.csv, and another instance might process the file named input2.csv. If you have one input file but initialize multiple compute instances, only one instance processes the input file and the rest of the instances are idle.

You can also split input files into mini-batches. For example, you might create a mini-batch from input1.csv by including only two of the records.

| Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM |
| Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM |

**Note**

SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the MaxPayloadInMB limit.

To split input files into mini-batches when you create a batch transform job, set the SplitType parameter value to Line. If SplitType is set to None or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request. Note that Batch Transform doesn't support CSV-formatted input that contains embedded newline characters. You can control the size of the mini-batches by using the BatchStrategy and MaxPayloadInMB parameters. MaxPayloadInMB must not be greater than 100 MB. If you specify the optional MaxConcurrentTransforms parameter, then the value of (MaxConcurrentTransforms * MaxPayloadInMB) must also not exceed 100 MB.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as input1.csv and input2.csv, the output files are named input1.csv.out and input2.csv.out. The batch transform job stores the output files in the specified location in Amazon S3, such as s3://awsexamplebucket/output/.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file input1.csv.out, based on the input file shown earlier, would look like the following.
Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM

To combine the results of multiple output files into a single output file, set the `AssembleWith` parameter to `Line`.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set `MaxPayloadInMB` to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the `CreateTransformJob` API. For more information about the correlation between batch transform input and output objects, see `OutputDataConfig`. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform (p. 89).

**Speed up a Batch Transform Job**

If you are using the `CreateTransformJob` API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as `MaxPayloadInMB`, `MaxConcurrentTransforms`, or `BatchStrategy`. The ideal value for `MaxConcurrentTransforms` is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the `Additional configuration` section of the `Batch transform job configuration` page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an `execution-parameters` endpoint.

**Use Batch Transform to Test Production Variants**

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 2028).

**Batch Transform Errors**

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as `failed`. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate usable results.
Exceeding the `MaxPayloadInMB` limit causes an error. This might happen with a large dataset if it can't be split, the `SplitType` parameter is set to `none`, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as `ERROR`, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

**Batch Transform Sample Notebooks**

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see *Batch Transform with PCA and DBSCAN Movie Clusters*. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see *Use Amazon SageMaker Notebook Instances* (p. 358). After creating and opening a notebook instance, choose the *SageMaker Examples* tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the *Advanced functionality* section. To open a notebook, choose its *Use* tab, then choose *Create copy*.

**Associate Prediction Results with Input Records**

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

**Topics**

- *Workflow for Associating Inferences with Input Records* (p. 2194)
- *Use Data Processing in Batch Transform Jobs* (p. 2195)
- *Supported JSONPath Operators* (p. 2196)
- *Batch Transform Examples* (p. 2197)

**Workflow for Associating Inferences with Input Records**

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

Use Data Processing in Batch Transform Jobs

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.
2. Join the raw input data with the transformed data with the `JoinSource` parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see `DataProcessing`.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for both input and output files. For example, with the `TransformOutput` field of the
CreateTransformJob API, you must set both the ContentType and Accept parameters to one of the following values: text/csv, application/json, or application/jsonlines. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 2197). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175).

The record delimiters for the input and output must also be consistent with your chosen file input. The SplitType parameter indicates how to split the records in the input dataset. The AssembleWith parameter indicates how to reassemble the records for the output. If you set input and output formats to text/csv, you must also set the SplitType and AssembleWith parameters to line. If you set the input and output formats to application/jsonlines, you can set both SplitType and AssembleWith to line.

For CSV files, you cannot use embedded newline characters. For JSON files, the attribute name SageMakerOutput is reserved for output. The JSON input file can’t have an attribute with this name. If it does, the data in the input file might be overwritten.

**Supported JSONPath Operators**

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. $[0], $[1:]. CSV data should also follow RFC format.

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td>[ '&lt;name&gt;' (, '&lt;name&gt;') ]</td>
<td>A bracket-notated element or multiple child elements.</td>
<td>$['id','SageMakerOutput']</td>
</tr>
<tr>
<td>[&lt;number&gt; (, &lt;number&gt;)]</td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1], $[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5], $[:5], $[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $.field1.['child1', 'child2'] is supported while $.field1.['child1', 'child2.grandchild'] is not.

For more information about JSONPath operators, see JsonPath on GitHub.
Batch Transform Examples

The following examples show some common ways to join input data with prediction results.

Topics

- Example: Output Only Inferences (p. 2197)
- Example: Output Inferences Joined with Input Data (p. 2197)
- Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV) (p. 2198)
- Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV) (p. 2199)

Example: Output Only Inferences

By default, the DataProcessing parameter doesn't join inference results with input. It outputs only the inference results.

If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK and specify the following settings in a transformer call.

```python
sm_transformer = sagemaker.transformer.Transformer(...)
sm_transformer.transform(..., input_filter="$", join_source= "None", output_filter="$")
```

To output inferences using the AWS SDK for Python, add the following code to your CreateTransformJob request. The following code mimics the default behavior.

```json
{
  "DataProcessing": {
    "InputFilter": "$",
    "JoinSource": "None",
    "OutputFilter": "$"
  }
}
```

Example: Output Inferences Joined with Input Data

If you're using the Amazon SageMaker Python SDK to combine the input data with the inferences in the output file, specify the assemble_with and accept parameters when initializing the transformer object. When you use the transform call, specify Input for the join_source parameter, and specify the split_type and content_type parameters as well. The split_type parameter must have the same value as assemble_with, and the content_type parameter must have the same value as accept. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(..., assemble_with="Line", accept="text/csv")
sm_transformer.transform(..., join_source="Input", split_type="Line", content_type="text/csv")
```

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the following code to your CreateTransformJob request. The values for Accept and ContentType must match, and the values for AssembleWith and SplitType must also match.

```json
{
  "DataProcessing": {
"
For JSON or JSON Lines input files, the results are in the SageMakerOutput key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`.

SageMaker stores both in the input file in the SageMakerInput key.

```
{
    "key":1,
    "SageMakerOutput":{"label":1}
}
```

**Note**

The joined result for JSON must be a key-value pair object. If the input isn’t a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the SageMakerInput key and the results are stored as the SageMakerOutput value.

For a CSV file, for example, if the record is `[1,2,3]`, and the label result is `[1]`, then the output file would contain `[1,2,3,1]`.

**Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK to join your input data with the inference output while excluding an ID column from the transformer input, specify the same parameters from the preceding example as well as a JSONPath subexpression for the `input_filter` in your transformer call. For example, if your input data includes five columns and the first one is the ID column, use the following transform request to select all columns except the ID column as features. The transformer still outputs all of the input columns joined with the inferences. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
input_filter="$[1:]", join_source="Input")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your `CreateTransformJob` request.

```
{
    "DataProcessing": {
        "InputFilter": "$[1:]",
        "JoinSource": "Input"
    },
    "TransformOutput": {
        "Accept": "text/csv",
        "AssembleWith": "Line"
    }
}
```
To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to `"$[1:]"`. The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, `$[1:4]` specifies the second through fifth columns.

If you omit the number after the colon, for example, `[5:]`, the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, `[::5]`, the subset includes all columns from the first column (index 0) through the sixth column.

**Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK, you can specify the output to join only specific input columns (such as the ID column) with the inferences by specifying the `output_filter` in the transformer call. The `output_filter` uses a JSONPath subexpression to specify which columns to return as output after joining the input data with the inference results. The following request shows how you can make predictions while excluding an ID column and then join the ID column with the inferences. Note that in the following example, the last column (-1) of the output contains the inferences. If you are using JSON files, SageMaker stores the inference results in the attribute `SageMakerOutput`. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
goingest_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
goingest_transformer.transform(…, split_type="Line", content_type="text/csv", input_filter="$[1:]", join_source="Input", output_filter="$[0,-1]"
```

If you are using the AWS SDK for Python (Boto 3), join only the ID column with the inferences by adding the following code to your `CreateTransformJob` request.

```json
dojson = json.loads(input_data)

new_json = {
    "InputFilter": "$[1:]",
    "JoinSource": "Input",
    "OutputFilter": "$[0,-1]"
}
```

**Warning**

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the inferences in the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.
Storage in Batch Transform

When you run a batch transform job, Amazon SageMaker attaches an Amazon Elastic Block Store storage volume to Amazon EC2 instances that process your job. The volume stores your model, and the size of the storage volume is fixed at 30 GB. You have the option to encrypt your model at rest in the storage volume.

**Note**
If you have a large model, you may encounter an `InternalServerError`.

For more information about Amazon EBS storage and features, see the following pages:

- Amazon EBS in the Amazon EC2 User Guide for Linux Instances
- Amazon EBS volumes in the Amazon EC2 User Guide for Linux Instances

**Note**
G4dn instances come with their own local SSD storage. To learn more about G4dn instances, see the Amazon EC2 G4 Instances page.

Deployment guardrails

Deployment guardrails are a set of model deployment options in Amazon SageMaker Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes, such as canary and linear, give you granular control over the traffic shifting process from your current model to the new one during the course of the update. There are also built-in safeguards such as auto-rollbacks that help you catch issues early and automatically take corrective action before they significantly impact production.

Deployment guardrails provide the following benefits:

- **Deployment safety while updating production environments.** A regressive update to a production environment can cause unplanned downtime and business impact, such as increased model latency and high error rates. Deployment guardrails help you mitigate those risks by providing best practices and built-in operational safety guardrails.
- **Fully managed deployment.** SageMaker takes care of setting up and orchestrating these deployments and integrates them with endpoint update mechanisms. You do not need to build and maintain orchestration, monitoring, or rollback mechanisms. You can leverage SageMaker to set up and orchestrate these deployments and focus on leveraging ML for your applications.
- **Visibility.** You can track the progress of your deployment through the `DescribeEndpoint` API or through Amazon CloudWatch Events (for supported endpoints (p. 2216)). To learn more about events in SageMaker, see the Endpoint deployment state change section in Automating Amazon SageMaker with Amazon EventBridge (p. 3836). Note that if your endpoint uses any of the features in the Exclusions (p. 2216) page, you cannot use CloudWatch Events.

**Note**
Deployment guardrails only apply to Asynchronous inference (p. 2175) and Real-time inference (p. 1976) endpoint types.

How to Get Started

We support blue/green deployments with multiple traffic shifting modes (p. 2203). A traffic shifting mode is a configuration that specifies how SageMaker routes endpoint traffic to a new fleet containing
your updates. The following traffic shifting modes provide you with different levels of control over the endpoint update process:

- **Blue/Green: All At Once (p. 2205)** shifts all of your endpoint traffic from the blue fleet to the green fleet. Once the traffic shifts to the green fleet, your pre-specified Amazon CloudWatch alarms begin monitoring the green fleet for a set amount of time (the baking period). If no alarms trip during the baking period, then SageMaker terminates the blue fleet.

- **Blue/Green: Canary (p. 2208)** lets you shift one small portion of your traffic (a canary) to the green fleet and monitor it for a baking period. If the canary succeeds on the green fleet, then SageMaker shifts the rest of the traffic from the blue fleet to the green fleet before terminating the blue fleet.

- **Blue/Green: Linear (p. 2212)** provides even more customization over the number of traffic-shifting steps and the percentage of traffic to shift for each step. While canary shifting lets you shift traffic in two steps, linear shifting extends this to $n$ linearly spaced steps.

You can create and manage your deployment through the [UpdateEndpoint](https://aws.amazon.com/sagemaker/) and [CreateEndpoint](https://aws.amazon.com/sagemaker/) SageMaker API and AWS Command Line Interface commands. See the individual deployment pages for more details on how to set up your deployment. Note that if your endpoint uses any of the features listed in the [Exclusions](https://aws.amazon.com/sagemaker/) page, you cannot use deployment guardrails.

To follow guided examples that shows how to use deployment guardrails, see our example [Jupyter notebooks](https://aws.amazon.com/sagemaker/) for the canary and linear traffic shifting modes.

### Auto-Rollback Configuration and Monitoring

Amazon CloudWatch alarms are a prerequisite for using baking periods in deployment guardrails. You can only use the auto-rollback functionality in deployment guardrails if you set up CloudWatch alarms that can monitor an endpoint. If any of your alarms trip during the specified monitoring period, SageMaker initiates a complete rollback to the old endpoint to protect your application. If you do not have any CloudWatch alarms set up to monitor your endpoint, then the auto-rollback functionality does not work during your deployment.

To learn more about Amazon CloudWatch, see [What is Amazon CloudWatch?](https://aws.amazon.com/sagemaker/) in the [Amazon CloudWatch User Guide](https://aws.amazon.com/sagemaker/).

### Alarm Examples

To help you get started, we provide the following examples to demonstrate the capabilities of CloudWatch alarms. In addition to using or modifying the following examples, you can create your own alarms and configure the alarms to monitor various metrics on the specified fleets for a certain period of time. To see more SageMaker metrics and dimensions you can add to your alarms, see [Monitor Amazon SageMaker with Amazon CloudWatch](https://aws.amazon.com/sagemaker/) (p. 3818).

**Topics**

- Monitor invocation errors on both old and new fleets (p. 2201)
- Monitor model latency on the new fleet (p. 2202)

**Monitor invocation errors on both old and new fleets**

The following CloudWatch alarm monitors an endpoint's average error rate. You can use this alarm with any deployment guardrails traffic shifting type to provide overall monitoring on both the old and new fleets. If the alarm trips, then SageMaker initiates a rollback to the old fleet.

Invocation errors coming from both the old fleet and new fleet contribute to the average error rate. If the average error rate exceeds the specified threshold, then the alarm trips. This particular example monitors the 4xx errors (client errors) on both the old and new fleets for the duration of a deployment. You can also monitor the 5xx errors (server errors) by using the metric `Invocation5XXErrors`.

---

2201
Note
For this alarm type, if your old fleet trips the alarm during the deployment, SageMaker terminates your deployment. Therefore, if your current production fleet already causes errors, consider using or modifying one of the following examples that only monitors the new fleet for errors.

```json
#Applied deployment type: all types
{
  "AlarmName": "EndToEndDeploymentHighErrorRateAlarm",
  "AlarmDescription": "Monitors the error rate of 4xx errors",
  "MetricName": "Invocation4XXErrors",
  "Namespace": "AWS/SageMaker",
  "Statistic": "Average",
  "Dimensions": [
    {
      "Name": "EndpointName",
      "Value": "<your-endpoint-name>"
    },
    {
      "Name": "VariantName",
      "Value": "AllTraffic"
    }
  ],
  "Period": 600,
  "EvaluationPeriods": 2,
  "Threshold": 1,
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:

- For **AlarmName** and **AlarmDescription**, enter a name and description you choose for the alarm.
- For **MetricName**, use the value **Invocation4XXErrors** to monitor for 4xx errors on the endpoint.
- For **Namespace**, use the value **AWS/SageMaker**. You can also specify your own custom metric, if applicable.
- For **Statistic**, use **Average**. This means that the alarm takes the average error rate over the evaluation periods when calculating whether the error rate has exceeded the threshold.
- For the dimension **EndpointName**, use the name of the endpoint you are updating as the value.
- For the dimension **VariantName**, use the value **AllTraffic** to specify all endpoint traffic.
- For **Period**, use 600. This sets the alarm's evaluation periods to 10 minutes long.
- For **EvaluationPeriods**, use 2. This value tells the alarm to consider the two most recent evaluation periods when determining the alarm status.

Monitor model latency on the new fleet

The following CloudWatch alarm example monitors the new fleet's model latency during your deployment. You can use this alarm to monitor only the new fleet and exclude the old fleet. The alarm lasts for the entire deployment. This example gives you comprehensive, end-to-end monitoring of the new fleet and initiates a rollback to the old fleet if the new fleet has any response time issues.

CloudWatch publishes the metrics with the dimension `EndpointConfigName: {New-Ep-Config}` after the new fleet starts receiving traffic, and these metrics last even after the deployment is complete.

You can use the following alarm example with any deployment type.

```json
#Applied deployment type: all types
```
{  
  "AlarmName": "NewEndpointConfigVersionHighModelLatencyAlarm",
  "AlarmDescription": "Monitors the model latency on new fleet",
  "MetricName": "ModelLatency",
  "Namespace": "AWS/SageMaker",
  "Statistic": "Average",
  "Dimensions": [
    {
      "Name": "EndpointName",
      "Value": "<your-endpoint-name>
    },
    {
      "Name": "VariantName",
      "Value": "AllTraffic"
    },
    {
      "Name": "EndpointConfigName",
      "Value": "<your-config-name>
    }
  ],
  "Period": 300,
  "EvaluationPeriods": 2,
  "Threshold": 100000, # 100ms
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
}

In the previous example, note the values for the following fields:

- For MetricName, use the value ModelLatency to monitor the model's response time.
- For Namespace, use the value AWS/SageMaker. You can also specify your own custom metric, if applicable.
- For the dimension EndpointName, use the name of the endpoint you are updating as the value.
- For the dimension VariantName, use the value AllTraffic to specify all endpoint traffic.
- For the dimension EndpointConfigName, the value should refer to the endpoint configuration name for your new or updated endpoint.

Note

If you want to monitor your old fleet instead of the new fleet, you can change the dimension EndpointConfigName to specify the name of your old fleet's configuration.

**Blue/Green Deployments**

When you update your endpoint, Amazon SageMaker automatically uses a blue/green deployment to maximize the availability of your endpoints. In a blue/green deployment, SageMaker provisions a new fleet with the updates (the green fleet). Then, SageMaker shifts traffic from the old fleet (the blue fleet) to the green fleet. Once the green fleet operates smoothly for a set evaluation period (called the baking period), SageMaker terminates the blue fleet. With the additional capabilities in blue/green deployments, you can utilize traffic shifting modes and auto-rollback monitoring to protect your endpoint from significant production impact.

The following list describes the key features of blue/green deployments in SageMaker:

- **Traffic shifting modes.** The traffic shifting modes for deployment guardrails let you control the volume of traffic and number of traffic-shifting steps between the blue fleet and the green fleet. This capability gives you the ability to progressively evaluate the performance of the green fleet without fully committing to a 100% traffic shift.
- **Baking period.** The baking period is a set amount of time to monitor the green fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking
period, then all endpoint traffic rolls back to the blue fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.

- **Auto-rollback**. You can specify Amazon CloudWatch alarms that SageMaker uses to monitor the green fleet. If an issue with the updated code trips any of the alarms, SageMaker initiates an auto-rollback to the blue fleet in order to maintain availability thereby minimizing risk.

### Traffic Shifting Modes

The various traffic shifting modes in blue/green deployments give you more granular control over traffic shifting between the blue fleet and the green fleet. The available traffic shifting modes for blue/green deployments are all at once, canary, and linear. The following table shows a comparison of the options.

**Important**  
For blue/green deployments that involve multiple stage traffic shifting or baking periods, you are billed for both the fleets for the duration of the update, irrespective of the traffic to the fleet. This is in contrast to blue/green deployments with all at once traffic shifting and no baking periods, where you are only billed for one fleet during the course of the update.

<table>
<thead>
<tr>
<th>Name</th>
<th>What is it?</th>
<th>Pros</th>
<th>Cons</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>All at once</td>
<td>Shifts all of the traffic to the new fleet in a single step.</td>
<td>Minimizes the overall update duration.</td>
<td>Regressive updates affect 100% of the traffic.</td>
<td>Use this option to minimize update time and cost.</td>
</tr>
<tr>
<td>Canary</td>
<td>Traffic shifts in two steps. The first (canary) step shifts a small portion of the traffic followed by the second step, which shifts the remainder of the traffic.</td>
<td>Confines the blast radius of regressive updates to only the canary fleet.</td>
<td>Both fleets are operational in parallel for entire deployment.</td>
<td>Use this option to balance between minimizing the blast radius of regressive updates and minimizing the time that two fleets are operational.</td>
</tr>
<tr>
<td>Linear</td>
<td>A fixed portion of the traffic shifts in a pre-specified number of equally spaced steps.</td>
<td>Minimizes the risk of regressive updates by shifting traffic over several steps.</td>
<td>The update duration and cost are proportional to the number of steps.</td>
<td>Use this option to minimize risk by spreading out deployment across multiple steps.</td>
</tr>
</tbody>
</table>

### Get Started

Once you specify your desired deployment configuration, SageMaker handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing **UpdateEndpoint** and **CreateEndpoint** SageMaker API and AWS Command Line Interface commands. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2216) page, you cannot use deployment guardrails. See the individual deployment pages for more details on how to set up your deployment:

- **Blue/Green Update with All At Once Traffic Shifting** (p. 2205)
- **Blue/Green Update with Canary Traffic Shifting** (p. 2208)
- **Blue/Green Update with Linear Traffic Shifting** (p. 2212)
To follow guided examples that show how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

**All At Once Traffic Shifting**

With all at once traffic shifting, you can quickly roll out an endpoint update using the safety guardrails of a blue/green deployment. You can use this traffic shifting option to minimize the update duration while still taking advantage of the availability guarantees of blue/green deployments. The baking period feature helps you to monitor the performance and functionality of your new instances before terminating your old instances, ensuring that your new fleet is fully operational.

The following diagram shows how all at once traffic shifting manages the old and new fleets.
When you use all at once traffic shifting, SageMaker routes 100% of the traffic to the new fleet (green fleet). Once the green fleet starts receiving traffic, the baking period begins. The baking period is a set amount of time in which pre-specified Amazon CloudWatch alarms monitor the performance of the green fleet. If no alarms trip during the baking period, SageMaker terminates the old fleet (blue fleet). If any alarms trip during the baking period, then an auto-rollback initiates and 100% of the traffic shifts back to the blue fleet.

**Prerequisites**

Before setting up a deployment with all at once traffic shifting, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic rolls back to your blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page *Auto-Rollback Configuration and Monitoring* (p. 2201). To learn more about CloudWatch alarms, see *Using Amazon CloudWatch alarms* in the *Amazon CloudWatch User Guide*.

**Configure All At Once Traffic Shifting**

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the SageMaker *UpdateEndpoint* API or the *update-endpoint* command in the AWS Command Line Interface to initiate the deployment.

**Topics**
- How to update an endpoint (API) (p. 2206)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2207)
- How to update an endpoint (CLI) (p. 2207)

**How to update an endpoint (API)**

The following example shows how you can update your endpoint with all at once traffic shifting using *UpdateEndpoint* in the Amazon SageMaker API.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "ALL_AT_ONCE"
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                { "AlarmName": "<your-cw-alarm>" }]
        }
    }
)
```

To configure the all at once traffic shifting option, do the following:
- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
• Under DeploymentConfig and BlueGreenUpdatePolicy, in TrafficRoutingConfiguration, set the Type parameter to ALL_AT_ONCE. This specifies that the deployment uses the all at once traffic shifting mode.
• For TerminationWaitInSeconds, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
• For MaximumExecutionTimeoutInSeconds, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
• In AutoRollbackConfiguration, within the Alarms field, you can add your CloudWatch alarms by name. Create one AlarmName: <your-cw-alarm> entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same DeploymentConfig options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the RetainDeploymentConfig option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set RetainDeploymentConfig to True to keep the DeploymentConfig options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green all at once deployment using the update-endpoint command.

```bash
update-endpoint
   --endpoint-name <your-endpoint-name>
   --endpoint-config-name <your-config-name>
   --deployment-config '{"BlueGreenUpdatePolicy": {
   "TrafficRoutingConfiguration": {
   "Type": "ALL_AT_ONCE"},
   "TerminationWaitInSeconds": 600, 
   "MaximumExecutionTimeoutInSeconds": 1800
   },
   "AutoRollbackConfiguration": {
   "Alarms": [{"AlarmName": "<your-alarm>"}]
   }}'
```

To configure the all at once traffic shifting option, do the following:

• For endpoint-name, use the name of the endpoint you want to update.
• For endpoint-config-name, use the name of the endpoint configuration you want to use.
• For deployment-config, use a BlueGreenUpdatePolicy JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.
Canary Traffic Shifting

With canary traffic shifting, you can test a portion of your endpoint traffic on the new fleet while the old fleet serves the remainder of the traffic. This testing step is a safety guardrail that validates the new fleet's functionality before shifting all of your traffic to the new fleet. You still have the benefits of a blue/green deployment, and the added canary feature lets you ensure that your new (green) fleet can serve inference before letting it handle 100% of the traffic.

The portion of your green fleet that turns on to receive traffic is called the canary, and you can choose the size of this canary. Note that the canary size should be less than or equal to 50% of the new fleet's capacity. Once the baking period finishes and no pre-specified Amazon CloudWatch alarms trip, the rest of the traffic shifts from the old (blue) fleet to the green fleet. Canary traffic shifting provides you with more safety during your deployment since any issues with the updated model only impact the canary.

The following diagram shows how canary traffic shifting manages the distribution of traffic between the blue and green fleets.
Blue/Green Deployments

Deployment Stages

Canary - Create

Canary - CanaryFlipTraffic

Canary - CanaryBake

Canary - FirstFlipTraffic

Canary - FirstBake

Canary - Cleanup
Once SageMaker provisions the green fleet, SageMaker routes a portion of the incoming traffic (for example, 25%) to the canary. Then the baking period begins, during which your CloudWatch alarms monitor the performance of the green fleet. During this time, both the blue fleet and green fleet are partially active and receiving traffic. If any of the alarms trip during the baking period, then SageMaker initiates a rollback and all traffic returns to the blue fleet. If none of the alarms trip, then all of the traffic shifts to the green fleet and there is a final baking period. If the final baking period finishes without tripping any alarms, then the green fleet serves all traffic and SageMaker terminates the blue fleet.

**Prerequisites**

Before setting up a deployment with canary traffic shifting, you must create Amazon CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2201). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure Canary Traffic Shifting**

Once you are ready for your deployment and have set up Amazon CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker `UpdateEndpoint` API or the `update-endpoint` command in the AWS CLI to initiate the deployment.

**Topics**

- How to update an endpoint (API) (p. 2210)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2211)
- How to update an endpoint (CLI) (p. 2211)

**How to update an endpoint (API)**

The following example of the `UpdateEndpoint` API shows how you can update an endpoint with canary traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "CANARY",
                "CanarySize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 30
                },
                "WaitIntervalInSeconds": 600
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>
                }
            ]
        }
    }
)
```

2210
To configure the canary traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **CANARY**. This specifies that the deployment uses canary traffic shifting.
- In the **CanarySize** field, you can change the size of the canary by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the canary, and then set **Value** to 30. In this example, you use 30% of the green fleet's capacity as the canary. Note that the canary size should be equal to or less than 50% of the green fleet's capacity.
- For **WaitIntervalInSeconds**, use 600. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each interval shift. This interval is the duration of the canary baking period. In the preceding example, SageMaker waits for 10 minutes after the canary shift and then completes the second and final traffic shift.
- For **TerminationWaitInSeconds**, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
- For **MaximumExecutionTimeoutInSeconds**, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

**How to update an endpoint with an existing blue/green update policy (API)**

When you use the **CreateEndpoint** API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same **DeploymentConfig** options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the **UpdateEndpoint** API to update your endpoint. When updating your endpoint, you can use the **RetainDeploymentConfig** option to keep the deployment configuration you specified when you created the endpoint.

When calling the **UpdateEndpoint** API, set **RetainDeploymentConfig** to **True** to keep the **DeploymentConfig** options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

**How to update an endpoint (CLI)**

If you are using the AWS CLI, the following example shows how to start a blue/green canary deployment using the **update-endpoint** command.
To configure the canary traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

### Linear Traffic Shifting

Linear traffic shifting enables you to gradually shift traffic from your old fleet (blue fleet) to your new fleet (green fleet). With linear traffic shifting, you can shift traffic in multiple steps, minimizing the chance of a disruption to your endpoint. This blue/green deployment option gives you the most granular control over traffic shifting.

You can choose either the number of instances or the percentage of the green fleet's capacity to activate during each step. Each linear step should only be between 10-50% of the green fleet's capacity. For each step, there is a baking period during which your pre-specified Amazon CloudWatch alarms monitor metrics on the green fleet. Once the baking period finishes and no alarms trip, the active portion of your green fleet continues receiving traffic and a new step begins. If alarms trip during any of the baking periods, 100% of the endpoint traffic rolls back to the blue fleet.

The following diagram shows how linear traffic shifting routes traffic to the blue and green fleets.
Once SageMaker provisions the new fleet, the first portion of the green fleet turns on and receives traffic. SageMaker deactivates the same size portion of the blue fleet, and the baking period begins. If any alarms trip, all of the endpoint traffic rolls back to the blue fleet. If the baking period finishes, then the next step begins. Another portion of the green fleet activates and receives traffic, part of the blue fleet deactivates, and another baking period begins. The same process repeats until the blue fleet is fully deactivated and the green fleet is fully active and receiving all traffic. If an alarm goes off at any point, SageMaker terminates the shifting process and 100% of the traffic rolls back to the blue fleet.

Prerequisites

Before setting up a deployment with linear traffic shifting, you must create CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2201). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

Configure Linear Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the update-endpoint command in the AWS CLI to initiate the deployment.

Topics

- How to update an endpoint (API) (p. 2214)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2215)
- How to update an endpoint (CLI) (p. 2211)

How to update an endpoint (API)

The following example of the UpdateEndpoint API shows how you can update an endpoint with linear traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig=
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "LINEAR",
                "LinearStepSize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 20
                },
                "WaitIntervalInSeconds": 300
            },
            "TerminationWaitInSeconds": 300,
            "MaximumExecutionTimeoutInSeconds": 3600
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {"AlarmName": "<your-cw-alarm>"}
            ]
        }
    )
```

2214
To configure the linear traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **LINEAR**. This specifies that the deployment uses linear traffic shifting.
- In the **LinearStepSize** field, you can change the size of the steps by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the step size, and then set **Value** to 20. In this example, you turn on 20% of the green fleet's capacity for each traffic shifting step. Note that when customizing your linear step size, you should only use steps that are 10-50% of the green fleet's capacity.
- For **WaitIntervalInSeconds**, use 300. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each traffic shift. This interval is the duration of the baking period between each linear step. In the preceding example, SageMaker waits for 5 minutes between each traffic shift.
- For **TerminationWaitInSeconds**, use 300. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 5 minutes after the final baking period before terminating the blue fleet.
- For **MaximumExecutionTimeoutInSeconds**, use 3600. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 1 hour to finish.
- In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the **CreateEndpoint** API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same **DeploymentConfig** options as the previous **UpdateEndpoint** API example. There are no changes to the **CreateEndpoint** API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the **UpdateEndpoint** API to update your endpoint. When updating your endpoint, you can use the **RetainDeploymentConfig** option to keep the deployment configuration you specified when you created the endpoint.

When calling the **UpdateEndpoint** API, set **RetainDeploymentConfig** to **True** to keep the **DeploymentConfig** options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green linear deployment using the **update-endpoint** command.

```bash
update-endpoint
```
To configure the linear traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

**Exclusions**

You can only use deployment guardrails with newly created endpoints. There are also feature-based exclusions that make your endpoint incompatible with deployment guardrails at this time. If your endpoint uses any of the following features, you cannot use deployment guardrails on your endpoint, and your endpoint will fall back to using a blue/green deployment with all at once traffic shifting and no final baking period.

- Marketplace containers
- Endpoints that use Inf1 (Inferentia-based) instances
- Amazon Elastic Inference endpoints

**Inference cost optimization best practices**

The following content provides techniques and considerations for optimizing the cost of endpoints. You can use these recommendations to optimize the cost for both new and existing endpoints.

**Best practices**

To optimize your SageMaker Inference costs, follow these best practices.

**Pick the best inference option for the job.**

SageMaker offers 4 different inference options to provide the best inference option for the job. You may be able to save on costs by picking the inference option that best matches your workload.

- Use **real-time inference** for low latency workloads with predictable traffic patterns that need to have consistent latency characteristics and are always available. You pay for using the instance.
- Use **serverless inference** for synchronous workloads that have a spiky traffic pattern and can accept variations in the p99 latency. Serverless inference automatically scales to meet your workload traffic so you don’t pay for any idle resources. You only pay for the duration of the inference request. The same model and containers can be used with both real-time and serverless inference so you can switch between these two modes if your needs change.
• Use **asynchronous inference** for asynchronous workloads that process up to 1 GB of data (such as text corpus, image, video, and audio) that are latency insensitive and cost sensitive. With asynchronous inference, you can control costs by specifying a fixed number of instances for the optimal processing rate instead of provisioning for the peak. You can also scale down to zero to save additional costs.

• Use **batch inference** for workloads for which you need inference for a large set of data for processes that happen offline (that is, you don’t need a persistent endpoint). You pay for the instance for the duration of the batch inference job.

**Opt in to a SageMaker Savings Plan.**

• If you have a consistent usage level across all SageMaker services, you can opt in to a SageMaker Savings Plan to help reduce your costs by up to 64%.

• **Amazon SageMaker Savings Plans** provide a flexible pricing model for Amazon SageMaker, in exchange for a commitment to a consistent amount of usage (measured in $/hour) for a one-year or three-year term. These plans automatically apply to eligible SageMaker ML instance usages including SageMaker Studio Notebook, SageMaker On-Demand Notebook, SageMaker Processing, SageMaker Data Wrangler, SageMaker Training, SageMaker Real-Time Inference, and SageMaker Batch Transform regardless of instance family, size, or Region. For example, you can change usage from a CPU ml.c5.xlarge instance running in US East (Ohio) to a ml.Inf1 instance in US West (Oregon) for inference workloads at any time and automatically continue to pay the Savings Plans price.

**Optimize your model to run better.**

• Unoptimized models can lead to longer run times and use more resources. You may choose to use more or bigger instances to improve performance; however, this leads to higher costs.

• By optimizing your models to be more performant, you may be able to lower costs by using fewer or smaller instances while keeping the same or better performance characteristics. You can use **SageMaker Neo** with SageMaker Inference to automatically optimize models. For more details and samples, see **Optimize model performance using Neo** (p. 2305).

**Use the most optimal instance type and size for real-time inference.**

• SageMaker Inference has over 70 instance types and sizes that can be used to deploy ML models including AWS Inferentia and Graviton chipsets that are optimized for ML. Choosing the right instance for your model helps ensure you have the most performant instance at the lowest cost for your models.

• By using **Inference Recommender**, you can quickly compare different instances to understand the performance of the model and the costs. With these results, you can choose the instance to deploy with the best return on investment.

**Improve efficiency and costs by combining multiple endpoints into a single endpoint for real-time inference.**

• Costs can quickly add up when you deploy multiple endpoints, especially if the endpoints don’t fully utilize the underlying instances. To understand if the instance is under-utilized, check the utilization metrics (CPU, GPU, etc) in Amazon CloudWatch for your instances. If you have more than one of these endpoints, you can combine the models or containers on these multiple endpoints into a single endpoint.

• Using **Multi-model endpoints (MME)** or **Multi-container endpoints (MCE)**, you can deploy multiple ML models or containers in a single endpoint to share the instance across multiple models or containers and improve your return on investment. To learn more, see this **Save on inference costs by using**
Set up autoscaling to match your workload requirements for real-time and asynchronous inference.

- Without autoscaling, you need to provision for peak traffic or risk model unavailability. Unless the traffic to your model is steady throughout the day, there will be excess unused capacity. This leads to low utilization and wasted resources.
- **Autoscaling** is an out-of-the-box feature that monitors your workloads and dynamically adjusts the capacity to maintain steady and predictable performance at the possible lowest cost. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances, helping you reduce your compute cost. To learn more, see Configuring autoscaling inference endpoints in Amazon SageMaker on the AWS Machine Learning blog.

Shadow tests

With Amazon SageMaker you can evaluate any changes to your model serving infrastructure by comparing its performance against the currently deployed infrastructure. This practice is known as shadow testing. Shadow testing can help you catch potential configuration errors and performance issues before they impact end users. With SageMaker, you don't need to invest in building your shadow testing infrastructure, so you can focus on model development.

You can use this capability to validate changes to any component of your production variant, namely the model, the container, or the instance, without any end user impact. It is useful in situations including but not limited to the following:

- You are considering promoting a new model that has been validated offline to production, but want to evaluate operational performance metrics such as latency and error rate before making this decision.
- You are considering changes to your serving infrastructure container, such as patching vulnerabilities or upgrading to newer versions, and want to assess the impact of these changes prior to promotion to production.
- You are considering changing your ML instance and want to evaluate how the new instance would perform with live inference requests.

The SageMaker console provides a guided experience to manage the workflow of shadow testing. You can setup shadow tests for a predefined duration of time, monitor the progress of the test through a live dashboard, clean up upon completion, and act on the results. Select a production variant you want to test against, and SageMaker automatically deploys the new variant in shadow mode and routes a copy of the inference requests to it in real time within the same endpoint. Only the responses of the production variant are returned to the calling application. You can choose to discard or log the responses of the shadow variant for offline comparison. For more information on production and shadow variants, see Safely validate models in production (p. 2051).

See Create a shadow test (p. 2218) for instructions on creating a shadow test.

Create a shadow test

You can create a shadow test to compare the performance of a shadow variant against a production variant. You can run the test on an existing endpoint that is serving inference requests or you can create a new endpoint on which to run the test.
To create a shadow test you need to specify the following:

- A production variant that receives and responds to 100 percent of the incoming inference requests.
- A shadow variant that receives a percentage of the incoming requests, replicated from the production variant, but does not return any responses.

For each variant, you can use SageMaker to control the model, instance type, and instance count. You can configure the percentage of incoming requests, known as the traffic sampling percentage, that you want replicated to your shadow variant. SageMaker manages the replication of requests to your shadow variant and you can modify the traffic sampling percentage when your test is scheduled or running. You can also optionally turn on Data Capture to log requests and responses of your production and shadow variants.

**Note**
SageMaker supports a maximum of one shadow variant per endpoint. For an endpoint with a shadow variant, there can be a maximum of one production variant.

You can schedule the test to start at any time and continue for a specified duration. The default duration is 7 days and the maximum is 30 days. After the test is complete, the endpoint reverts to the state it was in prior to starting the test. This ensures that you do not have to manually clean up resources upon the completion of the test.

You can monitor a test that is running through a dashboard in the SageMaker console. The dashboard provides a side by side comparison of invocation metrics and instance metrics between the production and shadow variants, along with a tabular view with relevant metric statistics. This dashboard is also available for completed tests. Once you have reviewed the metrics, you can either choose to promote the shadow variant to be the new production variant or retain the existing production variant. Once you promote the shadow variant, it responds to all incoming requests. For more information, see [Promote a shadow variant](p. 2231).

The following procedure describes how to create a shadow test through the SageMaker console. There are variations in the workflow depending on whether you want to use an existing endpoint or to create a new endpoint for the shadow test.

**Topics**
- Prerequisites (p. 2219)
- Enter shadow test details (p. 2219)
- Enter shadow test settings (p. 2220)

**Prerequisites**

Before creating a shadow test with the SageMaker console, you must have a SageMaker model ready to use. For more information about how to create a SageMaker model, see [Create a Model](p. 1980).

You can get started with shadow tests with an existing endpoint with a production variant and a shadow variant, an existing endpoint with only a production variant, or just the SageMaker models you’d like to compare. Shadow tests support creating an endpoint and adding variants before your test begins.

**Enter shadow test details**

To start creating your shadow test, fill out the Enter shadow test details page by doing the following:

1. Open the SageMaker console.
2. In the left navigation panel, choose Inference, and then choose Shadow tests.
3. Choose **Create shadow test**.
4. Under **Name**, enter a name for the test.
5. (Optional) Under **Description**, enter a description for the test.
6. (Optional) Specify **Tags** using **Key** and **Value** pairs.
7. Choose **Next**.

**Enter shadow test settings**

After filling out the **Enter shadow test details** page, fill out the **Enter shadow test settings** page. If you already have a SageMaker Inference endpoint and a production variant, follow the **Use an existing endpoint** workflow. If you don't already have an endpoint, follow the **Create a new endpoint** workflow.

**Use an existing endpoint**

If you want to use an existing endpoint for your test, fill out the **Enter shadow test settings** page by doing the following:

1. Choose a role that has the **AmazonSageMakerFullAccess** IAM policy attached.
2. Choose **Use an existing endpoint**, and then choose one of the available endpoints.
3. (Optional) To encrypt the storage volume on your endpoint, either choose an existing KMS key or choose **Enter a KMS key ARN** from the dropdown list under **Encryption key**. If you choose the second option, a field to enter the KMS key ARN appears. Enter the KMS key ARN in that field.
4. If you have multiple production variants behind that endpoint, remove the ones you don't want to use for the test. You can remove a model variant by selecting it and then choosing **Remove**.
5. If you do not already have a shadow variant, add a shadow variant. To add a shadow variant, do the following:
   a. Choose **Add**.
   b. Choose **Shadow variant**.
   c. In the **Add model** dialog box, choose the model you want to use for your shadow variant.
   d. Choose **Save**.
6. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. For more information on filling out this dialog box, see **Edit a shadow test** (p. 2229).
7. In the **Schedule** section, enter the duration of the test by doing the following:
   a. Choose the box under **Duration**. A popup calender appears.
   b. Select the start and end dates from the calender, or enter the start and end dates in the fields for **Start date** and **End date**, respectively.
   c. (Optional) For the fields **Start time** and **End time**, enter the start and end times, respectively, in the 24 hour format.
   d. Choose **Apply**.

The minimum duration is 1 hour, and the maximum duration is 30 days.
8. (Optional) Turn on **Enable data capture** to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.
9. Choose **Create shadow test**.
Create a new endpoint

If you don't have an existing endpoint, or you want to create a new endpoint for your test, fill out the **Enter shadow test settings** page by doing the following:

1. Choose a role that has the AmazonSageMakerFullAccess IAM policy attached.
2. Choose **Create a new endpoint**.
3. Under **Name**, enter a name for the endpoint.
4. Add one production variant and one shadow variant to the endpoint:
   - To add a production variant choose **Add**, and then choose **Production variant**. In the **Add model** dialog box, choose the model you want to use for your production variant, and then choose **Save**.
   - To add a shadow variant choose **Add**, and then choose **Shadow variant**. In the **Add model** dialog box, choose the model you want to use for your shadow variant, and then choose **Save**.
5. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. For more information on filling out this dialog box, see **Edit a shadow test** (p. 2229).
6. In the **Schedule** section, enter the duration of the test by doing the following:
   a. Choose the box under **Duration**. A popup calendar appears.
   b. Select the start and end dates from the calendar, or enter the start and end dates under **Start date** and **End date**, respectively.
   c. (Optional) Under **Start time** and **End time**, enter the start and end times, respectively, in the 24 hour format.
   d. Choose **Apply**.

   The minimum duration is 1 hour, and the maximum duration is 30 days.
7. (Optional) Turn on **Enable data capture** to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.
8. Choose **Create shadow test**.

After completing the preceding procedures, you should now have a test scheduled to begin at your specified start date and time. You can view the progress of the test from a dashboard. For more information about viewing your test and the actions you can take, see **View, monitor, and edit shadow tests** (p. 2221).

**View, monitor, and edit shadow tests**

You can view the statuses of your shadow tests, monitor their progress from a dashboard, and perform actions, such as starting or stopping an test early or deleting an test. The following sections show how you can view and modify your shadow tests using the SageMaker console.

**Topics**

- View shadow tests (p. 2222)
- Monitor a shadow test (p. 2224)
- Start a shadow test early (p. 2228)
- Complete a shadow test early (p. 2229)
- Delete a shadow test (p. 2229)
View shadow tests

You can view the statuses of all of your shadow tests on the Shadow tests page on the SageMaker console.

To view your tests in the console, do the following:

1. Open the SageMaker console.
2. In the navigation panel, choose Inference.
3. Choose Shadow tests to view the page that lists all of your shadow tests. The page should look like the following screenshot, with all the tests listed under the Shadow test section.

Shadow test

Create shadow tests to monitor and edit serving infrastructure impact on end users for a specified duration in a self-service manner. Tear down resources when done.
You can see the status of a test in the console on the **Shadow tests** page by checking the **Status** field for the test.

The following are the possible statuses for a test:

- **Creating** – SageMaker is creating your test.
- **Created** – SageMaker has finished creating your test, and it will begin at the scheduled time.
- **Updating** – When you make changes to your test, your test shows as updating.
- **Starting** – SageMaker is beginning your test.
- **Running** – Your test is in progress.
- **Stopping** – SageMaker is stopping your test.
- **Completed** – Your test has completed.
- **Cancelled** – When you conclude your test early, it shows as cancelled.

### Monitor a shadow test

You can view the details of a shadow test and monitor it while it is in progress or after it has completed. SageMaker presents a live dashboard comparing the operational metrics like model latency, and error rate aggregated, of the production and shadow variants.

To view the details of an individual test in the console, do the following:

1. Select the test you want to monitor from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **View**. An overview page with the details of the test and a metrics dashboard appears.

The overview page has the following three sections.

#### Summary

This section summarizes the progress and status of the test. It also shows the summary statistics of the metric chosen from the **Select metric** dropdown list in the **Metrics** subsection. The following screenshot shows this section.
View, monitor, and edit shadow tests

**shadow-test-demo-2**

**Summary**

**Status**

Running

**Reason**

-

**Metrics**

**Select metric**

View the selected metric summary and statistics from the start of experiment to present.

ModellLatency

- A lower value of the latency metric usually indicates a faster model response.
In the preceding screenshot, the Settings, and Details tabs show the settings that you selected, and the details that you entered when creating the test.

**Analysis**

This section shows a metrics dashboard with separate graphs for the following metrics:

- Invocations
- InvocationsPerInstance
- ModelLatency
- Invocation4XXErrors
- Invocation5XXErrors
- InvocationModelErrors
- CPUUtilization
- MemoryUtilization
- DiskUtilization

The last three metrics monitor the model container runtime resource usage. The rest are CloudWatch metrics that you can use to analyse the performance of your variant. In general, fewer errors indicate a more stable model. A lower latency indicates either a faster model or a faster infrastructure. For more information about CloudWatch metrics, see SageMaker Endpoint Invocation Metrics (p. 3819). The following screenshot shows the metrics dashboard.
Environment

This section shows the variants that you compared in the test. If you are satisfied by the performance of the shadow variant, based on the aforementioned metrics, you can promote the shadow variant to production, by choosing **Deploy shadow variant**. For more details about deploying a shadow variant, see Promote a shadow variant (p. 2231). You can also change the traffic sampling percentage, and continue testing, by choosing **Edit traffic**. For more details about editing a shadow variant, see **Edit a shadow test** (p. 2229). The following screenshot shows this section.

---

Start a shadow test early

You can start your test before its scheduled start time. If the new duration of the test exceeds 30 days, SageMaker automatically sets the end of the test to 30 days after the new start time. This action starts the test immediately. If you want to change the start or end time of the test, see **Edit a shadow test** (p. 2229).

To immediately start your test, before its scheduled start time, through the console, do the following:
1. Select the test you want to start immediately from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Start. The Start shadow test? dialog box appears.
3. Choose Start now.

Complete a shadow test early

You can complete an in-progress test before the end of its scheduled duration. For more information see Complete a shadow test early (p. 2230).

Delete a shadow test

You can delete a test that you no longer need. Deleting your test only deletes the test metadata and not your endpoint, variants, or data captured in Amazon S3. If you want your endpoint to stop running, you must delete your endpoint. For more information about deleting an endpoint, see Delete Endpoints and Resources (p. 1983)

To delete a test through the console, do the following:

1. Select the test you want to delete from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Delete. The Delete shadow test dialog box appears.
3. In the To confirm deletion, type delete in the field. text box, enter delete.
4. Choose Delete.

Edit a shadow test

You can modify both scheduled and in-progress tests. Before your test starts, you can change the description, the shadow variant configuration, the start date, and the end date of the test. You can also turn on or turn off data capture.

After your test starts, you can only change the description, the traffic sampling percentage for the shadow variant, and the end date.

To edit the details of your test through the console, do the following:

1. Select the test you want to edit from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Edit. The Enter shadow test details page appears.
3. (Optional) Under Description, enter a description of your test.
4. Choose Next. The Enter shadow test settings page appears.
5. (Optional) To edit your shadow variant, do the following:
   a. Select the shadow variant and choose Edit. The Edit shadow variant dialog box appears. If your test has already started, then you can only change the traffic sampling percentage.
   b. (Optional) Under Name, enter the new name to replace the old name.
   c. (Optional) Under Traffic sample, enter the new traffic sampling percentage to replace the old traffic sampling percentage.
   d. (Optional) Under Instance type, select the new instance type from the dropdown list.
   e. (Optional) Under Instance count, enter the new instance count to replace the old instance count.
   f. Choose Apply.
You cannot change the model in your shadow variant using the above procedure. If you want to change the model, first remove the shadow variant by selecting it and choosing Remove. Then add a new shadow variant.

6. (Optional) To edit the duration of the test, do the following:
   a. Choose the box under Duration in the Schedule section. A popup calendar appears.
   b. If your test is yet to start, you can change both the start and end dates. Select the new start and end dates from the calendar, or enter the new start and end dates under Start date and End date, respectively.
      
      If your test has already started, you can only change the end date. Enter the new end date under End date.
   c. (Optional) If your test is yet to start, you can change both the start and end times. Enter the new start and end times under Start time, and End time, respectively, in the 24 hour format.
      
      If your test has already started, you can only change the end time. Enter the new end time under End time, in the 24 hour format.
   d. Choose Apply.

7. (Optional) Turn on or turn off Enable data capture.

8. Choose Update shadow test.

Complete a shadow test

Your test automatically completes at the end of the scheduled duration, or you can stop an in-progress test early. After your test has completed, the test's status in the Shadow tests section on the Shadow tests page shows as Complete. Then you can review and analyze the final metrics of your test.

You can use the metrics dashboard to decide whether to promote the shadow variant to production. For more information about analyzing the metrics dashboard of your test, see Monitor a shadow test (p. 2224).

For instructions on how to complete your test before the end of its scheduled completion time, see Complete a shadow test early (p. 2230).

For instructions on promoting your shadow variant to production, see Promote a shadow variant (p. 2231).

Complete a shadow test early

One reason you might want to complete an in-progress shadow test is if you've decided that the metrics for your shadow variant look good and you want to promote it to production. You might also decide to complete the test if one or more of the variants aren't performing well.

To complete your test before its scheduled end date, do the following:

1. Select the test you want to mark complete from the Shadow tests section on the Shadow tests page.
2. From the Actions dropdown list, choose Complete, and the Complete shadow test dialog box appears.
3. In the dialog box, choose one of the following options:
   - Yes, deploy shadow variant
• No, remove shadow variant

4. (Optional) In the Comment text box, enter your reason for completing the test before its scheduled end time.

5. 1. If you decided to deploy the shadow variant, choose Complete and proceed to deploy. The Deploy shadow variant page appears. For instructions on how to fill out this page, see Promote a shadow variant (p. 2231).

2. If you decide to remove the shadow variant, choose Confirm.

**Promote a shadow variant**

If you've decided that you want to replace your production variant with your shadow variant, you can update your endpoint and promote your shadow variant to respond to inference requests. This removes your current production variant from production and replaces it with your shadow variant.

If your shadow test is still in-progress, you must first complete your test. To complete your shadow test before its scheduled end, follow the instructions in Complete a shadow test early (p. 2230) before continuing with this section.

When you promote a shadow variant to production, you have the following options for the instance count of the shadow variant.

• You can retain the instance count and type from the production variant. If you select this option, then your shadow variant launches in production with the current instance count, ensuring that your model can continue to process request traffic at the same scale.

• You can retain the instance count and type of your shadow variant. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

• You can use custom values for the instance count and type. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

Unless you are validating the instance type or count or both of the shadow variant, we highly recommend that you retain the instance count and type from the production variant when promoting your shadow variant.

To promote your shadow variant, do the following:

1. If your test has completed, do the following:
   a. Select the test from the Shadow test section on the Shadow tests page.
   b. From the Actions dropdown list, choose View. The dashboard appears.
   c. Choose Deploy shadow variant in the Environment section. The Deploy shadow variant page appears.

   If your test has not completed, see Complete a shadow test early (p. 2230) to complete it.

2. In the Variant settings section, select one of the following options:
   • Retain production settings
   • Retain shadow settings
   • Custom instance settings

   If you selected Custom instance settings, do the following:
Select the instance type from the **Instance type** dropdown list.

Under **Instance count**, enter the number of instances.

3. In **Enter ‘deploy’ to confirm deployment** text box, enter **deploy**.

4. Choose **Deploy shadow variant**.

Your SageMaker Inference endpoint is now using the shadow variant as your production variant, and your production variant has been removed from the endpoint.

**Best Practices**

When creating an inference experiment, keep the following information in mind:

- **Traffic sampling percentage** – Sampling 100 percent of the inference requests lets you validate that your shadow variant can handle production traffic when promoted. You may start off with a lower traffic sampling percentage and dial up as you gain confidence in your variant, but it is best practice to ensure that you've increased the traffic to 100 percent prior to promotion.

- **Instance type** – Unless you are using shadow variants to evaluate alternate instance types or sizes, we recommend that you use the same instance type, size, and count so that you can be certain that your shadow variant can handle the volume of inference requests after you promote it.

- **Auto scaling** – To ensure that your shadow variant can respond to spikes in the number of inference requests or changes in inference requests patterns, we highly recommend that you configure autoscaling on your shadow variants. To learn how to configure autoscaling, see [Automatically Scale Amazon SageMaker Models](p. 2035). If you have configured autoscaling, you can also validate changes to autoscaling policies without causing impact to users.

- **Metrics monitoring** – After you initiate a shadow experiment and have sufficient invocations, monitor the metrics dashboard to ensure that the metrics such as latency and error rate are within acceptable bounds. This helps you catch misconfigurations early and take corrective action. For information about how to monitor the metrics of an in-progress inference experiment, see [View, monitor, and edit shadow tests](p. 2221).

**Register and Deploy Models with Model Registry**

With the SageMaker model registry you can do the following:

- Catalog models for production.
- Manage model versions.
- Associate metadata, such as training metrics, with a model.
- Manage the approval status of a model.
- Deploy models to production.
- Automate model deployment with CI/CD.

Catalog models by creating model package groups that contain different versions of a model. You can create a model group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the model registry adds it to the model group as a new model version. A typical workflow might look like the following:

- Create a model group.
- Create an ML pipeline that trains a model. For information about SageMaker pipelines, see [Create and Manage SageMaker Pipelines](p. 3353).
For each run of the ML pipeline, create a model version that you register in the model group you created in the first step.

Model Registry Structure

The SageMaker Model Registry is structured as several model groups with model packages in each group. Each model package in a model group corresponds to a trained model. The version of each model package is a numerical value that starts at 1 and is incremented with each new model package added to a model group. For example, if 5 model packages are added to a model group, the model package versions will be 1, 2, 3, 4, and 5. The example Model Registry shown in the following image contains 3 model groups, where each group contains the model packages related to a particular ML problem.

There are two types of model packages in SageMaker. One type is used in the AWS Marketplace, and the other is used in the Model Registry. Model packages used in the AWS Marketplace are not versionable entities and are not associated with model groups in the Model Registry. For more information about model packages used in the AWS Marketplace, see Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace (p. 3585).

The model packages used in the Model Registry are versioned, and must be associated with a model group. The ARN of this model package type has the structure: ‘arn:aws:sagemaker:region:account:model-group/version’

The following topics show you how to use the Model Registry.

Topics
- Create a Model Group (p. 2234)
- Delete a Model Group (p. 2235)
- Register a Model Version (p. 2236)
- View Model Groups and Versions (p. 2243)
- View the Details of a Model Version (p. 2243)
- Share Models with SageMaker Canvas Users (p. 2245)
- Delete a Model Version (p. 2245)
- Update the Approval Status of a Model (p. 2246)
- Deploy a Model from the Registry (p. 2248)
- View the Deployment History of a Model (p. 2252)
Create a Model Group

A model group contains a group of versioned models. Create a model group by using either the AWS SDK for Python (Boto3) or Amazon SageMaker Studio.

Create a Model Package Group (Boto3)

To create a model group by using Boto3, call the create_model_package_group method and specify a name and description as parameters. The following example shows how to create a model group. The response from the create_model_package_group call is the Amazon Resource Name (ARN) of the new model package group.

First, import the required packages and set up the SageMaker Boto3 client.

```python
import time
import os
from sagemaker import get_execution_role, session
import boto3

region = boto3.Session().region_name
role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the model group.

```python
import time
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}
create_model_package_group_response = sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn : {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
```

Create a Model Package Group (Amazon SageMaker Studio)

To create a model group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon (”).
3. Choose Models, and then Model registry.
4. Choose Create model group.
5. In the Create new model group dialog box, enter the following information:
   - Enter the name of the new model group in the Name field.
   - (Optional) Enter a description for the model group in the Description field.
   - (Optional) Enter any key-value pairs you want to associate with the model group in the Tags field.
   For information about using tags, see Tagging AWS resources in the AWS General Reference.
Delete a Model Group

This procedure demonstrates how to delete a model group in Amazon SageMaker Studio.

Delete a Model Package Group (Amazon SageMaker Studio)

To delete a model group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon ( ).
3. Choose Models, and then Model registry. A list of your model groups appears.
4. From the model groups list, select the model group you want to delete.
5. In the **Actions** dropdown menu in the top right corner of the model details tab, choose **Delete**.

6. In the confirmation dialog box, choose **Delete**.

## Register a Model Version

You can register an Amazon SageMaker model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model) and the inference code for the model.

An *inference pipeline* is a SageMaker model composed of a linear sequence of two to fifteen containers that process inference requests. You register an inference pipeline by specifying the containers and the associated environment variables. For more information on inference pipelines, see [Host models along with pre-processing logic as serial inference pipeline behind one endpoint](#).

You can register a model with an inference pipeline, by specifying the containers and the associated environment variables. To create a model version with an inference pipeline by using either the AWS SDK for Python (Boto3) or by creating a step in a SageMaker model building pipeline, use the following steps.
Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a RegisterModel step in your pipeline. For information about creating a RegisterModel step as part of a pipeline, see Step 8: Define a RegisterModel Step to Create a Model Package (p. 3364).

Register a Model Version (Boto3)

To register a model version by using Boto3, call the create_model_package method.

First, you set up the parameter dictionary to pass to the create_model_package method.

```python
# Specify the model source
model_url = "s3://your-bucket-name/model.tar.gz"

modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.2-1',
                "ModelDataUrl": model_url
            },
            "SupportedContentTypes": ["text/csv"],
            "SupportedResponseMIMETypes": ["text/csv"],
        }
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"["Containers"[0]["ModelDataUrl"]]=model_url

create_model_package_input_dict = {
    "ModelPackageGroupName": model_package_group_name,
    "ModelPackageDescription": "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus": "PendingManualApproval"
}

create_model_package_input_dict.update(modelpackage_inference_specification)

Then you call the create_model_package method, passing in the parameter dictionary that you just set up.

```python
create_model_package_response = sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

Register a Model Version from a Different Account

To register model versions with a model package group created by a different AWS account, you must add a cross-account AWS Identity and Access Management resource policy to enable that account.
For example, one AWS account in your organization is responsible for training models, and a different account is responsible for managing, deploying, and updating models. You create IAM resource policies and apply the policies to the specific account resource to which you want to grant access for this case. For more information about cross-account resource policies in AWS, see Cross-account policy evaluation logic in the AWS Identity and Access Management User Guide.

**Note**
You must also use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model registry in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions. The following is an example that creates cross-account policies for the model package group and applies these policies to that specific resource.

The following configuration must be set in the source account which registers models cross-account in a model package group. In this example, the source account is the model training account which will train and then register the model cross-account into the Model Registry of the model registry account.

The example assumes that you previously defined the following variables:

- `model_package_group_name` - The model group to which you want to grant access.
- `model_package_group_arn` - The model group arn to which you want to grant cross-account access.
- `bucket` - The S3 bucket where the model training artifacts are stored.

To be able to deploy a model created in a different account, the user must have a role that has access to SageMaker actions, such as a role with the AmazonSageMakerFullAccess managed policy. For information about SageMaker managed policies, see AWS Managed Policies for Amazon SageMaker (p. 3694).

**Required IAM resource policies**

The following diagram captures the policies required to allow cross-account model registration. As shown, these policies need to be active during model training to properly register the model into the model registry account.
Amazon ECR, Amazon S3, and AWS KMS policies are demonstrated in the following code samples.

**Sample Amazon ECR policy**

```json
{
   'Version': '2012-10-17',
   'Statement': [
      {
         'Sid': 'AddPerm',
         'Effect': 'Allow',
      }
   ]
}
```
'Principal': {
    'AWS': 'arn:aws:iam::{model_registry_account}:root'
},
'Action': [
    'ecr:BatchGetImage',
    'ecr:Describe*'  
]
}
]
]
]

Sample Amazon S3 policy

[
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': [
                's3:GetObject',
                's3:GetBucketAcl',
                's3:GetObjectAcl'
            ],
            'Resource': 'arn:aws:s3:::{bucket}/*'
        }
    ]
]

Sample AWS KMS policy

[
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': [
                'kms:Decrypt',
                'kms:GenerateDataKey*'  
            ],
            'Resource': '***'
        }
    ]
]

Apply resource policies to accounts

The following policy configuration applies the policies discussed in the previous section and must be put in the model training account.

```python
import json

# The model registry account id of the model package group
model_registry_account = '111111111111'
```
# The model training account id where training happens
model_training_account = '222222222222'

# 1. Create a policy for access to the ECR repository
# in the model training account for the model registry account model package group
ecr_repository_policy = {'Version': '2012-10-17',
  'Statement': [{'Sid': 'AddPerm',
    'Effect': 'Allow',
    'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
    'Action': ['ecr:BatchGetImage', 'ecr:Describe*']}
  ]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
  registryId = model_training_account,
  repositoryName = 'decision-trees-sample',
  policyText = ecr_repository_policy
)

# 2. Create a policy in the model training account for access to the S3 bucket
# where the model is present in the model registry account model package group
bucket_policy = {'Version': '2012-10-17',
  'Statement': [{'Sid': 'AddPerm',
    'Effect': 'Allow',
    'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
    'Action': ['s3:GetObject', 's3:GetBucketAcl', 's3:GetObjectAcl']
  },
  'Resource': 'arn:aws:s3:::{bucket}/*'
  ]
}

# Convert the S3 policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new bucket policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
  Bucket = bucket,
  Policy = bucket_policy
)

# 3. Create the KMS grant for the key used during training for encryption
# in the model training account to the model registry account model package group
client = boto3.client('kms')
response = client.create_grant(
  GranteePrincipal=model_registry_account,
  KeyId=kms_key_id,
  Operations=['Decrypt', 'GenerateDataKey'],
)
The following configuration needs to be put in the model registry account where the model package group exists.

```python
# The model registry account id of the model package group
model_registry_account = '111111111111'

# 1. Create policy to allow the model training account to access the ModelPackageGroup
model_package_group_policy = {'Version': '2012-10-17',
   'Statement': [
      {'Sid': 'AddPermModelPackageVersion',
       'Effect': 'Allow',
       'Principal': {'AWS': f'arn:aws:iam::{model_training_account}:root'},
       'Action': ['sagemaker:CreateModelPackage'],
       'Resource': f'arn:aws:sagemaker:{region}:{model_registry_account}:model-package/{model_package_group_name}/*'
      }
   ]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(ModelPackageGroupName = model_package_group_name,
                                                     ResourcePolicy = model_package_group_policy)

Finally, use the create_model_package action from the model training account to register the model package in the cross-account.

```python
# Specify the model source
model_url = "s3://(bucket)/model.tar.gz"

# Set up the parameter dictionary to pass to the create_model_package method
modelpackage_inference_specification = {
   "InferenceSpecification": {
      "Containers": [
         {
            "Image": f'{model_training_account}.dkr.ecr.us-east-2.amazonaws.com/decision-trees-sample:latest',
            "ModelDataUrl": model_url
         }
      ],
      "SupportedContentTypes": [ "text/csv" ],
      "SupportedResponseMIMETypes": [ "text/csv" ],
   }
}

# Alternatively, you can specify the model source like this:
modelpackage_inference_specification["InferenceSpecification"]['Containers'][0]["ModelDataUrl"]=model_url

create_model_package_input_dict = {
   "ModelPackageGroupName" : model_package_group_arn,
   "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
   "ModelApprovalStatus" : "PendingManualApproval"
}
```
View Model Groups and Versions

Model groups and versions help you organize your models. You can view a list of the model versions in a model group.

View a List of Model Versions in a Group

You can view all of the model versions that are associated with a model group. If a model group represents all models that you train to address a specific ML problem, you can view all of those related models.

View a List of Model Versions in a Group (Boto3)

To view model versions associated with a model group by using Boto3, call the `list_model_packages` method, and pass the name of the model group as the value of the `ModelPackageGroupName` parameter. The following code lists the model versions associated with the model group you created in Create a Model Package Group (Boto3) (p. 2234).

```
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

View a List of Model Versions in a Group (Amazon SageMaker Studio)

To view a list of the model versions in a model group, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.

View the Details of a Model Version

You can view details of a specific model version by using either the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio.

View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a model group.
sm_client.list_model_packages(ModelPackageName="ModelGroup1")

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.

```json
{
'ModelPackageSummaryList': [
'{
'ModelPackageGroupName': 'AbaloneMPG-1603932988329896',
'ModelPackageVersion': 1,
'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
'ModelPackageDescription': 'TestMe',
'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
'ModelPackageStatus': 'Completed',
'ModelApprovalStatus': 'Approved'}],
'ResponseMetadata': {
'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',
'HTTPStatusCode': 200,
'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbccddeeff',
'content-type': 'application/x-amz-json-1.1',
'content-length': '349',
'date': 'Mon, 23 Nov 2020 04:56:50 GMT'},
'RetryAttempts': 0}
}
```

2. Call describe_model_package to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to list_model_packages.

```python
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

```json
{
'ModelPackageGroupName': 'ModelGroup1',
'ModelPackageVersion': 1,
'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
'ModelPackageDescription': 'Test Model',
'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
'InferenceSpecification': {
'Containers': [{'Image': '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.0-1-cpu-py3',
'ImageDigest': 'sha256:99fa602cffe19aee33297a5926f849797bdca391b7d600300204ee8f803bca66',
'ModelDataUrl': 's3://sagemaker-us-east-2-123456789012/modelGroup1/pipelines-0gdonceek709-abaloneTrain-stmilyhtIR/output/model.tar.gz'}],
'SupportedTransformInstanceTypes': ['ml.m5.xlarge'],
'SupportedRealtimeInferenceInstanceTypes': ['ml.t2.medium', 'ml.m5.xlarge'],
'SupportedContentTypes': ['text/csv'],
'SupportedResponseMIMETypes': ['text/csv'],
'ModelPackageStatus': 'Completed',
'ModelPackageStatusDetails': {'Validationstatuses': []},
'ImageDigest': 'sha256:99fa602cffe19aee33297a5926f849797bdca391b7d600300204ee8f803bca66',
'ModelDataUrl': 's3://sagemaker-us-east-2-123456789012/modelGroup1/pipelines-0gdonceek709-abaloneTrain-stmilyhtIR/output/model.tar.gz'},
'CertifyForMarketplace': False,
'ModelApprovalStatus': 'PendingManualApproval',
'LastModifiedTime': datetime.datetime(2020, 10, 29, 1, 28, 0, 438000, tzinfo=tzlocal()),
'ResponseMetadata': {'Requestid': '12345678-abcd-1234-abcd-aabbcdddeeff',
'HTTPStatus': 200,
'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbcdddeeff',
'content-type': 'application/x-amz-json-1.1',
'content-length': '1038',
'date': 'Mon, 23 Nov 2020 04:59:38 GMT'},
'RetryAttempts': 0}}
```
View the Details of a Model Version (Amazon SageMaker Studio)

To view the details of a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon ( )
3. Choose Models, and then Model registry.
4. From the model groups list, select the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.
6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose one of the following to see details about the model version:
   - Activity: Shows events for the model version, such as approval status updates.
   - Model quality: Reports metrics related to your Model Monitor model quality checks, which compare model predictions to Ground Truth. For more information about Model Monitor model quality checks, see Monitor model quality (p. 2106).
   - Explainability: Reports metrics related to your Model Monitor feature attribution checks, which compare the relative rankings of your features in training data versus live data. For more information about Model Monitor explainability checks, see Monitor Feature Attribution Drift for Models in Production (p. 2123).
   - Bias report: Reports metrics related to your Model Monitor bias drift checks, which compare the distribution of live data to training data. For more information about Model Monitor bias drift checks, see Monitor Bias Drift for Models in Production (p. 2114).
   - Inference recommender: Provides initial instance recommendations for optimal performance based on your model and sample payloads.
   - Load test: Runs load tests across your choice of instance types when you provide your specific production requirements, such as latency and throughput constraints.
   - Settings: Shows information such as the project with which the model version is associated, the pipeline that generated the model, the model group, and the model's location in Amazon S3.

Share Models with SageMaker Canvas Users

You might have a model registered in your model registry that you want to share with a user in SageMaker Canvas. You can share a model that's been trained outside of SageMaker as long as it's registered in your model registry. With this functionality, SageMaker Canvas users can import models that you've trained and generate predictions with them. For more information about how to share a model with a SageMaker Canvas user, see Bring your own model to SageMaker Canvas (p. 298).

Delete a Model Version

This procedure demonstrates how to delete a model version in Amazon SageMaker Studio.

Delete a Model Version (Amazon SageMaker Studio)

To delete a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon.
3. Choose Models, and then Model registry. A list of your model groups appears.
4. From the model groups list, select the model group of the model version you want to delete.
   The model details tab opens.
5. From the list of model versions in the model details tab, double-click the model version you want to delete.
6. Choose the Settings tab.
7. Choose Delete Version in the Settings tab.
8. In the confirmation dialog box, choose Delete.

Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to Approved. Setting the status to Approved can initiate CI/CD deployment for the
model. If the model version does not perform to your requirements, you can update the approval status to Rejected.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker pipeline. For information about creating a condition step in a SageMaker pipeline, see Pipeline Steps (p. 3313).

When you use one of the SageMaker provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.

- PendingManualApproval to Approved – initiates CI/CD deployment for the approved model version
- PendingManualApproval to Rejected – No action
- Rejected to Approved – initiates CI/CD deployment for the approved model version
- Approved to Rejected – initiates CI/CD to deploy the latest model version with an Approved status

You can update the approval status of a model version by using the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio. You can also update the approval status of a model version as part of a condition step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see SageMaker Pipelines Overview (p. 3306).

**Update the Approval Status of a Model (Boto3)**

When you created the model version in Register a Model Version (p. 2236), you set the ModelApprovalStatus to PendingManualApproval. You update the approval status for the model by calling update_model_package. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to Approved.

```python
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response = sm_client.update_model_package(**model_package_update_input_dict)
```

**Update the Approval Status of a Model (Amazon SageMaker Studio)**

The following procedure shows how to manually change the approval status from Approved to Rejected.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the model groups list, choose the model group you want to view. A new tab opens with a list of the model versions in the group.
5. In the list of model versions, right-click the model version you want to update and choose Update model version status.
6. In the Update model version status dialog box, for Status choose Rejected, and then choose Update status.
Deploy a Model from the Registry

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.
When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the model registry are automatically deployed to production. For information about using SageMaker MLOps projects, see Automate MLOps with SageMaker Projects (p. 3378).

You can also enable an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models.

Topics
- Deploy a Model from the Registry (SageMaker SDK) (p. 2249)
- Deploy a Model from the Registry (Boto3) (p. 2249)
- Deploy a Model Version from a Different Account (p. 2250)

Deploy a Model from the Registry (SageMaker SDK)

To deploy a model version using the Amazon SageMaker Python SDK use the following code snippet:

```python
from sagemaker import ModelPackage
from time import gmtime, strftime

model_package_arn = 'arn:aws:sagemaker:us-east-2:12345678901:model-package/modeltest/1'
model = ModelPackage(role=role,
                      model_package_arn=model_package_arn,
                      sagemaker_session=sagemaker_session)
model.deploy(initial_instance_count=1, instance_type='ml.m5.xlarge')
```

Deploy a Model from the Registry (Boto3)

To deploy a model version using the AWS SDK for Python (Boto3), complete the following steps:

1. Create a model object from the model version by calling the `create_model` method. Pass the Amazon Resource Name (ARN) of the model version as part of the `Containers` for the model object.

   The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`, and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

   ```python
   model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
   print("Model name : {}").format(model_name)
   container_list = ["ModelPackageName": model_version_arn]

   create_model_response = sm_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = role,
       Containers = container_list
   )
   print("Model arn : {}").format(create_model_response["ModelArn"])
   
   endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
   print(endpoint_config_name)
   create_endpoint_config_response = sm_client.create_endpoint_config(
```
Deploy Model

```python
EndpointConfigName = endpoint_config_name,
ProductionVariants=
[
    'InstanceType': 'ml.m4.xlarge',
    'InitialVariantWeight': 1,
    'InitialInstanceCount': 1,
    'ModelName': model_name,
    'VariantName': 'AllTraffic'
]
```

3. Create the endpoint by calling `create_endpoint`.

```python
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))
create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

**Deploy a Model Version from a Different Account**

You can permit an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create these resource policies, you apply the policy to the specific resource to which you want to grant access. For more information about cross-account resource policies in AWS, see [Cross-account policy evaluation logic](https://docs.aws.amazon.com/whitepapers/latest/iam-policy-deployment-roadmap/cross-account-policy-deployment.html) in the *AWS Identity and Access Management User Guide*.

**Note**

You must use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the model group resides, and the Amazon S3 bucket where the model versions are stored.

To be able to deploy a model that was created in a different account, you must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see [AWS Managed Policies for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-managed-policies.html).

The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

The example assumes that you previously defined the following variables:

- `bucket` - The Amazon S3 bucket where the model versions are stored.
- `kms_key_id` - The KMS key used to encrypt the training output.
- `model_package_group_name` - The model group to which you want to grant cross-account access.
- `model_package_group_arn` - The model group arn to which you want to grant cross-account access.

```python
import json

# The cross-account id to grant access to
cross_account_id = "123456789012"
```
# Create the policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': [':ecr:*']
    }]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# Create a policy for accessing the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['s3:*'],
        'Resource': f'arn:aws:s3:::{bucket}/*'
    }]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy
)

# Create the KMS grant for encryption in the source account to the model registry account model package group
client = boto3.client('kms')
response = client.create_grant(
    GranteePrincipal=cross_account_id,
    KeyId=kms_key_id
    Operations=[
        'Decrypt',
        'GenerateDataKey',
    ],
)

# 3. Create a policy for access to the model package group.
model_package_group_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPermModelPackageGroup',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': [':sagemaker:*']
    }]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)
View the Deployment History of a Model

View the deployments for a model version Amazon SageMaker Studio by opening the tab for that model version.

**View the deployment history for a model version**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.
6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose Activity. Deployments for the model version appear as events in the activity list with an Event type of ModelDeployment.

Amazon SageMaker Model Registry FAQ

Use the following FAQ items to find answers to commonly asked questions about SageMaker Model Registry.
Q. How should I organize my models into model groups and model packages in the SageMaker Model Registry?

A model package is the actual model that is registered into the model registry as a versioned entity. Please note there are two ways you can use model packages in SageMaker. One is with SageMaker Marketplace — these model packages are not versioned. The other is with the SageMaker Model Registry, in which the model package must be versioned. The model registry receives every new model that you retrain, gives it a version, and assigns it to a model group inside the model registry. The following image shows an example of a model group with 25 consecutively-versioned models.
### Model Registry FAQ

Q. How does a model registry differ from Amazon Elastic Container Registry (Amazon ECR)?

SageMaker’s Model Registry is a metadata store for your machine learning models. Amazon Elastic Container Registry is a repository that stores all of your containers. Within the model registry, models are versioned and registered as model packages within model groups. Each model package contains an Amazon S3 URI to the model files associated with the trained model and an Amazon ECR URI that points to the container used while serving the model.

Deploy models at the edge with SageMaker Edge Manager

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

Why Use Edge Manager?

Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay overtime. Monitoring models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

How Does it Work?

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker inference engine (Edge Manager agent), and maintaining models on the devices.
SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker Ground Truth and retrain the models in SageMaker.

How Do I Use SageMaker Edge Manager?

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. **Read the Getting Started section** - This section walks you through setting up your first edge packaging job and creating your first fleet.

2. **Explore Edge Manager Jupyter notebook examples** - Example notebooks are stored in the `amazon-sagemaker-examples` GitHub repository in the `sagemaker_edge_manager` folder.

### Getting Started

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker Edge Manager prerequisites.

**Topics**

- Setting Up (p. 2257)
- Train, Compile, and Package Your Model (p. 2259)
- Create and Register Fleets and Authenticate Devices (p. 2262)
- Download and Set Up Edge Manager (p. 2265)
- Run Agent (p. 2268)
Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker and AWS IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

1. **Set up an AWS account.**

   Create an AWS account and an IAM administrator user. For instructions on how to set up your AWS account, see [How do I create and activate a new AWS account?](#). For instructions on how to create an administrator user in your AWS account, see [Creating your first IAM admin user and group](#).

2. **Create an IAM role for Amazon SageMaker.**

   SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3. Using this role, SageMaker can run under your account and access to your Amazon S3 bucket.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
   b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
   c. For **Select type of trusted entity**, choose **AWS service**.
   d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker**. Then choose **Next: Permissions**.
      - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose **Next: Tags**.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
   g. Choose **Next: Review**.
   h. Type in a **Role name**.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For **Role description**, type a description for the new role.
   k. Review the role and then choose **Create role**.

   Note the SageMaker Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:

   i. Go to the IAM console: [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/)
   ii. Select **Roles**.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the **Summary** page.

3. **Create an IAM role for AWS IoT.**
The AWS IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker client object.

Configure an IAM role in your AWS account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with AWS IoT services.

Create a role for AWS IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker.

a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
c. For Select type of trusted entity, choose AWS service.
d. Choose the service that you want to allow to assume this role. In this case, choose IoT. Select IoT as the Use Case.
e. Choose Next: Permissions.
f. Choose Next: Tags.
g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
h. Choose Next: Review.
i. Type in a Role name. The role name must start with SageMaker.
j. (Optional) For Role description, type a description for the new role.
k. Review the role and then choose Create role.
l. Once the role is created, choose Roles in the IAM console. Search for the role you created by typing in role name in the Search field.
m. Choose your role.

n. Next, choose Attach Policies.
o. Search for AmazonSageMakerEdgeDeviceFleetPolicy in the Search field. Select AmazonSageMakerEdgeDeviceFleetPolicy.
p. Choose Attach policy.
q. Add the following policy statement to the trust relationship:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {"Service": "credentials.iot.amazonaws.com"},
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {"Service": "sagemaker.amazonaws.com"},
            "Action": "sts:AssumeRole"
        }
    ]
}
```

A trust policy is a JSON policy document in which you define the principals that you trust to assume the role. For more information about trust policies, see Roles terms and concepts.

r. Note the AWS IoT role ARN. You use the AWS IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:
i. Go to the IAM console: https://console.aws.amazon.com/iam/

ii. Choose Roles.

iii. Search for the role you created by typing in the name of the role in the Search field.

iv. Select the role.

v. The role ARN is on the Summary page.

4. **Create an Amazon S3 bucket.**

SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

b. Choose Create bucket.

c. In Bucket name, enter a name for your bucket.

d. In Region, choose the AWS Region where you want the bucket to reside.

e. In Bucket settings for Block Public Access, choose the settings that you want to apply to the bucket.

f. Choose Create bucket.

For more information about creating Amazon S3 buckets, see [Getting started with Amazon S3](https://docs.aws.amazon.com/AmazonS3/latest/userguide/creating-buckets.html).

---

**Train, Compile, and Package Your Model**

In this section you will create SageMaker and AWS IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. **Import libraries and create client objects.**

   This tutorial uses the AWS SDK for Python (Boto3) to create clients to interact with SageMaker, Amazon S3, and AWS IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:

   ```python
   import boto3
   import json
   import time

   AWS_REGION = 'us-west-2'  # Specify your Region
   bucket = 'bucket-name'

   sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)
   iot_client = boto3.client('iot', region_name=AWS_REGION)
   ```

   Define variables and assign them the role ARN you created for SageMaker and AWS IoT as strings:

   ```python
   # Replace with the role ARN you created for SageMaker
   sagemaker_role_arn = "arn:aws:iam::<account>::role/*"

   # Replace with the role ARN you created for AWS IoT.
   # Note: The name must start with 'SageMaker'
   iot_role_arn = "arn:aws:iam::<account>::role/SageMaker*"
   ```
2. **Train a machine learning model.**

   See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

   If you do not have a model yet, you can use a pre-trained model for the next steps in this tutorial. For example, you can save the MobileNet V2 models from the TensorFlow framework. MobileNet V2 is an image classification model optimized for mobile applications. For more information about MobileNet V2, see the [MobileNet GitHub README](#).

   Type the following into your Jupyter Notebook to save the pre-trained MobileNet V2 model:

   ```python
   # Save the MobileNet V2 model to local storage
   import tensorflow as tf
   model = tf.keras.applications.MobileNetV2()
   model.save("mobilenet_v2.h5")
   ```

   **Note**

   - If you do not have TensorFlow installed, you can do so by running `pip install tensorflow=2.4`
   - Use TensorFlow version 2.4 or lower for this tutorial.

   The model will be saved into the `mobilenet_v2.h5` file. Before packaging the model, you will need to first compile your model using SageMaker Neo. See [Supported Frameworks, Devices, Systems, and Architectures](p. 2347) to check if your version of TensorFlow (or other framework of choice) is currently supported by SageMaker Neo.

   SageMaker Neo requires models to be stored as a compressed TAR file. Repackage it as a compressed TAR file (*.tar.gz):  

   ```python
   # Package MobileNet V2 model into a TAR file
   import tarfile
   tarfile_name='mobilenet-v2.tar.gz'
   with tarfile.open(tarfile_name, mode='w:gz') as archive:
       archive.add('mobilenet-v2.h5')
   ```

3. **Upload your model to Amazon S3.**

   Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an AWS CLI command to upload the model the to the Amazon S3 bucket you created earlier in a directory called `models`. Type in the following into your Jupyter Notebook:

   ```bash
   !aws s3 cp mobilenet-v2.tar.gz s3://{bucket}/models/
   ```

4. **Compile your model with SageMaker Neo.**

   Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URI where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

   For the MobileNet V2 model, use the following:

   ```python
   framework = 'tensorflow'
   target_device = 'jetson_nano'
   ```
SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect? (p. 2307). For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures (p. 2347).

Use the CreateCompilationJob API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker to store your compiled model, and your edge device target.

```python
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{}/{}/{}'.format(bucket, model_directory, tarfile_name)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{}/{}/'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
RoleArn=sagemaker_role_arn,
InputConfig={
'S3Uri': s3_model_uri,
'DataInputConfig': data_shape,
'Framework': framework.upper()},
OutputConfig={
'S3OutputLocation': s3_output_location,
'TargetDevice': target_device,
'StoppingCondition': {'MaxRuntimeInSeconds': 900}})
```

5. **Package your compiled model.**

Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the create_edge_packaging API or the SageMaker console.

You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up (p. 2257) section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```python
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version="1.1"

# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

Use CreateEdgePackagingJob to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was
stored in the variable `compilation_job_name`). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker to store the packaged model.

```python
sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output
    }
)
```

### Create and Register Fleets and Authenticate Devices

In this section you will create your AWS IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to AWS IoT Core, associate the role alias with AWS IoT that was generated when you created your fleet, get your AWS account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.

1. **Create AWS IoT things.**

   SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and endpoints in the AWS cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to AWS IoT, you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure the IAM role for your devices.

   First, create AWS IoT thing objects with the AWS IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

   ```python
   iot_thing_name = 'sample-device'
   iot_thing_type = 'getting-started-demo'

   iot_client.create_thing_type(
       thingTypeName=iot_thing_type
   )

   # Create an AWS IoT thing objects
   iot_client.create_thing(
       thingName=iot_thing_name,
       thingTypeName=iot_thing_type
   )
   ```

2. **Create your device fleet.**

   Create a device fleet with the SageMaker client object defined in a previous step. You can also use the SageMaker console to create a device fleet.

   ```python
   import time
   device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
   device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
   
   Specify your IoT role ARN. This lets AWS IoT grant temporary credentials to devices.
device_model_directory='device_output'
s3_device_fleet_output = 's3://{}{}'.format(bucket, device_model_directory)

sagemaker_client.create_device_fleet(
    DeviceFleetName=device_fleet_name,
    RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
    OutputConfig={
        'S3OutputLocation': s3_device_fleet_output
    }
)

An AWS IoT role alias is created when you create a device fleet. This role alias is associated with AWS IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the AWS IoT thing name as shown in the following example:

```python
# Device name should be 36 characters
device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]

sagemaker_client.register_devices(
    DeviceFleetName=device_fleet_name,
    Devices=[
        {
            "DeviceName": device_name,
            "IotThingName": iot_thing_name
        }
    ]
)
```

4. **Create X.509 certificates.**

After creating the AWS IoT thing object, you must create an X.509 device certificate for your thing object. This certificate authenticates your device to AWS IoT Core.

Use the following to create a private key, public key, and a X.509 certificate file using the AWS IoT client defined (`iot_client`) earlier.

```python
# Creates a 2048-bit RSA key pair and issues an X.509 # certificate
# using the issued public key.
create_cert = iot_client.create_keys_and_certificate(setAsActive=True)

# Get certificate from dictionary object and save in its own
# with open('./device.pem.crt', 'w') as f:
#     for line in create_cert['certificatePem'].split('
'):
#         f.write(line)
#     f.write('
')
# Get private key from dictionary object and save in its own
# with open('./private.pem.key', 'w') as f:
#     for line in create_cert['keyPair']['PrivateKey'].split('
'):
#         f.write(line)
#     f.write('
')
# Get a private key from dictionary object and save in its own
# with open('./public.pem.key', 'w') as f:
#     for line in create_cert['keyPair']['PublicKey'].split('
'):
#         f.write(line)
```
5. **Associate the role alias with AWS IoT.**

When you create a device fleet with SageMaker (sagemaker_client.create_device_fleet()), a role alias is generated for you. An AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates, and then obtain short-lived AWS credentials from an IAM role that is associated with an AWS IoT role alias. The role alias allows you to change the role of the device without having to update the device. Use DescribeDeviceFleet to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name = sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
start_index = full_role_alias_name.find('SageMaker') # Find beginning of role name
role_alias_name = full_role_alias_name[start_index:]
```

Use the iot_client to facilitate associating the role alias generated from creating the device fleet with AWS IoT:

```python
role_alias = iot_client.describe_role_alias(
    roleAlias=role_alias_name)
```

For more information about IAM role alias, see [Role alias allows access to unused services](#).

You created and registered a certificate with AWS IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

```python
alias_policy = {
    "Version": "2012-10-17",
    "Statement": [
        "Effect": "Allow",
        "Action": "iot:AssumeRoleWithCertificate",
        "Resource": role_alias['roleAliasDescription']['roleAliasArn']
    ]
}

policy_name = 'aliaspolicy-'+ str(time.time()).split('.')[0]
aliaspolicy = iot_client.create_policy(policyName=policy_name, policyDocument=json.dumps(alias_policy))

# Attach policy
iot_client.attach_policy(policyName=policy_name, target=create_cert['certificateArn'])
```

6. **Get your AWS account-specific endpoint for the credentials provider.**

Edge devices need an endpoint in order to assume credentials. Obtain your AWS account-specific endpoint for the credentials provider.

```python
# Get the unique endpoint specific to your AWS account that is making the call.
iot_endpoint = iot_client.describe_endpoint(
    endpointType='iot:CredentialProvider')
```
7. **Get the official Amazon root CA file and upload it to the Amazon S3 bucket.**

Use the following in your Jupyter Notebook or AWS CLI (if you use your terminal, remove the '!' magic function):

```bash
!wget https://www.amazontrust.com/repository/AmazonRootCA1.pem
```

Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses `curl`, but you can use any HTTP client.

```bash
!curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem $endpoint
```

If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

```bash
!aws s3 cp private.pem.key s3://{bucket}/authorization-files/
!aws s3 cp device.pem.crt s3://{bucket}/authorization-files/
!aws s3 cp AmazonRootCA1.pem s3://{bucket}/authorization-files/
```

Clean your working directory by moving your keys and certificate to a different directory:

```bash
# Optional - Clean up working directory
!mkdir authorization-files
!mv private.pem.key device.pem.crt AmazonRootCA1.pem authorization-files/
```

---

### Download and Set Up Edge Manager

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Jetson Nano which uses a Linux operating system and has an ARM64 architecture. For more information about what operating system and architecture supported devices use, see [Supported Devices, Chip Architectures, and Systems](p. 2349).

   Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the us-west-2 Region.

   ```bash
   !aws s3 ls s3://sagemaker-edge-release-store-us-west-2-linux-armv8/Releases/ | sort -r
   ```

   This returns release artifacts sorted by their version.
The version has the following format: <MAJOR_VERSION>.<YYYY-MM-DD>.<SHA-7>. It consists of three components:

- **<MAJOR_VERSION>**: The release version. The release version is currently set to 1.
- **<YYYY-MM-DD>**: The time stamp of the artifact release.
- **<SHA-7>**: The repository commit ID from which the release is built.

Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

```bash
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
```

Once you have the artifact, unzip the zipped TAR file. The following unzips the TAR file and stores it in a directory called `agent_demo`:

```bash
!mkdir agent_demo
!tar -xvzf 1.20201218.81f481f.tgz -C ./agent_demo
```

Upload the agent release artifacts to your Amazon S3 bucket. The following code example copies the content within `agent_demo` and uploads it to a directory within your Amazon S3 bucket called `agent_demo`:

```bash
!aws s3 cp --recursive ./agent_demo s3://{bucket}/agent_demo
```

You also need the signing root certificates from the release bucket:

```bash
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-west-2/us-west-2.pem ./
```

Upload the signing root certificate to your Amazon S3 bucket:

```bash
!aws s3 cp us-west-2.pem s3://{bucket}/authorization-files/
```

2. **Define a SageMaker Edge Manager agent configuration file.**

First, define the agent configuration file as follows:

```python
sagemaker_edge_config = {
    "sagemaker_edge_core_device_name": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_root_certs_path": "/agent_demo/certificates",
    "sagemaker_edge_provider_aws_ca_cert_file": "/agent_demo/iot-credentials/AmazonRootCA1.pem",
}```
Replace the following:

- "device_name" with the name of your device (this string was stored in an earlier step in a variable named device_name).
- "device_fleet_name" with the name of your device fleet (this string was stored in an earlier step in a variable named device_fleet_name).
- "endpoint" with your AWS account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named endpoint).

Next, save it as a JSON file:

```python
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
edge_config_file.close()
```

Upload the configuration file to your Amazon S3 bucket:

```bash
!aws s3 cp sagemaker_edge_config.json s3://{bucket}/
```

3. **Copy the release artifacts, configuration file, and credentials to your device.**

   The following instructions are performed on the edge device itself.

   **Note**
   You must first install Python, the AWS SDK for Python (Boto3), and the AWS CLI on your edge device.

   Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

   ```bash
   mkdir agent_demo
   cd agent_demo
   ```

   Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

   ```bash
   # Copy release artifacts
   aws s3 cp s3://<bucket-name>/agent_demo/ ./ --recursive
   ```

   (The contents of the release artifact was stored in a directory called agent_demo in a previous step). Replace <bucket-name> and agent_demo with the name of your Amazon S3 bucket and the file path to your release artifacts, respectively.

   Go the /bin directory and make the binary files executable:

   ```bash
   cd bin
   ```
chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example

cd agent_demo

Make a directory to store your AWS IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable bucket):

mkdir iot-credentials

cd iot-credentials

aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./

cd ../

Make a directory to store your model signing root certificates:

mkdir certificates

cd certificates

aws s3 cp s3://<bucket-name>/authorization-files/us-west-2.pem ./

cd agent_demo

Copy your configuration file to your device:

#Download config file from S3
aws s3 cp s3://<bucket-name>/sagemaker_edge_config.json ./

cd agent_demo

Your agent_demo directory on your edge device should look similar to the following:

```
###agent_demo
 | ### bin
 | | ### sagemaker_edge_agent_binary
 | | ### sagemaker_edge_agent_client_example
 | | ### sagemaker_edge_config.json
 | ### certificates
 | | ###us-west-2.pem
 | ### iot-credentials
 | | ### AmazonRootCA1.pem
 | | ### device.pem.crt
 | | ### private.pem.key
 | ### docs
 | | ### api
 | | | ### examples
 | | | ### ATTRIBUTIONS.txt
 | | | ### LICENSE.txt
 | | | ### RELEASE_NOTES.md
```

Run Agent

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.
1. **Launch the agent.**

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the [gRPC documentation](https://grpc.io)

   To use gRPC, perform the following steps:
   b. Generate server and client code using the protocol buffer compiler.
   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.
   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.

   The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the /bin directory of your release artifact. The `sagemaker_edge_agent_binary` binary executable is in this directory.

   To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

   ```bash
   ./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
   ```

2. **Check your device.**

   Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

   Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

   ```python
   sagemaker_client.describe_device(
       DeviceName=device_name,
       DeviceFleetName=device_fleet_name
   )
   ```

   For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

   ```json
   {
       "DeviceName": "sample-device",
       "DeviceFleetName": "demo-device-fleet",
       "IoTThingName": "sample-thing-name-1",
       "RegistrationTime": 1600977370,
       "LatestHeartbeat": 1600977370,
       "Models": [
           {
               "ModelName": "mobilenet_v2.tar.gz",
               "ModelVersion": "1.1",
               "LatestSampleTime": 1600977370,
               "LatestInference": 1600977370
           }
       ]
   }
   ```
The timestamp provided by `LastetHeartbeat` indicates the last signal that was received from the device. `LatestSampleTime` and `LatestInference` describe the time stamp of the last data sample and inference, respectively.

3. **Check your fleet.**

Check that your fleet is working with `GetDeviceFleetReport`. Provide the name of the fleet the device belongs to.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.

```json
# Sample output
{
    "DeviceFleetName": "sample-device-fleet",
    "OutputConfig": {
        "S3OutputLocation": "s3://fleet-bucket/package_output",
    },
    "AgentVersions": [{"Version": "1.1", "AgentCount": 2}]
    "DeviceStats": {"Connected": 2, "Registered": 2},
    "Models": [{
        "ModelName": "sample-model",
        "ModelVersion": "1.1",
        "OfflineDeviceCount": 0,
        "ConnectedDeviceCount": 2,
        "ActiveDeviceCount": 2,
        "SamplingDeviceCount": 100
    }]
}
```

---

### Set Up Devices and Fleets

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console.

**Topics**

- Create a Fleet (p. 2270)
- Register a Device (p. 2274)
- Check Status (p. 2276)

### Create a Fleet

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console. [https://console.aws.amazon.com/sagemaker](https://console.aws.amazon.com/sagemaker)
Create a Fleet (Boto3)

Use the CreateDeviceFleet API to create a fleet. Specify a name for the fleet, your AWS IoT Role ARN for the RoleArn field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an AWS KMS Key ID.

```python
code
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-fleet-name",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        S3OutputLocation="s3://bucket/",
        KMSKeyId: "1234abcd-12ab-34cd-56ef-1234567890ab",
    },
    Tags=[
        {"Key": "string", "Value": "string"}
    ],
)
```

An AWS IoT Role Alias is created for you when you create a device fleet. The AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates and then obtain short-lived AWS credentials from an IAM role that is associated with the AWS IoT role alias.

Use DescribeDeviceFleet to get the role alias name and ARN.

```python
code
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
```

Use DescribeDeviceFleet API to get a description of fleets you created.

```python
code
sagemaker_client.describe_device_fleet(
    DeviceFleetName="sample-fleet-name"
)
```

By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in AWS IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.

```
{ "DeviceFleetName": "sample-fleet-name",
  "IAMRole": "arn:aws:iam::9999999999:role/rolename",
  "Description": "this is a sample fleet",
  "IotRoleAlias": "arn:aws:iot:us-west-2:99999999999:rolealias/SagemakerEdge-sample-fleet-name"
  "OutputConfig": {
    "S3OutputLocation": "s3://bucket/folder",
    "KMSKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
  },
```
Create a Fleet (Console)

You can create a Edge Manager packaging job using the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose Edge Manager and then choose Edge device fleets.
2. Choose Create device fleet.

3. Enter a name for the device fleet in the Device fleet name field. Choose Next.
4. On the **Output configuration** page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by electing an existing AWS KMS key from the dropdown list or by entering a key's ARN. Choose **Submit**.
5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the Device fleet tags section.

Register a Device

Important

Device registration is required to use any part of SageMaker Edge Manager.

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console at https://console.aws.amazon.com/sagemaker.

Register a Device (Boto3)

To register your device, first create and register an AWS IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

To connect your device to AWS IoT you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure IAM role for your devices.

See the Getting Started Guide for an in-depth example or the Explore AWS IoT Core services in hands-on tutorial.

Use the RegisterDevices API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and AWS IoT thing name associated with the device.

```python
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
```
Register a Device (Console)

You can register your device using the SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose Edge Inference and then choose choose Edge devices.
2. Choose Register devices.

3. In the Device properties section, enter the name of the fleet the device belongs to under the Device fleet name field. Choose Next.

4. In the Device source section, add your devices one by one. You must include a Device Name for each device in your fleet. You can optionally provide a description (in the Description field) and an
Internet of Things (IoT) object name (in the IoT name field). Choose Submit once you have added all your devices.

The Devices page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and AWS IoT name, if you provided one.

Choose a device to view the device’s details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

### Check Status

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console at https://console.aws.amazon.com/s3/ to interactively choose a fleet for a status check. You can also use the AWS SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

  To check the status of an individual device, use DescribeDevice API. A list containing one or more models is provided if a models have been deployed to the device.

  ```python
  sagemaker_client.describe_device(
      DeviceName="sample-device-1",
      DeviceFleetName="sample-fleet-name"
  )
  ```

  Running DescribeDevice returns:

  ```json
  { "DeviceName": "sample-device", 
    "Description": "this is a sample device", 
    "DeviceFleetName": "sample-device-fleet", 
    "IoTThingName": "SampleThing", 
  ```
• **Check a fleet of devices.**

To check the status of the fleet, use the `GetDeviceFleetReport` API. Provide the name of the device fleet to get a summary of the fleet.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

• **Check for a heartbeat.**

Each device within a fleet periodically generates a signal, or “heartbeat”. The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

Check the last heartbeat with made by a device with the `DescribeDevice` API. Specify the name of the device and the fleet to which the edge device belongs.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

---

**Package Model**

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

**Topics**

- Prerequisites (p. 2277)
- Package a Model (Amazon SageMaker Console) (p. 2279)
- Package a Model (Boto3) (p. 2282)

**Prerequisites**

To package a model, you must do the following:

1. **Compile your machine learning model with SageMaker Neo.**

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see Compile and Deploy Models with Neo. If you are first-time user of SageMaker Neo, go through Getting Started with Neo Edge Devices.

2. **Get the name of your compilation job.**
Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and choose **Compilation jobs** to find a list of compilations that have been submitted to your AWS account. The names of submitted compilation jobs are in the **Name** column.

3. **Get your IAM ARN.**

You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

Use one of the following methods to get your IAM ARN:

- **Programmatically with the SageMaker Python SDK**

  ```python
  import sagemaker
  # Initialize SageMaker Session object so you can interact with AWS resources
  sess = sagemaker.Session()
  # Get the role ARN
  role = sagemaker.get_execution_role()
  print(role)
  >> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
  ```

  For more information about using the SageMaker Python SDK, see the [SageMaker Python SDK API](https://sagemaker.readthedocs.io/en/stable/).

- **Using the AWS Identity and Access Management (IAM) console**

  Navigate to the IAM console at https://console.aws.amazon.com/iam/. In the IAM **Resources** section, choose **Roles** to view a list of roles in your AWS account. Select or create a role that has AmazonSageMakerFullAccess, AWSIoTFullAccess, and AmazonS3FullAccess.

  For more information on IAM, see [What is IAM?](https://docs.aws.amazon.com/IdentityAndAccessManagement/latest/UserGuide/what-is-iam.html)

4. **Have an S3 bucket URI.**

You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

Use one of the following methods to create an Amazon S3 bucket:

- **Programmatically with the SageMaker Python SDK**

  You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: sagemaker-\-{region}\-{aws-account-id}. To create a default bucket with the SageMaker Python SDK, use the following:

  ```python
  import sagemaker
  session=sagemaker.create_session()
  bucket=session.default_bucket()
  ```

- **Using the Amazon S3 console**

Package a Model (Amazon SageMaker Console)

You can create a SageMaker Edge Manager packaging job using the SageMaker console at https://console.aws.amazon.com/sagemaker/. Before continuing, make sure you have satisfied the Prerequisites (p. 2277).

1. In the SageMaker console, choose Edge Inference and then choose Edge packaging jobs, as shown in the following image.

2. On the Job properties page, enter a name for your packaging job under Edge packaging job name. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under Model name and Model version, respectively.

3. Next, select an IAM role. You can chose a role or let AWS create a role for you. You can optionally specify a resource key ARN and job tags.

4. Choose Next.
5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose **Next**.
6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

**Output configuration**

Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optionally) set an encryption key.

**S3 bucket URI**

Enter your S3 bucket URI where you want devices to store sample data.

<s3://bucket-example/sagemaker-edge/device-output>

To find a path, go to Amazon S3

**Encryption key - optional**

Encrypt your data. Choose an existing KMS key or enter a key's ARN.

No Custom Encryption

The **Status** column on the **Edge packaging** jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.
The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

### Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the AWS SDK for Python (Boto3). Before continuing, make sure you have satisfied the [Prerequisites](#). To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```python
# Import AWS SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    }
)
```

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```python
response = sagemaker_client.describe_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name")
```

This returns a dictionary that can be used to poll the status of the packaging job:

```python
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name")

    if response['EdgePackagingJobStatus'] == 'Completed':
        break
    elif response['EdgePackagingJobStatus'] == 'Failed':
        raise RuntimeError('Packaging job failed')
    print('Packaging model...')
    time.sleep(30)
print('Done!')
```
For a list of packaging jobs, use `ListEdgePackagingJobs`. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for `NameContains`, a partial name for `ModelNameContains` to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with `SortBy`, and by which direction to sort for `SortOrder` (either `Ascending` or `Descending`).

```python
sagemaker_client.list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use `StopEdgePackagingJob` and provide the name of your edge packaging job.

```python
sagemaker_client.stop_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the Boto3 documentation.

### The Edge Manager Agent

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

There are two methods of installing and deploying the Edge Manager agent onto your edge devices:

1. Download the agent as a binary from the Amazon S3 release bucket. For more information, see Download and Set Up the Edge Manager Agent Manually (p. 2283).
2. Use the AWS IoT Greengrass V2 console or the AWS CLI to deploy `aws.greengrass.SageMakerEdgeManager`. See Create the AWS IoT Greengrass V2 Components (p. 2289).

### Download and Set Up the Edge Manager Agent Manually

Download the Edge Manager agent based on your operating system, architecture, and AWS Region. The agent is periodically updated, so you have the option to choose your agent based on release dates and versions. Once you have the agent, create a JSON configuration file. Specify the device IoT thing name, fleet name, device credentials, and other key-value pairs. See Running the Edge Manager agent (p. 2285) for full a list of keys you must specify in the configuration file. You can run the agent as an executable binary or link against it as a dynamic shared object (DSO).

### How the agent works

The agent runs on the CPU of your devices. The agent runs inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent supports the GPU in the provided Deep Learning Runtime (DLR).

The agent is released in binary format for supported operating systems. Check that your operating system is supported and meets the minimum OS requirement in the following table:

Linux

**Version:** Ubuntu 18.04
Supported Binary Formats: x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

Windows

Version: Windows 10 version 1909

Supported Binary Formats: x86-32 bit (DLL) and x86-64 bit (DLL)

Installing the Edge Manager agent

To use the Edge Manager agent, you first must obtain the release artifacts and a root certificate. The release artifacts are stored in an Amazon S3 bucket in the us-west-2 Region. To download the artifacts, specify your operating system (<OS>) and the <VERSION>.

Based on your operating system, replace <OS> with one of the following:

<table>
<thead>
<tr>
<th>Windows 32-bit</th>
<th>Windows 64-bit</th>
<th>Linux x86-64</th>
<th>Linux ARMv8</th>
</tr>
</thead>
<tbody>
<tr>
<td>windows-x86</td>
<td>windows-x64</td>
<td>linux-x64</td>
<td>linux-armv8</td>
</tr>
</tbody>
</table>

The VERSION is broken into three components: <MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>, where:

- <MAJOR_VERSION>: The release version. The release version is currently set to 1.
- <YYYY-MM-DD>: The time stamp of the artifacts release.
- <SHA-7>: The repository commit ID from which the release is built.

You must provide the <MAJOR_VERSION> and the time stamp in YYYY-MM-DD format. We suggest you use the latest artifact release time stamp.

Run the following in your command line to get the latest time stamp. Replace <OS> with your operating system:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0
  PRE 1.20201218.81f481f/
  PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version has a major release version of 1, a time stamp of 20201218 (in YYYY-MM-DD format), and a 81f481f SHA-7 commit ID.

**Note**

The preceding command assumes you have configured the AWS Command Line Interface. For more information, about how to configure the settings that the AWS CLI uses to interact with AWS, see Configuring the AWS CLI.
Based on your operating system, use the following commands to install the artifacts:

**Windows 32-bit**

```shell
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/<VERSION>/sha256_hex.shasum .
```

**Windows 64-bit**

```shell
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/Releases/<VERSION>/.<VERSION>.zip .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/Releases/<VERSION>/sha256_hex.shasum .
```

**Linux x86-64**

```shell
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/<VERSION>/.<VERSION>.tgz .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/<VERSION>/sha256_hex.shasum .
```

**Linux ARMv8**

```shell
```

You also must download a root certificate. This certificate validates model artifacts signed by AWS before loading them onto your edge devices.

Replace `<OS>` corresponding to your platform from the list of supported operation systems and replace `<REGION>` with your AWS Region.

```shell
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-<OS>/Certificates/<REGION>/<REGION>.pem .
```

**Running the Edge Manager agent**

You can run the SageMaker Edge Manager agent as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or you can link against it as a dynamic shared object (.dll). Linux supports running it as a standalone executable binary and is the preferred mode. Windows supports running it as a shared object (.dll).

On Linux, we recommend that you run the binary via a service that’s a part of your initialization (init) system. If you want to run the binary directly, you can do so in a terminal as shown in the following example. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent, first create a JSON configuration file. Specify the following key-value pairs:

- `sagemaker_edge_core_device_name`: The name of the device. This device name needs to be registered along with the device fleet in the SageMaker Edge Manager console.
• **sagemaker_edge_core_device_fleet_name**: The name of the fleet to which the device belongs.

• **sagemaker_edge_core_region**: The AWS Region associated with the device, the fleet and the Amazon S3 buckets. This corresponds to the Region where the device is registered and where the Amazon S3 bucket is created (they are expected to be the same). The models themselves can be compiled with SageMaker Neo in a different Region, this configuration is not related to model compilation Region.

• **sagemaker_edge_core_root_certs_path**: The absolute folder path to root certificates. This is used to validate the device with the relevant AWS account.

• **sagemaker_edge_provider_aws_ca_cert_file**: The absolute path to Amazon Root CA certificate (AmazonRootCA1.pem). This is used to validate the device with the relevant AWS account. AmazonCA is a certificate owned by AWS.

• **sagemaker_edge_provider_aws_cert_file**: The absolute path to AWS IoT signing root certificate (*.pem.crt).

• **sagemaker_edge_provider_aws_cert_pk_file**: The absolute path to AWS IoT private key. (*.pem.key).

• **sagemaker_edge_provider_aws_iot_cred_endpoint**: The AWS IoT credentials endpoint (identifier.iot.region.amazonaws.com). This endpoint is used for credential validation. See Connecting devices to AWS IoT for more information.

• **sagemaker_edge_provider_provider**: This indicates the implementation of the provider interface being used. The provider interface communicates with the end network services for uploads, heartbeats and registration validation. By default this is set to "Aws". We allow custom implementations of the provider interface. It can be set to None for no provider or Custom for custom implementation with the relevant shared object path provided.

• **sagemaker_edge_provider_provider_path**: Provides the absolute path to the provider implementation shared object. (.so or .dll file). The "Aws" provider .dll or .so file is provided with the agent release. This field is mandatory.

• **sagemaker_edge_provider_s3_bucket_name**: The name of your Amazon S3 bucket (not the Amazon S3 bucket URI). The bucket must have a sagemaker string within its name.

• **sagemaker_edge_log_verbose** (Boolean): Optional. This sets the debug log. Select either True or False.

• **sagemaker_edge_telemetry_libsystemd_path**: For Linux only, systemd implements the agent crash counter metric. Set the absolute path of libsystemd to turn on the crash counter metric. You can find the default libsystemd path can be found by running `whereis libsystemd` in the device terminal.

• **sagemaker_edge_core_capture_data_destination**: The destination for uploading capture data. Choose either "Cloud" or "Disk". The default is set to "Disk". Setting it to "Disk" writes the input and output tensor(s) and auxiliary data to the local file system at your preferred location of. When writing to "Cloud" use the Amazon S3 bucket name provided in the **sagemaker_edge_provider_s3_bucket_name** configuration.

• **sagemaker_edge_core_capture_data_disk_path**: Set the absolute path in the local file system, into which capture data files are written when "Disk" is the destination. This field is not used when "Cloud" is specified as the destination.

• **sagemaker_edge_core_folder_prefix**: The parent prefix in Amazon S3 where captured data is stored when you specify "Cloud" as the capture data destination (**sagemaker_edge_core_capture_data_disk_path**). Captured data is stored in a sub-folder under **sagemaker_edge_core_capture_data_disk_path** if "Disk" is set as the data destination.

• **sagemaker_edge_core_capture_data_buffer_size** (Integer value): The capture data circular buffer size. It indicates the maximum number of requests stored in the buffer.

• **sagemaker_edge_core_capture_data_batch_size** (Integer value): The capture data batch size. It indicates the size of a batch of requests that are handled from the buffer. This value must to be less than **sagemaker_edge_core_capture_data_buffer_size**. A maximum of half the size of the buffer is recommended for batch size.
- **sagemaker_edge_core_capture_data_push_period_seconds** (Integer value): The capture data push period in seconds. A batch of requests in the buffer is handled when there are batch size requests in the buffer, or when this time period has completed (whichever comes first). This configuration sets that time period.

- **sagemaker_edge_core_capture_data_base64_embed_limit**: The limit for uploading capture data in bytes. Integer value.

Your configuration file should look similar to the following example (with your specific values specified). This example uses the default AWS provider ("Aws") and does not specify a periodic upload.

```json
{
    "sagemaker_edge_core_device_name": "device-name",
    "sagemaker_edge_core_device_fleet_name": "fleet-name",
    "sagemaker_edge_core_region": "region",
    "sagemaker_edge_core_root_certs_path": "<Absolute path to root certificates>",
    "sagemaker_edge_core_aws_provider": "Aws",
    "sagemaker_edge_provider_aws_ca_cert_file": "<Absolute path to Amazon Root CA certificate>/AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "<Absolute path to AWS IoT signing root certificate>/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "<Absolute path to AWS IoT private key>/private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "https://<AWS IoT Endpoint Address>",
    "sagemaker_edge_core_folder_prefix": "Amazon S3 folder prefix",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_batch_size": 10,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4000,
    "sagemaker_edge_core_capture_data_base64_embed_limit": 2,
    "sagemaker_edge_log_verbose": false
}
```

The release artifact includes a binary executable called `sagemaker_edge_agent_binary` in the `/bin` directory. To run the binary, use the `-a` flag to create a socket file descriptor (.sock) in a directory of your choosing and specify the path of the agent JSON config file you created with the `-c` flag.

```
./sagemaker_edge_agent_binary -a <ADDRESS_TO_SOCKET> -c <PATH_TO_CONFIG_FILE>
```

The following example shows the code snippet with a directory and file path specified:

```
./sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
```

In this example, a socket file descriptor named `sagemaker_edge_agent_example.sock` is created in the `/tmp` directory and points to a configuration file that is in the same working directory as the agent called `sagemaker_edge_config.json`.

### Deploy the Model Package and Edge Manager Agent with AWS IoT Greengrass

SageMaker Edge Manager integrates AWS IoT Greengrass version 2 to simplify accessing, maintaining, and deploying the Edge Manager agent and model to your devices. Without AWS IoT Greengrass V2, setting up your devices and fleets to use SageMaker Edge Manager requires you to manually copy the Edge Manager agent from an Amazon S3 release bucket. You use the agent to make predictions with models loaded onto your edge devices. With AWS IoT Greengrass V2 and SageMaker Edge Manager
integration, you can use AWS IoT Greengrass V2 components. Components are pre-built software modules that can connect your edge devices to AWS services or third-party service via AWS IoT Greengrass.

You must install the AWS IoT Greengrass Core software onto your device(s) if you want to use AWS IoT Greengrass V2 to deploy the Edge Manager agent and your model. For more information about device requirements and how to set up your devices, see Setting up AWS IoT Greengrass core devices in the AWS IoT Greengrass documentation.

You use the following three components to deploy the Edge Manager agent:

- **A pre-built public component**: SageMaker maintains the public Edge Manager component.
- **A autogenerated private component**: The private component is autogenerated when you package your machine learning model with the CreateEdgePackagingJob API and specify GreengrassV2Component for the Edge Manager API field PresetDeploymentType.
- **A custom component**: This is the inference application that is responsible for preprocessing and making inferences on your device. You must create this component. See either ?? (p. 2291) in the SageMaker Edge Manager documentation or Create custom AWS IoT Greengrass components in the AWS IoT Greengrass documentation for more information on how to create custom components.

**Prerequisites**

SageMaker Edge Manager uses AWS IoT Greengrass V2 to simplify the deployment of the Edge Manager agent, your machine learning models, and your inference application to your devices with the use of components. To make it easier to maintain your AWS IAM roles, Edge Manager allows you to reuse your existing AWS IoT role alias. If you do not have one yet, Edge Manager generates a role alias as part of the Edge Manager packaging job. You no longer need to associate a role alias generated from the SageMaker Edge Manager packaging job with your AWS IoT role.

Before you start, you must complete the following prerequisites:

1. Install the AWS IoT Greengrass Core software. For detailed information, see Install the AWS IoT Greengrass Core software.
2. Set up AWS IoT Greengrass V2. For more information, see Install AWS IoT Greengrass Core software with manual resource provisioning.

   **Note**
   - Make sure the AWS IoT thing name is all lowercase and does not contain characters except (optionally) dashes (-).
   - The IAM Role must start with SageMaker*
3. Attach the following permission and inline policy to the IAM role created during AWS IoT Greengrass V2 setup.
   - Navigate to the IAM console https://console.aws.amazon.com/iam/.
   - Search for the role you created by typing in the role name in the Search field.
   - Choose your role.
   - Next, choose Attach policies.
   - Search for AmazonSageMakerEdgeDeviceFleetPolicy.
   - Select AmazonSageMakerFullAccess (This is an optional step that makes it easier for you to reuse this IAM role in model compilation and packaging).
   - Choose Add inline policy.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
```
Choose **Attach policy**.
Choose **Trust relationship**.
Choose **Edit trust relationship**.
Replace the content with the following.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "credentials.iot.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

4. Create an Edge Manager device fleet. For information on how to create a fleet, see Set Up Devices and Fleets (p. 2270).
5. Register your device with the same name as your AWS IoT thing name created during the AWS IoT Greengrass V2 setup.
6. Create at least one custom private AWS IoT Greengrass component. This component is the application that runs inference on the device. For more information, see Create a Hello World custom component (p. 2291)

**Note**

- The SageMaker Edge Manager and AWS IoT Greengrass integration only works for AWS IoT Greengrass v2.
- Both your AWS IoT thing name and Edge Manager device name must be the same.
- SageMaker Edge Manager does not load local AWS IoT certificates and call the AWS IoT credential provider endpoint directly. Instead, SageMaker Edge Manager uses the AWS IoT Greengrass v2 TokenExchangeService and it fetches a temporary credential from a TES endpoint.

Create the AWS IoT Greengrass V2 Components

AWS IoT Greengrass uses **components**, a software module that is deployed to and runs on a AWS IoT Greengrass core device. You need (at a minimum) three components:
1. A **public Edge Manager Agent AWS IoT Greengrass component** which deploys the Edge Manager agent binary.

2. A **model component** that is autogenerated when you package your machine learning model with either the AWS SDK for Python (Boto3) API or with the SageMaker console. For information, see Create an autogenerated component (p. 2290).

3. A **private, custom component** to implement the Edge Manager agent client application, and do any preprocessing and post-processing of the inference results. For more information about how to create a custom component, see Create an autogenerated component (p. 2290) or Create custom AWS IoT Greengrass components.

Create an autogenerated component

Generate the model component with the [CreateEdgePackagingJob API](https://console.aws.amazon.com/iot/) and specify GreengrassV2Component for the SageMaker Edge Manager packaging job API field. When you call the CreateEdgePackagingJob API, Edge Manager takes your SageMaker Neo–compiled model in Amazon S3 and creates a model component. The model component is automatically stored in your account. You can view any of your components by navigating to the AWS IoT console [https://console.aws.amazon.com/iot/](https://console.aws.amazon.com/iot/). Select Greengrass and then select Core devices. The page has a list of AWS IoT Greengrass core devices associated with your account. If a model component name is not specified in PresetDeploymentConfig, the default name generated consists of "SagemakerEdgeManager" and the name of your Edge Manager agent packaging job. The following example demonstrates how to specify to Edge Manager to create a AWS IoT Greengrass V2 component with the CreateEdgePackagingJob API.

```python
import sagemaker
import boto3

# Create a SageMaker client object to make it easier to interact with other AWS services.
sagemaker_client = boto3.client('sagemaker', region=<YOUR_REGION>)

# Replace with your IAM Role ARN
sagemaker_role_arn = "arn:aws:iam::<account>::role/*"

# Replace string with the name of your already created S3 bucket.
bucket = 'edge-manager-demo-bucket'

# Specify a name for your edge packaging job.
edge_packaging_name = "edge_packag_job_demo"

# Replace the following string with the name you used for the SageMaker Neo compilation job.
compilation_job_name = "getting-started-demo"

# The name of the model and the model version.
model_name = "sample-model"
model_version = "1.1"

# Output directory in S3 where you want to store the packaged model.
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

# The name you want your Greengrass component to have.
component_name = "SagemakerEdgeManager" + edge_packaging_name

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "GreengrassV2Component": True,
    }
)
```

2290
You can also create the autogenerated component with the SageMaker console. Follow steps 1-6 in Package a Model (Amazon SageMaker Console) (p. 2279)

Enter the Amazon S3 bucket URI where you want to store the output of the packaging job and optional encryption key.

Complete the following to create the model component:

1. Choose Preset deployment.
2. Specify the name of the component for the Component name field.
3. Optionally, provide a description of the component, a component version, the platform OS, or the platform architecture for the Component description, Component version, Platform OS, and Platform architecture, respectively.
4. Choose Submit.

Create a Hello World custom component

The custom application component is used to perform inference on the edge device. The component is responsible for loading models to SageMaker Edge Manager, invoking the Edge Manager agent for inference, and unloading the model when the component is shut down. Before you create your component, ensure the agent and application can communicate with Edge Manager. To do this, configure gRPC. The Edge Manager agent uses methods defined in Protobuf Buffers and the gRPC server to establish communication with the client application on the edge device and the cloud.

To use gRPC, you must:

1. Create a gRPC stub using the .proto file provided when you download the Edge Manager agent from Amazon S3 release bucket.
2. Write client code with the language you prefer.

You do not need to define the service in a .proto file. The service .proto files are included in the compressed TAR file when you download the Edge Manager agent release binary from the Amazon S3 release bucket.

Install gRPC and other necessary tools on your host machine and create the gRPC stubs agent_pb2_grpc.py and agent_pb2.py in Python. Make sure you have agent.proto in your local directory.

```bash
pip install grpcio
pip install grpcio-tools
python3 -m grpc_tools.protoc --proto_path=. --python_out=. --grpc_python_out=. agent.proto
```

The preceding code generates the gRPC client and server interfaces from your .proto service definition. In other words, it creates the gRPC model in Python. The API directory contains the Protobuf specification for communicating with the agent.

Next, use the gRPC API to write a client and server for your service (2). The following example script, edge_manager_python_example.py, uses Python to load, list, and unload a yolov3 model to the edge device.
```python
import grpc
from PIL import Image
import agent_pb2
import agent_pb2_grpc
import os

model_path = '<PATH-TO-SagemakerEdgeManager-COMPONENT>'
agent_socket = 'unix:///tmp/aws.greengrass.SageMakerEdgeManager.sock'
agent_channel = grpc.insecure_channel(agent_socket, options=('grpc.enable_http_proxy', 0))
agent_client = agent_pb2_grpc.AgentStub(agent_channel)

def list_models():
    return agent_client.ListModels(agent_pb2.ListModelsRequest())

def list_model_tensors(models):
    return {
        model.name: {
            'inputs': model.input_tensor_metadatas,
            'outputs': model.output_tensor_metadatas
        }
        for model in list_models().models
    }

def load_model(model_name, model_path):
    load_request = agent_pb2.LoadModelRequest()
    load_request.url = model_path
    load_request.name = model_name
    return agent_client.LoadModel(load_request)

def unload_model(name):
    unload_request = agent_pb2.UnLoadModelRequest()
    unload_request.name = name
    return agent_client.UnLoadModel(unload_request)

def predict_image(model_name, image_path):
    image_tensor = agent_pb2.Tensor()
    image_tensor.byte_data = Image.open(image_path).tobytes()
    image_tensor_metadata = list_model_tensors(list_models())[model_name]['inputs'][0]
    image_tensor.tensor_metadata.name = image_tensor_metadata.name
    image_tensor.tensor_metadata.data_type = image_tensor_metadata.data_type
    for shape in image_tensor_metadata.shape:
        image_tensor.tensor_metadata.shape.append(shape)
    predict_request = agent_pb2.PredictRequest()
    predict_request.name = model_name
    predict_request.tensors.append(image_tensor)
    predict_response = agent_client.Predict(predict_request)
    return predict_response

def main():
    try:
        unload_model('your-model')
    except:
        pass
    print('LoadModel...','end=''')
```

try:
    load_model('your-model', model_path)
    print('done.')
except Exception as e:
    print()
    print(e)
    print('Model already loaded!')

print('ListModels...', end='')
try:
    print(list_models())
    print('done.')
except Exception as e:
    print()
    print(e)
    print('List model failed!')

print('Unload model...', end='')
try:
    unload_model('your-model')
    print('done.')
except Exception as e:
    print()
    print(e)
    print('unload model failed!')

if __name__ == '__main__':
    main()
run:
  script: |
    python3 {{artifacts: path}}/edge_manager_python_example.py
Artifacts:
  - URI: <code-s3-path>
  - URI: <pb2-s3-path>
  - URI: <pb2-grpc-s3-path>

For detailed information about creating a Hello World recipe, see Create your first component in the AWS IoT Greengrass documentation.

**Deploy the components to your device**

Deploy your components with the AWS IoT console or with the AWS CLI.

**To deploy your components (console)**

Deploy your AWS IoT Greengrass components with the AWS IoT console.

1. In the AWS IoT Greengrass console at https://console.aws.amazon.com/iot/ navigation menu, choose Deployments.
2. On the Components page, on the Public components tab, choose `aws.greengrass.SageMakerEdgeManager`.
4. From Add to deployment, choose one of the following:
   a. To merge this component to an existing deployment on your target device, choose Add to existing deployment, and then select the deployment that you want to revise.
   b. To create a new deployment on your target device, choose Create new deployment. If you have an existing deployment on your device, choosing this step replaces the existing deployment.
5. On the Specify target page, do the following:
   a. Under Deployment information, enter or modify the friendly name for your deployment.
   b. Under Deployment targets, select a target for your deployment, and choose Next. You cannot change the deployment target if you are revising an existing deployment.
6. On the Select components page, under My components, choose:
   - com.<CUSTOM-COMPONENT-NAME>
   - `aws.greengrass.SageMakerEdgeManager`
   - `SagemakerEdgeManager.<YOUR-PACKAGING-JOB>`
7. On the Configure components page, choose `com.greengrass.SageMakerEdgeManager`, and do the following.
   a. Choose Configure component.
   b. Under Configuration update, in Configuration to merge, enter the following configuration.

```
{
  "DeviceFleetName": "device-fleet-name",
  "BucketName": "DOC-EXAMPLE-BUCKET"
}
```

Replace `device-fleet-name` with the name of the edge device fleet that you created, and replace `DOC-EXAMPLE-BUCKET` with the name of the Amazon S3 bucket that is associated with your device fleet.
   c. Choose Confirm, and then choose Next.
8. On the Configure advanced settings page, keep the default configuration settings, and choose Next.
To deploy your components (AWS CLI)

1. Create a deployment.json file to define the deployment configuration for your SageMaker Edge Manager components. This file should look like the following example.

```json
{
  "targetArn": "targetArn",
  "components": {
    "aws.greengrass.SageMakerEdgeManager": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
        "merge": {
          "DeviceFleetName": "device-fleet-name",
          "BucketName": "DOC-EXAMPLE-BUCKET"
        }
      }
    },
    "com.greengrass.SageMakerEdgeManager.ImageClassification": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
      }
    },
    "com.greengrass.SageMakerEdgeManager.ImageClassification.Model": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
      }  
    }
  }
}
```

• In the targetArn field, replace targetArn with the Amazon Resource Name (ARN) of the thing or thing group to target for the deployment, in the following format:
  • Thing: arn:aws:iot:region:account-id:thing/thingName
  • Thing group: arn:aws:iot:region:account-id:thinggroup/thingGroupName

• In the merge field, replace device-fleet-name with the name of the edge device fleet that you created, and replace DOC-EXAMPLE-BUCKET with the name of the Amazon S3 bucket that is associated with your device fleet.

• Replace the component versions for each component with the latest available version.

2. Run the following command to deploy the components on the device:

```bash
aws greengrassv2 create-deployment \
  --cli-input-json file://path/to/deployment.json
```

The deployment can take several minutes to complete. In the next step, check the component log to verify that the deployment completed successfully and to view the inference results.

For more information about deploying components to individual devices or groups of devices, see Deploy AWS IoT Greengrass components to devices.

### Deploy the Model Package Directly with SageMaker Edge Manager Deployment API

SageMaker Edge Manager provides a deployment API that you can use to deploy models to device targets without AWS IoT Greengrass. It is useful in situations where you want to update models independently of firmware updates or application deployment mechanisms. You can use the API to integrate your edge deployments into a CI/CD workflow to automatically deploy models once you have
validated your model for accuracy. The API also has convenient rollback and staged rollout options for you to ensure models work well in a particular environment before wider rollout.

To use the Edge Manager deployment API first compile and package your model. For information on how to compile and package your model, see Train, Compile, and Package Your Model (p. 2259). The following sections of this guide show how you can create edge deployments using SageMaker API, after you have compiled and packaged your models.

Topics

• Create an edge deployment plan (p. 2296)
• Start the edge deployment (p. 2297)
• Check the status of the deployment (p. 2297)

Create an edge deployment plan

You can create an edge deployment plan with the CreateEdgeDeploymentPlan API. The deployment plan can have multiple stages. You can configure each stage to rollout the deployment to a subset of edge devices (by percentage, or by device name). You can also configure how rollout failures are handled at each stage.

The following code snippet shows how you can create an edge deployment plan with 1 stage to deploy a compiled and package model to 2 specific edge devices:

```python
import boto3
client = boto3.client("sagemaker")

client.create_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    DeviceFleetName="device-fleet-name",
    ModelConfigs=[
        {
            "EdgePackagingJobName": "edge-packaging-job-name",
            "ModelHandle": "model-handle"
        }
    ],
    Stages=[
        {
            "StageName": "stage-name",
            "DeviceSelectionConfig": {
                "DeviceSubsetType": "SELECTION",
                "DeviceNames": ["device-name-1", "device-name-2"]
            },
            "DeploymentConfig": {
                "FailureHandlingPolicy": "ROLLBACK_ON_FAILURE"
            }
        }
    ]
)
```

Instead of specific devices, if you want to deploy to the model to a percentage of devices in your fleet, then set the value of DeviceSubsetType to "PERCENTAGE" and replace "DeviceNames": ["device-name-1", "device-name-2"] with "Percentage": desired-percentage in the above example.

Stages can be added after the deployment plan has been created with the CreateEdgeDeploymentStage API, in case you want to start rolling out new stages after validating your test rollout success. For more information about deployment stages see DeploymentStage.
Start the edge deployment

After creating the deployment plan and the deployment stages, you can start the deployment with the `StartEdgeDeploymentStage` API.

```python
client.start_edge_deployment_stage(
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    StageName="stage-name"
)
```

Check the status of the deployment

You can check the status of the edge deployment with the `DescribeEdgeDeploymentPlan` API.

```python
client.describe_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name"
)
```

Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.

SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.

The `proto` file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this `proto` file.

**Note**

There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where VERSION is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. See [Installing the Edge Manager agent](p. 2284) for information on how to obtain the release version (`<MAJOR_VERSION>`), time stamp of the release artifact (`<YYYY-MM-DD>`), and the repository commit ID (SHA-7).

**Linux**

The zip archive can be extracted with the command:

```bash
tar -xvzf <VERSION>.tgz
```

**Windows**

The zip archive can be extracted with the UI or command:
unzip <VERSION>.tgz

The release artifact hierarchy (after extracting the tar/zip archive) is shown below. The agent proto file is available under api/.

Topics
- Load Model (p. 2298)
- Unload Model (p. 2299)
- List Models (p. 2300)
- Describe Model (p. 2300)
- Capture Data (p. 2301)
- Get Capture Status (p. 2302)
- Predict (p. 2303)

Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the EdgePackagingJob operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model's signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```c
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
```
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
// rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);

Input

// request for LoadModel rpc call
message LoadModelRequest {
  string url = 1;
  string name = 2; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*$"
}

Output

// response for LoadModel rpc call
message LoadModelResponse {
  Model model = 1;
}

// Model represents the metadata of a model
// url - url representing the path of the model
// name - name of model
// input_tensor_metadatas - TensorMetadata array for the input tensors
// output_tensor_metadatas - TensorMetadata array for the output tensors
// Note:
// 1. input and output tensor metadata could empty for dynamic models.
message Model {
  string url = 1;
  string name = 2;
  repeated TensorMetadata input_tensor_metadatas = 3;
  repeated TensorMetadata output_tensor_metadatas = 4;
}

Unload Model

Unloads a previously loaded model. It is identified via the model alias which was provided during loadModel. If the alias is not found or model is not loaded then returns error.

// perform unload for a model
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist
// rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);

Input

//
Manage Model

// request for UnLoadModel rpc call
message UnLoadModelRequest {
  string name = 1; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*$"
}

List Models

Lists all the loaded models and their aliases.

// lists the loaded models
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// rpc ListModels(ListModelsRequest) returns (ListModelsResponse);

Describe Model

Describes a model that is loaded on the agent.

// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist at the url
// rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

Input

```
enum Encoding {
  CSV = 0;
  JSON = 1;
  NONE = 2;
  BASE64 = 3;
}
```

// AuxiliaryData represents a payload of extra data to be capture along with inputs and outputs of inference
// encoding - supports the encoding of the data
// data - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.

message AuxiliaryData {
  string name = 1;
  Encoding encoding = 2;
  oneof data {
...
Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the CaptureData() is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
// rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns
// (GetCaptureDataStatusResponse);
Input

```protobuf
// request for GetCaptureDataStatus rpc call
message GetCaptureDataStatusRequest {
  string capture_id = 1;
}
```

Output

```protobuf
enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}
```

```protobuf
// response for GetCaptureDataStatus rpc call
message GetCaptureDataStatusResponse {
  CaptureDataStatus status = 1;
}
```

**Predict**

The `predict` API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

```protobuf
// perform inference on a model.
// Note:
// 1. users can chose to send the tensor data in the protobuf message or
// through a shared memory segment on a per tensor basis, the Predict
// method with handle the decode transparently.
// 2. serializing large tensors into the protobuf message can be quite expensive,
// based on our measurements it is recommended to use shared memory of
// tenors larger than 256KB.
// 3. SMEdge IPC server will not use shared memory for returning output tensors,
// i.e., the output tensor data will always send in byte form encoded
// in the tensors of PredictResponse.
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all
// these call will be serialized under the hood. this shall be addressed
// in a later release.
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch
// rpc Predict(PredictRequest) returns (PredictResponse);
```
// message PredictRequest {
  string name = 1;
  repeated Tensor tensors = 2;
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in
two ways:
// a. send across the raw bytes of the multi-dimensional tensor
// b. send a SharedMemoryHandle which contains the posix shared
// memory segment
// id and offset in bytes to location of multi-dimensional
// tensor array.
// message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// TensorMetadata represents the metadata for a tensor
// name - name of the tensor
// data_type - data type of the tensor
// shape - array of dimensions of the tensor
// message TensorMetadata {
  string name = 1;
  DataType data_type = 2;
  repeated int32 shape = 3;
}

// SharedMemoryHandle represents a posix shared memory segment
// offset - offset in bytes from the start of the shared memory segment.
// segment_id - shared memory segment id corresponding to the posix shared memory
// segment.
// size - size in bytes of shared memory segment to use from the offset position.
Optimize model performance using Neo

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks (p. 2320) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures (p. 2347) for edge devices.

How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates...
binary code for the optimized operations, writes them to a shared object library, and saves the model
definition and parameters into separate files. Neo also provides a runtime for each target platform that
loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker console, the AWS Command Line
Interface (AWS CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a
model, see Use Neo to Compile a Model (p. 2307). With a few CLI commands, an API invocation, or a
few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker
endpoint or on an AWS IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

**Neo Sample Notebooks**

For sample notebooks that use SageMaker Neo to train, compile, optimize, and deploy machine learning
models to make inferences, see:

- **MNIST Training, Compilation and Deployment with MXNet Module**
- **MNIST Training, Compilation and Deployment with Tensorflow Module**
- **Deploying pre-trained PyTorch vision models with SageMaker Neo**
- **Model Optimization with an Image Classification Example**
- **Model Optimization with XGBoost Example**

For instructions on how to run these example notebooks in SageMaker, see Example Notebooks (p. 373).
If you need instructions on how to create a notebook instance to run these examples, see Use Amazon
SageMaker Notebook Instances (p. 358). To navigate to the relevant example in your notebook instance,
choose the **Amazon SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## Use Neo to Compile a Model

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the Neo CLI, the Amazon SageMaker console, or the Amazon SageMaker SDK.

### Topics

- Prepare Model for Compilation (p. 2307)
- Compile a Model (AWS Command Line Interface) (p. 2313)
- Compile a Model (Amazon SageMaker Console) (p. 2315)
- Compile a Model (Amazon SageMaker SDK) (p. 2320)

## Prepare Model for Compilation

SageMaker Neo requires machine learning models satisfy specific input data shape. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

### Topics

- What input data shapes does SageMaker Neo expect? (p. 2307)
- Saving Models for SageMaker Neo (p. 2308)

### What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:

**Keras**

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DatalInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{ 'input_1': [1, 3, 224, 224] }
- For two inputs: `{ 'input_1': [1, 3, 224, 224], 'input_2':[1,3,224,224] }

**MXNet/ONNX**

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{ 'data':[1,3,1024,1024] }
- For two inputs: `{ 'var1': [1,1,28,28], 'var2':[1,1,28,28] }
PyTorch

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: `{'input0':[1,3,224,224]}`
- For one input in list format: `[[1,3,224,224]]`
- For two inputs in dictionary format: `{'input0':[1,3,224,224], 'input1':[1,3,224,224]}`
- For two inputs in list format: `[[1,3,224,224], [1,3,224,224]]`

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,1024,1024,3]}`
- For two inputs: `{'data1': [1,28,28,1], 'data2':[1,28,28,1]}`

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,224,224,3]}`

Note

SageMaker Neo only supports TensorFlow Lite for edge device targets. For a list of supported SageMaker Neo edge device targets, see the SageMaker Neo Devices (p. 2349) page. For a list of supported SageMaker Neo cloud instance targets, see the SageMaker Neo Supported Instance Types and Frameworks (p. 2320) page.

XGBoost

An input data name and shape are not needed.

Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (*.tar.gz).

Keras

Keras models require one model definition file (.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the SavedModel after exporting.

Below is an example of how to export a tf.keras model as a frozen graph (option two):

```python
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend
```
tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
   input_shape=(224, 224, 3), pooling='avg')
model.summary()

# Save as a SavedModel
export_dir = 'saved_model/
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(':')[0] for inp in model.inputs]
output_node_names = [output.name.split(':')[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=['serve'])
frozen_graph = tf.graph_util.convert_variables_to_constants(sess,
    sess.graph.as_graph_def(),
    output_node_names)
   
tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb",
as_text=False)

import tarfile
tar = tarfile.open("frozen_graph.tar.gz", "w:gz")
tar.add("frozen_graph.pb")
tar.close()

**Warning**
Do not export your model with the SavedModel class using model.save(<path>,
save_format='tf'). This format is suitable for training, but it is not suitable for inference.

**MXNet**

MXNet models must be saved as a single symbol file *-symbol.json and a single parameter *.params files.

**Gluon Models**

Define the neural network using the HybridSequential Class. This will run the code in the style of
symbolic programming (as opposed to imperative programming).

```
from mxnet import nd, sym
from mxnet.gluon import nn
def get_net():
    net = nn.HybridSequential()  # Here we use the class HybridSequential.
    net.add(nn.Dense(256, activation='relu'),
            nn.Dense(128, activation='relu'),
            nn.Dense(2))
    net.initialize()
    return net

# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()

# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)

# hybridize model
net.hybridize()
net(x)
```
# export model
net.export('<model_name>') # this will create model-symbol.json and model-0000.params files

import tarfile
tar = tarfile.open('<model_name>.tar.gz', 'w:gz')
for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
    tar.add(name)
tar.close()

For more information about hybridizing models, see the MXNet hybridize documentation.

Gluon Model Zoo (GluonCV)

GluonCV model zoo models come pre-hybridized. So you can just export them.

```python
import numpy as np
import mxnet as mx
import gluoncv as gcv
from gluoncv.utils import export_block
import tarfile

net = gcv.model_zoo.get_model('<model_name>', pretrained=True) # For example, choose <model_name> as resnet18_v1
export_block('<model_name>', net, preprocess=True, layout='HWC')
tar = tarfile.open('<model_name>.tar.gz', 'w:gz')
for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
    tar.add(name)
tar.close()
```

Non Gluon Models

All non-Gluon models when saved to disk use *-symbol and *.params files. They are therefore already in the correct format for Neo.

```python
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>',0,sym,args,aux) # this will create <model_name>-symbol.json and <model_name>-0000.params files

import tarfile
tar = tarfile.open('<model_name>.tar.gz', 'w:gz')
for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
    tar.add(name)
tar.close()
```

PyTorch

PyTorch models must be saved as a definition file (.pt or .pth) with input datatype of float32.

To save your model, use torch.jit.trace followed by torch.save. This will save an object to a disk file and by default uses python pickle (pickle_module=pickle) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```python
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
```
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
import tarfile
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()

### TensorFlow

TensorFlow requires one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file is required.

**Pre-Trained Model**

The following code example shows how to use the tar Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the ! magic command at the beginning of the statement):

```
# Download SSD_Mobilenet trained model
!wget http://download.tensorflow.org/models/object_detection/ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
!tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Compress the tar file and save it in a directory called 'model.tar.gz'
!tar czvf model.tar.gz ssd_mobilenet_v2_coco_2018_03_29/frozen_inference_graph.pb
```

The command flags used in this example accomplish the following:

- **c**: Create an archive
- **z**: Compress the archive with gzip
- **v**: Display archive progress
- **f**: Specify the filename of the archive

**Built-In Estimators**

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in .fit method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(entry_point='mnist.py',
    role=role,  # param role can be arn of a sagemaker execution role
    framework_version='1.15.3',
    py_version='py3',
    training_steps=1000,
    evaluation_steps=100,
    instance_count=2,
    instance_type='ml.c4.xlarge')
```
Then train the model with `.fit` built-in method:

```python
estimator.fit(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```python
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/')[:-1])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                               input_shape={'data': [1, 784]},  # Batch size 1, 3 channels, 224x224 Images.
                                               output_path=output_path,
                                               framework='tensorflow', framework_version='1.15.3')
```

You can also use the `sagemaker.estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```python
import sagemaker
from sagemaker.image_uris import retrieve
sagemaker_session = sagemaker.Session()
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
training_image = retrieve(framework='image-classification',
                          region=aws_region, image_scope='training')

# Create estimator object for training
estimator = sagemaker.estimator.Estimator(image_uri=training_image,
                                          role=role,  #param role can be arn of a sagemaker execution role
                                          instance_count=1,
                                          instance_type='ml.p3.8xlarge',
                                          volume_size = 50,
                                          max_run = 360000,
                                          input_mode= 'File',
                                          output_path=s3_training_output_location,
                                          base_job_name='image-classification-training')

# Setup the input data_channels to be used later for training.
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,
                                            content_type='application/x-recordio',
                                            s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,
                                                  content_type='application/x-recordio',
                                                  s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}

# Train model
estimator.fit(inputs=data_channels, logs=True)

# Compile model with Neo
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                            input_shape={'data': [1, 784]},  # Batch size 1, 3 channels, 224x224 Images.
                                            output_path=output_path,
                                            framework='tensorflow', framework_version='1.15.3')
```
input_shape={'data':[1, 3, 224, 224],
output_path=s3_compilation_output_location,
framework='mxnet',
framework_version='1.7')

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker SDK) (p. 2320).

Compile a Model (AWS Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using AWS Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

1. Create a Compilation Job

With the CreateCompilationJob API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

The following table demonstrates how to configure CreateCompilationJob API based on whether your target is a device or a platform.

Device Example

```
{
  "CompilationJobName": "neo-compilation-job-demo",
  "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
  "InputConfig": {
    "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
    "DataInputConfig": "{'data': [1,3,1024,1024]}",
    "Framework": "MXNET"
  },
  "OutputConfig": {
    "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
    "TargetDevice": "ml_c5"
  },
  "StoppingCondition": {
    "MaxRuntimeInSeconds": 300
  }
}
```

You can optionally specify the framework version you used with the FrameworkVersion field if you used the PyTorch framework to train your model and your target device is a ml_* target.

```
{
  "CompilationJobName": "neo-compilation-job-demo",
  "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
  "InputConfig": {
    "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
    "DataInputConfig": "{'data': [1,3,1024,1024]}",
    "Framework": "PYTORCH"
  },
  "OutputConfig": {
    "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
    "TargetDevice": "ml_c5"
  },
  "StoppingCondition": {
    "MaxRuntimeInSeconds": 300
  }
}
```

2313
# excluding ml_inf. Supported values are 1.4 or 1.5 or 1.6. Default is 1.6
"FrameworkVersion": "1.6"
},
"OutputConfig": {
  "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
  # A target device specification example for a ml_c5 instance family
  "TargetDevice": "ml_c5",
  # When compiling for ml_* instances using PyTorch framework, use the
  "CompilerOptions" field in
  # OutputConfig to provide the correct data type ("dtype") of the model’s
  input. Default assumed is "float32"
  "CompilerOptions": "{'dtype': 'long'}"
},
"StoppingCondition": {
  "MaxRuntimeInSeconds": 300
}

**Note**
This API field is only supported for PyTorch.

**Platform Example**

```json
{
  "CompilationJobName": "neo-test-compilation-job",
  "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
  "InputConfig": {
    "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
    "DataInputConfig": "{'data': [1,3,1024,1024]}",
    "Framework": "MXNET"
  },
  "OutputConfig": {
    "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
    # A target platform configuration example for a p3.2xlarge instance
    "TargetPlatform": {
      "Os": "LINUX",
      "Arch": "X86_64",
      "Accelerator": "NVIDIA"
    },
    "CompilerOptions": "{'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code': 'sm_70'}"
  },
  "StoppingCondition": {
    "MaxRuntimeInSeconds": 300
  }
}
```

**Note**
For the OutputConfig API operation, the TargetDevice and TargetPlatform API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of DataInputConfig depending on frameworks, see [What input data shapes Neo expects](#).

For more information about setting up the configurations, see the **InputConfig**, **OutputConfig**, and **TargetPlatform** API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \ 
--region us-west-2 \
# You should get CompilationJobArn

3. Describe the compilation job by running the following command:

```bash
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \ 
--region us-west-2
```

4. Stop the compilation job by running the following command:

```bash
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \ 
--region us-west-2 \
# There is no output for compilation-job operation
```

5. List the compilation job by running the following command:

```bash
aws sagemaker list-compilation-jobs \
--region us-west-2
```

**Compile a Model (Amazon SageMaker Console)**

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

1. In the **Amazon SageMaker** console, choose **Compilation jobs**, and then choose **Create compilation job**.

   ![Amazon SageMaker console](image)

2. On the **Create compilation job** page, under **Job name**, enter a name. Then select an **IAM role**.
3. If you don’t have an IAM role, choose **Create a new role**.

4. On the **Create an IAM role** page, choose **Any S3 bucket**, and choose **Create role**.
5. Non PyTorch Frameworks

Within the **Input configuration** section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the **Location of model artifacts** input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

For the **Data input configuration** field, enter the JSON string that specifies the shape of the input data. For **Machine learning framework**, choose the framework of your choice.

To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).

**PyTorch Framework**

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for ml_* (except ml_inf) target, you can optionally specify the version of PyTorch you used.

To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).
Note
When compiling for ml_* instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (dtype) of the model’s input. The default is set to "float32".

**Warning**
If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: `ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file`

6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

   For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.
7. Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

8. Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.
Compile a Model (Amazon SageMaker SDK)

You can use the `compile_model` API in the Amazon SageMaker SDK for Python to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

**Note**
You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```python
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
                                                      input_shape=expected_trained_model_input,
                                                      output_path='insert s3 output path',
                                                      env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```

The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the Neo Model Compilation Sample Notebooks section.

Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and AWS Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the AWS CLI, the SageMaker Console, or the SageMaker SDK for Python. See, Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and AWS Inferentia instances using the SageMaker SDK for Python, AWS SDK for Python (Boto3), AWS CLI, or the AWS console.

If you deploy your model using AWS CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

Topics
- Supported Instance Types and Frameworks (p. 2320)
- Deploy a Model (p. 2324)
- Request Inferences from a Deployed Service (p. 2341)
- Inference Container Images (p. 2344)

Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, AWS Inferentia instance types, or Amazon Elastic Inference accelerators.
The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see Deploy a Model with Cloud Instances. For information on how to deploy your compiled model with Elastic Inference accelerators, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2379).

## Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.7.0</td>
<td>Supports 1.7.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.h5)</td>
<td></td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.4, 1.5, 1.6, 1.7, 1.8, or 1.12</td>
<td>Supports 1.4, 1.5, 1.6, 1.7, 1.8, and 1.12</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.3 or 2.9</td>
<td>Supports 1.15.3 and 2.9</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file</td>
<td></td>
</tr>
<tr>
<td>XGBoost</td>
<td>1.3.3</td>
<td>Supports 1.3.3 or earlier</td>
<td>Decision Trees</td>
<td>One XGBoost model file (.model) where the number of</td>
<td></td>
</tr>
</tbody>
</table>
Note
“Model Version” is the version of the framework used to train and export the model.

Instance Types
You can deploy your SageMaker compiled model to one of the cloud instances listed below:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Compute Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1_c4</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_c5</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_m4</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_m5</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_p2</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>m1_p3</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>m1_g4dn</td>
<td>Accelerated computing</td>
</tr>
</tbody>
</table>

For information on the available vCPU, memory, and price per hour for each instance type, see Amazon SageMaker Pricing.

Note
When compiling for m1_* instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model's input. The default is set to "float32".

AWS Inferentia
SageMaker Neo supports the following deep learning frameworks for Inferentia:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Framework Version</th>
<th>Model Version</th>
<th>Models</th>
<th>Toolkits</th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.5 or 1.8</td>
<td>Supports 1.8, 1.5 and earlier</td>
<td>Image Classification, Object Detection, Semantic</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
</tr>
</tbody>
</table>
--- | --- | --- | --- | --- | ---
 | | | | Segmentation, Pose Estimation, Activity Recognition | |
| PyTorch | 1.7, 1.8 or 1.9 | Supports 1.9 and earlier | Image Classification | One model definition file (.pt or .pth) with input dtype of float32 | |
| TensorFlow | 1.15 or 2.5 | Supports 2.5, 1.15 and earlier | Image Classification | For saved models, one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file. | |

**Note**

“Model Version” is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to AWS Inferentia-based Amazon EC2 Inf1 instances. AWS Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the ml_inf1 instance to deploy your compiled models.

**Amazon Elastic Inference**

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>2.3.2</td>
<td>Supports 2.3</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file.</td>
</tr>
</tbody>
</table>
You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2379).

**Deploy a Model**

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.

For **Inf1 instances**, models need to be compiled specifically for ml.inf1 instances. Models compiled for other instance types are not guaranteed to work with ml.inf1 instances.

For **Elastic Inference accelerators**, models need to be compiled specifically for ml_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2379).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: Amazon SageMaker SDK for Python, SDK for Python (Boto3), AWS Command Line Interface, and the SageMaker console https://console.aws.amazon.com/SageMaker.

**Note**
For deploying a model using AWS CLI, the console, or Boto3, see Neo Inference Container Images to select the inference image URI for your primary container.

**Topics**
- Prerequisites (p. 2324)
- Deploy a Compiled Model Using SageMaker SDK (p. 2330)
- Deploy a Compiled Model Using Boto3 (p. 2333)
- Deploy a Compiled Model Using the AWS CLI (p. 2334)
- Deploy a Compiled Model Using the Console (p. 2336)

**Prerequisites**

**Note**
Follow the instructions in this section if you compiled your model using AWS SDK for Python (Boto3), AWS CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from this list.
2. An entry point script file:
   a. For **PyTorch and MXNet models:**

   *If you trained your model using SageMaker,* the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo, the training script (mnist.py) implements the required functions.

   *If you did not train your model using SageMaker,* you need to provide an entry point script (inference.py) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MxNet or Model Directory Structure for PyTorch.
When using Neo Inference Optimized Container images with **PyTorch** and **MXNet** on CPU and GPU instance types, the inference script must implement the following functions:

- **model_fn**: Loads the model. (Optional)
- **input_fn**: Converts the incoming request payload into a numpy array.
- **predict_fn**: Performs the prediction.
- **output_fn**: Converts the prediction output into the response payload.
- Alternatively, you can define `transform_fn` to combine `input_fn`, `predict_fn`, and `output_fn`.

The following are examples of `inference.py` script within a directory named `code` (`code/inference.py`) for **PyTorch and MXNet (Gluon and Module)**. The examples first load the model and then serve it on image data on a GPU:

**MXNet Module**

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
cntx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
mod = mx.mod.Module(symbol=sym, context=cntx, label_names=None)
exe = mod.bind(for_training=False,
               data_shapes=[('data', (1,3,224,224))],
               label_shapes=mod._label_shapes)
mod.set_params(arg_params, aux_params, allow_missing=True)

    # Run warm-up inference on empty data during model load (required for GPU)

    batchified = batchified.to(device)
    output = model.forward(batchified)
    return json.dumps(output.cpu().numpy().tolist()), response_content_type
```
b. **For inf1 instances or onnx, xgboost, keras container images**

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- **neo_preprocess**: Converts the incoming request payload into a numpy array.
- **neo_postprocess**: Converts the prediction output from Neo Deep Learning Runtime into the response body.

**Note**
The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see [Neo Model Compilation Sample Notebooks](#).

c. **For TensorFlow models**

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script `inference.py` file that can be used at the time of inference. The script should implement either a pair of `input_handler` and `output_handler` functions or a single handler function.

**Note**
Note that if handler function is implemented, `input_handler` and `output_handler` are ignored.

The following is a code example of `inference.py` script that you can put together with the compile model to perform custom pre- and post-processing on an image classification model.

The SageMaker client sends the image file as an `application/x-image` content type to the `input_handler` function, where it is converted to JSON. The converted image file is then sent to the TensorFlow Model Server (TFX) using the REST API.

```python
import json
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """Pre-process request input before it is sent to TensorFlow Serving REST API

    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details

    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    """
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512))
    image = np.concatenate([image[0], image[1, :]] * batch_size)
    body = json.dumps({"signature_name": "serving_default", "instances":
        image.tolist()})
    return body
```
def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the client.
    Args:
    data (obj): the TensorFlow serving response
    context (Context): an object containing request and configuration details
    Returns:
    (bytes, string): data to return to client, response content type
    """
    if data.status_code != 200:
        raise ValueError(data.content.decode('utf-8'))
    response_content_type = context.accept_header
    prediction = data.content
    return prediction, response_content_type

If there is no custom pre- or post-processing, the SageMaker client converts the file image to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

Deploy a Compiled Model Using SageMaker SDK

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

Topics
- If you compiled your model using the SageMaker SDK (p. 2330)
- If you compiled your model using MXNet or PyTorch (p. 2330)
- If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow (p. 2332)

If you compiled your model using the SageMaker SDK

The sagemaker.Model object handle for the compiled model supplies the deploy() function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is ml_c5.

```python
predictor = compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.c5.4xlarge')
# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the deploy() API under the framework-specific Model APIs. For MXNet, it is MXNetModel and for PyTorch, it is PyTorchModel. When you are creating and deploying an SageMaker model, you must set MMS_DEFAULT_RESPONSE_TIMEOUT environment variable to 500 and specify the entry_point parameter as the inference script (inference.py) and the source_dir parameter as the directory location (code) of the inference script. To prepare the inference script (inference.py) follow the Prerequisites step.
The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

**MXNet**

```python
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.4 and Older**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.4.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.5 and Newer**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.5',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
)
```
# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

Note
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

Construct a TensorFlowModel object, then call deploy:

```python
role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
                           framework_version='1.15.3',
                           role=role,
                           image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
                           initial_instance_count=1)
```

See Deploying directly from model artifacts for more information.

You can select a Docker image Amazon ECR URI that meets your needs from this list.

For more information on how to construct a TensorFlowModel object, see the SageMaker SDK.

Note
Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as "warming up" the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```python
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
from tensorflow_serving.apis import regression_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data, shape=test_data.shape, dtype=tf.float32))
```
Deploy a Compiled Model Using Boto3

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).

Topics

- Deploy the Model (p. 2333)

Deploy the Model

After you have satisfied the prerequisites, use the create_model, create_endpoint_config, and create_endpoint APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```python
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': '<insert the ECR Image URI>',
        'ModelDataUrl': 's3://path/to/model/artifact/model.tar.gz',
        'Environment': {}
    },
    ExecutionRoleArn='ARN for AmazonSageMaker-
    ExecutionRole'
)
print("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-
    endpoint-configuration',
    ProductionVariants=[
        { 'VariantName': '<provide your variant name>',
          'ModelName': 'my-sagemaker-model',
          'InitialInstanceCount': 1,
          'InstanceType': '<provide your instance type here>'
        }
    ],
)
print("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
create_endpoint_api_response = client.create_endpoint(
    EndpointName='provide your endpoint name',
    EndpointConfigName='insert your endpoint config name',
)```
Note

The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

For full syntax of create_model, create_endpoint_config, and create_endpoint APIs, see create_model, create_endpoint_config, and create_endpoint, respectively.

If you did not train your model using SageMaker, specify the following environment variables:

### MXNet and PyTorch

```json
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

### TensorFlow

```json
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}
```

If you trained your model using SageMaker, specify the environment variable SAGEMAKER_SUBMIT_DIRECTORY as the full Amazon S3 bucket URI that contains the training script.

**Deploy a Compiled Model Using the AWS CLI**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the AWS CLI.

### Topics

- Deploy the Model (p. 2334)

**Deploy the Model**

After you have satisfied the prerequisites, use the create-model, create-endpoint-config, and create-endpoint AWS CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

**Create a Model**

From Neo Inference Container Images, select the inference image URI and then use create-model API to create a SageMaker model. You can do this with two steps:

1. Create a create_model.json file. Within the file, specify the name of the model, the image URI, the path to the model.tar.gz file in your Amazon S3 bucket, and your SageMaker execution role:
If you trained your model using SageMaker, specify the following environment variable:

```
"Environment": {
  "SAGEMAKER_SUBMIT_DIRECTORY" : "[Full S3 path for *.tar.gz file containing the training script]"
}
```

If you did not train your model using SageMaker, specify the following environment variables:

**MXNet and PyTorch**

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region",
  "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

**TensorFlow**

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region"
}
```

**Note**
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

```
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the create-model API, see `create-model`.

**Create an Endpoint Configuration**

After creating a SageMaker model, create the endpoint configuration using the `create-endpoint-config` API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as `create_config.json`:

```
{
  "EndpointConfigName": "<provide your endpoint config name>",
  "ProductionVariants": []
}
```
Now run the following AWS CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the `create-endpoint-config` API, see `create-endpoint-config`.

Create an Endpoint

After you have created your endpoint configuration, create an endpoint using the `create-endpoint` API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --endpoint-config-name '<insert your endpoint config name>'
```

For the full syntax of the `create-endpoint` API, see `create-endpoint`.

Deploy a Compiled Model Using the Console

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), the AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the SageMaker console https://console.aws.amazon.com/SageMaker.

Topics
- Deploy the Model (p. 2336)

Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

1. Choose Models, and then choose Create models from the Inference group. On the Create model page, complete the Model name, IAM role, and VPC fields (optional), if needed.
2. To add information about the container used to deploy your model, choose **Add container** container, then choose **Next**. Complete the **Container input options**, **Location of inference code image**, and **Location of model artifacts**, and optionally, **Container host name**, and **Environmental variables** fields.
3. To deploy Neo-compiled models, choose the following:

- **Container input options**: Choose **Provide model artifacts and inference image**.
- **Location of inference code image**: Choose the inference image URI from Neo Inference Container Images, depending on the AWS Region and kind of application.
- **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
- **Environment variables**:
  - Leave this field blank for **SageMaker XGBoost**.
  - If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
  - If you did not train your model using SageMaker, specify the following environment variables:

<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOG_LEVEL</td>
<td>20</td>
<td>20</td>
</tr>
</tbody>
</table>
### Key Values for MXNet and PyTorch | Values TensorFlow
---|---
SAGEMAKER_REGION | <your region> | <your region>
MMS_DEFAULT_RESPONSE_TIMEOUT | 500 | Leave this field blank for TF

4. Confirm that the information for the containers is accurate, and then choose Create model. On the Create model landing page, choose Create endpoint.

5. In Create and configure endpoint diagram, specify the Endpoint name. For Attach endpoint configuration, choose Create a new endpoint configuration.

6. In New endpoint configuration page, specify the Endpoint configuration name.
7. Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.
8. Choose Save.

9. On the New endpoint configuration page, choose Create endpoint configuration, and then choose Create endpoint.

Request Inferences from a Deployed Service

If you have followed instructions in Deploy a Model (p. 2324), you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

Topics
- Request Inferences from a Deployed Service (Amazon SageMaker SDK) (p. 2341)
- Request Inferences from a Deployed Service (Boto3) (p. 2343)
- Request Inferences from a Deployed Service (AWS CLI) (p. 2344)

Request Inferences from a Deployed Service (Amazon SageMaker SDK)

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires application/json as the content type.
PyTorch and MXNet

If you are using **PyTorch v1.4 or later** or **MXNet 1.7.0 or later** and you have an Amazon SageMaker endpoint InService, you can make inference requests using the `predictor` package of the SageMaker SDK for Python.

**Note**

The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

**SageMaker Python SDK v1.x**

```python
from sagemaker.predictor import RealTimePredictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**SageMaker Python SDK v2.x**

```python
from sagemaker.predictor import Predictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**TensorFlow**

The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```python
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```
image = image / 128 - 1
image = np.concatenate([[image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)

Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and invoke_endpoint() API once you have an SageMaker endpoint InService. The following code example shows how to send an image for inference:

**PyTorch and MXNet**

```python
import boto3
import json

endpoint = 'insert name of your endpoint here'

runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()

# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode())
```

**TensorFlow**

For TensorFlow submit an input with application/json for the content type.

```python
from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([[image[np.newaxis, :, :]] * batch_size]
body = json.dumps({"instances": image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(  
    EndpointName=ioc_predictor_endpoint_name,  
    Body=body,  
    ContentType=content_type  
)
```

**XGBoost**

For an XGBoost application, you should submit a CSV text instead:
import boto3
import json

endpoint = 'insert your endpoint name here'
runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv', Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())

Note that BYOM allows for a custom content type. For more information, see runtime_InvokeEndpoint.

Request Inferences from a Deployed Service (AWS CLI)

Inference requests can be made with the sagemaker-runtime invoke-endpoint once you have an Amazon SageMaker endpoint InService. You can make inference requests with the AWS Command Line Interface (AWS CLI). The following example shows how to send an image for inference:

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An output_file.txt with information about your inference requests is made if the inference was successful.

For TensorFlow submit an input with application/json as the content type.

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://input.json --content-type=application/json output_file.txt
```

Inference Container Images

Based on your use case, replace the highlighted portion in the inference image URI template provided below with appropriate values.

**Amazon SageMaker XGBoost**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

**Keras**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-keras:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Replace `fx_version` with 2.2.4. Replace `instance_type` with either cpu or gpu.
### MXNet

**CPU or GPU instance types**

```plaintext
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-mxnet:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.8.0.

Replace `instance_type` with either cpu or gpu.

**Inferentia instance types**

```plaintext
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-mxnet:fx_version-instance_type-py3
```

Replace `aws_region` with either us-east-1 or us-west-2.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.1.

Replace `instance_type` with inf.

### ONNX

```plaintext
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-onnx:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.0.

Replace `instance_type` with either cpu or gpu.

### PyTorch

**CPU or GPU instance types**

```plaintext
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-pytorch:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.4, 1.5, 1.6, 1.7 or 1.8.

Replace `instance_type` with either cpu or gpu.

**Inferentia instance types**

```plaintext
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-pytorch:fx_version-instance_type-py3
```
Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.5.1`.

Replace `instance_type` with `inf`.

**TensorFlow**

**CPU or GPU instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.15.3` or `2.9`.

Replace `instance_type` with either `cpu` or `gpu`.

**Inferentia instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Note that for instance type `inf` only `us-east-1` and `us-west-2` are supported.

Replace `fx_version` with `1.15.0`.

Replace `instance_type` with `inf`.

The following table maps `aws_account_id` with `aws_region`. Use this table to find the correct inference image URI you need for your application.

<table>
<thead>
<tr>
<th><code>aws_account_id</code></th>
<th><code>aws_region</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>785573368785</td>

</tbody>
</table>
Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments' Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use AWS services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 AWS Configuration for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics
- Supported Frameworks, Devices, Systems, and Architectures (p. 2347)
- Deploy Models (p. 2357)
- Getting Started with Neo on Edge Devices (p. 2358)

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models (p. 2352) section.
Note

- Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see Troubleshoot Ambarella Errors (p. 2369).
- TIM-VX (libtim-vx.so) is required for i.MX 8M Plus. For information on how to build TIM-VX, see the TIM-VX GitHub repository.

Topics

- Supported Frameworks (p. 2348)
- Supported Devices, Chip Architectures, and Systems (p. 2349)
- Tested Models (p. 2352)

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8</td>
<td>Supports 1.8</td>

<td>*For saved models, one .pb or one .pbtxt file and a variables directory that contains variables *For frozen models,</td>
<td></td>
</tr>
</tbody>
</table>
## Supported Devices, Chip Architectures, and Systems

Amazon SageMaker Neo supports the following devices, chip architectures, and operating systems.

**Devices**

You can select a device using the dropdown list in the Amazon SageMaker console or by specifying the TargetDevice in the output configuration of the CreateCompilationJob API.

You can choose from one of the following edge devices:

<table>
<thead>

**Tested Models**

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.

**Note**

This is not a comprehensive list of models that can be compiled with Neo.

See [Supported Frameworks](p. 2348) and [SageMaker Neo Supported Operators](#) to find out if you can compile your model with SageMaker Neo.

**DarkNet**

Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using DLR, or you can use AWS IoT Greengrass.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, Supported Frameworks, Devices, Systems, and Architectures to find out what edge devices are supported. Make
sure that you specified your target edge device when you submitted the compilation job, see Use Neo to Compile a Model.

**Deploy a Compiled Model (DLR)**

DLR is a compact, common runtime for deep learning models and decision tree models. DLR uses the TVM runtime, Treelite runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```bash
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```bash
```

**Deploy a Model (AWS IoT Greengrass)**

AWS IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With AWS IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all AWS IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with AWS IoT Greengrass, see How to configure optimized machine learning inference using the AWS Management Console.

**Getting Started with Neo on Edge Devices**

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using AWS CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

**Note**

You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.

**Prerequisites**

1. **Install Boto3**

   If you are running these commands on your edge device, you must install the AWS SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device's terminal or within a Jupyter notebook instance:
Terminal

```
pip install boto3
```

Jupyter Notebook

```
!pip install boto3
```

2. **Set Up AWS Credentials**

You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the AWS credentials should be stored in the file `~/.aws/credentials` on your edge device. Within the credentials file, you should see two environment variables: `aws_access_key_id` and `aws_secret_access_key`.

In your terminal, run:

```
$ more ~/.aws/credentials
[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

The [AWS General Reference Guide](https://docs.aws.amazon.com/general/latest/gr/aws-��presentation.html) has instructions on how to get the necessary `aws_access_key_id` and `aws_secret_access_key`. For more information on how to set up credentials on your device, see the [Boto3](https://boto3.amazonaws.com/v1/documentation/api/latest/index.html) documentation.

3. **Set up an IAM Role and attach policies.**

Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the AWS CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```python
import boto3
AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)
role_name = 'role-name'

policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        },
        {
            'Service': 'sagemaker.amazonaws.com',
        },
    ],
    'Version': '2012-10-17'
}
```

For more information on how to create an IAM role with the console, AWS CLI, or through the AWS API, see [Creating an IAM user in your AWS account](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html).

Create a dictionary describing the IAM policy you are attaching. This policy is used to create a new IAM role.
Create a new IAM role using the policy you defined above:

```python
import json
new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```python
role_arn = new_role['Role']['Arn']
```

Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```python
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
)
```

4. Create an Amazon S3 bucket to store your model artifacts

SageMaker Neo will access your model artifacts from Amazon S3

Boto3

```python
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if boto3.resource('s3').Bucket(bucket) not in boto3.resource('s3').buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
    )
else:
    print(f'Bucket {bucket} already exists. No action needed. ')
```

CLI

```shell
aws s3 mb s3://name-of-your-bucket' --region specify-your-region

# Check your bucket exists
aws s3 ls s3://name-of-your-bucket/'
```

5. Train a machine learning model
See Train a Model with Amazon SageMaker for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**
Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect?

If you do not have a model yet, use the curl command to get a local copy of the coco_ssd_mobilenet model from TensorFlow's website. The model you just copied is an object detection model trained from the COCO dataset. Type the following into your Jupyter notebook:

```bash
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip \   --output {model_zip_filename}
```

Note that this particular example was packaged in a .zip file. Unzip this file and repack it as a compressed tarfile (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```bash
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]
# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

Once you have trained your machine learning model, store it in an S3 bucket.

Boto3

```python
# Upload model
s3_client.upload_file(Filename=model_filename, Bucket=bucket, Key=model_filename)
```

CLI

Replace your-model-filename and your-S3-bucket with the name of your S3 bucket.

```bash
aws s3 cp your-model-filename s3://your-S3-bucket
```

**Step 1: Compile the Model**

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker Neo. You can compile your model using the AWS CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. The Amazon S3 bucket URI where you stored the trained model.
If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the AWS CLI:

```shell
aws s3 ls
```

For example:

```
$ aws s3 ls
2020-11-02 17:08:50 bucket
```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:

   ```python
   s3_output_location = f's3://{bucket}/output'
   ```

3. **The machine learning framework you used to train your model.**

   Define the framework you used to train your model.

   ```python
   framework = 'framework-name'
   ```

   For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

   ```python
   framework = 'tflite'
   ```

   For a complete list of Neo-supported frameworks, see [Supported Frameworks, Devices, Systems, and Architectures](#).

4. **The shape of your model's input.**

   Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. `value` is a list of the integer dimensions of an input tensor and `key` is the exact name of an input tensor in the model.

   ```python
   data_shape = '{"name": [tensor-shape]}'
   ```

   For example:

   ```python
   data_shape = '{"normalized_input_image_tensor": [1, 300, 300, 3]}'
   ```

   **Note**
   Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#) The key in this dictionary must be changed to the new input tensor’s name.

5. **Either the name of the target device to compile for or the general details of the hardware platform**

   ```python
   target_device = 'target-device-name'
   ```
For example, if you want to deploy to a Raspberry Pi 3, use:

```python
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in Supported Frameworks, Devices, Systems, and Architectures.

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```python
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')

response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time
while True:
    response = sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
    print('Done!')

If you want additional information for debugging, include the following print statement:

```python
print(response)
```

If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (s3_output_location). Download your compiled model locally:

```python
object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)
```
Step 2: Set Up Your Device

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install AWS IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the coco_ssd_mobilenet object detection algorithm and you will use DLR.

1. **Install additional packages**

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

   For example, for the coco_ssd_mobilenet object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.

   ```bash
   !pip3 install numpy pillow tensorflow matplotlib
   ```

2. **Install inference engine on your device**

   To run your Neo-compiled model, install the Deep Learning Runtime (DLR) on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86_64 CPU targets running Linux, you can install the latest release of the DLR package using the following pip command:

   ```bash
   !pip install dlr
   ```

   For installation of DLR on GPU targets or non-x86 edge devices, refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

   ```bash
   ```

Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

   ```bash
   # Download compiled model locally to edge device
   object_path = f'output/{model_name}-{target_device}.tar.gz'
   neo_compiled_model = f'compiled-{model_name}.tar.gz'
   s3_client.download_file(bucket_name, object_path, neo_compiled_model)

   # Extract model from .tar.gz so DLR can use it
   !mkdir ./dlr_model # make a directory to store your model (optional)
   !tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model
   ```

2. **Import DLR and an initialized DLRModel object.**

   ```python
   import dlr
   ```
3. **Download an image for inferencing and format it based on how your model was trained.**

For the coco_ssd_mobilenet example, you can download an image from the COCO dataset and then reform the image to 300x300:

```python
from PIL import Image

# Download an image for model to make a prediction
input_image_filename = './input_image.jpg'
!curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output {input_image_filename}

# Format image so model can make predictions
resized_image = image.resize((300, 300))

# Model is quantized, so convert the image to uint8
x = np.array(resized_image).astype('uint8')
```

4. **Use DLR to make inferences.**

Finally, you can use DLR to make a prediction on the image you just downloaded:

```python
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the neo-ai-dlr Github repository.

**Troubleshoot Errors**

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

- **Did you encounter an error before you deployed your model?** If yes, see Troubleshoot Neo Compilation Errors.
- **Did you encounter an error after you compiled your model?** If yes, see Troubleshoot Neo Inference Errors.
- **Did you encounter an error trying to compile your model for Ambarella devices?** If yes, see Troubleshoot Ambarella Errors (p. 2369).

**Error Classification Types**

This list classifies the user errors you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are system errors.

**Client permission error**

Neo passes the errors for these straight through from the dependent service.

- **Access Denied** when calling sts:AssumeRole
- **Any 400 error** when calling Amazon S3 to download or upload a client model
• *PassRole* error

Load error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (*.pb or *.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (*.pth).
- **MXNET**: Expect only one symbol file (*.json) and one parameter file (*.params).
- **XGBoost**: Expect only one XGBoost model file (*.model). The input model has size limitation.

Compilation error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:

- **OperatorNotImplemented**: An operator has not been implemented.
- **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.
- **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.
- **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

Troubleshoot Neo Compilation Errors

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

Topics

- How to Use This Page (p. 2366)
- Framework-Related Errors (p. 2367)
- Infrastructure-Related Errors (p. 2368)
- Check your compilation log (p. 2368)

How to Use This Page

Attempt to resolve your error by the going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See What input data shapes does SageMaker Neo expect? (p. 2307)
2. Check common framework-specific errors.
3. Check if your error is an infrastructure error.
4. Check your compilation log.
## Framework-Related Errors

### TensorFlow

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>InputConfiguration: Exactly one .pb file is allowed for TensorFlow models.</td>
<td>Make sure you only provide one .pb or .pbtxt file.</td>
</tr>
<tr>
<td>InputConfiguration: Exactly one .pb or .pbtxt file is allowed for TensorFlow models.</td>
<td>Make sure you only provide one .pb or .pbtxt file.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: TVM cannot convert &lt;model zoo&gt; model. Please make sure the framework you selected is correct. The following operators are not implemented: {&lt;operator name&gt;}</td>
<td>Check the operator you chose is supported. See SageMaker Neo Supported Frameworks and Operators.</td>
</tr>
</tbody>
</table>

### Keras

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>InputConfiguration: No h5 file provided in &lt;model path&gt;</td>
<td>Check your h5 file is in the Amazon S3 URI you specified.</td>
</tr>
<tr>
<td></td>
<td>Or</td>
</tr>
<tr>
<td></td>
<td>Check that the h5 file is correctly formatted.</td>
</tr>
<tr>
<td>InputConfiguration: Multiple h5 files provided, &lt;model path&gt;, when only one is allowed</td>
<td>Check you are only providing one h5 file.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Unable to load provided Keras model. Error: 'sample_weight_mode'</td>
<td>Check the Keras version you specified is supported. See supported frameworks for cloud instances and edge devices.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Input input has wrong shape in Input Shape dictionary. Input shapes should be provided in NCHW format.</td>
<td>Check that your model input follows NCHW format. See What input data shapes does SageMaker Neo expect?</td>
</tr>
</tbody>
</table>

### MXNet

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientError: InputConfiguration: Only one parameter file is allowed for MXNet model. Please make sure the framework you select is correct.</td>
<td>SageMaker Neo will select the first parameter file given for compilation.</td>
</tr>
</tbody>
</table>
Infrastructure-Related Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientError: InputConfiguration: S3 object does not exist. Bucket: &lt;bucket&gt;, Key: &lt;bucket key&gt;</td>
<td>Check the Amazon S3 URI you provided.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Bucket &lt;bucket name&gt; is in region &lt;region name&gt; which is different from AWS Sagemaker service region &lt;service region&gt;</td>
<td>Create an Amazon S3 bucket that is in the same region as the service.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file</td>
<td>Check that your model in Amazon S3 is compressed into a tar.gz file.</td>
</tr>
</tbody>
</table>

Check your compilation log

2. Select the region you created the compilation job from the Region dropdown list in the top right.
3. In the navigation pane of the Amazon CloudWatch, choose Logs. Select Log groups.
4. Search for the log group called /aws/sagemaker/CompilationJobs. Select the log group.
5. Search for the logstream named after the compilation job name. Select the log stream.

Troubleshoot Neo Inference Errors

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to PyTorch 1.4.0 or later and MXNet v1.7.0 or later.

- Make sure the first inference (warm-up inference) on a valid input data is done in model_fn(), if you defined a model_fn in your inference script, otherwise the following error message may be seen on the terminal when predict API is called:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
```

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

**On the terminal:**

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from <users-sagemaker-endpoint> with message "{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" } ".
```

**In CloudWatch:**

```
W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'
```

2368
Key                        | Value
---------------------------|-------
SAGEMAKER_PROGRAM          | inference.py
SAGEMAKER_SUBMIT_DIRECTORY | /opt/ml/model/code
SAGEMAKER_CONTAINER_LOG_LEVEL | 20
SAGEMAKER_REGION         | <your region>

- Make sure that the MMS_DEFAULT_RESPONSE_TIMEOUT environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."

### Troubleshoot Ambarella Errors

SageMaker Neo requires models to be packaged in a compressed TAR file (*.tar.gz). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
- A JSON configuration file
- Calibration images

For example, the contents of your compressed TAR file should look similar to the following example:

```text
###amba_config.json
###calib_data
|    ### data1
|    ### data2
|    ###.
|    ###.
|    ###.
|    ### data500
###mobilenet_v1_1.0_0224_frozen.pb
```

The directory is configured as follows:

- `amba_config.json`: Configuration file
- `calib_data`: Folder containing calibration images
- `mobilenet_v1_1.0_0224_frozen.pb`: TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see Supported Frameworks (p. 2348).
Setting up the Configuration File

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with *config.json. The following chart shows the contents of the configuration file.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputs</td>
<td>Dictionary mapping input layers to attribute.</td>
<td>{inputs:{&quot;data&quot;: {...}, &quot;data1&quot;: {...}}}</td>
</tr>
<tr>
<td>&quot;data&quot;</td>
<td>Input layer name. Note: &quot;data&quot; is an example of the name you can use to label the input layer.</td>
<td>&quot;data&quot;</td>
</tr>
<tr>
<td>shape</td>
<td>Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses.</td>
<td>&quot;shape&quot;: &quot;1,3,224,224&quot;</td>
</tr>
<tr>
<td>filepath</td>
<td>Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG.</td>
<td>&quot;filepath&quot;: &quot;calib_data/&quot;</td>
</tr>
<tr>
<td>colorformat</td>
<td>Color format that model expects. This will be used while converting images to binary. Supported values: [RGB, BGR]. Default is RGB.</td>
<td>&quot;colorformat&quot;: &quot;RGB&quot;</td>
</tr>
<tr>
<td>mean</td>
<td>Mean value to be subtracted from the input. Can be a single value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.</td>
<td>&quot;mean&quot;: 128.0</td>
</tr>
<tr>
<td>scale</td>
<td>Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.</td>
<td>&quot;scale&quot;: 255.0</td>
</tr>
</tbody>
</table>

The following is a sample configuration file:

```
{
    "inputs": {
        "data": {
            "shape": "1, 3, 224, 224",
            "filepath": "calib_data/",
            "colorformat": "RGB",
            "mean": [128, 128, 128],
            "scale": [128.0, 128.0, 128.0]
        }
    }
}
```
Calibration Images

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

How many images should you use?

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

What are the recommended image formats?

Calibration images can be in a raw binary format or image formats such as JPG and PNG.

Your calibration folder can contain a mixture of images and binary files. If the calibration folder contains both images and binary files, the toolchain first converts the images to binary files. Once the conversion is complete, it uses the newly generated binary files along with the binary files that were originally in the folder.

Can I convert the images into binary format first?

Yes. You can convert the images to the binary format with open-source packages such as OpenCV or PIL. Crop and resize the images so they satisfy the input layer of your trained model.

Mean and Scale

You can specify mean and scaling pre-processing options to the Amberalla toolchain. These operations are embedded into the network and are applied during inference on each input. Do not provide processed data if you specify the mean or scale. More specifically, do not provide data you have subtracted the mean from or have applied scaling to.

Check your compilation log

For information on checking compilation log for Ambarella devices, see Check your compilation log (p. 2368).

Use Amazon SageMaker Elastic Inference (EI)

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as Amazon SageMaker hosted models, but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker notebook instance so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into
MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see Importing an ONNX model into MXNet.

Topics

• How EI Works (p. 2372)
• Choose an EI Accelerator Type (p. 2372)
• Use EI in a SageMaker Notebook Instance (p. 2373)
• Use EI on a Hosted Endpoint (p. 2373)
• Frameworks that Support EI (p. 2373)
• Use EI with SageMaker Built-in Algorithms (p. 2374)
• EI Sample Notebooks (p. 2374)
• Set Up to Use EI (p. 2374)
• Attach EI to a Notebook Instance (p. 2377)
• Use EI on Amazon SageMaker Hosted Endpoints (p. 2379)

How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>
<tr>
<th>Accelerator Type</th>
<th>F32 Throughput in TFLOPS</th>
<th>F16 Throughput in TFLOPS</th>
<th>Memory in GB</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.eia2.medium</td>
<td>1</td>
<td>8</td>
<td>2</td>
</tr>
<tr>
<td>ml.eia2.large</td>
<td>2</td>
<td>16</td>
<td>4</td>
</tr>
<tr>
<td>ml.eia2.xlarge</td>
<td>4</td>
<td>32</td>
<td>8</td>
</tr>
<tr>
<td>ml.eia1.medium</td>
<td>1</td>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>ml.eia1.large</td>
<td>2</td>
<td>16</td>
<td>2</td>
</tr>
<tr>
<td>ml.eia1.xlarge</td>
<td>4</td>
<td>32</td>
<td>4</td>
</tr>
</tbody>
</table>

Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

• Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- Amazon Elastic Inference Overview
- Choosing an Instance and Accelerator Type for Your Model
- Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance (p. 2377). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances

Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2379).

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the EI-enabled PyTorch binary files from the public amazonei-pytorch Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.
• SageMaker Python SDK - Deploy TensorFlow models
• SageMaker Python SDK - Deploy MXNet models
• SageMaker Python SDK - Deploy PyTorch models

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use the low-level AWS SDK for Python (Boto 3).

Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification - MXNet (p. 1396) and Object Detection - MXNet (p. 1420) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:
• Using Amazon Elastic Inference with MXNet on Amazon SageMaker
• Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
• Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
• Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker

Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:
• You want to use a customized role or permission policy.
• You want to use a VPC for your hosted model or notebook instance.

Note
If you already have an execution role that has the AmazonSageMakerFullAccess managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

Topics
• Set Up Required Permissions (p. 2374)
• Use a Custom VPC to Connect to EI (p. 2377)

Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the AmazonSageMakerFullAccess managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see Creating a Role for an AWS Service (Console) in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see Adding and Removing IAM Policies.
Add these permissions specifically for connecting EI in an IAM policy.

```json
{
  "Effect": "Allow",
  "Action": [
    "elastic-inference:Connect",
    "ec2:DescribeVpcEndpoints"
  ],
  "Resource": "*"
}
```

The following IAM policy is the complete list of required permissions to use EI in SageMaker.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elastic-inference:Connect",
        "ec2:DescribeVpcEndpoints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage",
        "ecr:BatchCheckLayerAvailability",
        "cloudwatch:PutMetricData",
        "cloudwatch:PutMetricAlarm",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:DeleteAlarms",
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "application-autoscaling:DescribeScalableTargets",
        "application-autoscaling:DescribeScalingActivities",
        "application-autoscaling:DescribeScalingPolicies",
        "application-autoscaling:DescribeScheduledActions",
        "application-autoscaling:PutScalingPolicy",
        "application-autoscaling:PutScheduledAction",
        "application-autoscaling:RegisterScalableTarget",
        "logs:CreateLogGroup",
        "logs:CreateLogStream"
      ],
      "Resource": "*"
    }
  ]
}
```

}
Use a Custom VPC to Connect to EI

To use Ei with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. Ei uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use Ei within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for Ei.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.

For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use Ei with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the Ei service.

- Set up a VPC interface endpoint (PrivateLink) for the Ei. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose com.amazonaws.<region>.elastic-inference.runtime. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where Ei is available. Ei fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.

Attach Ei to a Notebook Instance

To test and evaluate inference performance using Ei, you can attach Ei to a notebook instance when you create or update a notebook instance. You can then use Ei in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and Ei accelerators to evaluate the configuration that works best for your use case.

Set Up to Use Ei

To use Ei locally in a notebook instance, create a notebook instance with an Ei instance.

To create a notebook instance with an Ei instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Notebook instances**.
3. Choose **Create notebook instance**.
4. For **Notebook instance name**, provide a unique name for your notebook instance.
5. For **notebook instance type**, choose a CPU instance such as `ml.t2.medium`.
6. For **Elastic Inference (EI)**, choose an instance from the list, such as `ml.eia2.medium`.
7. For **IAM role**, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For **VPC - Optional**, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as **No VPC**. If you use a VPC follow the instructions at Use a Custom VPC to Connect to EI (p. 2377).
9. (Optional) For **Lifecycle configuration - optional**, either leave it as **No configuration** or choose a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 366).
10. (Optional) For **Encryption key - optional**, if you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For **Volume Size In GB - optional**, leave the default value of 5.
12. (Optional) For **Tags**, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose **Create Notebook Instance**.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.

**Topics**
- Use EI in Local Mode in SageMaker (p. 2378)

**Use EI in Local Mode in SageMaker**

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see [https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview](https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview).

**Topics**
- Use EI in Local Mode with SageMaker TensorFlow Estimators and Models (p. 2378)
- Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models (p. 2379)
- Use EI in Local Mode with SageMaker PyTorch Estimators and Models (p. 2379)

**Use EI in Local Mode with SageMaker TensorFlow Estimators and Models**

The following code shows how to use local mode with an estimator object. To call the `deploy` method, you must have previously either:
- Trained the model by calling the `fit` method of an estimator.
- Pass a model artifact when you initialize the model object.
Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

To use EI with MXNet in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the deploy method of an estimator or a model object. For more information about Amazon SageMaker Python SDK MXNet estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
tf_predictor = tf_model.deploy(initial_instance_count=1,
                                instance_type='local',
                                accelerator_type='local_sagemaker_notebook')
```

For a complete example of using EI in local mode with MXNet, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html.

Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the deploy method of an estimator or a model object, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type`. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see SageMaker PyTorch Estimators and Models.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
                                          instance_type='local',
                                          accelerator_type='local_sagemaker_notebook')
```

Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the Image Classification - MXNet (p. 1396) or Object Detection - MXNet (p. 1420) build-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.
Use El with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,  
    instance_type='ml.m4.xlarge',  
    accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,  
    instance_type='ml.m4.xlarge',  
    accelerator_type='ml.eia2.medium')
```

Use El with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,  
    instance_type='ml.m4.xlarge',  
    accelerator_type='ml.eia2.medium')
```
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')

Use a Model Object

To use a model object with EI, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the deploy method of either the Estimator or Model objects. You then specify an accelerator type using the accelerator_type input argument. For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')

Use a Model Object

To use a model object with EI, when you use the deploy method, include the accelerator_type input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')

Use EI with Your Own Container

To use EI with a model in a custom container that you build, use the low-level AWS SDK for Python (Boto 3). download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.
**Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container**

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at console.aws.amazon.com/s3/buckets/amazonei-tensorflow. For information about building a container that uses the EI-enabled version of TensorFlow, see https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket at console.aws.amazon.com/s3/buckets/amazonei-apachemxnet. For information about building a container that uses the EI-enabled version of MXNet, see https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container. You can download the Elastic Inference enabled binary for PyTorch from the public Amazon S3 bucket at console.aws.amazon.com/s3/buckets/amazonei-pytorch. For information about building a container that uses the Elastic Inference enabled version of PyTorch, see Building your image.

**Create an EI Endpoint with AWS SDK for Python (Boto 3)**

To create an endpoint by using AWS SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you specify one of the EI instance types as the AcceleratorType field for that ProductionVariant. You then pass that endpoint configuration when you create the endpoint.

**Create an Endpoint Configuration**

To use EI, you need to specify an accelerator type in the endpoint configuration.

```python
# Create Endpoint Configuration
from time import gmtime, strftime

endpoint_config_name = 'ImageClassificationEndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sagemaker.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[
        {'InstanceType': 'ml.m4.xlarge',
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName': 'AllTraffic',
        'AcceleratorType': 'ml.elia2.medium'}])
print("Endpoint Config Arn: " + create_endpoint_config_response['EndpointConfigArn'])
```

**Create an Endpoint**

After you create an endpoint configuration with an accelerator type, you can create an endpoint.

```python
endpoint_name = 'ImageClassificationEndpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
endpoint_response = sagemaker.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

After creating the endpoint, you can invoke it using the invoke_endpoint method in a Boto3 runtime object, as you would any other endpoint.
Best practices to minimize interruptions during GPU driver upgrades

SageMaker Model Deployment upgrades GPU drivers on the ML instances for Real-time, Batch, and Asynchronous Inference options over time to provide customers access to improvements from the driver providers. Below you can see the GPU version supported for each Inference option. Different driver versions can change how your model interacts with the GPUs. Below are some strategies to help you understand how your application works with different driver versions.

Current versions and supported instance families

Amazon SageMaker Inference supports the following drivers and instance families:

<table>
<thead>
<tr>
<th>Service</th>
<th>GPU</th>
<th>Driver version</th>
<th>Instance types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real-time</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.g4dn.</em>, ml.g5*</td>
</tr>
<tr>
<td>Batch</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.g4dn.</em>, ml.g5*</td>
</tr>
<tr>
<td>Asynchronous Inference</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.g4dn.</em>, ml.g5*</td>
</tr>
</tbody>
</table>

Troubleshoot your model container with GPU capabilities

If you encounter an issue when running your GPU workload, see the following guidance:

GPU card detection failure or NVIDIA initialization error

Run the `nvidia-smi` (NVIDIA System Management Interface) command from within the Docker container. If the NVIDIA System Management Interface detects a GPU detection error or NVIDIA initialization error, it will return the following error message:

```
Failed to initialize NVML: Driver/library version mismatch
```

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the If you bring your own (BYO) model containers (p. 2384) dropdown.
- Follow the best practice recommendation described in the If you use a CUDA compatibility layer (p. 2384) dropdown.

Refer to the NVIDIA System Management Interface page on the NVIDIA website for more information.
Best practices for working with mismatched driver versions

The following provides information on how to update your GPU driver:

The driver my container depends on is lower than the version on the ML GPU instance

No action is required. NVIDIA provides backwards compatibility.

The driver my container depends on is greater than the version on the ML GPU instances

If it is a minor version difference, no action is required. NVIDIA provides minor version forward compatibility.

If it is a major version difference, the CUDA Compatibility Package will need to be installed. Please refer to CUDA Compatibility Package in the NVIDIA documentation.

Important
The CUDA Compatibility Package is not backwards compatible so it needs to be disabled if the driver version on the instance is greater than the CUDA Compatibility Package version.

If you bring your own (BYO) model containers

Ensure no NVIDIA driver packages are bundled in the image which could cause conflict with on host NVIDIA driver version.

If you use a CUDA compatibility layer

To verify if the platform Nvidia driver version supports the CUDA Compatibility Package version installed in the model container, see the CUDA documentation. If the platform Nvidia driver version does not support the CUDA Compatibility Package version, you can disable or remove the CUDA Compatibility Package from the model container image. If the CUDA compatibility libs version is supported by the latest Nvidia driver version, we suggest that you enable the CUDA Compatibility Package based on the detected Nvidia driver version for future compatibility by adding the code snippet below into the container start up shell script (at the ENTRYPOINT script).

The script demonstrates how to dynamically switch the use of the CUDA Compatibility Package based on the detected Nvidia driver version on the deployed host for your model container. When SageMaker releases a newer Nvidia driver version, the installed CUDA Compatibility Package can be turned off automatically if the CUDA application is supported natively on the new driver.

```bash
#!/bin/bash

verlte() {
    [ "$1" = "$2" ] || return 1 || [ "$2" = "`echo -e "$1
$2" | sort -V | head -n1`"
}

if [ -f /usr/local/cuda/compat/libcuda.so.1 ]; then
    cat /usr/local/cuda/version.txt
    CUDA_COMPAT_MAX_DRIVER_VERSION=$(readlink /usr/local/cuda/compat/libcuda.so.1 |cut -d'.' -f 3-)
    echo "CUDA compat package requires Nvidia driver #${CUDA_COMPAT_MAX_DRIVER_VERSION}"
    NVIDIA_DRIVER_VERSION=$(sed -n 's/^NVRM.*Kernel Module *\([0-9.]*\).*$/\1/p' /proc/driver/nvidia/version 2>/dev/null)
    echo "Current installed Nvidia driver version is ${NVIDIA_DRIVER_VERSION}" if [ $(verlte $CUDA_COMPAT_MAX_DRIVER_VERSION $NVIDIA_DRIVER_VERSION) ]
```
echo "Setup CUDA compatibility libs path to LD_LIBRARY_PATH"
export LD_LIBRARY_PATH=/usr/local/cuda/compat:$LD_LIBRARY_PATH
else
  echo "$LD_LIBRARY_PATH"
fi
echo "Skip CUDA compat libs setup as newer Nvidia driver is installed"
fi

Model Hosting FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Inference Hosting.

General Hosting

The following FAQ items answer common general questions for SageMaker Inference.

Q: What deployment options does Amazon SageMaker provide?

A: After you build and train models, Amazon SageMaker provides four options to deploy them so you can start making predictions. Real-Time Inference is suitable for workloads with millisecond latency requirements, payload sizes up to 6 MB, and processing times of up to 60 seconds. Batch Transform is ideal for offline predictions on large batches of data that are available up front. Asynchronous Inference is designed for workloads that do not have sub-second latency requirements, payload sizes up to 1 GB, and processing times of up to 15 minutes. With Serverless Inference, you can quickly deploy machine learning models for inference without having to configure or manage the underlying infrastructure, and you pay only for the compute capacity used to process inference requests, which is ideal for intermittent workloads.

Q: How do I choose a model deployment option in SageMaker?

A: The following diagram can help you choose a SageMaker Hosting model deployment option.

The preceding diagram walks you through the following decision process. If you want to process requests in batches, you might want to choose Batch Transform. Otherwise, if you want to receive inference for
each request to your model, you might want to choose Asynchronous Inference, Serverless Inference, or Real-Time Inference. You can choose Asynchronous Inference if you have long processing times or large payloads and want to queue requests. You can choose Serverless Inference if your workload has unpredictable or intermittent traffic. You can choose Real-Time Inference if you have sustained traffic and need lower and consistent latency for your requests.

**Q:** I’ve heard SageMaker Inference is expensive. What’s the best way to optimize my cost when hosting models?

**A:** To optimize your costs with SageMaker Inference, you should choose the right hosting option for your use case. You can also use Inference features such as Amazon SageMaker Savings Plans, model optimization with SageMaker Neo, Multi-Model Endpoints and Multi-Container Endpoints, or autoscaling. For tips on how to optimize your Inference costs, see Inference cost optimization best practices (p. 2216).

**Q:** Why should I use Amazon SageMaker Inference Recommender?

**A:** You should use Amazon SageMaker Inference Recommender if you need recommendations for the right endpoint configuration to improve performance and reduce costs. Previously, data scientists who wanted to deploy their models had to run manual benchmarks to select the right endpoint configuration. First, they had to select the right machine learning instance type out of more than 70 available instance types based on the resource requirements of their models and sample payloads, and then optimize the model to account for differing hardware. Then, they had to conduct extensive load tests to validate that latency and throughput requirements were met and that the costs were low. Inference Recommender eliminates this complexity by helping you do the following:

- Get started in minutes with an instance recommendation.
- Conduct load tests across instance types to get recommendations on your endpoint configuration within hours.
- Automatically tune container and model server parameters as well as perform model optimizations for a given instance type.

**Q:** What is a model server?

**A:** SageMaker endpoints are HTTP REST endpoints that use a containerized web server, which includes a model server. These containers are responsible for loading up and serving requests for a machine learning model. They implement a web server that responds to /invocations and /ping on port 8080.

Common model servers include TensorFlow Serving, TorchServe and Multi Model Server. SageMaker framework containers have these model servers built in.

**Q:** What is Bring Your Own Container with Amazon SageMaker?

**A:** Everything in SageMaker Inference is containerized. SageMaker provides managed containers for popular frameworks such as TensorFlow, SKLearn, and HuggingFace. For a comprehensive updated list of those images, see Available Images.

Sometimes there are custom frameworks for which you might need to build a container. This approach is known as Bring Your Own Container or BYOC. With the BYOC approach, you provide the Docker image to set up your framework or library. Then, you push the image to Amazon Elastic Container Registry (Amazon ECR) so that you can use the image with SageMaker. For an example of a BYOC approach, see Overview of Containers for Amazon SageMaker.

Alternatively, instead of building an image from scratch, you can extend a container. You can take one of the base images that SageMaker provides and add your dependencies on top of it in your Dockerfile.
Q: Do I need to train my models on SageMaker to host them on SageMaker endpoints?

A: SageMaker offers the capacity to bring your own trained framework model that you've trained outside of SageMaker and deploy it on any of the SageMaker hosting options.

SageMaker requires you to package the model in a model.tar.gz file and have a specific directory structure. Each framework has its own model structure (see the following question for example structures). For more information, see the SageMaker Python SDK documentation for TensorFlow, PyTorch, and MXNet.

While you can choose from prebuilt framework images such as TensorFlow, PyTorch, and MXNet to host your trained model, you can also build your own container to host your trained models on SageMaker endpoints. For a walkthrough, see the example Jupyter notebook Building your own algorithm container.

Q: How should I structure my model if I want to deploy on SageMaker but not train on SageMaker?

A: SageMaker requires your model artifacts to be compressed in a .tar.gz file, or a tarball. SageMaker automatically extracts this .tar.gz file into the /opt/ml/model/ directory in your container. The tarball shouldn't contain any symlinks or unnecessary files. If you are making use of one of the framework containers, such as TensorFlow, PyTorch, or MXNet, the container expects your TAR structure to be as follows:

**TensorFlow**

```
model.tar.gz/
    |--[model_version_number]/
    |   |--variables
    |   |--saved_model.pb
    code/
    |   |--inference.py
    |   |--requirements.txt
```

**PyTorch**

```
model.tar.gz/
    |-- model.pth
    |   |-- code/
    |       |-- inference.py
    |       |-- requirements.txt  # only for versions 1.3.1 and higher
```

**MXNet**

```
model.tar.gz/
    |-- model-symbol.json
    |-- model-shapes.json
    |-- model-0000.params
    |   |-- code/
    |       |-- inference.py
    |       |-- requirements.txt  # only for versions 1.6.0 and higher
```
Q: When invoking a SageMaker endpoint, I can provide a ContentType and Accept MIME Type. Which one is used to identify the data type being sent and received?

A: ContentType is the MIME type of the input data in the request body (the MIME type of the data you are sending to your endpoint). The model server uses the ContentType to determine if it can handle the type provided or not.

Accept is the MIME type of the inference response (the MIME type of the data your endpoint returns). The model server uses the Accept type to determine if it can handle returning the type provided or not.

Common MIME types include text/csv, application/json, and application/jsonlines.

Q: What are the supported data formats for SageMaker Inference?

A: SageMaker passes any request onto the model container without modification. The container must contain the logic to deserialize the request. For information about the formats defined for built-in algorithms, see Common Data Formats for Inference. If you are building your own container or using a SageMaker Framework container, you can include the logic to accept a request format of your choice.

Similarly, SageMaker also returns the response without modification, and then the client must deserialize the response. In case of the built-in algorithms, they return responses in specific formats. If you are building your own container or using a SageMaker Framework container, you can include the logic to return a response in the format you choose.

Q: How do I invoke my endpoint with binary data such as videos or images?

Use the Invoke Endpoint API call to make inference against your endpoint.

When passing your input as a payload to the InvokeEndpoint API, you must provide the correct type of input data that your model expects. When passing a payload in the InvokeEndpoint API call, the request bytes are forwarded directly to the model container. For example, for an image, you may use application/jpeg for the ContentType, and make sure that your model can perform inference on this type of data. This applies for JSON, CSV, video, or any other type of input with which you may be dealing.

Another factor to consider is payload size limits. In terms of real-time and serverless endpoints, the payload limit is 6 MB. You can split your video into multiple frames and invoke the endpoint with each frame individually. Alternatively, if your use case permits, you can send the whole video in the payload using an asynchronous endpoint, which supports up to 1 GB payloads.

For an example that showcases how to run computer vision inference on large videos with Asynchronous Inference, see this blog post.

Real-Time Inference

The following FAQ items answer common questions for SageMaker Real-Time Inference.

Q: How do I create a SageMaker endpoint?

A: You can create a SageMaker endpoint through AWS-supported tooling such as the AWS SDKs, the SageMaker Python SDK, the AWS Management Console, AWS CloudFormation, and the AWS Cloud Development Kit (AWS CDK).

There are three key entities in endpoint creation: a SageMaker model, a SageMaker endpoint configuration, and a SageMaker endpoint. The SageMaker model points towards the model data and image you are using. The endpoint configuration defines your production variants, which might include the instance type and instance count. You can then use either the create_endpoint API call or the
Q: Do I need to use the SageMaker Python SDK to create/invoke endpoints?

A: No, you can use the various AWS SDKs (see Invoke/Create for available SDKs) or even call the corresponding web APIs directly.

Q: What is the difference between Multi-Model Endpoints (MME) and Multi Model Server (MMS)?

A: A Multi-Model Endpoint is a Real-Time Inference option that SageMaker provides. With Multi-Model Endpoints, you can host thousands of models behind one endpoint. Multi Model Server is an open-source framework for serving machine learning models. It provides the HTTP front-end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and perform inference on a specified loaded model.

Q: What are the different model deployment architectures supported by Real-Time Inference?

A: SageMaker Real-Time Inference supports various model deployment architecture such as Multi-Model Endpoints, Multi-Container Endpoints, and Serial Inference Pipelines.

Multi-Model Endpoints (MME) – MME allows customers to deploy 1000s of hyper-personalized models in a cost effective way. All the models are deployed on a shared-resource fleet. MME works best when the models are of similar size and latency and belong to the same ML framework. These endpoints are ideal for when you have don’t need to call the same model at all times. You can dynamically load respective models onto the SageMaker endpoint to serve your request.

Multi-Container Endpoints (MCE) – MCE allows customers to deploy 15 different containers with diverse ML frameworks and functionalities with no cold starts while only using one SageMaker endpoint. You can directly invoke these containers. MCE is best for when you want to keep all the models in memory.

Serial Inference Pipelines (SIP) – You can use SIP to chain together 2-15 containers on a single endpoint. SIP is mostly suitable for combining preprocessing and model inference in one endpoint and for low latency operations.

Serverless Inference

The following FAQ items answer common questions for Amazon SageMaker Serverless Inference.

Q: What is Amazon SageMaker Serverless Inference?

A: Serverless Inference (p. 2159) is a purpose-built serverless model serving option that makes it easy to deploy and scale ML models. Serverless Inference endpoints automatically start compute resources and scale them in and out depending on traffic, eliminating the need for you to choose instance type, run provisioned capacity, or manage scaling. You can optionally specify the memory requirements for your serverless endpoint. You pay only for the duration of running the inference code and the amount of data processed, not for idle periods.

Q: Why should I use Serverless Inference?

A: Serverless Inference simplifies the developer experience by eliminating the need to provision capacity up front and manage scaling policies. Serverless Inference can scale instantly from tens to thousands of inferences within seconds based on the usage patterns, making it ideal for ML applications with intermittent or unpredictable traffic. For example, a chatbot service used by a payroll processing
company experiences an increase in inquiries at the end of the month while traffic is intermittent for rest of the month. Provisioning instances for the entire month in such scenarios is not cost-effective, as you end up paying for idle periods.

Serverless Inference helps address these types of use cases by providing you automatic and fast scaling out of the box without the need for you to forecast traffic up front or manage scaling policies. Additionally, you pay only for the compute time to run your inference code and for data processing, making it ideal for workloads with intermittent traffic.

Q: How do I choose the right memory size for my serverless endpoint?

A: Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs.

Choose your endpoint’s memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Batch Transform

The following FAQ items answer common questions for SageMaker Batch Transform.

Q: How does Batch Transform split my data?

A: For specific file formats such as CSV, RecordIO and TFRecord, SageMaker can split your data into single-record or multi-record mini batches and send this as a payload to your model container. When the value of BatchStrategy is MultiRecord, SageMaker sends the maximum number of records in each request, up to the MaxPayloadInMB limit. When the value of BatchStrategy is SingleRecord, SageMaker sends individual records in each request.

Q: What is the maximum timeout for Batch Transform and payload limit for a single record?

A: The maximum timeout for Batch Transform is 3600 seconds. The maximum payload size for a record (per mini batch) is 100 MB.

Q: How do I speed up a Batch Transform job?

A: If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. The ideal value for MaxConcurrentTransforms is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Q: What are the data formats natively supported in Batch Transform?

A: Batch Transform supports CVS and JSON.

Asynchronous Inference

The following FAQ items answer common general questions for SageMaker Asynchronous Inference.
Q: What is Amazon SageMaker Asynchronous Inference?

A: Asynchronous Inference queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes or long processing times that need to be processed as they arrive. Optionally, you can configure auto-scaling settings to scale down the instance count to zero when not actively processing requests.

Q: How do I scale my endpoints to 0 when there's no traffic?

A: Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up. For more information, see Autoscale an asynchronous endpoint.

Amazon SageMaker Serverless Inference also automatically scales down to zero. You won’t see this because SageMaker manages scaling your serverless endpoints, but if you are not experiencing any traffic, the same infrastructure applies.
Using Docker containers with SageMaker

Amazon SageMaker makes extensive use of Docker containers for build and runtime tasks. SageMaker provides prebuilt Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases. For information on how to bring your own containers for use with Amazon SageMaker Studio, see Bring your own SageMaker image (p. 157).

Topics

- Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker (p. 2392)
- Docker Container Basics (p. 2393)
- Use Prebuilt SageMaker Docker images (p. 2393)
- Adapting Your Own Docker Container to Work with SageMaker (p. 3266)
- Create a container with your own algorithms and models (p. 3282)
- Example Notebooks: Use Your Own Algorithm or Model (p. 3302)
- Troubleshooting your Docker containers (p. 3304)

Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. However, your level of engagement with containers depends on your use case.

- **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK by specifying the algorithm or framework version when creating your Estimator. The built-in algorithms available are itemized and described in the Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175) topic. For more information on the available frameworks, see ML Frameworks and Toolkits (p. 14). For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get Started with Amazon SageMaker (p. 34) topic.

- **Use prebuilt SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks currently supported by SageMaker, see Prebuilt SageMaker Docker Images for Deep Learning (p. 2394). For information on the scikit-learn and SparkML prebuilt container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2394).
For more information about using frameworks with the Amazon SageMaker Python SDK, see their respective topics in Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 14).

- **Extend a prebuilt SageMaker container image.** If you would like to extend a prebuilt SageMaker algorithm or model Docker image, you can modify the SageMaker image to satisfy your needs. For an example, see Extending our PyTorch containers.
- **Adapt an existing container image:** If you would like to adapt a pre-existing container image to work with SageMaker, you need to modify the Docker container to enable either the SageMaker Training or Inference toolkit. For an example that shows how to build your own containers to train and host an algorithm, see Bring Your Own R Algorithm.

### Docker Container Basics

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see Docker overview.

The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

#### SageMaker Functions

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used. While you don't need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

#### Containers with SageMaker Studio

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you must create your Docker container following the steps in Bring your own SageMaker image (p. 157).

### Use Prebuilt SageMaker Docker images

Amazon SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the prebuilt SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

**Note**
For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see SageMaker RL Containers.

**Topics**
- Prebuilt SageMaker Docker Images for Deep Learning (p. 2394)
- Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2394)
- Docker Registry Paths and Example Code (p. 2396)
- Train a Deep Graph Network (p. 3255)
Prebuilt SageMaker Docker Images for Deep Learning

Amazon SageMaker provides prebuilt Docker images that include deep learning frameworks and other dependencies needed for training and inference. For a complete list of the prebuilt Docker images managed by SageMaker, see Docker Registry Paths and Example Code (p. 2396).

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>
<td>PyTorch</td>
<td>Using PyTorch with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>

Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Extending Our PyTorch Containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.

Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.
**Library** | **Prebuilt Docker Image Source Code** | **Instructions**
--- | --- | ---
scikit-learn | SageMaker Scikit-learn Containers | Using Scikit-learn with the Amazon SageMaker Python SDK
Spark ML | SageMaker Spark ML Serving Containers | SparkML Python SDK Documentation

---

### Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark M:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>

  For example, `746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:0.23-1-cpu-py3`

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>`

  For example, `341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4`

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>746614075791</td>
<td>us-west-1</td>
</tr>
<tr>
<td>246618743249</td>
<td>us-west-2</td>
</tr>
<tr>
<td>683313688378</td>
<td>us-east-1</td>
</tr>
<tr>
<td>257758044811</td>
<td>us-east-2</td>
</tr>
<tr>
<td>354813040037</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td>366743142698</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>121021644041</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>783357654285</td>
<td>ap-southeast-2</td>
</tr>
<tr>

</tr>
<tr>
<td>492215442770</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>341280168497</td>
<td>ca-central-1</td>
</tr>
</tbody>
</table>

---

2395
Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available sagemaker-sparkml-serving image in the ca-central-1 Region:

```
aws ecr describe-images
  --region ca-central-1
  --registry-id 341280168497
  --repository-name sagemaker-sparkml-serving
```

Docker Registry Paths and Example Code

The following topics list the Docker registry path and other parameters for each of the Amazon SageMaker provided algorithms and Deep Learning Containers (DLC).

Use the path as follows:

- To create a training job (create_training_job), specify the Docker registry path (TrainingImage) and the training input mode (TrainingInputMode) for the training image. You create a training job to train a model using a specific dataset.
- To create a model (create_model), specify the Docker registry path (Image) for the inference image (PrimaryContainer Image). SageMaker launches machine learning compute instances that are based on the endpoint configuration and deploys the model, which includes the artifacts (the result of model training).

**Note**

For the registry path, use the :1 version tag to ensure that you are using a stable version of the algorithm/DLC. You can reliably host a model trained using an image with the :1 tag on an inference image that has the :1 tag. Using the :latest tag in the registry path provides you with the most up-to-date version of the algorithm/DLC, but might cause problems with backward compatibility. Avoid using the :latest tag for production purposes.

**Important**

When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1263) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

To find the registry path, choose the AWS Region, then choose the algorithm or DLC.

**Topics**

- Docker Registry Paths and Example Code for US East (Ohio) (us-east-2) (p. 2397)
- Docker Registry Paths and Example Code for US East (N. Virginia) (us-east-1) (p. 2433)
- Docker Registry Paths and Example Code for US West (N. California) (us-west-1) (p. 2471)

Docker Registry Paths and Example Code for US East (N. Virginia) (us-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 2434)
- BlazingText (algorithm) (p. 2435)
- Chainer (DLC) (p. 2435)
- Clarify (algorithm) (p. 2436)
- Data Wrangler (algorithm) (p. 2436)
- Debugger (algorithm) (p. 2437)
- DeepAR Forecasting (algorithm) (p. 2437)
- Factorization Machines (algorithm) (p. 2437)
- Hugging Face (algorithm) (p. 2438)
- IP Insights (algorithm) (p. 2441)
- Image classification (algorithm) (p. 2441)
- Inferentia MXNet (DLC) (p. 2442)
- Inferentia PyTorch (DLC) (p. 2442)
- K-Means (algorithm) (p. 2443)
- KNN (algorithm) (p. 2443)
- LDA (algorithm) (p. 2443)
- Linear Learner (algorithm) (p. 2444)
- MXNet (DLC) (p. 2444)
- MXNet Coach (DLC) (p. 2447)
- Model Monitor (algorithm) (p. 2448)
- NTM (algorithm) (p. 2448)
- Neo Image Classification (algorithm) (p. 2448)
- Neo MXNet (DLC) (p. 2449)
- Neo PyTorch (DLC) (p. 2449)
- Neo Tensorflow (DLC) (p. 2450)
- Neo XGBoost (algorithm) (p. 2450)
- Object Detection (algorithm) (p. 2451)
- Object2Vec (algorithm) (p. 2451)
- PCA (algorithm) (p. 2451)
- PyTorch (DLC) (p. 2452)
- Random Cut Forest (algorithm) (p. 2455)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-east-1', image_scope='inference', version='0.4')

# Output path
'763104351884.dkr.ecr.us-east-1.amazonaws.com/autogluon-inference:0.4-cpu-py38'
```

</tr>
</tbody>
</table>

**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='us-east-1')
# Output path
'503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest'
```

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-east-1')
# Output path
'522234722520.dkr.ecr.us-east-1.amazonaws.com/forecasting-deepar:1'
```

**Factorization Machines (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-east-1')
```
Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='us-east-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')

# Output path
'763104351884.dkr.ecr.us-east-1.amazonaws.com/huggingface-tensorflow-training:2.4.1-transformers4.4.2-gpu-py37'

Docker Registry Paths and Example Code for US West (N. California) (us-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 2472)
- BlazingText (algorithm) (p. 2473)
- Chainer (DLC) (p. 2473)
- Clarify (algorithm) (p. 2474)
- Data Wrangler (algorithm) (p. 2474)
- Debugger (algorithm) (p. 2475)
- DeepAR Forecasting (algorithm) (p. 2475)
- Factorization Machines (algorithm) (p. 2475)
- Hugging Face (algorithm) (p. 2475)
- IP Insights (algorithm) (p. 2479)
- Image classification (algorithm) (p. 2479)
- Inferentia MXNet (DLC) (p. 2479)
- Inferentia PyTorch (DLC) (p. 2480)
- K-Means (algorithm) (p. 2480)
- KNN (algorithm) (p. 2481)
- LDA (algorithm) (p. 2481)
- Linear Learner (algorithm) (p. 2481)
- MXNet (DLC) (p. 2481)
- MXNet Coach (DLC) (p. 2484)
- Model Monitor (algorithm) (p. 2485)
- NTM (algorithm) (p. 2485)
- Neo Image Classification (algorithm) (p. 2485)
- Neo MXNet (DLC) (p. 2486)
- Neo PyTorch (DLC) (p. 2486)
- Neo Tensorflow (DLC) (p. 2487)
- Neo XGBoost (algorithm) (p. 2487)
- Object Detection (algorithm) (p. 2487)
- Object2Vec (algorithm) (p. 2488)
- PCA (algorithm) (p. 2488)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-west-1', image_scope='inference', version='0.4')
```

**Docker Registry Paths and Example Code for US West (Oregon) (us-west-2)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 2507)
- BlazingText (algorithm) (p. 2509)
- Chainer (DLC) (p. 2509)
- Clarify (algorithm) (p. 2510)
• Data Wrangler (algorithm) (p. 2510)
• Debugger (algorithm) (p. 2510)
• DeepAR Forecasting (algorithm) (p. 2510)
• Factorization Machines (algorithm) (p. 2511)
• Hugging Face (algorithm) (p. 2511)
• IP Insights (algorithm) (p. 2514)
• Image classification (algorithm) (p. 2515)
• Inferentia MXNet (DLC) (p. 2515)
• Inferentia PyTorch (DLC) (p. 2515)
• K-Means (algorithm) (p. 2516)
• KNN (algorithm) (p. 2516)
• LDA (algorithm) (p. 2516)
• Linear Learner (algorithm) (p. 2517)
• MXNet (DLC) (p. 2517)
• MXNet Coach (DLC) (p. 2520)
• Model Monitor (algorithm) (p. 2520)
• NTM (algorithm) (p. 2521)
• Neo Image Classification (algorithm) (p. 2521)
• Neo MXNet (DLC) (p. 2521)
• Neo PyTorch (DLC) (p. 2522)
• Neo Tensorflow (DLC) (p. 2522)
• Neo XGBoost (algorithm) (p. 2523)
• Object Detection (algorithm) (p. 2523)
• Object2Vec (algorithm) (p. 2523)
• PCA (algorithm) (p. 2524)
• PyTorch (DLC) (p. 2524)
• Random Cut Forest (algorithm) (p. 2527)
• Ray PyTorch (DLC) (p. 2528)
• Scikit-learn (algorithm) (p. 2528)
• Semantic Segmentation (algorithm) (p. 2529)
• Seq2Seq (algorithm) (p. 2529)
• Spark (algorithm) (p. 2529)
• SparkML Serving (algorithm) (p. 2530)
• Tensorflow (DLC) (p. 2530)
• Tensorflow Coach (DLC) (p. 2539)
• Tensorflow Inferentia (DLC) (p. 2540)
• Tensorflow Ray (DLC) (p. 2540)
• VW (algorithm) (p. 2541)
• XGBoost (algorithm) (p. 2541)

**AutoGluon (algorithm)**

**Docker Registry Paths and Example Code for Africa (Cape Town) (af-south-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 2543)
- BlazingText (algorithm) (p. 2545)
- Chainer (DLC) (p. 2545)
- Clarify (algorithm) (p. 2545)
• Data Wrangler (algorithm) (p. 2546)
• Debugger (algorithm) (p. 2546)
• DeepAR Forecasting (algorithm) (p. 2546)
• Factorization Machines (algorithm) (p. 2547)
• Hugging Face (algorithm) (p. 2547)
• IP Insights (algorithm) (p. 2550)
• Image classification (algorithm) (p. 2550)
• Inferentia MXNet (DLC) (p. 2551)
• Inferentia PyTorch (DLC) (p. 2551)
• K-Means (algorithm) (p. 2552)
• KNN (algorithm) (p. 2552)
• Linear Learner (algorithm) (p. 2552)
• MXNet (DLC) (p. 2552)
• MXNet Coach (DLC) (p. 2555)
• Model Monitor (algorithm) (p. 2556)
• NTM (algorithm) (p. 2556)
• Neo Image Classification (algorithm) (p. 2556)
• Neo MXNet (DLC) (p. 2557)
• Neo PyTorch (DLC) (p. 2557)
• Neo Tensorflow (DLC) (p. 2558)
• Neo XGBoost (algorithm) (p. 2558)
• Object Detection (algorithm) (p. 2559)
• Object2Vec (algorithm) (p. 2559)
• PCA (algorithm) (p. 2559)
• PyTorch (DLC) (p. 2559)
• Random Cut Forest (algorithm) (p. 2563)
• Scikit-learn (algorithm) (p. 2563)
• Semantic Segmentation (algorithm) (p. 2563)
• Seq2Seq (algorithm) (p. 2564)
• Spark (algorithm) (p. 2564)
• SparkML Serving (algorithm) (p. 2565)
• Tensorflow (DLC) (p. 2565)
• Tensorflow Coach (DLC) (p. 2573)
• Tensorflow Inferentia (DLC) (p. 2574)
• Tensorflow Ray (DLC) (p. 2574)
• XGBoost (algorithm) (p. 2575)

**AutoGluon (algorithm)**

Docker Registry Paths and Example Code for Asia Pacific (Hong Kong) (ap-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 2577)
- BlazingText (algorithm) (p. 2578)
- Chainer (DLC) (p. 2579)
- Clarify (algorithm) (p. 2579)
- Data Wrangler (algorithm) (p. 2579)
- Debugger (algorithm) (p. 2580)
- DeepAR Forecasting (algorithm) (p. 2580)
- Factorization Machines (algorithm) (p. 2580)
- Hugging Face (algorithm) (p. 2581)
- IP Insights (algorithm) (p. 2584)
- Image classification (algorithm) (p. 2584)
- Inferentia MXNet (DLC) (p. 2584)
- Inferentia PyTorch (DLC) (p. 2585)
- K-Means (algorithm) (p. 2585)
- KNN (algorithm) (p. 2586)
- Linear Learner (algorithm) (p. 2586)
- MXNet (DLC) (p. 2586)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-east-1',image_scope='inference',version='0.4')
```

Docker Registry Paths and Example Code for Asia Pacific (Mumbai) (ap-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 2611)
- BlazingText (algorithm) (p. 2612)
- Chainer (DLC) (p. 2613)
- Clarify (algorithm) (p. 2613)
- Data Wrangler (algorithm) (p. 2614)
- Debugger (algorithm) (p. 2614)
- DeepAR Forecasting (algorithm) (p. 2614)
- Factorization Machines (algorithm) (p. 2614)
- Hugging Face (algorithm) (p. 2615)
- IP Insights (algorithm) (p. 2618)
- Image classification (algorithm) (p. 2618)
- Inferentia MXNet (DLC) (p. 2619)
- Inferentia PyTorch (DLC) (p. 2619)
- K-Means (algorithm) (p. 2619)
- KNN (algorithm) (p. 2620)
- LDA (algorithm) (p. 2620)
- Linear Learner (algorithm) (p. 2620)
- MXNet (DLC) (p. 2621)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-south-1', image_scope='inference', version='0.4')
```

<table>

### Docker Registry Paths and Example Code for Asia Pacific (Osaka) (ap-northeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

2645
• AutoGluon (algorithm) (p. 2646)
• BlazingText (algorithm) (p. 2648)
• Clarify (algorithm) (p. 2648)
• Debugger (algorithm) (p. 2648)
• DeepAR Forecasting (algorithm) (p. 2649)
• Factorization Machines (algorithm) (p. 2649)
• Hugging Face (algorithm) (p. 2649)
• IP Insights (algorithm) (p. 2652)
• Image classification (algorithm) (p. 2653)
• Inferentia MXNet (DLC) (p. 2653)
• Inferentia PyTorch (DLC) (p. 2653)
• K-Means (algorithm) (p. 2654)
• KNN (algorithm) (p. 2654)
• Linear Learner (algorithm) (p. 2654)
• MXNet (DLC) (p. 2655)
• Model Monitor (algorithm) (p. 2656)
• NTM (algorithm) (p. 2657)
• Neo Image Classification (algorithm) (p. 2657)
• Neo MXNet (DLC) (p. 2657)
• Neo PyTorch (DLC) (p. 2657)
• Neo Tensorflow (DLC) (p. 2658)
• Neo XGBoost (algorithm) (p. 2659)
• Object Detection (algorithm) (p. 2659)
• Object2Vec (algorithm) (p. 2659)
• PCA (algorithm) (p. 2659)
• PyTorch (DLC) (p. 2660)
• Random Cut Forest (algorithm) (p. 2663)
• Scikit-learn (algorithm) (p. 2663)
• Semantic Segmentation (algorithm) (p. 2663)
• Seq2Seq (algorithm) (p. 2664)
• Tensorflow (DLC) (p. 2664)
• Tensorflow Inferentia (DLC) (p. 2670)
• XGBoost (algorithm) (p. 2671)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-northeast-3',image_scope='inference',version='0.4')
```

</table>

### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='ap-northeast-3', version='1.5-1')
```
Docker Registry Paths and Example Code for Asia Pacific (Seoul) (ap-northeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 2673)
- BlazingText (algorithm) (p. 2674)
- Chainer (DLC) (p. 2674)
- Clarify (algorithm) (p. 2675)
- Data Wrangler (algorithm) (p. 2675)
- Debugger (algorithm) (p. 2675)
- DeepAR Forecasting (algorithm) (p. 2676)
- Factorization Machines (algorithm) (p. 2676)
- Hugging Face (algorithm) (p. 2676)
- IP Insights (algorithm) (p. 2680)
- Image classification (algorithm) (p. 2680)
- Inferentia MXNet (DLC) (p. 2680)
- Inferentia PyTorch (DLC) (p. 2681)
- K-Means (algorithm) (p. 2681)
- KNN (algorithm) (p. 2681)
- LDA (algorithm) (p. 2682)
- Linear Learner (algorithm) (p. 2682)
- MXNet (DLC) (p. 2682)
- MXNet Coach (DLC) (p. 2685)
- Model Monitor (algorithm) (p. 2685)
- NTM (algorithm) (p. 2686)
- Neo Image Classification (algorithm) (p. 2686)
- Neo MXNet (DLC) (p. 2686)
- Neo PyTorch (DLC) (p. 2687)
- Neo Tensorflow (DLC) (p. 2687)
- Neo XGBoost (algorithm) (p. 2688)
- Object Detection (algorithm) (p. 2688)
- Object2Vec (algorithm) (p. 2688)
- PCA (algorithm) (p. 2689)
- PyTorch (DLC) (p. 2689)
- Random Cut Forest (algorithm) (p. 2693)
- Ray PyTorch (DLC) (p. 2693)
- Scikit-learn (algorithm) (p. 2693)
- Semantic Segmentation (algorithm) (p. 2694)
- Seq2Seq (algorithm) (p. 2694)
- Spark (algorithm) (p. 2694)
- SparkML Serving (algorithm) (p. 2695)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-northeast-2',image_scope='inference',version='0.4')
```

Docker Registry Paths and Example Code for Asia Pacific (Singapore) (ap-southeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 2708)
- BlazingText (algorithm) (p. 2710)
- Chainer (DLC) (p. 2710)
- Clarify (algorithm) (p. 2711)
• Data Wrangler (algorithm) (p. 2711)
• Debugger (algorithm) (p. 2711)
• DeepAR Forecasting (algorithm) (p. 2711)
• Factorization Machines (algorithm) (p. 2712)
• Hugging Face (algorithm) (p. 2712)
• IP Insights (algorithm) (p. 2715)
• Image classification (algorithm) (p. 2716)
• Inferentia MXNet (DLC) (p. 2716)
• Inferentia PyTorch (DLC) (p. 2716)
• K-Means (algorithm) (p. 2717)
• KNN (algorithm) (p. 2717)
• LDA (algorithm) (p. 2717)
• Linear Learner (algorithm) (p. 2718)
• MXNet (DLC) (p. 2718)
• MXNet Coach (DLC) (p. 2721)
• Model Monitor (algorithm) (p. 2721)
• NTM (algorithm) (p. 2722)
• Neo Image Classification (algorithm) (p. 2722)
• Neo MXNet (DLC) (p. 2722)
• Neo PyTorch (DLC) (p. 2723)
• Neo Tensorflow (DLC) (p. 2723)
• Neo XGBoost (algorithm) (p. 2724)
• Object Detection (algorithm) (p. 2724)
• Object2Vec (algorithm) (p. 2724)
• PCA (algorithm) (p. 2725)
• PyTorch (DLC) (p. 2725)
• Random Cut Forest (algorithm) (p. 2728)
• Ray PyTorch (DLC) (p. 2729)
• Scikit-learn (algorithm) (p. 2729)
• Semantic Segmentation (algorithm) (p. 2730)
• Seq2Seq (algorithm) (p. 2730)
• Spark (algorithm) (p. 2730)
• SparkML Serving (algorithm) (p. 2731)
• Tensorflow (DLC) (p. 2731)
• Tensorflow Coach (DLC) (p. 2740)
• Tensorflow Inferentia (DLC) (p. 2741)
• Tensorflow Ray (DLC) (p. 2741)
• VW (algorithm) (p. 2742)
• XGBoost (algorithm) (p. 2742)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
```python
image_uris.retrieve(framework='autogluon',region='ap-southeast-1',image_scope='inference',version='0.4')
```

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='ap-southeast-1')```
## Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='ap-southeast-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='ap-southeast-1', version='0.23-1', image_scope='inference')
```
<table>

### Docker Registry Paths and Example Code for Asia Pacific (Sydney) (ap-southeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 2744)
- BlazingText (algorithm) (p. 2746)
- Chainer (DLC) (p. 2746)
- Clarify (algorithm) (p. 2746)
- Data Wrangler (algorithm) (p. 2747)
- Debugger (algorithm) (p. 2747)
- DeepAR Forecasting (algorithm) (p. 2747)
- Factorization Machines (algorithm) (p. 2748)
- Hugging Face (algorithm) (p. 2748)
- IP Insights (algorithm) (p. 2751)
• Image classification (algorithm) (p. 2751)
• Inferentia MXNet (DLC) (p. 2752)
• Inferentia PyTorch (DLC) (p. 2752)
• K-Means (algorithm) (p. 2753)
• KNN (algorithm) (p. 2753)
• LDA (algorithm) (p. 2753)
• Linear Learner (algorithm) (p. 2753)
• MXNet (DLC) (p. 2754)
• MXNet Coach (DLC) (p. 2757)
• Model Monitor (algorithm) (p. 2757)
• NTM (algorithm) (p. 2757)
• Neo Image Classification (algorithm) (p. 2758)
• Neo MXNet (DLC) (p. 2758)
• Neo PyTorch (DLC) (p. 2758)
• Neo Tensorflow (DLC) (p. 2759)
• Neo XGBoost (algorithm) (p. 2760)
• Object Detection (algorithm) (p. 2760)
• Object2Vec (algorithm) (p. 2760)
• PCA (algorithm) (p. 2760)
• PyTorch (DLC) (p. 2761)
• Random Cut Forest (algorithm) (p. 2764)
• Ray PyTorch (DLC) (p. 2764)
• Scikit-learn (algorithm) (p. 2765)
• Semantic Segmentation (algorithm) (p. 2765)
• Seq2Seq (algorithm) (p. 2766)
• Spark (algorithm) (p. 2766)
• SparkML Serving (algorithm) (p. 2766)
• Tensorflow (DLC) (p. 2767)
• Tensorflow Coach (DLC) (p. 2775)
• Tensorflow Inferentia (DLC) (p. 2776)
• Tensorflow Ray (DLC) (p. 2777)
• VW (algorithm) (p. 2778)
• XGBoost (algorithm) (p. 2778)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

## Docker Registry Paths and Example Code for Asia Pacific (Jakarta) (ap-southeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics
- AutoGluon (algorithm) (p. 2780)
- BlazingText (algorithm) (p. 2781)
- Clarify (algorithm) (p. 2781)
- DeepAR Forecasting (algorithm) (p. 2781)
- Factorization Machines (algorithm) (p. 2782)
- Hugging Face (algorithm) (p. 2782)
- IP Insights (algorithm) (p. 2785)
- Image classification (algorithm) (p. 2786)
- K-Means (algorithm) (p. 2786)
- KNN (algorithm) (p. 2786)
- Linear Learner (algorithm) (p. 2786)
- MXNet (DLC) (p. 2787)
- NTM (algorithm) (p. 2788)
- Object Detection (algorithm) (p. 2788)
- Object2Vec (algorithm) (p. 2789)
- PCA (algorithm) (p. 2789)
- PyTorch (DLC) (p. 2789)
- Random Cut Forest (algorithm) (p. 2792)
- Scikit-learn (algorithm) (p. 2792)
- Semantic Segmentation (algorithm) (p. 2793)
- Seq2Seq (algorithm) (p. 2793)
- Spark (algorithm) (p. 2794)
- Tensorflow (DLC) (p. 2794)

### Registry path | Version | Package version | Job types (image scope) 
--- | --- | --- | ---
`sagemaker-xgboost:<tag>` | | | 
544295431143.dkr.ecr.ap-southeast-2.amazonaws.com/xgboost:<tag> | 0.72 | | inference, training 
783357654285.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-xgboost:<tag> | 0.90 | | inference, training 
783357654285.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-xgboost:<tag> | 0.90 | | inference, training
• XGBoost (algorithm) (p. 2800)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-southeast-3', image_scope='inference', version='0.4')
```

<table>

### Docker Registry Paths and Example Code for Asia Pacific (Tokyo) (ap-northeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics
- AutoGluon (algorithm) (p. 2802)
- BlazingText (algorithm) (p. 2804)
- Chainer (DLC) (p. 2804)
- Clarify (algorithm) (p. 2804)
- Data Wrangler (algorithm) (p. 2805)
- Debugger (algorithm) (p. 2805)
- Inferentia MXNet (DLC) (p. 2810)
- DeepAR Forecasting (algorithm) (p. 2805)
- Factorization Machines (algorithm) (p. 2806)
- Hugging Face (algorithm) (p. 2806)
- IP Insights (algorithm) (p. 2809)
- Image classification (algorithm) (p. 2809)

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='ap-northeast-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```
## Registry path | Version | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
sagemaker-rl-coach-container:coach-1.0.0-tf
520713654638.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1
training | CPU, GPU | py3
520713654638.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0
training | CPU, GPU | py3
520713654638.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11
training | CPU, GPU | py3
520713654638.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1
training | CPU, GPU | py3
520713654638.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10
training | CPU, GPU | py3

### Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='ap-northeast-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

## Registry path | Version | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
941853720454.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-neo-tensorflow
inference | inf | py3
941853720454.dkr.ecr.ap-northeast-1.amazonaws.com/sagemaker-neo-tensorflow
inference | inf | py3
### Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='ap-northeast-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

### Docker Registry Paths and Example Code for Canada (Central) (ca-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 2838)
- BlazingText (algorithm) (p. 2839)
- Chainer (DLC) (p. 2840)
- Clarify (algorithm) (p. 2840)
- Data Wrangler (algorithm) (p. 2840)
- Debugger (algorithm) (p. 2841)
- DeepAR Forecasting (algorithm) (p. 2841)
- Factorization Machines (algorithm) (p. 2841)
- Hugging Face (algorithm) (p. 2842)
- IP Insights (algorithm) (p. 2845)
- Image classification (algorithm) (p. 2845)
- Inferentia MXNet (DLC) (p. 2845)
- Inferentia PyTorch (DLC) (p. 2846)
- K-Means (algorithm) (p. 2846)
- KNN (algorithm) (p. 2847)
- LDA (algorithm) (p. 2847)
- Linear Learner (algorithm) (p. 2847)
- MXNet (DLC) (p. 2848)
- MXNet Coach (DLC) (p. 2850)
- Model Monitor (algorithm) (p. 2851)
- NTM (algorithm) (p. 2851)
- Neo Image Classification (algorithm) (p. 2851)
- Neo MXNet (DLC) (p. 2852)

### Docker Registry Paths and Example Code for China (Beijing) (cn-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

2872
• AutoGluon (algorithm) (p. 2873)
• BlazingText (algorithm) (p. 2874)
• Chainer (DLC) (p. 2874)
• Clarify (algorithm) (p. 2875)
• Data Wrangler (algorithm) (p. 2875)
• Debugger (algorithm) (p. 2876)
• DeepAR Forecasting (algorithm) (p. 2876)
• Factorization Machines (algorithm) (p. 2876)
• Hugging Face (algorithm) (p. 2876)
• IP Insights (algorithm) (p. 2880)
• Image classification (algorithm) (p. 2880)
• Inferentia MXNet (DLC) (p. 2880)
• Inferentia PyTorch (DLC) (p. 2881)
• K-Means (algorithm) (p. 2881)
• KNN (algorithm) (p. 2882)
• Linear Learner (algorithm) (p. 2882)
• MXNet (DLC) (p. 2882)
• MXNet Coach (DLC) (p. 2885)
• Model Monitor (algorithm) (p. 2885)
• NTM (algorithm) (p. 2886)
• Neo Image Classification (algorithm) (p. 2886)
• Neo MXNet (DLC) (p. 2886)
• Neo PyTorch (DLC) (p. 2887)
• Neo Tensorflow (DLC) (p. 2887)
• Neo XGBoost (algorithm) (p. 2888)
• Object Detection (algorithm) (p. 2888)
• Object2Vec (algorithm) (p. 2888)
• PCA (algorithm) (p. 2889)
• PyTorch (DLC) (p. 2889)
• Random Cut Forest (algorithm) (p. 2892)
• Scikit-learn (algorithm) (p. 2893)
• Semantic Segmentation (algorithm) (p. 2893)
• Seq2Seq (algorithm) (p. 2894)
• Spark (algorithm) (p. 2894)
• SparkML Serving (algorithm) (p. 2894)
• Tensorflow (DLC) (p. 2895)
• Tensorflow Coach (DLC) (p. 2903)
• Tensorflow Inferentia (DLC) (p. 2904)
• Tensorflow Ray (DLC) (p. 2904)
• XGBoost (algorithm) (p. 2905)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```

2873
```python
image_uris.retrieve(framework='autogluon', region='cn-north-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>727897471807.dkr.ecr.cn-north-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
def image_uris.retrieve(framework='coach-tensorflow', region='cn-north-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

### Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics
- AutoGluon (algorithm) (p. 2907)
- BlazingText (algorithm) (p. 2908)
- Chainer (DLC) (p. 2908)
- Clarify (algorithm) (p. 2909)
- Data Wrangler (algorithm) (p. 2909)
- Debugger (algorithm) (p. 2909)
- DeepAR Forecasting (algorithm) (p. 2910)
- Factorization Machines (algorithm) (p. 2910)
- Hugging Face (algorithm) (p. 2910)
- IP Insights (algorithm) (p. 2913)
- Image classification (algorithm) (p. 2914)
- Inferentia MXNet (DLC) (p. 2914)
- Inferentia PyTorch (DLC) (p. 2914)
