f. Choose an evaluation dataset. You can choose to use your own dataset or use a built-in dataset. If you want to use your own dataset to evaluate the model, it must be formatted in a way that FMEval can use. It must also be located in an S3 bucket that has the CORS permissions referenced in the previous *Set up your environment* section. For more information about how to format a custom dataset see *Use a custom input dataset*.

g. Input an S3 bucket location where you want to save the output evaluation results. This file is in jsonlines (.jsonl) format.

h. Configure your processor in the **Processor configuration** section using the following parameters:

   • **Use Instance count** to specify the number of compute instances you want to use to run your model. If you use more than 1 instance, your model is run in parallel instances.

   • **Use Instance type** to choose the kind of compute instance you want to use to run your model. For more information about instance types, see *Available Studio Classic Instance Types*.

   • **Use Volume KMS key** to specify your AWS Key Management Service (AWS KMS) encryption key. SageMaker uses your AWS KMS key to encrypt incoming traffic from the model and your Amazon S3 bucket. For more information about keys, see *AWS Key Management Service*.

   • **Use Output KMS key** to specify your AWS KMS encryption key for outgoing traffic.

   • **Use IAM Role** to specify the access and permissions for the default processor. Enter the IAM role that you set up in *Set up your environment*.

i. After you specify your model and criteria, choose **Next**. The main window skips to **Step 5 Review and Save**.

**Review and run your evaluation job**

1. Review all of the parameters, model, and data that you selected for your evaluation.

2. Choose **Create resource** to run your evaluation.
3. To check your job status, go to the top of the **Model Evaluations** section on the page.

**View analysis results from your automatic evaluation**

This section lists three outputs for an automatic evaluation that is run in the UI.

1. The `output.json` file contains aggregate scores for your dataset. An example JSON output follows.

```json
{
    "evaluations": [
        {
            "evaluation_name": "factual_knowledge",
            "dataset_name": "trex",
            "prompt_template": "<s>[INST] <<SYS>>Answer the question at the end in as few words as possible. Do not repeat the question. Do not answer in complete sentences.<</SYS> Question: $feature [/INST]",
            "dataset_scores": [
                {
                    "name": "factual_knowledge",
                    "value": 0.2966666666666667
                }
            ],
            "category_scores": [
                {
                    "name": "Author",
                    "scores": [
                        {
                            "name": "factual_knowledge",
                            "value": 0.4117647058823529
                        }
                    ]
                },
                ...,
                {
                    "name": "Capitals",
                    "scores": [
                        {
                            "name": "factual_knowledge",
                            "value": 0.2857142857142857
                        }
                    ]
                }
            ]
        }
    ]
}
```
In the previous output example, the model scored on average of 0.2966666666666667. Average scores for each category are listed following the aggregate score.

2. One `evaluation_name_dataset_name`.jsonl file containing instance-wise results for each jsonlines request. If you had 300 requests in your jsonlines input data, this jsonlines output file contains 300 responses. The output file contains the request made to your model followed by the score for that evaluation. An example instance-wide output follows.

3. An Evaluation Report that contains the results of your foundation model evaluation. The content of the evaluation report depends on the kind of task you used to evaluate your model. Each report contains the following sections:
   
   a. The overall scores for each successful evaluation under the evaluation task. As an example of one evaluation with one dataset, if you evaluated your model for a classification task for Accuracy and Semantic Robustness, then a table summarizing the evaluation results for Accuracy and Accuracy Semantic Robustness appears at the top of your report. Other evaluations with other datasets may be structured differently.
   
   b. The configuration for your evaluation job including the model name, type, which evaluation methods were used and what datasets your model was evaluated against.
   
   c. A Detailed Evaluation Results section that summarizes the evaluation algorithm, provides information about and links to any built-in datasets, how scores are calculated, and tables showing some sample data with their associated scores.
   
   d. A Failed Evaluations section that contains a list of evaluations that did not complete. If no evaluations failed, this section of the report is omitted.

Use the fmeval library to run an automatic evaluation

Using the fmeval library in your own code gives you the most flexibility to customize your workflow. You can use the fmeval library to evaluate any LLM, and also to have more flexibility with your custom input datasets. The following steps show you how to set up your environment and how to run both a starting and a customized workflow using the fmeval library.
Get started using the \texttt{fmeval} library

You can configure your foundation model evaluation and customize it for your use case in a Studio notebook. Your configuration depends both on the kind of task that your foundation model is built to predict, and how you want to evaluate it. FMEval supports open-ended generation, text summarization, question answering, and classification tasks. The steps in this section show you how to set up a starting workflow. This starting workflow includes setting up your environment and running an evaluation algorithm using either a SageMaker JumpStart or an Amazon Bedrock foundation model with built-in datasets. If you must use a custom input dataset and workflow for a more specific use case, see \texttt{Customize your workflow using the fmeval library}.

Set up your environment

If you don’t want to run a model evaluation in a Studio notebook, skip to step 11 in the following \texttt{Get started using Studio} section.

Prerequisites

- To run a model evaluation in a Studio UI, your AWS Identity and Access Management (IAM) role and any input datasets must have the correct permissions. If you do not have a SageMaker Domain or IAM role, follow the steps from the top of \texttt{Onboard from the console} through all of \texttt{Step 1. General Settings}.

To set permissions for your Amazon S3 bucket

After your domain and role are created, use the following steps to add the permissions needed to evaluate your model.

1. Open the Amazon SageMaker console at \url{https://console.aws.amazon.com/sagemaker/}.
2. In the navigation pane, enter \texttt{S3} into the search bar at the top of the page.
3. Choose \texttt{S3} under \texttt{Services}.
4. Choose \texttt{Buckets} from the navigation pane.
5. In the \texttt{General purpose buckets} section, under \texttt{Name}, choose the name of the S3 bucket that you want to use to store your model input and output in the console. If you do not have an S3 bucket, do the following:

- 1. Select \texttt{Create bucket} to open a new \texttt{Create bucket} page.
2. In the **General configuration** section, under **AWS Region**, select the AWS region where your foundation model is located.

3. Name your S3 bucket in the input box under **Bucket name**.

4. Accept all of the default choices.

5. Select **Create bucket**.

6. In the **General purpose buckets** section, under **Name**, select the name of the S3 bucket that you created.

6. Choose the **Permissions** tab.

7. Scroll to the **Cross-origin resource sharing (CORS)** section at the bottom of the window. Choose **Edit**.

8. To add permissions to your bucket for foundation evaluations, ensure that the following code appears in the input box. You can also copy and paste the following into the input box.

```json
[
  {
    "AllowedHeaders": [
      "*"
    ],
    "AllowedMethods": [
      "GET",
      "PUT",
      "POST",
      "DELETE"
    ],
    "AllowedOrigins": [
      "*"
    ],
    "ExposeHeaders": [
      "Access-Control-Allow-Origin"
    ]
  }
]
```

9. Choose **Save changes**.

**To add permissions to your IAM policy**

1. In the search bar at the top of the page, enter **IAM**.
2. Under Services, select Identity and Access Management (IAM).
3. Choose Policies from the navigation pane.
4. Input AmazonSageMakerFullAccess into the search bar. Select the radio button next to the policy that appears. The Actions button can now be selected.
5. Choose the down arrow next to Actions. Two options appear.
6. Choose Attach.
7. In the IAM listing that appears, search for the name of the role you created. Select the check box next to the name.
8. Choose Attach policy.

Get started using Studio

1. In the search bar at the top of the page, enter SageMaker.
2. Under Services, select Amazon SageMaker.
3. Choose Studio from the navigation pane.
4. Choose your domain from the Get Started section, after expanding the down arrow under Select Domain.
5. Choose your user profile from the Get Started section after expanding the down arrow under Select user profile.
6. Choose Open Studio to open the landing page for Studio.
7. Select the file browser from the navigation pane and navigate to the root directory.
8. Select Create notebook.
9. In the notebook environment dialog box that opens, select the Data Science 3.0 image.
10. Choose Select.
11. Install the fmeval package in your development environment, as shown in the following code example:

```bash
!pip install fmeval
```

Note

Install the fmeval library into an environment that uses Python 3.10. For more information about requirements needed to run fmeval, see fmeval dependencies.
Configure ModelRunner

FMEval uses a high-level wrapper called ModelRunner to compose input, invoke and extract output from your model. The fmeval package can evaluate any LLM, however the procedure to configure ModelRunner depends on what kind of model you want to evaluate. This section explains how to configure ModelRunner for a SageMaker JumpStart or Amazon Bedrock model. If you want to use a custom input dataset and custom ModelRunner, see Customize your workflow using the fmeval library.

Use a SageMaker JumpStart model

To use ModelRunner to evaluate a SageMaker JumpStart model, create or provide an endpoint, define the model and the built-in dataset, configure, and test ModelRunner.

Define a SageMaker JumpStart model and configure a ModelRunner

1. Provide an endpoint by doing either of the following:

   - Specify the EndpointName to an existing SageMaker JumpStart endpoint, the model_id, and model_version.
   - Specify the model_id and model_version for your model, and create a SageMaker JumpStart endpoint.

The following code example shows how create an endpoint for a Llama 2 foundation model that's available through SageMaker JumpStart.

```python
import sagemaker
from sagemaker.jumpstart.model import JumpStartModel

#JumpStart model and version
model_id, model_version = "meta-textgeneration-llama-2-7b-f", "*

my_model = JumpStartModel(model_id=model_id)
predictor = my_model.deploy()
endpoint_name = predictor.endpoint_name

# Accept the EULA, and test the endpoint to make sure it can predict.
predictor.predict({'inputs': [[{'role': 'user', 'content': 'Hello how are you?'}]]}, custom_attributes='accept_eula=true')
```
The previous code example refers to EULA, which stands for end-use-license-agreement (EULA). The EULA can be found in the model card description of the model that you are using. To use some SageMaker JumpStart models, you must specify `accept_eula=true`, as shown in the previous call to `predict`. For more information about EULA, see the Licenses and model sources section in Choose a foundation model.

You can find a list of available SageMaker JumpStart models at Built-in Algorithms with pre-trained Model Table.

2. Configure ModelRunner by using the JumpStartModelRunner, as shown in the following configuration example:

   ```python
   from fmeval.model_runners.sm_jumpstart_model_runner import JumpStartModelRunner
   js_model_runner = JumpStartModelRunner(
       endpoint_name=endpoint_name,
       model_id=model_id,
       model_version=model_version
   )
   ```

   In the previous configuration example, use the same values for `endpoint_name`, `model_id`, and `model_version` that you used to create the endpoint.

3. Test your ModelRunner. Send a sample request to your model as shown in the following code example:

   ```python
   js_model_runner.predict("What is the capital of London")
   ```

Use an Amazon Bedrock model

To evaluate an Amazon Bedrock model, you must define the model and built-in dataset, and configure ModelRunner.

Define an Amazon Bedrock model and configure a ModelRunner

1. To define and print model details, use the following code example for a Titan model that is available through Amazon Bedrock:

   ```python
   import boto3
   ```
import json
bedrock = boto3.client(service_name='bedrock')
bedrock_runtime = boto3.client(service_name='bedrock-runtime')

model_id = "amazon.titan-tg1-large"
accept = "application/json"
content_type = "application/json"

print(bedrock.get_foundation_model(modelIdentifier=modelId).get('modelDetails'))

In the previous code example, the accept parameter specifies the format of the data that you want to use to evaluate your LLM. The contentType specifies the format of the input data in the request. Only MIME_TYPE_JSON is supported for accept and contentType for Amazon Bedrock models. For more information about these parameters, see InvokeModelWithResponseStream.

2. To configure ModelRunner, use the BedrockModelRunner, as shown in the following configuration example:

from fmeval.model_runners.bedrock_model_runner import BedrockModelRunner

bedrock_model_runner = BedrockModelRunner(
    model_id=model_id,
    output='results[0].outputText',
    content_template='{"inputText": $prompt, "textGenerationConfig": {
        "maxTokenCount": 4096, "stopSequences": [], "temperature": 1.0, "topP": 1.0}},{"results": "this is the output"},
)

Parametrize the ModelRunner configuration as follows.

• Use the same values for model_id that you used to deploy the model.

• Use output to specify the format of the generated json response. As an example, if your LLM provided the response [{"results": "this is the output"}], then output='results[0].outputText' returns this is the output.

• Use content_template to specify how your LLM interacts with requests. The following configuration template is detailed solely to explain the previous configuration example, and it's not required.

• In the previous configuration example, the variable inputText specifies the prompt, which captures the request made by the user.
The variable `textGenerationConfig` specifies how the LLM generates responses as follows:

- The parameter `maxTokenCount` is used to limit the length of the response by limiting the number of tokens returned by the LLM.
- The parameter `stopSequences` is used to specify a list of character sequences that tell your LLM to stop generating a response. The model output is stopped the first time any of the listed strings are encountered in the output. As an example, you can use a carriage return sequence to limit the model response to a single line.
- The parameter `topP` controls the randomness by limiting the set of tokens to consider when generating the next token. This parameter accepts values between 0.0 and 1.0. Higher values of `topP` allow for a set containing a broader vocabulary and lower values restrict the set of tokens to more probable words.
- The parameter `temperature` controls the randomness of the generated text, and accepts positive values. Higher values of `temperature` instruct the model to generate more random and diverse responses. Lower values generate responses that are more predictable. Typical ranges for `temperature` lie between 0.2 and 2.0.

For more information about parameters for a specific Amazon Bedrock foundation model, see [Inference parameters for foundation models](#).

The format of the `content_template` parameter depends on the inputs and parameters supported by your LLM. For example, Anthropic’s Claude 2 model can support the following `content_template`:

```json
"content_template": 
{"prompt": $prompt, "max_tokens_to_sample": 500}
```

As another example, the Falcon 7b model can support the following `content_template`.

```json
"content_template": 
{"inputs": $prompt, "parameters": {"max_new_tokens": 10, "top_p": 0.9, "temperature": 0.8}}
```

Lastly, test your ModelRunner. Send a sample request to your model as shown in the following code example:

```python
bedrock_model_runner.predict("What is the capital of London?")
```
Evaluate your model

After you configure your data and `ModelRunner`, you can run an evaluation algorithm on the responses generated by your LLM. To see a list of all of the available evaluation algorithms, run the following code:

```python
from fmeval.eval_algo_mapping import EVAL_ALGORITHMS
print(EVAL_ALGORITHMS.keys())
```

Each algorithm has both an `evaluate` and an `evaluate_sample` method. The `evaluate` method computes a score for the entire dataset. The `evaluate_sample` method evaluates the score for a single instance.

The `evaluate_sample` method returns `EvalScore` objects. `EvalScore` objects contain aggregated scores of how well your model performed during evaluation. The `evaluate_sample` method has the following optional parameters:

- `model_output` – The model response for a single request.
- `model_input` – A prompt containing the request to your model.
- `target_output` – The expected response from the prompt contained in `model_input`.

The following code example shows how to use the `evaluate_sample`:

```python
# Evaluate your custom sample
model_output = model_runner.predict("London is the capital of?")[0]
eval_algo.evaluate_sample(target_output="UK<OR>England<OR>United Kingdom",
model_output=model_output)
```

The `evaluate` method has the following optional parameters:

- `model` – An instance of `ModelRunner` using the model that you want to evaluate.
- `dataset_config` – The dataset configuration. If `dataset_config` is not provided, the model is evaluated using all of the built-in datasets that are configured for this task.
- `prompt_template` – A template used to generate prompts. If `prompt_template` is not provided, your model is evaluated using a default prompt template.
- `save` – If set to `True`, record-wise prompt responses and scores are saved to the file `EvalAlgorithmInterface.EVAL_RESULTS_PATH`. Defaults to `False`.

Use an automatic evaluation
• **num_records** – The number of records that are sampled randomly from the input dataset for evaluation. Defaults to 300.

The evaluate algorithm returns a list of EvalOutput objects that can include the following:

• **eval_name** – The name of the evaluation algorithm.

  dataset_name – The name of dataset used by the evaluation algorithm.

  prompt_template – A template used to compose prompts that is consumed if the parameter model_output is not provided in the dataset. For more information, see prompt_template in the [Configure a SageMaker JumpStart ModelRunner section](#).

  dataset_scores – An aggregated score computed across the whole dataset.

  category_scores – A list of CategoryScore objects that contain the scores for each category in the dataset.

  output_path – The local path to the evaluation output. This output contains prompt-responses with record-wise evaluation scores.

  error – A string error message for a failed evaluation job.

The following dimensions are available for model evaluation:

• Accuracy
• Factual knowledge
• Prompt stereotyping
• Semantic robustness
• Toxicity

**Accuracy**

You can run an accuracy algorithm for a question answering, text summarization, or classification task. The algorithms are different for each task in order to accommodate the different data input types and problems as follows:

• For question answering tasks, run the QAAccuracy algorithm with a QAAccuracyConfig file.
• For text summarization tasks, run the `SummarizationAccuracy` algorithm with a `SummarizationAccuracyConfig`.

• For classification tasks, run the `ClassificationAccuracy` algorithm with a `ClassificationAccuracyConfig`.

The QA accuracy algorithm returns a list of EvalOutput objects that contains one accuracy score for each sample. To run the question answer accuracy algorithm, instantiate a QAAccuracyConfig and pass in either `<OR>` or None as the `target_output_delimiter`. The question answer accuracy algorithm compares the response that your model generates with a known response. If you pass in `<OR>` as the target delimiter, then the algorithm scores the response as correct if it generates any of the content separated by `<OR>` in the answer. If you pass None or an empty string as the `target_output_delimiter`, the code throws an error.

Call the `evaluate` method and pass in your desired parameters as shown in the following code example:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.qa_accuracy import QAAccuracy, QAAccuracyConfig

eval_algo = QAAccuracy(QAAccuracyConfig(target_output_delimiter="<OR>"))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config,
                                 prompt_template="$feature", save=True)
```

The `SummarizationAccuracy` algorithm returns a list of EvalOutput objects that contain scores for ROUGE-N, Meteor, and BERTScore. For more information about these scores, see the Text summarization section in Foundation model evaluation overview. To run the text summarization accuracy algorithm, instantiate a `SummarizationAccuracyConfig` and pass in the following:

• Specify the type of `ROUGE` metric you want to use in your evaluation to `rouge_type`. You can choose `rouge1`, `rouge2`, or `rougeL`. These metrics compare generated summaries to reference summaries. ROUGE-1 compares the generated summaries and reference summaries using overlapping unigrams (sequences of one item such as “the”, “is”). ROUGE-2 compares the generated and reference summaries using bigrams (groups of two sequences such as “the large”, “is home”). ROUGE-L compares the longest matching sequence of words. For more information about ROUGE, see [ROUGE: A Package for Automatic Evaluation of Summaries](https://www.aaai.org/ojs/index.php/ROUGE/article/view/1708).

•
• Set `use_stemmer_for_rouge` to True or False. A stemmer removes affixes from words before comparing them. For example, a stemmer removes the affixes from “swimming” and “swam” so that they are both “swim” after stemming.

• Set `model_type_for_bertscore` to the model that you want to use to calculate a BERTScore. You can choose `ROBERTA_MODEL` or the more advanced `MICROSOFT_DEBERTA_MODEL`.

Lastly, call the `evaluate` method and pass in your desired parameters as shown in the following code example:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.summarization_accuracy import SummarizationAccuracy, SummarizationAccuracyConfig

eval_algo = SummarizationAccuracy(SummarizationAccuracyConfig(rouge_type="rouge1",model_type_for_bertscore="MICROSOFT_DEBERTA_MODEL"))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config, prompt_template="$feature", save=True)
```

The `ClassificationAccuracy` algorithm returns a list of EvalOutput objects that contain the classification accuracy, precision, recall, and balanced accuracy scores for each sample. For more information about these scores, see the Classification section in Foundation model evaluation overview. To run the classification accuracy algorithm, instantiate a `ClassificationAccuracyConfig` and pass in an averaging strategy to `multiclass_average_strategy`. You can choose micro, macro, samples, weighted, or binary. The default value is micro. Then, pass in a list containing the names of the columns that contain the true labels for your classification categories to `valid_labels`. Lastly, call the `evaluate` method and pass in your desired parameters as shown in the following code example:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.classification_accuracy import ClassificationAccuracy, ClassificationAccuracyConfig

eval_algo = ClassificationAccuracy(ClassificationAccuracyConfig(multiclass_average_strategy="samples",valid_labels=['animal_type','plant_type','fungi_type']))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config, prompt_template="$feature", save=True)
```
Factual knowledge

You can run the factual knowledge algorithm for open-ended generation. To run the factual knowledge algorithm, instantiate a `FactualKnowledgeConfig` and optionally pass a delimiter string (by default, this is `<OR>`). The factual knowledge algorithm compares the response that your model generates with a known response. The algorithm scores the response as correct if it generates any of the content separated by the delimiter in the answer. If you pass `None` as the `target_output_delimiter`, then the model must generate the same response as the answer to be scored as correct. Lastly, call the `evaluate` method and pass in your desired parameters.

Factual knowledge returns a list of `EvalScore` objects. These contain aggregated scores on how well your model is able to encode factual knowledge as described in the Foundation model evaluation overview section. The scores range between 0 and 1 with the lowest score corresponding to a lower knowledge of real-world facts.

The following code example shows how to evaluate your LLM using the factual knowledge algorithm:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.factual_knowledge import FactualKnowledge,
        FactualKnowledgeConfig

eval_algo = FactualKnowledge(FactualKnowledgeConfig())
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config,
        prompt_template="$feature", save=True)
```

Prompt stereotyping

You can run the prompt stereotyping algorithm for open-ended generation. To run the prompt stereotyping algorithm, your `DataConfig` must identify the columns in your input dataset that contain a less stereotypical sentence in `sent_less_input_location` and a more stereotypical sentence in `sent_more_output_location`. For more information about `DataConfig`, see the previous section 2. Configure ModelRunner. Next, call the `evaluate` method and pass in your desired parameters.

Prompt stereotyping returns a list of `EvalOutput` objects that contain a score for each input record and overall scores for each type of bias. The scores are calculated by comparing the probability of the more and less stereotypical sentences. The overall score reports how often the model preferred the stereotypical sentence in that the model assigns a higher probability to the
more stereotypical compared to the less stereotypical sentence. A score of 0.5 indicates that your model is unbiased, or that it prefers more and less stereotypical sentences at equal rates. A score of greater than 0.5 indicates that your model is likely to generate a response that is more stereotypical. Scores less than 0.5 indicate that your model is likely to generate a response that is less stereotypical.

The following code example shows how to evaluate your LLM using the prompt stereotyping algorithm:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.prompt_stereotyping import PromptStereotyping

eval_algo = PromptStereotyping()
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config, prompt_template="$feature", save=True)
```

**Semantic robustness**

You can run a semantic robustness algorithm for any FMEval task, however your model should be deterministic. A deterministic model is one that always generate the same output for the same input. One may typically achieve determinism by setting a random seed in the decoding process. The algorithms are different for each task in order to accommodate the different data input types and problems as follows:

- For open-ended generation, question answering, or task classification run the GeneralSemanticRobustness algorithm with a GeneralSemanticRobustnessConfig file.
- For text summarization, run the SummarizationAccuracySemanticRobustness algorithm with a SummarizationAccuracySemanticRobustnessConfig file.

The GeneralSemanticRobustness algorithm returns a list of EvalScore objects that contain accuracy with values between 0 and 1 quantifying the difference between the perturbed and unperturbed model outputs. To run the general semantic robustness algorithm, instantiate a GeneralSemanticRobustnessConfig and pass in a perturbation_type. You can choose one of the following for perturbation_type:

- **Butterfinger** – A perturbation that mimics spelling mistakes using character swaps based on keyboard distance. Input a probability that a given character is perturbed. Butterfinger is the default value for perturbation_type.
• **RandomUpperCase** – A perturbation that changes a fraction of characters to uppercase. Input a decimal from 0 to 1.

• **WhitespaceAddRemove** – The probability that a white space character is added in front of a non-white space character into white.

You can also specify the following parameters:

• **num_perturbations** – The number of perturbations for each sample to introduce into the generated text. The default is 5.

• **butter_finger_perturbation_prob** – The probability that a character is be perturbed. Used only when perturbation_type is Butterfinger. The default is 0.1.

• **random_uppercase_corrupt_proportion** – The fraction of characters to be changed to uppercase. Used only when perturbation_type is RandomUpperCase. The default is 0.1.

• **whitespace_add_prob** – Given a white space, the probability of removing it from a sample. Used only when perturbation_type is WhitespaceAddRemove. The default is 0.05.

• **whitespace_remove_prob** – Given a non-white space, the probability of adding a white space in front of it. Used only when perturbation_type is WhitespaceAddRemove. The default is 0.1.

Lastly, call the evaluate method and pass in your desired parameters as shown in the following code example:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.general_semantic_robustness import GeneralSemanticRobustness, GeneralSemanticRobustnessConfig

eval_algo = GeneralSemanticRobustness(GeneralSemanticRobustnessConfig(perturbation_type="RandomUpperCase", num_perturbations=2, random_uppercase_corrupt_proportion=0.3))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config, prompt_template="$feature", save=True)
```

The **SummarizationAccuracySemanticRobustness** algorithm returns a list of **EvalScore** objects that contain the difference (or delta) between the **ROUGE-N**, **Meteor**, and **BERTScore** values between the generated and reference summaries. For more information about these scores, see the **Text summarization** section in [Foundation model evaluation](#).
Overview. To run the text summarization semantic robustness algorithm, instantiate a `SummarizationAccuracySemanticRobustnessConfig` and pass in a `perturbation_type`.

You can choose one of the following for `perturbation_type`:

- **Butterfinger** – A perturbation that mimics spelling mistakes using character swaps based on keyboard distance. Input a probability that a given character is perturbed. Butterfinger is the default value for `perturbation_type`.
- **RandomUpperCase** – A perturbation that changes a fraction of characters to uppercase. Input a decimal from 0 to 1.
- **WhitespaceAddRemove** – Input a probability that a white space character is added in front of a non-white space character into white.

You can also specify the following parameters:

- **num_perturbations** – The number of perturbations for each sample to introduce into the generated text. Default is 5.
- **butter_finger_perturbation_prob** – The probability that a character is perturbed. Used only when `perturbation_type` is Butterfinger. Default is 0.1.
- **random_uppercase_corrupt_proportion** – The fraction of characters to be changed to uppercase. Used only when `perturbation_type` is RandomUpperCase. Default is 0.1.
- **whitespace_add_prob** – Given a white space, the probability of removing it from a sample. Used only when `perturbation_type` is WhitespaceAddRemove. Default is 0.05.
- **whitespace_remove_prob** – Given a non-white space, the probability of adding a white space in front of it. Used only when `perturbation_type` is WhitespaceAddRemove, Default is 0.1.
- **rouge_type** – Metrics that compare generated summaries to reference summaries. Specify the type of ROUGE metric you want to use in your evaluation to `rouge_type`. You can choose `rouge1`, `rouge2`, or `rougeL`. ROUGE-1 compares the generated summaries and reference summaries using overlapping unigrams (sequences of one item such as “the”, “is”). ROUGE-2 compares the generated and reference summaries using bigrams (groups of two sequences such as “the large”, “is home”). ROUGE-L compares the longest matching sequence of words. For more information about ROUGE, see [ROUGE: A Package for Automatic Evaluation of Summaries](https://linqs.soe.ucsc.edu/ROUGE).
- Set `user_stemmer_for_rouge` to True or False. A stemmer removes affixes from words before comparing them. For example, a stemmer removes the affixes from “swimming” and “swam” so that they are both “swim” after stemming.
• Set `model_type_for_bertscore` to the model that you want to use to calculate a BERTScore. You can choose `ROBERTA_MODEL` or the more advanced `MICROSOFT_DEBERTA_MODEL`.

Call the `evaluate` method and pass in your desired parameters as shown in the following code example:

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.summarization_accuracy_semantic_robustness import SummarizationAccuracySemanticRobustness,
                           SummarizationAccuracySemanticRobustnessConfig

eval_algo = SummarizationAccuracySemanticRobustness(SummarizationAccuracySemanticRobustnessConfig(perturbation_type="Butterfinger",num_perturbations=3,butter_finger_perturbation_prob=0.2))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config, prompt_template="$feature", save=True)
```

**Toxicity**

You can run the a toxicity algorithm for open-ended generation, text summarization, or question answering. There are three distinct classes depending on the task.

• For open-ended generation, run the Toxicity algorithm with a ToxicityConfig file.
• For summarization, use the class Summarization_Toxicity.
• For question answering, use the class QAToxicity.

The toxicity algorithm returns one or more a list of EvalScore objects (depending on the toxicity detector) that contain scores between 0 and 1. To run the toxicity algorithm, instantiate a ToxicityConfig and pass in a toxicity model to use to evaluate your model against in `model_type`. You can choose the following for `model_type`:

• `detoxify` for UnitaryAI Detoxify-unbiased, a multilabel text classifier trained on Toxic Comment Classification Challenge and Jigsaw Unintended Bias in Toxicity Classification. The model provides 7 scores for the following classes: toxicity, severe toxicity, obscenity, threat, insult, sexual explicitness and identity attack.

The following is example output from the detoxity model:

```python
EvalScore(name='toxicity', value=0.01936926692724228),
```
EvalScore(name='severe_toxicity', value=3.375677577573806e-06),
EvalScore(name='obscene', value=0.00022437423467636108),
EvalScore(name='identity_attack', value=0.0006707844440825284),
EvalScore(name='insult', value=0.005559926386922598),
EvalScore(name='threat', value=0.0016682750720065087),
EvalScore(name='sexual_explicit', value=4.828436431125738e-05)

• `toxigen` for Toxigen-roberta, a binary RoBERTa-based text classifier fine-tuned on the ToxiGen dataset, which contains sentences with subtle and implicit toxicity pertaining to 13 minority groups.

Lastly, call the evaluate method and pass in your desired parameters as shown in the following code example.

```python
from fmeval.eval import get_eval_algorithm
from fmeval.eval_algorithms.toxicity import Toxicity, ToxicityConfig

eval_algo = Toxicity(ToxicityConfig(model_type="detoxify"))
eval_output = eval_algo.evaluate(model=model_runner, dataset_config=config,
                                 prompt_template="$feature", save=True)
```

**Customize your workflow using the fmeval library**

Foundation Model Evaluations (FMEval) is in preview release for Amazon SageMaker Clarify and is subject to change.

⚠️ **Important**

In order to use SageMaker Clarify Foundation Model Evaluations, you must upgrade to the new Studio experience. As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The foundation evaluation feature can only be used in the updated experience. For information about how to update
You can customize your model evaluation to allow for a model that is not a SageMaker JumpStart or Amazon Bedrock model or use a custom workflow for evaluation. If you use your own model, you have to create a custom ModelRunner. If you use your own dataset for evaluation, you must configure a DataConfig object. The following section shows how to format your input dataset, customize a DataConfig object to use your custom dataset, and create a custom ModelRunner.

Use a custom input dataset

If you want to use your own dataset to evaluate your model, you must use a DataConfig object to specify the dataset_name and the dataset_uri of the dataset that you want to evaluate. If you use a built-in dataset, the DataConfig object is already configured as the default for evaluation algorithms.

You can use one custom dataset every time you use the evaluate function. You can invoke evaluate any number of times to use any number of datasets that you want.

Configure a custom dataset with your model request specified in the question column, and the target answer specified in the column answer, as follows:

```python
from fmeval.data_loaders.data_config import DataConfig
from fmeval.constants import MIME_TYPE_JSONLINES

cfg = DataConfig(
    dataset_name="tiny_dataset",
    dataset_uri="tiny_dataset.jsonl",
    dataset_mime_type=MIME_TYPE_JSONLINES,
    model_input_location="question",
    target_output_location="answer",
)
```

The DataConfig class contains the following parameters:

- **dataset_name** – The name of the dataset that you want to use to evaluate your LLM.
- **dataset_uri** – The local path or uniform resource identifier (URI) to the S3 location of your dataset.
- dataset_mime_type – The format of the input data that you want to use to evaluate your LLM. The FMEval library can support both MIME_TYPE_JSON and MIME_TYPE_JSONLINES.

- model_input_location – (Optional) The name of the column in your dataset that contains the model inputs or prompts that you want to evaluate.

Use a model_input_location that specifies the name of your column. The column must contain the following values corresponding to the following associated tasks:

- For open-ended generation, toxicity, and accuracy evaluations, specify the column that contains the prompt that your model should respond to.

- For a question answering task, specify the column that contains the question that your model should generate a response to.

- For a text summarization task, specify the name of the column that contains the text that you want your model to summarize.

- For a classification task, specify the name of the column that contains the text that you want your model to classify.

- For a factual knowledge evaluations, specify the name of the column that contains the question that you want the model to predict the answer to.

- For semantic robustness evaluations, specify the name of the column that contains the input that you want your model to perturb.

- For prompt stereotyping evaluations, use the sent_more_input_location and sent_less_input_location instead of model_input_location, as shown in the following parameters.

- model_output_location – (Optional) The name of the column in your dataset that contains the predicted output that you want to compare against the reference output that is contained in target_output_location. If you provide model_output_location, then FMEval won't send a request to your model for inference. Instead, it uses the output contained in the specified column to evaluate your model.

- target_output_location – The name of the column in the reference dataset that contains the true value to compare against the predicted value that is contained in model_output_location. Required only for factual knowledge, accuracy, and semantic robustness. For factual knowledge, each row in this column should contain all possible answers separated by a delimiter. For example, if the answers for a question are [“UK”, “England”], then the column should contain “UK<OR>England”. The model prediction is correct if it contains any of the answers separated by the delimiter.
- **category_location** – The name of the column that contains the name of a category. If you provide a value for `category_location`, then scores are aggregated and reported for each category.

- **sent_more_input_location** – The name of the column that contains a prompt with more bias. Required only for prompt stereotyping. Avoid unconscious bias. For bias examples, see the [CrowS-Pairs dataset](#).

- **sent_less_input_location** – The name of the column that contains a prompt with less bias. Required only for prompt stereotyping. Avoid unconscious bias. For bias examples, see the [CrowS-Pairs dataset](#).

- **sent_more_output_location** – (Optional) The name of the column that contains a predicted probability that your model’s generated response will contain more bias. This parameter is only used in prompt stereotyping tasks.

- **sent_less_output_location** – (Optional) The name of the column that contains a predicted probability that your model’s generated response will contain less bias. This parameter is only used in prompt stereotyping tasks.

If you want to add a new attribute that corresponds to a dataset column to the `DataConfig` class, you must add the suffix `_location` to the end of the attribute name.

### Use a custom ModelRunner

To evaluate a custom model, use a base data class to configure your model and create a custom `ModelRunner`. Then, you can use this `ModelRunner` to evaluate any language model. Use the following steps to define a model configuration, create a custom `ModelRunner`, and test it.

The `ModelRunner` interface has one abstract method as follows:

```python
def predict(self, prompt: str) -> Tuple[Optional[str], Optional[float]]
```

This method takes in a prompt as a string input, and returns a Tuple containing a model text response and an input log probability. Every `ModelRunner` must implement a `predict` method.

### Create a custom ModelRunner

1. Define a model configuration.
The following code example shows how to apply a dataclass decorator to a custom HFModelConfig class so that you can define a model configuration for a Hugging Face model:

```python
from dataclasses import dataclass

class HFModelConfig:
    model_name: str
    max_new_tokens: int
    seed: int = 0
    remove_prompt_from_generated_text: bool = True
```

In the previous code example, the following applies:

- The parameter `max_new_tokens` is used to limit the length of the response by limiting the number of tokens returned by an LLM. The type of model is set by passing a value for `model_name` when the class is instantiated. In this example, the model name is set to `gpt2`, as shown in the end of this section. The parameter `max_new_tokens` is one option to configure text generation strategies using a `gpt2` model configuration for a pre-trained OpenAI GPT model. See AutoConfig for other model types.

- If the parameter `remove_prompt_from_generated_text` is set to `True`, then the generated response won't contain the originating prompt sent in the request.

For other text generation parameters, see the Hugging Face documentation for GenerationConfig.

2. Create a custom ModelRunner and implement a predict method. The following code example shows how to create a custom ModelRunner for a Hugging Face model using the HFModelConfig class created in the previous code example.

```python
from typing import Tuple, Optional
import torch
from transformers import AutoModelForCausalLM, AutoTokenizer
from fmeval.model_runners.model_runner import ModelRunner

class HuggingFaceCausalLLMModelRunner(ModelRunner):
    def __init__(self, model_config: HFModelConfig):
        self.config = model_config
```
```python
self.model = AutoModelForCausalLM.from_pretrained(self.config.model_name)
self.tokenizer = AutoTokenizer.from_pretrained(self.config.model_name)

def predict(self, prompt: str) -> Tuple[Optional[str], Optional[float]]:
    input_ids = self.tokenizer(prompt, return_tensors="pt").to(self.model.device)
    generations = self.model.generate(**input_ids,
        max_new_tokens=self.config.max_new_tokens,
        pad_token_id=self.tokenizer.eos_token_id,
    )
    generation_contains_input = (input_ids["input_ids"][0] == generations[0][:input_ids["input_ids"].shape[1]]).all()
    if self.config.remove_prompt_from_generated_text and not generation_contains_input:
        warnings.warn("Your model does not return the prompt as part of its generations."
            "
            "remove_prompt_from_generated_text` does nothing."
        )
    if self.config.remove_prompt_from_generated_text and generation_contains_input:
        output = self.tokenizer.batch_decode(generations[:,:input_ids["input_ids"].shape[1] :])[0]
    else:
        output = self.tokenizer.batch_decode(generations, skip_special_tokens=True)[0]

    with torch.inference_mode():
        input_ids = self.tokenizer(self.tokenizer.bos_token + prompt, return_tensors="pt")["input_ids"]
        model_output = self.model(input_ids, labels=input_ids)
        probability = -model_output[0].item()

    return output, probability
```

The previous code uses a custom HuggingFaceCausalLMMdlewModelRunner class that inherits properties from the FMEval ModelRunner class. The custom class contains a constructor and a definition for a predict function, which returns a Tuple.

For more ModelRunner examples, see the model_runner section of the fmeval library.
The HuggingFaceCausalLLMModelRunner constructor contains the following definitions:

- The configuration is set to HFModelConfig, defined in the beginning of this section.
- The model is set to a pre-trained model from the Hugging Face Auto Class that is specified using the model_name parameter upon instantiation.
- The tokenizer is set to a class from the Hugging Face tokenizer library that matches the pre-trained model specified by model_name.

The predict method in the HuggingFaceCausalLLMModelRunner class uses the following definitions:

- input_ids – A variable that contains input for your model. The model generates the input as follows.
  - A tokenizer Converts the request contained in prompt into token identifiers (IDs). These token IDs, which are numerical values that represent a specific token (word, sub-word or character), can be used directly by your model as input. The token IDs are returned as a PyTorch tensor objects, as specified by return_tensors="pt". For other types of return tensor types, see the Hugging Face documentation for apply_chat_template.
  - Token IDs are sent to a device where the model is located so that they can be used by the model.
- generations – A variable that contains the response generated by your LLM. The model's generate function uses the following inputs to generate the response:
  - The input_ids from the previous step.
  - The parameter max_new_tokens specified in HFModelConfig.
  - A pad_token_id adds an end of sentence (eos) token to the response. For other tokens that you can use, see the Hugging Face documentation for PreTrainedTokenizer.
- generation_contains_input – A boolean variable that returns True when the generated response includes the input prompt in its response, and False otherwise. The return value is calculated using an element-wise comparison between the following.
  - All of the token IDs in the input prompt that are contained in input_ids["input_ids"][0].
  - The beginning of the generated content that is contained in generations[0][:input_ids["input_ids"].shape[1]].
The predict method returns a warning if you directed the LLM to remove_prompt_from_generated_text in your configuration but the generated response doesn't contain the input prompt.

The output from the predict method contains a string returned by the batch_decode method, which converts token IDs returned in the response into human readable text. If you specified remove_prompt_from_generated_text as True, then the input prompt is removed from the generated text. If you specified remove_prompt_from_generated_text as False, the generated text will be returned without any special tokens that you included in the dictionary special_token_dict, as specified by skip_special_tokens=True.

3. Test your ModelRunner. Send a sample request to your model.

The following example shows how to test a model using the gpt2 pre-trained model from the Hugging Face AutoConfig class:

```python
hf_config = HFModelConfig(model_name="gpt2", max_new_tokens=32)
model = HuggingFaceCausalLLMModelRunner(model_config=hf_config)

model_output = model.predict("London is the capital of?")[0]
print(model_output)
eval_algo.evaluate_sample()
```

In the previous code example, model_name specifies the name of the pre-trained model. The HFModelConfig class is instantiated as hf_config with a value for the parameter max_new_tokens, and used to initialize ModelRunner.

If you want to use another pre-trained model from Hugging Face, choose a pretrained_model_name_or_path in from_pretrained under AutoClass.

Lastly, test your ModelRunner. Send a sample request to your model as shown in the following code example:

```python
model_output = model.predict("London is the capital of?")[0]
print(model_output)
eval_algo.evaluate_sample()
```
Notebook tutorials

Foundation Model Evaluations (FMEval) is in preview release for Amazon SageMaker Clarify and is subject to change.

⚠ Important

In order to use SageMaker Clarify Foundation Model Evaluations, you must upgrade to the new Studio experience. As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The foundation evaluation feature can only be used in the updated experience. For information about how to update Studio, see [Migrating from Amazon SageMaker Studio Classic](#). For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

This section provides the following notebook tutorials, which include example code and explanations:

- How to evaluate a SageMaker JumpStart model for prompt stereotyping.
- How to evaluate an Amazon Bedrock model for text summarization accuracy.

How to evaluate a SageMaker JumpStart model for prompt stereotyping

You can use a high-level `ModelRunner` wrapper to evaluate an Amazon SageMaker JumpStart model for prompt stereotyping. The prompt stereotyping algorithm measures the probability of your model encoding biases in its response. These biases include those for race, gender, sexual orientation, religion, age, nationality, disability, physical appearance, and socioeconomic status.

This tutorial shows how to load the **Falcon 7-B** model from the [Technology Innovation Institute](#), available in SageMaker JumpStart, and ask this model to generate responses to prompts. Then, this tutorial shows how to evaluate the responses for prompt stereotyping against the built-in **CrowSPairs** open source challenge dataset.

The sections of this tutorial show how to do the following:

- Set up your environment.
Run your model evaluation.

View your analysis results.

Set up your environment

Prerequisites

Use a base Python 3.10 kernel environment and an ml.g4dn.2xlarge Amazon Elastic Compute Cloud (Amazon EC2) instance before starting this tutorial.

For more information about instance types and their recommended use cases, see Available Studio Classic Instance Types.

Install required libraries

1. Install the SageMaker, fmeval, and other required libraries in your code as follows:

   ```
   !pip3 install sagemaker
   !pip3 install -U pyarrow
   !pip3 install -U accelerate
   !pip3 install "ipywidgets>=8"
   !pip3 install jsonlines
   !pip install fmeval
   !pip install boto3==1.28.65
   import sagemaker
   ```

2. Download the sample JSON Lines dataset crows-pairs_sample.jsonl, into your current working directory.

3. Check that your environment contains the sample input file using the following code:

   ```
   import glob
   
   # Check for fmeval wheel and built-in dataset
   if not glob.glob("crows-pairs_sample.jsonl"):  
       print("ERROR - please make sure file exists: crows-pairs_sample.jsonl")
   ```

4. Define a SageMaker JumpStart model as follows:

   ```
   from sagemaker.jumpstart.model import JumpStartModel
   ```
5. Deploy the SageMaker JumpStart model and create an endpoint as follows:

```python
model_id, model_version, = (
    "huggingface-llm-falcon-7b-instruct-bf16",
    "*",
)

my_model = JumpStartModel(model_id=model_id)
predictor = my_model.deploy()
endpoint_name = predictor.endpoint_name
```

6. Define a prompt and the format of the model request, or payload, as follows:

```python
prompt = "London is the capital of"
payload = {
    "inputs": prompt,
    "parameters": {
        "do_sample": True,
        "top_p": 0.9,
        "temperature": 0.8,
        "max_new_tokens": 1024,
        "decoder_input_details" : True,
        "details" : True
    },
}
```

In the previous code example, the following parameters are included in the model request:

- **do_sample** – Instructs the model to sample from the raw model outputs (prior to normalization) during model inference to introduce diversity and creativity into model responses. Defaults to False. If you set do_sample to True, then you must specify a value for one of the following parameters: temperature, top_k, top_p, or typical_p.

- **top_p** – Controls the randomness by limiting the set of tokens to consider when generating the next token. Higher values of top_p allow for a set containing a broader vocabulary. Lower values restrict the set of tokens to more probable words. Ranges for top_p are greater than 0 and less than 1.

- **temperature** – Controls the randomness of the generated text. Higher values of temperature instruct the model to generate more random and diverse responses. Lower
values generate responses that are more predictable. Values for temperature must be positive.

- `max_new_tokens` – Limits the length of the response by limiting the number of tokens returned by your model. Defaults to 20.
- `decoder_input_details` – Returns information about the log probabilities assigned by the model to each potential next token and the corresponding token IDs. If `decoder_input_details` is set to `True`, you must also set `details` to `True` in order to receive the requested details. Defaults to `False`.

For more information about parameters for this Hugging Face model, see `types.py`.

**Send a sample inference request**

To test your model, send a sample request to your model and print the model response as follows:

```python
response = predictor.predict(payload)
print(response[0]["generated_text"])
```

In the previous code example, if your model provided the response `[{"response": "this is the output"}]`, then the `print` statement returns `this is the output`.

**Set up FMEval**

1. Load the required libraries to run FMEval as follows:

```python
import fmeval
from fmeval.data_loaders.data_config import DataConfig
from fmeval.model_runners.sm_jumpstart_model_runner import JumpStartModelRunner
from fmeval.constants import MIME_TYPE_JSONLINES
from fmeval.eval_algorithms.prompt_stereotyping import PromptStereotyping,
    PROMPT_STEREOTYPING
from fmeval.eval_algorithms import EvalAlgorithm
```

2. Set up the data configuration for your input dataset.

   If you don't use a built-in dataset, your data configuration must identify the column that contains more bias in `sent_more_input_location`. You must also identify the column that contains less bias in `sent_less_input_location`. If you are using a built-in dataset from
SageMaker JumpStart, these parameters are passed to FM-Eval automatically through the model metadata.

Specify the `sent_more_input_location` and `sent_less_input_location` columns for a prompt stereotyping task, the name, uniform resource identifier (URI), and MIME type.

```python
cfg = DataConfig(
    dataset_name="crows-pairs_sample",
    dataset_uri="crows-pairs_sample.jsonl",
    dataset_mime_type=MIME_TYPE_JSONLINES,
    sent_more_input_location="sent_more",
    sent_less_input_location="sent_less",
    category_location="bias_type",
)
```

For more information about column information that other tasks require, see the Use a custom input dataset section in Use a custom input dataset.

3. Set up a custom ModelRunner as shown in the following code example:

```python
js_model_runner = JumpStartModelRunner(
    endpoint_name=endpoint_name,
    model_id=model_id,
    model_version=model_version,
    output='[0].generated_text',
    log_probability='[0].details.prefill[*].logprob',
    content_template='{"inputs": $prompt, "parameters":
    {"do_sample": true, "top_p": 0.9, "temperature": 0.8, "max_new_tokens": 1024,
    "decoder_input_details": true,"details": true}}',
)
```

The previous code example specifies the following:

- **endpoint_name** – The name of the endpoint that you created in the previous Install required libraries step.
- **model_id** – The id used to specify your model. This parameter was specified when the SageMaker JumpStart model was defined.
- **model_version** – The version of your model used to specify your model. This parameter was specified when the SageMaker JumpStart model was defined.
• output – Captures the output from the Falcon 7b model, which returns its response in a generated_text key. If your model provided the response `[{"generated_text": "this is the output"}]`, then `[0].generated_text` returns `this is the output`.

• log_probability – Captures the log probability returned by this SageMaker JumpStart model.

• content_template – Specifies how your model interacts with requests. The example configuration template is detailed solely to explain the previous example, and it's not required. The parameters in the content template are the same ones that are declared for payload. For more information about parameters for this Hugging Face model, see types.py.

4. Configure your evaluation report and save it to a directory as shown in the following example code:

   ```python
   import os
   eval_dir = "results-eval-prompt-stereotyping"
   curr_dir = os.getcwd()
   eval_results_path = os.path.join(curr_dir, eval_dir) + "/"
   os.environ["EVAL_RESULTS_PATH"] = eval_results_path
   if os.path.exists(eval_results_path):
       print(f"Directory '{eval_results_path}' exists.")
   else:
       os.mkdir(eval_results_path)
   ```

5. Set up a parallelization factor as follows:

   ```python
   os.environ["PARALLELIZATION_FACTOR"] = "1"
   ```

   A PARALLELIZATION_FACTOR is a multiplier for the number of concurrent batches sent to your compute instance. If your hardware allows for parallelization, you can set this number to multiply the number of invocations for your evaluation job. For example, if you have 100 invocations, and PARALLELIZATION_FACTOR is set to 2, then your job will run 200 invocations. You can increase PARALLELIZATION_FACTOR up to 10, or remove the variable entirely. To read a blog about how AWS Lambda uses PARALLELIZATION_FACTOR see New AWS Lambda scaling controls for Kinesis and DynamoDB event sources.
Run your model evaluation

1. Define your evaluation algorithm. The following example shows how to define a PromptStereotyping algorithm:

   ```python
eval_algo = PromptStereotyping()
```

For examples of algorithms that calculate metrics for other evaluation tasks, see **Evaluate your model** in Use the fmeval library to run an automatic evaluation.

2. Run your evaluation algorithm. The following code example uses the model and data configuration that was previously defined, and a prompt_template that uses feature to pass your prompt to the model as follows:

   ```python
eval_output = eval_algo.evaluate(model=js_model_runner, dataset_config=config, prompt_template="$feature", save=True)
```

Your model output may be different than the previous sample output.

View your analysis results

1. Parse an evaluation report from the eval_output object returned by the evaluation algorithm as follows:

   ```python
   import json
   print(json.dumps(eval_output, default=vars, indent=4))
   ```

The previous command returns the following output (condensed for brevity):

```
[
  {
    "eval_name": "prompt_stereotyping",
    "dataset_name": "crows-pairs_sample",
    "dataset_scores": [
      {
        "name": "prompt_stereotyping",
        "value": 0.6666666666666666
      }
    ],
    "prompt_template": "$feature",
```
"category_scores": [  
  {  
    "name": "disability",  
    "scores": [  
      {  
        "name": "prompt_stereotyping",  
        "value": 0.5  
      }  
    ]  
  },  
  ...,  
  {  
    "output_path": "/home/sagemaker-user/results-eval-prompt-stereotyping/prompt_stereotyping_crows-pairs_sample.jsonl",  
    "error": null  
  }  
]

The previous example output displays an overall score for dataset following "name": prompt_stereotyping. This score is the normalized difference in log probabilities between the model response providing more versus less bias. If the score is greater than 0.5, this means that your model response is more likely to return a response containing more bias. If the score is less than 0.5, your model is more likely to return a response containing less bias. If the score is 0.5, the model response does not contain bias as measured by the input dataset.

You will use the output_path to create a Pandas DataFrame in the following step.

2. Import your results and read them into a DataFrame, and attach the prompt stereotyping scores to the model input, model output, and target output as follows:

```python
import pandas as pd
data = []
with open(os.path.join(eval_results_path,  
"prompt_stereotyping_crows-pairs_sample.jsonl"), "r") as file:
  for line in file:
    data.append(json.loads(line))
df = pd.DataFrame(data)
df['eval_algo'] = df['scores'].apply(lambda x: x[0]['name'])
df['eval_score'] = df['scores'].apply(lambda x: x[0]['value'])
df
```
For a notebook that contains the code examples given in this section, see `jumpstart-falcon-stereotyping.ipynb`.

**How to evaluate an Amazon Bedrock model for text summarization accuracy**

You can use a high-level `ModelRunner` wrapper to create a custom evaluation based on a model that is hosted outside of SageMaker JumpStart.

This tutorial shows how to load the **Anthropic Claude 2 model**, which is available in Amazon Bedrock, and ask this model to summarize text prompts. Then, this tutorial shows how to evaluate the model response for accuracy using the **Rouge-L**, **Meteor**, and **BERTScore** metrics.

The tutorials show how to do the following:

- Set up your environment.
- Run your model evaluation.
- View your analysis results.

**Set up your environment**

**Prerequisites**

- Use a base Python 3.10 kernel environment and an `ml.m5.2xlarge` Amazon Elastic Compute Cloud (Amazon EC2) instance before starting this tutorial.

  For additional information about instance types and their recommended use cases, see [Available Studio Classic Instance Types](#).

**Set up Amazon Bedrock**

Before you can use an Amazon Bedrock model, you have to request access to it.

1. Sign into your AWS account.
   - If you do not have an AWS account, see [Sign up for an AWS account](#) in **Set up Amazon Bedrock**.
2. Open the Amazon Bedrock console.
3. In the **Welcome to Amazon Bedrock!** section that opens, choose **Manage model access**.
4. In the **Model access** section that appears, choose **Manage model access**.

5. In the **Base models** section that appears, check the box next to **Claude** listed under the **Anthropic** subsection of **Models**.

6. Choose **Request model access**.

7. If your request is successful, a check mark with **Access granted** should appear under **Access status** next to your selected model.

8. You may need to log back into your AWS account to be able to access the model.

**Install required libraries**

1. In your code, install the `fmeval` and `boto3` libraries as follows:

   ```bash
   !pip install fmeval
   !pip3 install boto3==1.28.65
   ```

2. Import libraries, set a parallelization factor, and invoke an Amazon Bedrock client as follows:

   ```python
   import boto3
   import json
   import os

   # Dependent on available hardware and memory
   os.environ['PARALLELIZATION_FACTOR'] = "1"

   # Bedrock clients for model inference
   bedrock = boto3.client(service_name='bedrock')
   bedrock_runtime = boto3.client(service_name='bedrock-runtime')
   ```

   In the previous code example, the following applies:

   - **PARALLELIZATION_FACTOR** – A multiplier for the number of concurrent batches sent to your compute instance. If your hardware allows for parallelization, you can set this number to multiply the number of invocations for your evaluation job by. For example, if you have 100 invocations, and PARALLELIZATION_FACTOR is set to 2, then your job will run 200 invocations. You can increase PARALLELIZATION_FACTOR up to 10, or remove the variable entirely. To read a blog about how AWS Lambda uses PARALLELIZATION_FACTOR see [New AWS Lambda scaling controls for Kinesis and DynamoDB event sources](https://aws.amazon.com/blogs/compute/new-aws-lambda-scaling-controls-for-kinesis-and-dynamodb-event-sources).
3. Download the sample JSON Lines dataset, `xsum_sample.jsonl`, into your current working directory.

4. Check that your environment contains the sample input file as follows:

   ```python
   import glob
   
   # Check for the built-in dataset
   if not glob.glob("xsum_sample.jsonl"):
       print("ERROR - please make sure file exists: xsum_sample.jsonl")
   ```

**Send a sample inference request to your model**

1. Define the model and the MIME type of your prompt. For an Anthropic Claude 2 model hosted on Amazon Bedrock, your prompt must be structured as follows:

   ```python
   import json
   model_id = 'anthropic.claude-v2'
   accept = "application/json"
   contentType = "application/json"
   
   # Ensure that your prompt has the correct format
   prompt_data = """Human: Who is Barack Obama?
   Assistant: """
   ```

   For more information about how to structure the body of your request, see Model invocation request body field. Other models may have different formats.

2. Send a sample request to your model. The body of your request contains the prompt and any additional parameters that you want to set. A sample request with the `max_tokens_to_sample` set to 500 follows:

   ```python
   body = json.dumps({"prompt": prompt_data, "max_tokens_to_sample": 500})
   response = bedrock_runtime.invoke_model(
       body=body, modelId=model_id, accept=accept, contentType=contentType
   )
   response_body = json.loads(response.get("body").read())
   print(response_body.get("completion"))
   ```

   In the previous code example, you can set the following parameters:
• **temperature** – Controls the randomness of the generated text, and accepts positive values. Higher values of temperature instruct the model to generate more random and diverse responses. Lower values generate responses that are more predictable. Ranges for temperature lie between 0 and 1, with a default value of 0.5.

• **topP** – Controls the randomness by limiting the set of tokens to consider when generating the next token. Higher values of topP allow for a set containing a broader vocabulary and lower values restrict the set of tokens to more probable words. Ranges for topP are 0 to 1, with a default value of 1.

• **topK** – Limits the model predictions to the top k most probable tokens. Higher values of topK allow for more inventive responses. Lower values generate responses that are more coherent. Ranges for topK are 0 to 500, with a default value of 250.

• **max_tokens_to_sample** – Limits the length of the response by limiting the number of tokens returned by your model. Ranges for max_tokens_to_sample are 0 to 4096, with a default value of 200.

• **stop_sequences** – Specifies a list of character sequences that tell your model to stop generating a response. The model output is stopped the first time any of the listed strings are encountered in the output. The response does not contain the stop sequence. For example, you can use a carriage return sequence to limit the model response to a single line. You can configure up to 4 stop sequences.

For more information about the parameters that you can specify in a request, see Anthropic Claude models.

### Set up FMEval

1. Load the required libraries to run FMEval as follows:

   ```python
   from fmeval.data_loaders.data_config import DataConfig
   from fmeval.model_runners.bedrock_model_runner import BedrockModelRunner
   from fmeval.constants import MIME_TYPE_JSONLINES
   from fmeval.eval_algorithms.summarization_accuracy import SummarizationAccuracy, SummarizationAccuracyConfig
   ```

2. Set up the data configuration for your input dataset.

   The following sample input is one line from `xsum_sample.jsonl`:
It's the highest rating a tropical storm can get and is the first one of this magnitude to hit mainland Mexico since 1959. But how are the categories decided and what do they mean? Newsround reporter Jenny Lawrence explains.

Hurricane Patricia has been rated as a category 5 storm.

The previous sample input contains the text to summarize inside the document key. The reference against which to evaluate your model response is in the summary key. You must use these keys inside your data configuration to specify which columns contain the information that FMEval needs to evaluate the model response.

Your data configuration must identify the text that your model should summarize in model_input_location. You must identify the reference value with target_output_location.

The following data configuration example refers to the previous input example to specify the columns required for a text summarization task, the name, uniform resource identifier (URI), and MIME type:

```python
config = DataConfig(
    dataset_name="xsum_dataset",
    dataset_uri="xsum_sample.jsonl",
    dataset_mime_type=MIME_TYPE_JSONLINES,
    model_input_location="document",
    target_output_location="summary"
)
```

For more information about the column information required for other tasks, see the Use a custom input dataset section in Use an automatic evaluation.

3. Set up a custom ModelRunner as shown in the following code example:

```python
bedrock_model_runner = BedrockModelRunner(
    model_id=model_id,
)```
The previous code example specifies the following:

- `model_id` – The id used to specify your model.
- `output` – Captures the output from the Anthropic Claude 2 model, which returns its response in a completion key.
- `content_template` – Specifies how your model interacts with requests. The example configuration template is detailed as follows solely to explain the previous example, and it's not required.

  - In the previous `content_template` example, the following apply:
    - The variable `prompt` specifies the input prompt, which captures the request made by the user.
    - The variable `max_tokens_to_sample` specifies the maximum number of tokens to 500, in order to limit the length of the response.

    For more information about the parameters that you can specify in your request, see Anthropic Claude models.

The format of the `content_template` parameter depends on the inputs and parameters supported by your LLM. In this tutorial, Anthropic’s Claude 2 model uses the following `content_template`:

```
"content_template": "{"prompt": $prompt, "max_tokens_to_sample": 500}
```

As another example, the Falcon 7b model can support the following `content_template`:

```
"content_template": "{"inputs": $prompt, "parameters": {"max_new_tokens": 10, "top_p": 0.9, "temperature": 0.8}}
```
Run your model evaluation

Define and run your evaluation algorithm

1. Define your evaluation algorithm. The following example shows how to define a SummarizationAccuracy algorithm, which is used to determine accuracy for text summarization tasks:

```python
eval_algo = SummarizationAccuracy(SummarizationAccuracyConfig())
```

For examples of algorithms that calculate metrics for other evaluation tasks, see Evaluate your model in Use the fmeval library to run an automatic evaluation.

2. Run your evaluation algorithm. The following code example uses the data configuration that was previously defined, and a prompt_template that uses the Human and Assistant keys:

```python
eval_output = eval_algo.evaluate(model=bedrock_model_runner,
dataset_config=config,
prompt_template="Human: $feature\n\nAssistant:", save=True)
```

In the previous code example, feature contains the prompt in the format that Amazon Bedrock model expects.

View your analysis results

1. Parse an evaluation report from the eval_output object returned by the evaluation algorithm as follows:

```python
# parse report
print(json.dumps(eval_output, default=vars, indent=4))
```

The previous command returns the following output:

```
[
  {
    "eval_name": "summarization_accuracy",
    "dataset_name": "xsum_dataset",
    "dataset_scores": [
      {
        "name": "meteor",
```
The previous example output displays the three accuracy scores: **Meteor**, **Rouge**, and **BERTScore**, the input prompt_template, a category_score if you requested one, any errors, and the output_path. You will use the output_path to create a Pandas DataFrame in the following step.

2. Import your results and read them into a DataFrame, and attach the accuracy scores to the model input, model output, and target output as follows:

```python
import pandas as pd
data = []
with open("/tmp/eval_results/summarization_accuracy_xsum_dataset.jsonl", "r") as file:
    for line in file:
        data.append(json.loads(line))
df = pd.DataFrame(data)
df['meteor_score'] = df['scores'].apply(lambda x: x[0]['value'])
df['rouge_score'] = df['scores'].apply(lambda x: x[1]['value'])
df['bert_score'] = df['scores'].apply(lambda x: x[2]['value'])
df
```

In this invocation, the previous code example returns the following output (contracted for brevity):
<table>
<thead>
<tr>
<th>model_input</th>
<th>model_output</th>
<th>target_output</th>
<th>prompt</th>
<th>scores</th>
</tr>
</thead>
<tbody>

Your model output may be different than the previous sample output.

For a notebook that contains the code examples given in this section, see `bedrock-claude-summarization-accuracy.ipynb`.

### Additional notebooks

The [fmeval GitHub](https://github.com/anthropic-dev/fmeval) directory contains the following additional example notebooks:

- **bedrock-claude-factual-knowledge.ipynb** – Evaluates an Anthropic Claude 2 model hosted on Amazon Bedrock for factual knowledge.

- **byo-model-outputs.ipynb** – Evaluates a Falcon 7b model hosted on SageMaker JumpStart for factual knowledge where you bring your own model outputs instead of sending inference requests to your model.

- **custom_model_runner_chat_gpt.ipynb** – Evaluates a custom ChatGPT 3.5 model hosted on Hugging Face for factual knowledge.
FM Eval Troubleshooting guide

Foundation Model Evaluations (FM Eval) is in preview release for Amazon SageMaker Clarify and is subject to change.

⚠️ Important

In order to use SageMaker Clarify Foundation Model Evaluations (FM Eval), you must upgrade to the new Studio experience.

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. FM Eval isn't available in Amazon SageMaker Studio Classic.

For information about how to upgrade to the new Studio experience, see [Migrating from Amazon SageMaker Studio Classic](https://docs.aws.amazon.com/sagemaker/latest/dg/migrate-studio-classic.html). For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](https://docs.aws.amazon.com/sagemaker/latest/dg/studio-classic-overview.html).

If you run into an error while creating a foundation model evaluation, use the following list to troubleshoot your evaluation. If you need further assistance, contact [AWS Support](https://aws.amazon.com/support/) or [AWS Developer Forums for Amazon SageMaker](https://aws.amazon.com/community/).

Topics

- Error uploading your data from an Amazon S3 bucket
- The processing job failed to complete
- You can't find foundation model evaluations in the SageMaker console
- Your model does not support prompt stereotyping

Error uploading your data from an Amazon S3 bucket

When you create a foundation model evaluation, you must set the correct permissions for the S3 bucket that you want to store your model input and output in. If the Cross-origin resource sharing (CORS) permissions are not set correctly, SageMaker generates the following error:

Error: Failed to put object in s3: Error while uploading object to s3
Error: Failed to put object in S3: NetworkError when attempting to fetch resource.
To set the correct bucket permissions, follow the instructions under **Set up your environment** in **Use an automatic evaluation in a UI**.

**The processing job failed to complete**

The most common reasons that your processing job failed to complete include the following:

- **Insufficient quota**
- **Insufficient memory**
- **Did not pass ping check**

See the following sections to help you mitigate each issue.

**Insufficient quota**

When you run a foundation model evaluation for a non-deployed SageMaker JumpStart model, SageMaker Clarify deploys your large language model (LLM) to a SageMaker endpoint in your account. If your account does not have sufficient quota to run the selected SageMaker JumpStart model, the job fails with a **ClientError**. To increase your quota, follow these steps:

**Request an AWS Service Quotas increase**

1. Retrieve the instance name, current quota and necessary quota from the on screen error message. For example, in the following error:

   - The instance name is `ml.g5.12xlarge`.
   - The current quota from the number following `current utilization` is 0 instances
   - The additional required quota from the number following `request delta` is 1 instances.

   The sample error follows:

   ```
   ClientError: An error occurred (ResourceLimitExceeded) when calling the CreateEndpoint operation: The account-level service limit 'ml.g5.12xlarge for endpoint usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please use AWS Service Quotas to request an increase for this quota. If AWS...
   ```
Service Quotas is not available, contact AWS support to request an increase for this quota

2. Sign into the AWS Management Console and open the Service Quotas console.

3. In the navigation pane, under Manage quotas, input Amazon SageMaker.

4. Choose View quotas.

5. In the search bar under Service quotas, input the name of the instance from Step 1. For example, using the information contained in the error message from Step 1, input ml.g5.12xlarge.

6. Choose the Quota name that appears next to your instance name and ends with for endpoint usage. For example, using the information contained in the error message from Step 1, choose ml.g5.12xlarge for endpoint usage.

7. Choose Request increase at account-level.

8. Under Increase quota value, input the necessary required quota from the information given in the error message from Step 1. Input the total of current utilization and request delta. In the previous example error, the current utilization is 0 Instances, and the request delta is 1 Instances. In this example, request a quota of 1 to supply the required quota.

9. Choose Request.

10. Choose Quota request history from the navigation pane.

11. When the Status changes from Pending to Approved, rerun your job. You may need to refresh your browser to see the change.

For more information about requesting an increase in your quota, see Requesting a quota increase.

Insufficient memory

If you start a foundation model evaluation on an Amazon EC2 instance that does not have sufficient memory to run an evaluation algorithm, the job fails with the following error:

The actor is dead because its worker process has died. Worker exit type: SYSTEM_ERROR Worker exit detail: Worker unexpectedly exits with a connection error code 2. End of file. There are some potential root causes. (1) The process is killed by SIGKILL by OOM killer due to high memory usage. (2) ray stop --force is called. (3) The worker is crashed
unexpectedly due to SIGSEGV or other unexpected errors. The actor never ran - it was cancelled before it started running.

To increase the memory available for your evaluation job, change your instance to one that has more memory. If you are using the user interface, you can choose an instance type under **Processor configuration** in **Step 2**. If you are running your job inside the SageMaker console, launch a new space using an instance with increased memory capacity.

For a list of Amazon EC2 instances, see [Instance types](#).

For more information, about instances with larger memory capacity, see [Memory optimized instances](#).

**Did not pass ping check**

In some instances, your foundation model evaluation job will fail because it did not pass a ping check when SageMaker was deploying your endpoint. If it does not pass a ping test, the following error appears:

```
ClientError: Error hosting endpoint your_endpoint_name: Failed. Reason: The primary container for production variant AllTraffic did not pass the ping health check. Please check CloudWatch logs for this endpoint..., Job exited for model: your_model_name of model_type: your_model_type
```

If your job generates this error, wait a few minutes and run your job again. If the error persists, contact [AWS Support](#) or [AWS Developer Forums for Amazon SageMaker](#).

**You can't find foundation model evaluations in the SageMaker console**

In order to use SageMaker Clarify Foundation Model Evaluations, you must upgrade to the new Studio experience. As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The foundation evaluation feature can only be used in the updated experience. For information about how to update Studio, see [Migrating from Amazon SageMaker Studio Classic](#). For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

**Your model does not support prompt stereotyping**

Only some SageMaker JumpStart models support prompt stereotyping. If you select a SageMaker JumpStart model that is not supported, the following error appears:
"evaluationMetrics":"This model does not support Prompt stereotyping evaluation. Please remove that evaluation metric or select another model that supports it."

If you receive this error, you cannot use your selected model in a foundation evaluation. SageMaker Clarify is currently working to update all SageMaker JumpStart models for prompt stereotyping tasks so that they can be used in a foundation model evaluation.

Use SageMaker Clarify to explain and detect bias

This topic describes how to understand fairness and model explainability and how to explain and detect bias using Amazon SageMaker Clarify. You can configure an SageMaker Clarify processing job to compute bias metrics and feature attributions and generate reports for model explainability. SageMaker Clarify processing jobs are implemented using a specialized SageMaker Clarify container image. The following instructions show you how to configure, run, and troubleshoot a SageMaker Clarify processing job and how to configure an analysis.

What is fairness and model explainability for machine learning predictions?

Machine learning (ML) models are helping make decisions in domains including financial services, healthcare, education, and human resources. Policymakers, regulators, and advocates have raised awareness about the ethical and policy challenges posed by ML and data-driven systems. Amazon SageMaker Clarify can help you understand why your ML model made a specific prediction and whether this bias impacts this prediction during training or inference. SageMaker Clarify also provides tools that can help you build less biased and more understandable machine learning models. SageMaker Clarify can also generate model governance reports that you can provide to risk and compliance teams and external regulators. With SageMaker Clarify, you can do the following:

• Detect bias in and help explain your model predictions.

• Identify types of bias in pre-training data.

• Identify types of bias in post-training data that can emerge during training or when your model is in production.
SageMaker Clarify helps explain how your models make predictions using feature attributions. It can also monitor inference models that are in production for both bias and feature attribution drift. This information can help you in the following areas:

- **Regulatory** – Policymakers and other regulators can have concerns about discriminatory impacts of decisions that use output from ML models. For example, an ML model may encode bias and influence an automated decision.

- **Business** – Regulated domains may need reliable explanations for how ML models make predictions. Model explainability may be particularly important to industries that depend on reliability, safety, and compliance. These can include financial services, human resources, healthcare, and automated transportation. For example, lending applications may need to provide explanations about how ML models made certain predictions to loan officers, forecasters, and customers.

- **Data Science** – Data scientists and ML engineers can debug and improve ML models when they can determine if a model is making inferences based on noisy or irrelevant features. They can also understand the limitations of their models and failure modes that their models may encounter.

For a blog post that shows how to architect and build a complete machine learning model for fraudulent automobile claims that integrates SageMaker Clarify into a SageMaker pipeline, see the [Architect and build the full machine learning lifecycle with AWS: An end-to-end Amazon SageMaker demo](#). This blog post discusses how to assess and mitigate pre-training and post-training bias, and how the features impact the model prediction. The blog post contains links to example code for each task in the ML lifecycle.

**Best practices to evaluate fairness and explainability in the ML lifecycle**

**Fairness as a process** – Notions of bias and fairness depend on their application. The measurement of bias and the choice of the bias metrics may be guided by social, legal, and other non-technical considerations. The successful adoption of fairness-aware ML approaches includes building consensus and achieving collaboration across key stakeholders. These may include product, policy, legal, engineering, AI/ML teams, end users, and communities.

**Fairness and explainability by design in the ML lifecycle** – Consider fairness and explainability during each stage of the ML lifecycle. These stages include problem formation, dataset construction, algorithm selection, the model training process, the testing process, deployment, and
monitoring and feedback. It is important to have the right tools to do this analysis. We recommend asking the following questions during the ML lifecycle:

- Does the model encourage feedback loops that can produce increasingly unfair outcomes?
- Is an algorithm an ethical solution to the problem?
- Is the training data representative of different groups?
- Are there biases in labels or features?
- Does the data need to be modified to mitigate bias?
- Do fairness constraints need to be included in the objective function?
- Has the model been evaluated using relevant fairness metrics?
- Are there unequal effects across users?
- Is the model deployed on a population for which it was not trained or evaluated?

Guide to the SageMaker explanations and bias documentation

Bias can occur and be measured in the data both before and after training a model. SageMaker Clarify can provide explanations for model predictions after training and for models deployed to production. SageMaker Clarify can also monitor models in production for any drift in their baseline explanatory attributions, and calculate baselines when needed. The documentation for explaining and detecting bias using SageMaker Clarify is structured as follows:
• For information on setting up a processing job for bias and explainability, see Configure a SageMaker Clarify Processing Job.

• For information on detecting bias in pre-processing data before it's used to train a model, see Detect Pre-training Data Bias.

• For information on detecting post-training data and model bias, see Detect Post-training Data and Model Bias.

• For information on the model-agnostic feature attribution approach to explain model predictions after training, see Model Explainability.

• For information on monitoring for feature contribution drift away from the baseline that was established during model training, see Monitor Feature Attribution Drift for Models in Production.

• For information about monitoring models that are in production for baseline drift, see Monitor Bias Drift for Models in Production.

• For information about obtaining explanations in real time from a SageMaker endpoint, see Online Explainability with SageMaker Clarify.

How SageMaker Clarify Processing Jobs Work

You can use SageMaker Clarify to analyze your datasets and models for explainability and bias. A SageMaker Clarify processing job uses the SageMaker Clarify processing container to interact with an Amazon S3 bucket containing your input datasets. You can also use SageMaker Clarify to analyze a customer model that is deployed to a SageMaker inference endpoint.

The following graphic shows how a SageMaker Clarify processing job interacts with your input data and optionally, with a customer model. This interaction depends on the specific type of analysis being performed. The SageMaker Clarify processing container obtains the input dataset and configuration for analysis from an S3 bucket. For certain analysis types, including feature analysis, the SageMaker Clarify processing container must send requests to the model container. Then it retrieves the model predictions from the response that the model container sends. After that, the SageMaker Clarify processing container computes and saves analysis results to the S3 bucket.
You can run a SageMaker Clarify processing job at multiple stages in the lifecycle of the machine learning workflow. SageMaker Clarify can help you compute the following analysis types:

- **Pre-training bias metrics.** These metrics can help you understand the bias in your data so that you can address it and train your model on a more fair dataset. See [Measure Pre-training Bias](#) for information about pre-training bias metrics. To run a job to analyze pre-training bias metrics, you must provide the dataset and a JSON analysis configuration file to [Configure the Analysis](#).

- **Post-training bias metrics.** These metrics can help you understand any bias introduced by an algorithm, hyperparameter choices, or any bias that wasn't apparent earlier in the flow. For more information about post-training bias metrics, see [Measure Post-training Data and Model Bias](#). SageMaker Clarify uses the model predictions in addition to the data and labels to identify bias. To run a job to analyze post-training bias metrics, you must provide the dataset and a JSON analysis configuration file. The configuration should include the model or endpoint name.

- **Shapely values,** which can help you understand what impact your feature has on what your model predicts. For more information about Shapely values, see [Feature Attributions that Use Shapley Values](#). This feature requires a trained model.

- **Partial dependence plots (PDPs),** which can help you understand how much your predicted target variable would change if you varied the value of one feature. For more information about PDPs, see [Partial dependence plots (PDPs) analysis](#). This feature requires a trained model.

SageMaker Clarify needs model predictions to compute post-training bias metrics and feature attributions. You can provide an endpoint or SageMaker Clarify will create an ephemeral endpoint using your model name, also known as a *shadow endpoint*. The SageMaker Clarify container deletes the shadow endpoint after the computations are completed. At a high level, the SageMaker Clarify container completes the following steps:

1. Validates inputs and parameters.
2. Creates the shadow endpoint (if a model name is provided).
3. Loads the input dataset into a data frame.
4. Obtains model predictions from the endpoint, if necessary.
5. Computes bias metrics and features attributions.
6. Deletes the shadow endpoint.
7. Generate the analysis results.

After the SageMaker Clarify processing job is complete, the analysis results will be saved in the output location that you specified in the processing output parameter of the job. These results include a JSON file with bias metrics and global feature attributions, a visual report, and additional files for local feature attributions. You can download the results from the output location and view them.

For additional information about bias metrics, explainability and how to interpret them, see Learn How Amazon SageMaker Clarify Helps Detect Bias, Fairness Measures for Machine Learning in Finance, and the Amazon AI Fairness and Explainability Whitepaper.

**Configure a SageMaker Clarify Processing Job**

To analyze your data and models for bias and explainability using SageMaker Clarify, you must configure a SageMaker Clarify processing job. This guide shows how to specify the input dataset name, analysis configuration file name, and output location for a processing job. To configure the processing container, job inputs, outputs, resources and other parameters, you have two options. You can either use the SageMaker CreateProcessingJob API, or use the SageMaker Python SDK API SageMaker ClarifyProcessor.

For information about parameters that are common to all processing jobs, see Amazon SageMaker API Reference.

**Configure a SageMaker Clarify processing job using the SageMaker API**

The following instructions show how to provide each portion of the SageMaker Clarify specific configuration using the CreateProcessingJob API.

1. Input the uniform research identifier (URI) of a SageMaker Clarify container image inside the AppSpecification parameter, as shown in the following code example.

```json
{
    "AppSpecification": {
        "Type": "container",
        "ImageUri": "<SageMaker Clarify container image URI>",
        "ContainerArguments": ["--<input_dataset_name>"],
        "Environment": {
            "<environment_key>": "<environment_value>",
            ...
        }
    }
}
```
Note

The URI must identify a pre-built SageMaker Clarify container image. ContainerEntrypoint and ContainerArguments are not supported. For more information about SageMaker Clarify container images, see Get Started with a SageMaker Clarify Container.

2. Specify both the configuration for your analysis and parameters for your input dataset inside the ProcessingInputs parameter.

   a. Specify the location of the JSON analysis configuration file, which includes the parameters for bias analysis and explainability analysis. The InputName parameter of the ProcessingInput object must be analysis_config as shown in the following code example.

   ```
   {
     "InputName": "analysis_config",
     "S3Input": {
       "S3Uri": "s3://your-bucket/analysis_config.json",
       "S3DataType": "S3Prefix",
       "S3InputMode": "File",
       "LocalPath": "/opt/ml/processing/input/config"
     }
   }
   ```

   For more information about the schema of the analysis configuration file, see Configure the Analysis.

   b. Specify the location of the input dataset. The InputName parameter of the ProcessingInput object must be dataset. This parameter is optional if you have provided the "dataset_uri" in the analysis configuration file. The following values are required in the S3Input configuration.

   i. S3Uri can be either an Amazon S3 object or an S3 prefix.

   ii. S3InputMode must be of type File.

   iii. S3CompressionType must be of type None (the default value).

   iv. S3DataDistributionType must be of type FullyReplicated (the default value).

Configure a SageMaker Clarify Processing Job
v. S3DataType can be either S3Prefix or ManifestFile. To use ManifestFile, the S3Uri parameter should specify the location of a manifest file that follows the schema from the SageMaker API Reference section S3Uri. This manifest file must list the S3 objects that contain the input data for the job.

The following code shows an example of an input configuration.

```json
{
    "InputName": "dataset",
    "S3Input": {
        "S3Uri": "s3://your-bucket/your-dataset.csv",
        "S3DataType": "S3Prefix",
        "S3InputMode": "File",
        "LocalPath": "/opt/ml/processing/input/data"
    }
}
```

3. Specify the configuration for the output of the processing job inside the ProcessingOutputConfig parameter. A single ProcessingOutput object is required in the Outputs configuration. The following are required of the output configuration:

   a. OutputName must be **analysis_result**.

   b. S3Uri must be an S3 prefix to the output location.

   c. S3UploadMode must be set to **EndOfJob**.

The following code shows an example of an output configuration.

```json
{
    "Outputs": [{
        "OutputName": "analysis_result",
        "S3Output": {
            "S3Uri": "s3://your-bucket/result/",
            "S3UploadMode": "EndOfJob",
            "LocalPath": "/opt/ml/processing/output"
        }
    }]
}
```

4. Specify the configuration ClusterConfig for the resources that you use in your processing job inside the ProcessingResources parameter. The following parameters are required inside the ClusterConfig object.
a. InstanceCount specifies the number of compute instances in the cluster that runs the processing job. Specify a value greater than 1 to activate distributed processing.

b. InstanceType refers to the resources that runs your processing job. Because SageMaker SHAP analysis is compute-intensive, using an instance type that is optimized for compute should improve runtime for analysis. The SageMaker Clarify processing job doesn't use GPUs.

The following code shows an example of resource configuration.

```json
{
    "ClusterConfig": {
        "InstanceCount": 1,
        "InstanceType": "ml.m5.xlarge",
        "VolumeSizeInGB": 20
    }
}
```

5. Specify the configuration of the network that you use in your processing job inside the NetworkConfig object. The following values are required in the configuration.

a. EnableNetworkIsolation must be set to False (default) so that SageMaker Clarify can invoke an endpoint, if necessary, for predictions.

b. If the model or endpoint that you provided to the SageMaker Clarify job is within an Amazon Virtual Private Cloud (Amazon VPC), then the SageMaker Clarify job must also be in the same VPC. Specify the VPC using VpcConfig. Additionally, the VPC must have endpoints to an Amazon S3 bucket, SageMaker service and SageMaker Runtime service.

If distributed processing is activated, you must also allow communication between different instances in the same processing job. Configure a rule for your security group that allows inbound connections between members of the same security group. For more information, see Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC.

The following code gives an example of a network configuration.

```json
{
    "EnableNetworkIsolation": false,
    "VpcConfig": {
        ...
    }
}
```
6. Set the maximum time that the job will run using the StoppingCondition parameter. The longest that a SageMaker Clarify job can run is 7 days or 604800 seconds. If the job cannot be completed within this time limit, it will be stopped and no analysis results will be provided. As an example, the following configuration limits the maximum time that the job can run to 3600 seconds.

```json
{
    "MaxRuntimeInSeconds": 3600
}
```

7. Specify an IAM role for the RoleArn parameter. The role must have a trust relationship with Amazon SageMaker. It can be used to perform the SageMaker API operations listed in the following table. We recommend using the Amazon SageMakerFullAccess managed policy, which grants full access to SageMaker. For more information on this policy, see AWS managed policy: AmazonSageMakerFullAccess. If you have concerns about granting full access, the minimal permissions required depend on whether you provide a model or an endpoint name. Using an endpoint name allows for granting fewer permissions to SageMaker.

The following table contains API operations used by the SageMaker Clarify processing job. An `X` under **Model name** and **Endpoint name** notes the API operation that is required for each input.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Model name</th>
<th>Endpoint name</th>
<th>What is it used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListTags</td>
<td>X</td>
<td></td>
<td>Tags of the job are applied to the shadow endpoint.</td>
</tr>
<tr>
<td>CreateEndpointConfig</td>
<td>X</td>
<td></td>
<td>Create endpoint config using the model name that you provided</td>
</tr>
<tr>
<td>CreateEndpoint</td>
<td>X</td>
<td></td>
<td>Create shadow endpoint using the endpoint config.</td>
</tr>
<tr>
<td>DescribeEndpoint</td>
<td>X</td>
<td>X</td>
<td>Describe endpoint for its status, the</td>
</tr>
</tbody>
</table>
## API Operation

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Model name</th>
<th>Endpoint name</th>
<th>What is it used for</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>InvokeEndpoint</code></td>
<td>X</td>
<td>X</td>
<td>endpoint must be InService to serve requests.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Invoke the endpoint for predictions.</td>
</tr>
</tbody>
</table>

For more information about required permissions, see [Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference](#).

For more information about passing roles to SageMaker, see [Passing Roles](#).

After you have the individual pieces of the processing job configuration, combine them to configure the job.

### Configure a SageMaker Clarify processing job using the AWS SDK for Python

The following code example shows how to launch a SageMaker Clarify processing job using the [AWS SDK for Python](https://boto3.amazonaws.com/v1/documentation/api/latest/).

```python
sagemaker_client.create_processing_job(
    ProcessingJobName="your-clarify-job-name",
    AppSpecification={
        "ImageUri": "the-clarify-container-image-uri",
    },
    ProcessingInputs=[
        {
            "InputName": "analysis_config",
            "S3Input": {
                "S3Uri": "s3://your-bucket/analysis_config.json",
                "S3DataType": "S3Prefix",
                "S3InputMode": "File",
                "LocalPath": "/opt/ml/processing/input/config",
            },
        },
        {
            "InputName": "dataset",
            "S3Input": {
                "S3Uri": "s3://your-bucket/your-dataset.csv",
                "S3DataType": "S3Prefix",
            },
        },
    ],
)
```
"S3InputMode": "File",
    "LocalPath": "/opt/ml/processing/input/data",
},
],
ProcessingOutputConfig={
    "Outputs": [{
        "OutputName": "analysis_result",
        "S3Output": {
            "S3Uri": "s3://your-bucket/result/",
            "S3UploadMode": "EndOfJob",
            "LocalPath": "/opt/ml/processing/output",
        },
    }],
},
ProcessingResources={
    "ClusterConfig": {
        "InstanceCount": 1,
        "InstanceType": "ml.m5.xlarge",
        "VolumeSizeInGB": 20,
    },
},
NetworkConfig={
    "EnableNetworkIsolation": false,
    "VpcConfig": {
        
    },
},
StoppingCondition={
    "MaxRuntimeInSeconds": 3600,
},
RoleArn="arn:aws:iam::<your-account-id>::role/service-role/AmazonSageMaker-ExecutionRole",
)

For an example notebook with instructions for running a SageMaker Clarify processing job using AWS SDK for Python, see Fairness and Explainability with SageMaker Clarify using AWS SDK for Python. Any S3 bucket used in the notebook must be in the same AWS Region as the notebook instance that accesses it.
Configure a SageMaker Clarify processing job using the SageMaker Python SDK

You can also configure a SageMaker Clarify processing job using the SageMaker ClarifyProcessor in the SageMaker Python SDK API. For more information, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability.

Get Started with a SageMaker Clarify Container

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process data in your account.

The image URIs for the containers are in the following form:

```
<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0
```

For example:

```
205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0
```

The following table lists the addresses by AWS Region.

Docker Images for SageMaker Clarify Processing Jobs

<table>
<thead>
<tr>
<th>Region</th>
<th>Image address</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1</td>

</table>
Configure the Analysis

To analyze your data and models for explainability and bias using SageMaker Clarify, you must configure a processing job. Part of the configuration for this processing job includes the configuration of an analysis file. The analysis file specifies the parameters for bias analysis and explainability. See Configure a SageMaker Clarify Processing Job to learn how to configure a processing job and analysis file.

This guide describes the schema and parameters for this analysis configuration file. This guide also includes examples of analysis configuration files for computing bias metrics for a tabular dataset, and generating explanations for natural language processing (NLP) and computer vision (CV) problems.
You can create the analysis configuration file or use the SageMaker Python SDK to generate one for you with the SageMaker ClarifyProcessor API. Viewing the file contents can be helpful for understanding the underlying configuration used by the SageMaker Clarify job.

Topics

- Schema for the analysis configuration file
- Example analysis configuration files

Schema for the analysis configuration file

The following section describes the schema for the analysis configuration file including requirements and descriptions of parameters.

Requirements for the analysis configuration file

The SageMaker Clarify processing job expects the analysis configuration file to be structured with the following requirements:

- The processing input name must be `analysis_config`.
- The analysis configuration file is in JSON format, and encoded in UTF-8.
- The analysis configuration file is an Amazon S3 object.

You can specify additional parameters in the analysis configuration file. The following section provides various options to tailor the SageMaker Clarify processing job for your use case and desired types of analysis.

Parameters for analysis configuration files

In the analysis configuration file, you can specify the following parameters.

- `version` – (Optional) The version string of the analysis configuration file schema. If a version is not provided, SageMaker Clarify uses the latest supported version. Currently, the only supported version is `1.0`.
- `dataset_type` – The format of the dataset. The input dataset format can be any of the following values:
  - `text/csv` for CSV
  - `application/jsonlines` for SageMaker JSON Lines dense format
• application/json for JSON
• application/x-parquet for Apache Parquet
• application/x-image to activate explainability for computer vision problems

• dataset_uri – (Optional) The uniform resource identifier (URI) of the main dataset. If you provide a S3 URI prefix, the SageMaker Clarify processing job recursively collects all S3 files located under the prefix. You can provide either a S3 URI prefix or a S3 URI to an image manifest file for computer vision problems. If dataset_uri is provided, it takes precedence over the dataset processing job input. For any format type except image, the SageMaker Clarify processing job loads the input dataset into a tabular data frame, as a tabular dataset. This format allows SageMaker to easily manipulate and analyze the input dataset.

• headers – (Optional) An array of strings containing the column names of a tabular dataset. If a value for headers is not provided, then the SageMaker Clarify processing job reads the headers from the dataset. If the dataset doesn't have headers, then the SageMaker Clarify processing job will automatically generate placeholder names based on zero-based column index. As an example, placeholder names for the first and second columns will be column_0, column_1.

Note

By convention, if dataset_type is application/jsonlines or application/json then headers should contain the following names in order: feature names, label name (if label is specified), and predicted label name (if predicted_label is specified). An example for headers for an application/jsonlines dataset type if label is specified is: ["feature1","feature2","feature3","target_label"].

• label – (Optional) A string or a zero-based integer index. If provided, label is used to locate the ground truth label, also known as an observed label or target attribute in a tabular dataset. The ground truth label is used to compute bias metrics. The value for label is specified depending on the value of the dataset_type parameter as follows.

  • If dataset_type is text/csv, label can be specified as either of the following:
    • A valid column name
    • An index that lies within the range of dataset columns
  • If dataset_type is application/parquet, label must be a valid column name.
  • If dataset_type is application/jsonlines, label must be a JMESPath expression written to extract the ground truth label from the dataset. By convention, if headers is specified, then it should contain the label name.
• If dataset_type is **application/json**, label must be a [JMESPath](https://aws.amazon.com/sagemaker/jmespath) expression written to extract the ground truth label for each record in the dataset. This JMESPath expression must produce a list of labels where the \(i\)th label correlates to the \(i\)th record.

• **predicted_label** – (Optional) A string or a zero-based integer index. If provided, predicted_label is used to locate the column containing the predicted label in a tabular dataset. The predicted label is used to compute post-training **bias metrics**. The parameter predicted_label is optional if the dataset doesn’t include predicted label. If predicted labels are required for computation, then the SageMaker Clarify processing job will get predictions from the model.

The value for predicted_label is specified depending on the value of the dataset_type as follows:

• If dataset_type is **text/csv**, predicted_label can be specified as either of the following:
  
  • A valid column name. If predicted_label_dataset_uri is specified, but predicted_label is not provided, the default predicted label name is "predicted_label".
  
  • An index that lies within the range of dataset columns. If predicted_label_dataset_uri is specified, then the index is used to locate the predicted label column in the predicted label dataset.

• If dataset_type is **application/x-parquet**, predicted_label must be a valid column name.

• If dataset_type is **application/jsonlines**, predicted_label must be a valid JMESPath expression written to extract the predicted label from the dataset. By convention, if headers is specified, then it should contain the predicted label name.

• If dataset_type is **application/json**, predicted_label must be a JMESPath expression written to extract the predicted label for each record in the dataset. The JMESPath expression should produce a list of predicted labels where the \(i\)th predicted label is for the \(i\)th record.

• **features** – Required if dataset_type is application/jsonlines or application/json. A JMESPath string expression written to locate the features in the input dataset. For application/jsonlines, a JMESPath expression will be applied to each line to extract the features for that record. For application/json, a JMESPath expression will be applied to the whole input dataset. The JMESPath expression should extract a list of lists, or a 2D array/matrix of features where the \(i\)th row contains the features that correlate to the \(i\)th record. For a dataset_type of text/csv or application/x-parquet, all columns except for the ground truth label and predicted label columns are automatically assigned to be features.
• **predicted_label_dataset_uri** – Only applicable when dataset_type is text/csv. The S3 URI for a dataset containing predicted labels used to compute post-training bias metrics. The SageMaker Clarify processing job will load the predictions from the provided URI instead of getting predictions from the model. In this case, **predicted_label** is required to locate the predicted label column in the predicted label dataset. If the predicted label dataset or the main dataset is split across multiple files, an identifier column must be specified by **joinsource_name_or_index** to join the two datasets.

• **predicted_label_headers** – Only applicable when **predicted_label_dataset_uri** is specified. An array of strings containing the column names of the predicted label dataset. Besides the predicted label header, **predicted_label_headers** can also contain the header of the identifier column to join the predicted label dataset and the main dataset. For more information, see the following description for the parameter **joinsource_name_or_index**.

• **joinsource_name_or_index** – The name or zero-based index of the column in tabular datasets to be used as a identifier column while performing an inner join. This column is only used as an identifier. It isn’t used for any other computations like bias analysis or feature attribution analysis. A value for **joinsource_name_or_index** is needed in the following cases:
  
  • There are multiple input datasets, and any one is split across multiple files.
  • Distributed processing is activated by setting the SageMaker Clarify processing job **InstanceCount** to a value greater than 1.

• **excluded_columns** – (Optional) An array of names or zero-based indices of columns to be excluded from being sent to the model as input for predictions. Ground truth label and predicted label are automatically excluded already.

• **probability_threshold** – (Optional) A floating point number above which, a label or object is selected. The default value is 0.5. The SageMaker Clarify processing job uses **probability_threshold** in the following cases:
  
  • In post-training bias analysis, **probability_threshold** converts a numeric model prediction (probability value or score) to a binary label, if the model is a binary classifier. A score greater than the threshold is converted to 1. Whereas, a score less than or equal to the threshold is converted to 0.
  
  • In computer vision explainability problems, if model_type is **OBJECT_DETECTION**, **probability_threshold** filters out objects detected with confidence scores lower than the threshold value.

• **label_values_or_threshold** – Required for bias analysis. An array of label values or a threshold number, which indicate positive outcome for ground truth and predicted labels for bias metrics.
For more information, see positive label values in Amazon SageMaker Clarify Terms for Bias and Fairness. If the label is numeric, the threshold is applied as the lower bound to select the positive outcome. To set label_values_or_threshold for different problem types, refer to the following examples:

- For a binary classification problem, the label has two possible values, 0 and 1. If label value 1 is favorable to a demographic group observed in a sample, then label_values_or_threshold should be set to [1].

- For a multiclass classification problem, the label has three possible values, bird, cat, and dog. If the latter two define a demographic group that bias favors, then label_values_or_threshold should be set to ["cat", "dog"].

- For a regression problem, the label value is continuous, ranging from 0 to 1. If a value greater than 0.5 should designate a sample as having a positive result, then label_values_or_threshold should be set to 0.5.

- facet – Required for bias analysis. An array of facet objects, which are composed of sensitive attributes against which bias is measured. You can use facets to understand the bias characteristics of your dataset and model even if your model is trained without using sensitive attributes. For more information, see Facet in Amazon SageMaker Clarify Terms for Bias and Fairness. Each facet object includes the following fields:

  - name_or_index – The name or zero-based index of the sensitive attribute column in a tabular dataset. If facet_dataset_uri is specified, then the index refers to the facet dataset instead of the main dataset.

  - value_or_threshold – Required if facet is numeric and label_values_or_threshold is applied as the lower bound to select the sensitive group). An array of facet values or a threshold number, that indicates the sensitive demographic group that bias favors. If facet data type is categorical and value_or_threshold is not provided, bias metrics are computed as one group for every unique value (rather than all values). To set value_or_threshold for different facet data types, refer to the following examples:

    - For a binary facet data type, the feature has two possible values, 0 and 1. If you want to compute the bias metrics for each value, then value_or_threshold can be either omitted or set to an empty array.

    - For a categorical facet data type, the feature has three possible values bird, cat, and dog. If the first two define a demographic group that bias favors, then value_or_threshold should be set to ["bird", "cat"]. In this example, the dataset samples are split into two demographic groups. The facet in the advantaged group has value bird or cat, while the facet in the disadvantaged group has value dog.
For a numeric facet data type, the feature value is continuous, ranging from 0 to 1. As an example, if a value greater than 0.5 should designate a sample as favored, then value_or_threshold should be set to 0.5. In this example, the dataset samples are split into two demographic groups. The facet in the advantaged group has value greater than 0.5, while the facet in the disadvantaged group has value less than or equal to 0.5.

**group_variable** – The name or zero-based index of the column that indicates the subgroup to be used for the bias metric Conditional Demographic Disparity (CDD) or Conditional Demographic Disparity in Predicted Labels (CDDPL).

**facet_dataset_uri** – Only applicable when dataset_type is text/csv. The S3 URI for a dataset containing sensitive attributes for bias analysis. You can use facets to understand the bias characteristics of your dataset and model even if your model is trained without using sensitive attributes.

---

**Note**

If the facet dataset or the main dataset is split across multiple files, an identifier column must be specified by joinsource_name_or_index to join the two datasets. You must use the parameter facet to identify each facet in the facet dataset.

---

**facet_headers** – (Only applicable when facet_dataset_uri is specified) An array of strings containing column names for the facet dataset, and optionally, the identifier column header to join the facet dataset and the main dataset, see joinsource_name_or_index.

**methods** – An object containing one or more analysis methods and their parameters. If any method is omitted, it is neither used for analysis nor reported.

**pre_training_bias** – Include this method if you want to compute pre-training bias metrics. The detailed description of the metrics can be found in Measure Pre-training Bias. The object has the following parameters:

- **methods** – An array that contains any of the pre-training bias metrics from the following list that you want to compute. Set methods to **all** to compute all pre-training bias metrics. As an example, the array ["CI", "DPL"] will compute Class Imbalance and Difference in Proportions of Labels.
  - CI for [Class Imbalance (CI)]
  - DPL for [Difference in Proportions of Labels (DPL)]
  - KL for [Kullback-Leibler Divergence (KL)]
  - JS for [Jensen-Shannon Divergence (JS)]
- LP for $L_p$-norm (LP)
- TVD for Total Variation Distance (TVD)
- KS for Kolmogorov-Smirnov (KS)
- CDDL for Conditional Demographic Disparity (CDD)

**post_training_bias** – Include this method if you want to compute post-training bias metrics. The detailed description of the metrics can be found in Measure Post-training Data and Model Bias. The post_training_bias object has the following parameters.

- **methods** – An array that contains any of the post-training bias metrics from the following list that you want to compute. Set methods to all to compute all post-training bias metrics. As an example, the array ['DPPL', 'DI'] computes the Difference in Positive Proportions in Predicted Labels and Disparate Impact. The available methods are as follows.
  - DPPL for Difference in Positive Proportions in Predicted Labels (DPPL)
  - DI for Disparate Impact (DI)
  - DCA for Difference in Conditional Acceptance (DCAcc)
  - DCR for Difference in Conditional Rejection (DCR)
  - SD for Specificity difference (SD)
  - RD for Recall Difference (RD)
  - DAR for Difference in Acceptance Rates (DAR)
  - DRR for Difference in Rejection Rates (DRR)
  - AD for Accuracy Difference (AD)
  - TE for Treatment Equality (TE)
  - CDDLPL for Conditional Demographic Disparity in Predicted Labels (CDDPL)
  - FT for Counterfactual Flippetest (FT)
  - GE for Generalized entropy (GE)

- **shap** – Include this method if you want to compute SHAP values. The SageMaker Clarify processing job supports the Kernel SHAP algorithm. The shap object has the following parameters.
  - **baseline** – (Optional) The SHAP baseline dataset, also known as the background dataset. Additional requirements for the baseline dataset in a tabular dataset or computer vision problem are as follows. For more information about SHAP Baselines, see SHAP Baselines for Explainability.
• For a **tabular** dataset, baseline can be either the in-place baseline data or the S3 URI of a baseline file. If baseline is not provided, the SageMaker Clarify processing job computes a baseline by clustering the input dataset. The following are required of the baseline:

    • The format must be the same as the dataset format specified by `dataset_type`.
    • The baseline can only contain features that the model can accept as input.
    • The baseline dataset can have one or more instances. The number of baseline instances directly affects the synthetic dataset size and job runtime.
    • If `text_config` is specified, then the baseline value of a text column is a string used to replace the unit of text specified by `granularity`. For example, one common placeholder is "[MASK]", which is used to represent a missing or unknown word or piece of text.

The following examples show how to set in-place baseline data for different `dataset_type` parameters:

• If `dataset_type` is either `text/csv` or `application/x-parquet`, the model accepts four numeric features, and the baseline has two instances. In this example, if one record has all zero feature values and the other record has all one feature values, then baseline should be set to `[[0,0,0,0],[1,1,1,1]]`, without any header.

• If `dataset_type` is `application/jsonlines`, and `features` is the key to a list of four numeric feature values. In addition, in this example, if the baseline has one record of all zero values, then `baseline` should be `[{"features":[0,0,0,0]}].`

• If `dataset_type` is `application/json`, the baseline dataset should have the same structure and format as the input dataset.

• For **computer vision** problems, baseline can be the S3 URI of an image that is used to mask out features (segments) from the input image. The SageMaker Clarify processing job loads the mask image and resizes it to the same resolution as the input image. If baseline is not provided, the SageMaker Clarify processing job generates a mask image of **white noise** at the same resolution as the input image.

• **features_to_explain** – (Optional) An array of strings or zero-based indices of feature columns to compute SHAP values for. If `features_to_explain` is not provided, SHAP values are computed for all feature columns. These feature columns cannot include the label column or predicted label column. The `features_to_explain` parameter is only supported for tabular datasets with numeric and categorical columns.
- **num_clusters** – (Optional) The number of clusters that the dataset is divided into to compute the baseline dataset. Each cluster is used to compute one baseline instance. If baseline is not specified, the SageMaker Clarify processing job attempts to compute the baseline dataset by dividing the tabular dataset into an optimal number of clusters between 1 and 12. The number of baseline instances directly affects the runtime of SHAP analysis.

- **num_samples** – (Optional) The number of samples to be used in the Kernel SHAP algorithm. If *num_samples* is not provided, the SageMaker Clarify processing job chooses the number for you. The number of samples directly affects both the synthetic dataset size and job runtime.

- **seed** – (Optional) An integer used to initialize the pseudo random number generator in the SHAP explainer to generate consistent SHAP values for the same job. If seed is not specified, then each time that the same job runs, the model may output slightly different SHAP values.

- **use_logit** – (Optional) A Boolean value that indicates that you want the logit function to be applied to the model predictions. Defaults to false. If *use_logit* is true, then the SHAP values are calculated using the logistic regression coefficients, which can be interpreted as log-odds ratios.

- **save_local_shap_values** – (Optional) A Boolean value that indicates that you want the local SHAP values of each record in the dataset to be included in the analysis result. Defaults to false.

  If the main dataset is split across multiple files or distributed processing is activated, also specify an identifier column using the parameter *joinsource_name_or_index*. The identifier column and the local SHAP values are saved in the analysis result. This way, you can map each record to its local SHAP values.

- **agg_method** – (Optional) The method used to aggregate the local SHAP values (the SHAP values for each instance) of all instances to the global SHAP values (the SHAP values for the entire dataset). Defaults to mean_abs. The following methods can be used to aggregate SHAP values.
  - **mean_abs** – The mean of absolute local SHAP values of all instances.
  - **mean_sq** – The mean of squared local SHAP values of all instances.
  - **median** – The median of local SHAP values of all instances.
  - **text_config** – Required for natural language processing explainability. Include this configuration if you want to treat text columns as text and explanations should be provided for individual units of text. For an example of an analysis configuration for natural language
processing explainability, see Analysis configuration for natural language processing explainability

- **granularity** – The unit of granularity for the analysis of text columns. Valid values are token, sentence, or paragraph. Each unit of text is considered a feature, and local SHAP values are computed for each unit.

- **language** – The language of the text columns. Valid values are chinese, danish, dutch, english, french, german, greek, italian, japanese, lithuanian, multi-language, norwegian bokmål, polish, portuguese, romanian, russian, spanish, afrikaans, albanian, arabic, armenian, basque, bengali, bulgarian, catalan, czech, estonian, finnish, gujarati, hebrew, hindi, hungarian, icelandic, indonesian, irish, kannada, kyrgyz, latvian, ligurian, luxembourgish, macedonian, malayalam, marathi, nepali, persian, sanskrit, serbian, setswana, sinhala, slovak, slovenian, swedish, tagalog, tamil, tatar, telugu, thai, turkish, ukranian, urdu, vietnamese, yoruba. Enter multi-language for a mix of multiple languages.

- **max_top_tokens** – (Optional) The maximum number of top tokens, based on global SHAP values. Defaults to 50. It is possible for a token to appear multiple times in the dataset. The SageMaker Clarify processing job aggregates the SHAP values of each token, and then selects the top tokens based on their global SHAP values. The global SHAP values of the selected top tokens are included in the global_top_shap_text section of the analysis.json file.

- The local SHAP value of aggregation.

- **image_config** – Required for computer vision explainability. Include this configuration if you have an input dataset consisting of images and you want to analyze them for explainability in a computer vision problem.

- **model_type** – The type of the model. Valid values include:
  - IMAGE_CLASSIFICATION for an image classification model.
  - OBJECT_DETECTION for an object detection model.

- **max_objects** – Applicable only when model_type is OBJECT_DETECTION. The max number of objects, ordered by confidence score, detected by the computer vision model. Any objects ranked lower than the top max_objects by confidence score are filtered out. Defaults to 3.
• **context** – Applicable only when `model_type` is **OBJECT_DETECTION**. It indicates if the area around the bounding box of the detected object is masked by the baseline image or not. Valid values are 0 to mask everything, or 1 to mask nothing. Defaults to 1.

• **iou_threshold** – Applicable only when `model_type` is **OBJECT_DETECTION**. The minimum intersection over union (IOU) metric for evaluating predictions against the original detection. A high IOU metric corresponds to a large overlap between the predicted and ground truth detection box. Defaults to 0.5.

• **num_segments** – (Optional) An integer that determines the approximate number of segments to be labeled in the input image. Each segment of the image is considered a feature, and local SHAP values are computed for each segment. Defaults to 20.

• **segment_compactness** – (Optional) An integer that determines the shape and size of the image segments generated by the scikit-image slic method. Defaults to 5.

• **pdp** – Include this method to compute partial dependence plots (PDPs). For an example of an analysis configuration to generate PDPs, see [Compute partial dependence plots (PDPs)].

• **features** – Mandatory if the shap method is not requested. An array of feature names or indices to compute and plot PDP plots.

• **top_k_features** – (Optional) Specifies the number of top features used to generate PDP plots. If `features` is not provided, but the shap method is requested, then the SageMaker Clarify processing job chooses the top features based on their SHAP attributions. Defaults to 10.

• **grid_resolution** – The number of buckets to divide the range of numeric values into. This specifies the granularity of the grid for the PDP plots.

• **report** – (Optional) Use this object to customize the analysis report. There are three copies of the same report as part of the analysis result: Jupyter Notebook report, HTML report, and PDF report. The object has the following parameters:

  • **name** – File name of the report files. For example, if name is `MyReport`, then the report files are `MyReport.ipynb`, `MyReport.html`, and `MyReport.pdf`. Defaults to report.

  • **title** – (Optional) Title string for the report. Defaults to SageMaker Analysis Report.

• **predictor** – Required if the analysis requires predictions from the model. For example, when the shap, pdp, or post_training_bias method is requested, but predicted labels are not provided as part of the input dataset. The following are parameters to be used in conjunction with predictor:

  • **model_name** – The name of your SageMaker model created by the [CreateModel](aws.amazon.com) API. If you specify `model_name` instead of `endpoint_name`, the SageMaker Clarify processing job
creates an ephemeral endpoint with the model name, known as a shadow endpoint, and gets predictions from the endpoint. The job deletes the shadow endpoint after the computations are completed. If the model is multi-model, then the target_model parameter must be specified. For more information about multi-model endpoints, see Host multiple models in one container behind one endpoint.

- **endpoint_name_prefix** – (Optional) A custom name prefix for the shadow endpoint. Applicable if you provide model_name instead of endpoint_name. For example, provide endpoint_name_prefix if you want to restrict access to the endpoint by endpoint name. The prefix must match the EndpointName pattern, and its maximum length is 23. Defaults to sm-clarify.

- **initial_instance_count** – Specifies the number of instances for the shadow endpoint. Required if you provide model_name instead of endpoint_name. The value for initial_instance_count can be different from the InstanceCount of the job, but we recommend a 1:1 ratio.

- **instance_type** – Specifies the instance type for the shadow endpoint. Required if you provide model_name instead of endpoint_name. As an example, instance_type can be set to "ml.m5.large". In some cases, the value specified for instance_type can help reduce model inference time. For example, to run efficiently, natural language processing models and computer vision models typically require a graphics processing unit (GPU) instance type.

- **accelerator_type** – (Optional) Specifies the type of Elastic Inference (EI) accelerator to attach to the shadow endpoint. Applicable if you provide model_name instead of endpoint_name for accelerator_type. An example value for accelerator_type is ml.eia2.large. Defaults to not use an accelerator.

- **endpoint_name** – The name of your SageMaker endpoint created by the CreateEndpoint API. If provided, endpoint_name takes precedence over the model_name parameter. Using an existing endpoint reduces the shadow endpoint bootstrap time, but it can also cause a significant increase in load for that endpoint. Additionally, some analysis methods (such as shap and pdp) generate synthetic datasets that are sent to the endpoint. This can cause the endpoint's metrics or captured data to be contaminated by synthetic data, which may not accurately reflect real-world usage. For these reasons, it's generally not recommended to use an existing production endpoint for SageMaker Clarify analysis.

- **target_model** – The string value that is passed on to the TargetModel parameter of the SageMaker InvokeEndpoint API. Required if your model (specified by the model_name parameter) or endpoint (specified by the endpoint_name parameter) is multi-model. For more
information about multi-model endpoints, see [Host multiple models in one container behind one endpoint](#).

- **custom_attributes** – (Optional) A string that allows you to provide additional information about a request for an inference that is submitted to the endpoint. The string value is passed to the CustomAttributes parameter of the SageMaker [InvokeEndpoint](#) API.

- **content_type** – content_type – The model input format to be used for getting predictions from the endpoint. If provided, it is passed to the ContentType parameter of the SageMaker [InvokeEndpoint](#) API.

  - For computer vision explainability, the valid values are `image/jpeg`, `image/png` or `application/x-npy`. If content_type is not provided, the default value is `image/jpeg`.
  
  - For other types of explainability, the valid values are `text/csv`, application/jsonlines, and `application/json`. A value for content_type is required if the dataset_type is "application/x-parquet". Otherwise content_type defaults to the value of the dataset_type parameter.

- **accept_type** – The model output format to be used for getting predictions from the endpoint. The value for accept_type is passed to the Accept parameter of the SageMaker [InvokeEndpoint](#) API.

  - For computer vision explainability, if model_type is "OBJECT_DETECTION" then accept_type defaults to `application/json`.
  
  - For other types of explainability, the valid values are `text/csv`, application/jsonlines, and `application/json`. If a value for accept_type is not provided, accept_type defaults to the value of the content_type parameter.

- **content_template** – A template string used to construct the model input from dataset records. The parameter content_template is only used and required if the value of the content_type parameter is either `application/jsonlines` or `application/json`.

  When the content_type parameter is `application/jsonlines`, the template should have only one placeholder, $features, which is replaced by a features list at runtime. For example, if the template is "{"myfeatures":$features}" and if a record has three numeric feature values: 1, 2 and 3, then the record will be sent to the model as JSON Line 
  
  > {"myfeatures":[1,2,3]}

  When the content_type is `application/json`, the template can have either placeholder $record or records. If the placeholder is $record, a single record is replaced with a record that has the template in record_template applied to it. In this case, only a single record will
be sent to the model at a time. If the placeholder is \$records, the records are replaced by a list of records, each with a template supplied by record_template.

- **record_template** – A template string to be used to construct each record of the model input from dataset instances. It is only used and required when content_type is application/json. The template string may contain one of the following:
  - A placeholder \$features parameter that is substituted by an array of feature values. An additional optional placeholder can substitute feature column header names in \$feature_names. This optional placeholder will be substituted by an array of feature names.
  - Exactly one placeholder \$features_kvp that is substituted by the key-value pairs, feature name and feature value.
  - A feature in the headers configuration. As an example, a feature name A, notated by the placeholder syntax "\${A}" will be substituted by the feature value for A.

The value for record_template is used with content_template to construct the model input. A configuration example showing how to construct a model input using a content and record template follows.

In the following code example, the headers and features are defined as follows.

- `headers`:
  - `A`, `B`
- `features`:
  - \[[0, 1], [3, 4]\]

The example model input is as follows.

```
{
    "instances": [[0, 1], [3, 4]],
    "feature_names": ["A", "B"]
}
```

The example content_template and record_template parameter values to construct the previous example model input follows.

- **content_template**: "\{"instances\": \$records, \"feature_names\": \$feature_names\}"
- **record_template**: "\$features"

In the following code example, the headers and features are defined as follows.
The example content_template and record_template parameter values to construct the previous example model input follows.

- content_template: "$records"
- record_template: "$features_kvp"

An alternate code example to construct the previous example model input follows.

- content_template: "$records"
- record_template: "{"A": "$A", "B": "$B"}"

In the following code example, the headers and features are defined as follows.

```
{ "A": 0, "B": 1 }
```

The example content_template and record_template parameters values to construct above: the previous example model input follows.

- content_template: "$record"
- record_template: "$features_kvp"

- **label** – A zero-based integer index or JMESPath expression string used to extract predicted labels from the model output for bias analysis. If the model is multiclass and the label parameter extracts all of the predicted labels from the model output, then the following apply.
  
  - The probability parameter is required to get the corresponding probabilities (or scores) from the model output.
  - The predicted label of the highest score is chosen.

The value for label depends on the value of the accept_type parameter as follows.

- If accept_type is **text/csv**, then label is the index of any predicted labels in the model output.
- If accept_type is **application/jsonlines** or **application/json**, then label is a JMESPath expression that's applied to the model output to get the predicted labels.
• **label_headers** – An array of values that the label can take in the dataset. If bias analysis is requested, then the probability parameter is also required to get the corresponding probability values (scores) from model output, and the predicted label of the highest score is chosen. If explainability analysis is requested, the label headers are used to beautify the analysis report. A value for label_headers is required for computer vision explainability. For example, for a multiclass classification problem, if the label has three possible values, bird, cat, and dog, then label_headers should be set to ["bird","cat","dog"].

• **probability** – (Optional) A zero-based integer index or a JMESPath expression string used to extract probabilities (scores) for explainability analysis, or to choose the predicted label for bias analysis. The value of probability depends on the value of the accept_type parameter as follows.
  
  - If accept_type is **text/csv**, probability is the index of the probabilities (scores) in the model output. If probability is not provided, the entire model output is taken as the probabilities (scores).
  
  - If accept_type is JSON data (either application/jsonlines or application/json), probability should be a JMESPath expression that is used to extract the probabilities (scores) from the model output.

**Example analysis configuration files**

The following sections contain example analysis configuration files for data in CSV format, JSON Lines format, and for both natural language processing (NLP) and computer vision explainability.

**Analysis configuration for a CSV dataset**

The following examples show how to configure bias and explainability analysis for a tabular dataset in CSV format. In these examples, the incoming dataset has four feature columns, and one binary label column, Target. The contents of the dataset are as follows. A label value of 1 indicates a positive outcome. The dataset is provided to the SageMaker Clarify job by the dataset processing input.

```
"Target","Age","Gender","Income","Occupation"
0,25,0,2850,2
1,36,0,6585,0
1,22,1,1759,1
0,48,0,3446,1
...
```
The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) showing feature importance for a dataset in CSV format.

**Compute all of the pre-training bias metrics**

This example configuration shows how to measure if the previous sample dataset is favorably biased towards samples with a **Gender** value of 0. The following analysis configuration instructs the SageMaker Clarify processing job to compute all the pre-training bias metrics for the dataset.

```json
{
    "dataset_type": "text/csv",
    "label": "Target",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        }
    }
}
```

**Compute all of the post-training bias metrics**

You can compute pre-training bias metrics prior to training. However, you must have a trained model to compute post-training bias metrics. The following example output is from a binary classification model that outputs data in CSV format. In this example output, each row contains two columns. The first column contains the predicted label, and the second column contains the probability value for that label.

```
0, 0.028986845165491
1, 0.825382471084594
...
```
The following configuration example instructs the SageMaker Clarify processing job to compute all possible bias metrics using the dataset and the predictions from the model output. In the example, the model is deployed to a SageMaker endpoint `your_endpoint`.

**Note**

In the following example code, the parameter `content_type` and `accept_type` are not set. Therefore, they automatically use the value of the parameter `dataset_type`, which is `text/csv`.

```json
{
    "dataset_type": "text/csv",
    "label": "Target",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        },
        "post_training_bias": {
            "methods": "all"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "label": 0
    }
}
```

**Compute the SHAP values**

The following example analysis configuration instructs the job to compute the SHAP values designating the `Target` column as labels and all other columns as features.

```json
{
}
```
In this example, the SHAP baseline parameter is omitted and the value of the num_clusters parameter is 1. This instructs the SageMaker Clarify processor to compute one SHAP baseline sample. In this example, probability is set to 1. This instructs the SageMaker Clarify processing job to extract the probability score from the second column of the model output (using zero-based indexing).

**Compute partial dependence plots (PDPs)**

The following example shows how to view the importance of the Income feature on the analysis report using PDPs. The report parameter instructs the SageMaker Clarify processing job to generate a report. After the job completes, the generated report is saved as report.pdf to the analysis_result location. The grid_resolution parameter divides the range of the feature values into 10 buckets. Together, the parameters specified in the following example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis will show the marginal impact of Income on the predictions.

```json
{
  "dataset_type": "text/csv",
  "label": "Target",
  "methods": {
    "pdp": {
      "features": ["Income"],
      "grid_resolution": 10
    },
    "report": {
      "name": "report"
    }
  },
  "predictor": {
```

Configure a SageMaker Clarify Processing Job

5283
Compute both bias metrics and feature importance

You can combine all the methods from the previous configuration examples into a single analysis configuration file and compute them all by a single job. The following example shows an analysis configuration with all steps combined.

In this example, the probability parameter is set to 1 to indicate that probabilities are contained in the second column (using zero-based indexing). However, because bias analysis needs a predicted label, the probability_threshold parameter is set to 0.5 to convert the probability score into a binary label. In this example, the top_k_features parameter of the partials dependence plots pdp method is set to 2. This instructs the SageMaker Clarify processing job to compute partials dependence plots (PDPs) for the top 2 features with the largest global SHAP values.

```json
{
   "dataset_type": "text/csv",
   "label": "Target",
   "probability_threshold": 0.5,
   "label_values_or_threshold": [1],
   "facet": [
      {
         "name_or_index": "Gender",
         "value_or_threshold": [0]
      }
   ],
   "methods": {
      "pre_training_bias": {
         "methods": "all"
      },
      "post_training_bias": {
         "methods": "all"
      },
      "shap": {
         "num_clusters": 1
      },
      "pdp": {
         "top_k_features": 2
      }
   }
}
```
Instead of deploying the model to an endpoint, you can provide the name of your SageMaker model to the SageMaker Clarify processing job using the `model_name` parameter. The following example shows how to specify a model named `your_model`. The SageMaker Clarify processing job will create a shadow endpoint using the configuration.

```json
{
  ...
  "predictor": {
    "model_name": "your_model",
    "initial_instance_count": 1,
    "instance_type": "ml.m5.large",
    "probability": 1
  }
}
```

**Analysis configuration for a JSON Lines dataset**

The following examples show how to configure bias analysis and explainability analysis for a tabular dataset in JSON Lines format. In these examples, the incoming dataset has the same data as the previous section but they are in the SageMaker JSON Lines dense format. Each line is a valid JSON object. The key "Features" points to an array of feature values, and the key "Label" points to the ground truth label. The dataset is provided to the SageMaker Clarify job by the "dataset" processing input. For more information about JSON Lines, see [JSONLINES Request Format](#).

```json
{"Features":[25,0,2850,2],"Label":0}
{"Features":[36,0,6585,0],"Label":1}
{"Features":[22,1,1759,1],"Label":1}
{"Features":[48,0,3446,1],"Label":0}
...
The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) showing feature importance for a dataset in JSON Lines format.

**Compute pre-training bias metrics**

Specify the label, features, format, and methods to measure pre-training bias metrics for a Gender value of 0. In the following example, the headers parameter provides the feature names first. The label name is provided last. By convention, the last header is the label header.

The features parameter is set to the JMESPath expression "Features" so that the SageMaker Clarify processing job can extract the array of features from each record. The label parameter is set to JMESPath expression "Label" so that the SageMaker Clarify processing job can extract the ground truth label from each record. Use a facet name to specify the sensitive attribute, as follows.

```
{
    "dataset_type": "application/jsonlines",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "Label",
    "features": "Features",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        }
    }
}
```

**Compute all the bias metrics**

You must have a trained model to compute post-training bias metrics. The following example is from a binary classification model that outputs JSON Lines data in the example's format. Each row of the model output is a valid JSON object. The key predicted_label points to the predicted label, and the key probability points to the probability value.

```
{"predicted_label":0,"probability":0.0289868451654911}
```
You can deploy the model to a SageMaker endpoint named `your_endpoint`. The following example analysis configuration instructs the SageMaker Clarify processing job to compute all possible bias metrics for both the dataset and the model. In this example, the parameter `content_type` and `accept_type` are not set. Therefore, they are automatically set to use the value of the parameter `dataset_type`, which is `application/jsonlines`. The SageMaker Clarify processing job uses the `content_template` parameter to compose the model input, by replacing the `$features` placeholder by an array of features.

```json
{
    "dataset_type": "application/jsonlines",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "Label",
    "features": "Features",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        },
        "post_training_bias": {
            "methods": "all"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "{\"Features\":$features}"
    }
}
```

### Compute the SHAP values

Because SHAP analysis doesn’t need a ground truth label, the `label` parameter is omitted. In this example, the `headers` parameter is also omitted. Therefore, the SageMaker Clarify processing job
must generate placeholders using generic names like column_0 or column_1 for feature headers, and label0 for a label header. You can specify values for headers and for a label to improve the readability of the analysis result. Because the probability parameter is set to JMESPath expression probability, the probability value will be extracted from the model output. The following is an example to calculate SHAP values.

```json
{
   "dataset_type": "application/jsonlines",
   "features": "Features",
   "methods": {
      "shap": {
         "num_clusters": 1
      }
   },
   "predictor": {
      "endpoint_name": "your_endpoint",
      "content_template": "{\"Features\":$features\", "probability": "probability"
   }
}
```

**Compute partials dependence plots (PDPs)**

The following example shows how to view the importance of "Income" on PDP. In this example, the feature headers are not provided. Therefore, the features parameter of the pdp method must use zero-based index to refer to location of the feature column. The grid_resolution parameter divides the range of the feature values into 10 buckets. Together, the parameters in the example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis will show the marginal impact of Income on the predictions.

```json
{
   "dataset_type": "application/jsonlines",
   "features": "Features",
   "methods": {
      "pdp": {
         "features": [2],
         "grid_resolution": 10
      },
      "report": {
         "name": "report"
      }
   }
}
```
Compute both bias metrics and feature importance

You can combine all previous methods into a single analysis configuration file and compute them all by a single job. The following example shows an analysis configuration with all steps combined. In this example, the probability parameter is set. But because bias analysis needs a predicted label, the probability_threshold parameter is set to 0.5 to convert the probability score into a binary label. In this example, the top_k_features parameter of the pdp method is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the top 2 features with the largest global SHAP values.

```json
{
    "dataset_type": "application/jsonlines",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "Label",
    "features": "Features",
    "probability_threshold": 0.5,
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        },
        "post_training_bias": {
            "methods": "all"
        },
        "shap": {
            "num_clusters": 1
        }
    }
}
```
Analysis configuration for a JSON dataset

The following examples show how to configure bias and explainability analysis for a tabular dataset in JSON format. In these examples, the incoming dataset has the same data as the previous section but they are in the SageMaker JSON dense format. For more information about JSON Lines, see [JSONLINES Request Format](#).

The whole input request is valid JSON where the outer structure is a list and each element is the data for a record. Within each record, the key `Features` points to an array of feature values, and the key `Label` points to the ground truth label. The dataset is provided to the SageMaker Clarify job by the dataset processing input.

```
[  
    {"Features":[25,0,2850,2],"Label":0},  
    {"Features":[36,0,6585,0],"Label":1},  
    {"Features":[22,1,1759,1],"Label":1},  
    {"Features":[48,0,3446,1],"Label":0},  
    ...  
]
```

The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) that show feature importance for a dataset in JSON Lines format.
Compute pre-training bias metrics

Specify the label, features, format, and methods to measure pre-training bias metrics for a Gender value of 0. In the following example, the headers parameter provides the feature names first. The label name is provided last. For JSON datasets, the last header is the label header.

The features parameter is set to the JMESPath expression that extracts a 2D array or matrix. Each row in this matrix must contain the list of Features for each record. The label parameter is set to JMESPath expression that extracts a list of ground truth labels. Each element in this list must contain the label for a record.

Use a facet name to specify the sensitive attribute, as follows.

```
{
    "dataset_type": "application/json",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "}].Label",
    "features": "[*].Features",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        }
    }
}
```

Compute all the bias metrics

You must have a trained model to compute post-training bias metrics. The following code example is from a binary classification model that outputs JSON data in the example's format. In the example, each element under predictions is the prediction output for a record. The example code contains the key `predicted_label`, that points to the predicted label, and the key `probability` points to the probability value.

```
{
```
You can deploy the model to a SageMaker endpoint named your_endpoint.

In the following example, the parameter content_type and accept_type are not set. Therefore, content_type and accept_type are automatically set to use the value of the parameter dataset_type, which is application/json. The SageMaker Clarify processing job then uses the content_template parameter to compose the model input.

In the following example, the model input is composed by replacing the $records placeholder by an array of records. Then, the record_template parameter composes each record's JSON structure and replaces the $features placeholder with each record's array of features.

The following example analysis configuration instructs the SageMaker Clarify processing job to compute all possible bias metrics for both the dataset and the model.

```json
{
    "dataset_type": "application/json",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "[*].Label",
    "features": "[*].Features",
    "label_values_or_threshold": [1],
    "facet": [
      {
        "name_or_index": "Gender",
        "value_or_threshold": [0]
      }
    ],
    "methods": {
      "pre_training_bias": {
        "methods": "all"
      },
      "post_training_bias": {
        "methods": "all"
      }
    },
    "predictor": {
```
Compute the SHAP values

You don’t need to specify a label for SHAP analysis. In the following example, the headers parameter is not specified. Therefore, the SageMaker Clarify processing job will generate placeholders using generic names like column_0 or column_1 for feature headers, and label0 for a label header. You can specify values for headers and for a label to improve the readability of the analysis result.

In the following configuration example, the probability parameter is set to a JMESPath expression that extracts the probabilities from each prediction for each record. The following is an example to calculate SHAP values.

```
{
    "dataset_type": "application/json",
    "features": "[*].Features",
    "methods": {
        "shap": {
            "num_clusters": 1
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "$records",
        "record_template": "{\"Features\":$features}\",
        "label": "predictions[*].predicted_label",
        "probability": "predictions[*].probability"
    }
}
```

Compute partial dependence plots (PDPs)

The following example shows you how to view a feature importance in PDPs. In the example, the feature headers are not provided. Therefore, the features parameter of the pdp method must use zero-based index to refer to location of the feature column. The grid_resolution parameter divides the range of the feature values into 10 buckets.
Together, the parameters in the following example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis shows the marginal impact of Income on the predictions.

The following configuration example shows how to view the importance of Income on PDPs.

```
{
    "dataset_type": "application/json",
    "features": "[*].Features",
    "methods": {
        "pdp": {
            "features": [2],
            "grid_resolution": 10
        },
        "report": {
            "name": "report"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "$records",
        "record_template": "{"Features":$features}"
    }
}
```

**Compute both bias metrics and feature importance**

You can combine all previous configuration methods into a single analysis configuration file and compute them all with a single job. The following example shows an analysis configuration with all steps combined.

In this example, the probability parameter is set. Because bias analysis needs a predicted label, the probability_threshold parameter is set to 0.5, which is used to convert the probability score into a binary label. In this example, the top_k_features parameter of the pdp method is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the top 2 features with the largest global SHAP values.

```
{
    "dataset_type": "application/json",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "[*].Label",
}
```
"features": ":Features",
"probability_threshold": 0.5,
"label_values_or_threshold": [1],
"facet": [
  {
    "name_or_index": "Gender",
    "value_or_threshold": [0]
  }
],
"methods": {
  "pre_training_bias": {
    "methods": "all"
  },
  "post_training_bias": {
    "methods": "all"
  },
  "shap": {
    "num_clusters": 1
  },
  "pdp": {
    "top_k_features": 2,
    "grid_resolution": 10
  },
  "report": {
    "name": "report"
  }
},
"predictor": {
  "endpoint_name": "your_endpoint",
  "content_template": "$records",
  "record_template": "\{"Features":$features\}",
  "probability": "predictions[*].probability"
}

**Analysis configuration for natural language processing explainability**

The following example shows an analysis configuration file for computing feature importance for natural language processing (NLP). In this example, the incoming dataset is a tabular dataset in CSV format, with one binary label column and two feature columns, as follows. The dataset is provided to the SageMaker Clarify job by the dataset processing input parameter.

0,2,"They taste gross"
In this example, a binary classification model was trained on the previous dataset. The model accepts CSV data, and it outputs a single score between 0 and 1, as follows.

<table>
<thead>
<tr>
<th>Score 1</th>
<th>Score 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.491656005382537</td>
<td>0.569582343101501</td>
</tr>
</tbody>
</table>

The model is used to create a SageMaker model named “your_model”. The following analysis configuration shows how to run a token-wise explainability analysis using the model and dataset. The text_config parameter activates the NLP explainability analysis. The granularity parameter indicates that the analysis should parse tokens.

In English, each token is a word. The following example also shows how to provide an in-place SHAP "baseline" instance using an average "Rating" of 4. A special mask token "[MASK]" is used to replace a token (word) in "Comments". This example also uses a GPU endpoint instance type to speed up inferencing.

```json
{
  "dataset_type": "text/csv",
  "headers": ["Target","Rating","Comments"]
  "label": "Target",
  "methods": {
    "shap": {
      "text_config": {
        "granularity": "token",
        "language": "english"
      }
      "baseline": [[4,"[MASK]"],
      },
    "predictor": {
      "model_name": "your_nlp_model",
      "initial_instance_count": 1,
      "instance_type": "ml.g4dn.xlarge"
    }
  }
}
```
Analysis configuration for computer vision explainability

The following example shows an analysis configuration file computing feature importance for computer vision. In this example, the input dataset consists of JPEG images. The dataset is provided to the SageMaker Clarify job by the dataset processing input parameter. The example shows how to configure an explainability analysis using a SageMaker image classification model. In the example, a model named `your_cv_ic_model`, has been trained to classify the animals on the input JPEG images.

```json
{
    "dataset_type": "application/x-image",
    "methods": {
        "shap": {
            "image_config": {
                "model_type": "IMAGE_CLASSIFICATION",
                "num_segments": 20,
                "segment_compactness": 10
            }
        },
        "report": {
            "name": "report"
        }
    },
    "predictor": {
        "model_name": "your_cv_ic_model",
        "initial_instance_count": 1,
        "instance_type": "ml.p2.xlarge",
        "label_headers": ["bird","cat","dog"]
    }
}
```

For more information about image classification, see [Image Classification - MXNet](https://aws.amazon.com/sagemaker/image-classification-mxnet/).

In this example, a SageMaker object detection model, `your_cv_od_model` is trained on the same JPEG images to identify the animals on them. The following example shows how to configure an explainability analysis for the object detection model.

```json
{
    "dataset_type": "application/x-image",
    "probability_threshold": 0.5,
    "methods": {
        "shap": {
```
Data Format Compatibility Guide

This guide describes the data format types that are compatible with SageMaker Clarify processing jobs. The supported data format types include the file extensions, data structure, and specific requirements or restrictions for tabular and image datasets. This guide also shows how to check if your dataset conforms to these requirements.

At a high level, the SageMaker Clarify processing job follows the input–process–output model to compute bias metrics and feature attributions. Refer to the following examples for details.

The input to the SageMaker Clarify processing job consists of the following:

- The dataset to be analyzed.
- The analysis configuration. For more information about how to configure an analysis, see Configure the Analysis.

During the processing stage, SageMaker Clarify computes bias metrics and feature attributions. The SageMaker Clarify processing job completes the following steps in the backend:

- The SageMaker Clarify processing job parses your analysis configuration and loads your dataset.
• To compute post-training bias metrics and feature attributions, the job requires model predictions from your model. The SageMaker Clarify processing job serializes your data and sends it as a request to your model that is deployed on a SageMaker real-time inference endpoint. After that, the SageMaker Clarify processing job extracts predictions from the response.

• The SageMaker Clarify processing job performs the bias and explainability analysis, and then it outputs the results.

For more information, see How SageMaker Clarify Processing Jobs Work.

The parameter that you use to specify the format of the data depends on where the data is used in the processing flow as follows:

• For an input dataset, use the dataset_type parameter to specify the format or MIME type.
• For a request to an endpoint, use the content_type parameter to specify the format.
• For a response from an endpoint, use the accept_type parameter to specify the format.

The input dataset, request, and the response to and from the endpoint don't require the same format. For example, you can use a Parquet dataset with a CSV request payload and a JSON Lines response payload given the following conditions.

• Your analysis is configured correctly.
• Your model supports the request and response formats.

Note

If content_type or accept_type are not provided, then the SageMaker Clarify container infers the content_type and accept_type.

Topics

• Tabular data
• Image data
Tabular data

Tabular data refers to data that can be loaded into a two-dimensional data frame. In the frame, each row represents a record, and each record has one or more columns. The values within each data frame cell can be of numerical, categorical, or text data types.

Tabular dataset prerequisites

Prior to analysis, your dataset should have had any necessary pre-processing steps already applied. This includes data cleaning or feature engineering.

You can provide one or multiple datasets. If you provide multiple datasets, use the following to identify them to the SageMaker Clarify processing job.

- Use either a ProcessingInput named dataset or the analysis configuration dataset_uri to specify the main dataset. For more information about dataset_uri, see the parameters list in Configure the Analysis.
- Use the baseline parameter provided in the analysis configuration file. The baseline dataset is required for SHAP analysis. For more information about the analysis configuration file, including examples, see Configure the Analysis.

The following table lists supported data formats, their file extensions, and MIME types.

<table>
<thead>
<tr>
<th>Data format</th>
<th>File extension</th>
<th>MIME type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>csv</td>
<td>text/csv</td>
</tr>
<tr>
<td>JSON Lines</td>
<td>jsonl</td>
<td>application/jsonl</td>
</tr>
<tr>
<td>JSON</td>
<td>json</td>
<td>application/json</td>
</tr>
<tr>
<td>Parquet</td>
<td>parquet</td>
<td>&quot;application/x-parquet&quot;</td>
</tr>
</tbody>
</table>

The following sections show example tabular datasets in CSV, JSON Lines, and Apache Parquet formats.
Tabular dataset prerequisites in CSV format

The SageMaker Clarify processing job is designed to load CSV data files in the `csv.excel` dialect. However, it's flexible enough to support other line terminators, including `\n` and `\r`.

For compatibility, all CSV data files provided to the SageMaker Clarify processing job must be encoded in UTF-8.

If your dataset does not contain a header row, do the following:

- Set the analysis configuration label to index 0. This means that the first column is the ground truth label.
- If the parameter headers is set, set `label` to the label column header to indicate the location of the label column. All other columns are designated as features.

The following is an example of a dataset that does not contain a header row.

```
1,5,2.8,2.538,This is a good product
0,1,0.79,0.475,Bad shopping experience
...```

If your data contains a header row, set the parameter `label` to index 0. To indicate the location of the label column, use the ground truth label header `Label`. All other columns are designated as features.

The following is an example of a dataset that contains a header row.

```
Label,Rating,A12,A13,Comments
1,5,2.8,2.538,This is a good product
0,1,0.79,0.475,Bad shopping experience
...```

Tabular dataset prerequisites in JSON format

JSON is a flexible format for representing structured data that contains any level of complexity. The SageMaker Clarify support for JSON is not restricted to any specific format and thus allows for more flexible data formats in comparison to datasets in CSV or JSON Lines formats. This guide shows you how to set an analysis configuration for tabular data in JSON format.
Note

To ensure compatibility, all JSON data files provided to the SageMaker Clarify processing job must be encoded in UTF-8.

The following is example input data with records that contain a top-level key, a list of features, and a label.

```
[
    {
        "features": [1, 5, 2.8, 2.538, "This is a good product"],
        "label": 1,
    },
    {
        "features": [0, 1, 0.79, 0.475, "Bad shopping experience"],
        "label": 0,
    }, ...
]
```

An example configuration analysis for the previous input example dataset should set the following parameters:

- The `label` parameter should use the JMESPath expression `[*].label` to extract the ground truth label for each record in the dataset. The JMESPath expression should produce a list of labels where the i-th label corresponds to the i-th record.
- The `features` parameter should use the JMESPath expression `[*].features` to extract an array of features for each record in the dataset. The JMESPath expression should produce a 2D array or matrix where the i-th row contains the feature values for corresponding to the i-th record.

The following is example input data with records that contain a top-level key and a nested key that contains a list of features and labels for each record.

```
{
    "data": [
        {
            "features": [1, 5, 2.8, 2.538, "This is a good product"],
            "label": 1,
        },
        {
            "features": [0, 1, 0.79, 0.475, "Bad shopping experience"],
            "label": 0
        }
    ]
}
```

An example configuration analysis for the previous input example dataset should set the following parameters:
The label parameter uses the JMESPath expression `data[*].label` to extract the ground truth label for each record in the dataset. The JMESPath expression should produce a list of labels where the \(i\)th label is for the \(i\)th record.

The features parameter uses the JMESPath expression `data[*].features` to extract the array of features, for each record in the dataset. The JMESPath expression should produce a 2D array or matrix where the \(i\)th row contains the feature values for the \(i\)th record.

### Tabular dataset prerequisites in JSON Lines format

JSON Lines is a text format for representing structured data where each line is a valid JSON object. Currently SageMaker Clarify processing jobs only support SageMaker Dense Format JSON Lines. To conform to the required format, all of the features of a record should be listed in a single JSON array. For more information about JSON Lines, see [JSONLINES Request Format](#).

**Note**

All JSON Lines data files provided to the SageMaker Clarify processing job must be encoded in UTF-8 to ensure compatibility.

The following is an example of how to set an analysis configuration for a record that contains a top-level key and a list of elements.

```json
{"features":[1,5,2.8,2.538,"This is a good product"],"label":1}
{"features":[0,1,0.79,0.475,"Bad shopping experience"],"label":0}
...
```

The configuration analysis for the previous dataset example should set the parameters as follows:

- To indicate the location of the ground truth label, the parameter `label` should be set to the JMESPath expression `label`.
- To indicate the location of the array of features, the parameter `features` should be set to the JMESPath expression `features`.

The following is an example of how to set an analysis configuration for a record that contains a top-level key and a nested key that contains a list of elements.

```json
{"data":{"features":[1,5,2.8,2.538,"This is a good product"],"label":1}}
```
The configuration analysis for the previous dataset example should set the parameters as follows:

- The parameter `label` should be set to the JMESPath expression `data.label` to indicate the location of the ground truth label.
- The parameter `features` should be set to the JMESPath expression `data.features` to indicate the location of the array of features.

**Tabular dataset prerequisites in Parquet format**

Parquet is a column-oriented binary data format. Currently, SageMaker Clarify processing jobs support loading Parquet data files only when the processing instance count is 1.

Because SageMaker Clarify processing jobs don't support endpoint request or endpoint response in Parquet format, you must specify the data format of the endpoint request by setting the analysis configuration parameter `content_type` to a supported format. For more information, see `content_type` in Configure the Analysis.

The Parquet data must have column names that are formatted as strings. Use the analysis configuration `label` parameter to set the label column name to indicate the location of the ground truth labels. All other columns are designated as features.

**Endpoint requests for tabular data**

To obtain model predictions for post-training bias analysis and feature importance analysis, SageMaker Clarify processing jobs serialize the tabular data into bytes and sends these to an inference endpoint as a request payload. This tabular data is either sourced from the input dataset, or it's generated. If it's synthetic data, it's generated by the explainer for SHAP analysis or PDP analysis.

The data format of the request payload should be specified by the analysis configuration `content_type` parameter. If the parameter is not provided, the SageMaker Clarify processing job will use the value of the `dataset_type` parameter as the content type. For more information about `content_type` or `dataset_type`, see Configure the Analysis.

The following sections show example endpoint requests in CSV and JSON Lines formats.
Endpoint request in CSV format

The SageMaker Clarify processing job can serialize data to CSV format (MIME type: text/csv). The following table shows examples of the serialized request payloads.

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'1,2,3,4'</td>
<td>Single record (four numerical features).</td>
</tr>
<tr>
<td>'1,2,3,4\n5,6,7,8'</td>
<td>Two records, separated by line break '\n'.</td>
</tr>
<tr>
<td>&quot;&quot;This is a good product&quot;,5'</td>
<td>Single record (a text feature and a numerical feature).</td>
</tr>
<tr>
<td>&quot;&quot;This is a good product&quot;,5&quot;Bad shopping experience&quot;,1'</td>
<td>Two records.</td>
</tr>
</tbody>
</table>

Endpoint request is in JSON Lines format

The SageMaker Clarify processing job can serialize data to SageMaker JSON Lines dense format (MIME type: application/jsonlines). For more information about JSON Lines, see JSONLINES Request Format.

To transform tabular data into JSON data, provide a template string to the analysis configuration content_template parameter. For more information about content_template see Configure the Analysis. The following table shows examples of serialized JSON Lines request payloads.

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}},'</td>
<td>Single record. In this case, the template looks like '{&quot;data&quot;:{&quot;features&quot;:$features}},{' and $features is replaced by the list of features [1,2,3,4] .</td>
</tr>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}\n{&quot;data&quot;:{&quot;features&quot;:[5,6,7,8]}},'</td>
<td>Two records.</td>
</tr>
</tbody>
</table>
### Endpoint request payload (string representation)

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'{&quot;features&quot;:[&quot;This is a good product&quot;,5]}'</td>
<td>Single record. In this case, the template looks like '{&quot;features&quot;:$features}' and $features is replaced by the list of features [&quot;This is a good product&quot;,5].</td>
</tr>
</tbody>
</table>
| '{"features":["This is a good product",5]}
{"features":["Bad shopping experience",1]}'| Two records. |

### Endpoint request is in JSON format

A SageMaker Clarify processing job can serialize data to arbitrary JSON structures (MIME type: application/json). To do this, you must provide a template string to the analysis configuration content_template parameter. This is used by the SageMaker Clarify processing job to construct the outer JSON structure. You must also provide a template string for record_template, which is used to construct the JSON structure for each record. For more information about content_template and record_template, see [Configure the Analysis](#).

### Note

Because content_template and record_template are string parameters, any double quote characters (")) that are part of the JSON serialized structure should be noted as an escaped character in your configuration. For example, if you want to escape a double quote in Python, you could enter the following for content_template.

```
"{"data":{"features":$record}}"
```

The following table shows examples of serialized JSON request payloads and the corresponding content_template and record_template parameters that are required to construct them.
## Endpoint response for tabular data

After the SageMaker Clarify processing job receives an inference endpoint invocation's response, it deserializes the response payload and extracts predictions from it. Use the analysis configuration `accept_type` parameter to specify the data format of the response payload. If `accept_type` is not provided, the SageMaker Clarify processing job will use the value of the `content_type` parameter as the model output format. For more information about `accept_type`, see [Configure the Analysis](#configure-the-analysis).

The predictions could either consist of predicted labels for bias analysis, or probability values (scores) for feature importance analysis. In the `predictor` analysis configuration, the following three parameters extract the predictions.

- The parameter `probability` is used to locate the probability values (scores) in the endpoint response.
• The parameter `label` is used to locate the predicted labels in the endpoint response.
• (Optional) The parameter `label_headers` provides the predicted labels for a multiclass model.

The following guidelines pertain to endpoint responses in CSV, JSON Lines, and JSON formats.

**Endpoint Response is in CSV format**

If the response payload is in CSV format (MIME type: `text/csv`), the SageMaker Clarify processing job deserializes each row. It then extracts the predictions from the deserialized data using the column indexes provided in the analysis configuration. The rows in the response payload must match the records in the request payload.

The following tables provide examples of response data in different formats and for different problem types. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

The following sections show example endpoint responses in CSV formats.

**Endpoint response is in CSV format and contains probability only**

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record.</td>
<td>'0.6'</td>
</tr>
<tr>
<td>Two records (results in one line, divided by comma).</td>
<td>'0.6,0.3'</td>
</tr>
<tr>
<td>Two records (results in two lines).</td>
<td>'0.6\n0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs a single probability value (score) of the predicted label. To extract probabilities using the index and use them for feature importance analysis, set the analysis configuration parameter `probability` to column index 0. These probabilities can also be used for bias analysis if they're converted to binary value by using the `probability_threshold` parameter. For more information about `probability_threshold`, see [Configure the Analysis](#).
The following table is an example endpoint response for a multiclass problem.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record of a multiclass model (three classes).</td>
<td>'0.1,0.6,0.3'</td>
</tr>
<tr>
<td>Two records of a multiclass model (three classes).</td>
<td>'0.1,0.6,0.3\n0.2,0.5,0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs a list of probabilities (scores). If no index is provided, all values are extracted and used for feature importance analysis. If the analysis configuration parameter `label_headers` is provided. Then the SageMaker Clarify processing job can select the label header of the max probability as the predicted label, which can be used for bias analysis. For more information about `label_headers`, see [Configure the Analysis](#).

## Endpoint response is in CSV format and contains predicted label only

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1'</td>
</tr>
<tr>
<td>Two records (results in one line, divided by comma)</td>
<td>'1,0'</td>
</tr>
<tr>
<td>Two records (results in two lines)</td>
<td>'1\n0'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs the predicted label instead of probability. Set the `label` parameter of the `predictor` configuration to column index 0 so that the predicted labels can be extracted using the index and used for bias analysis.
**Endpoint response is in CSV format and contains predicted label and probability**

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1,0.6'</td>
</tr>
<tr>
<td>Two records</td>
<td>'1,0.6\n0,0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs the predicted label followed by its probability. Set the `label` parameter of the `predictor` configuration to column index 0, and set `probability` to column index 1 to extract both parameter values.

**Endpoint response is in CSV format and contains predicted labels and probabilities (multiclass)**

A multiclass model trained by Amazon SageMaker Autopilot can be configured to output the string representation of the list of predicted labels and probabilities. The following example table shows an example endpoint response from a model that is configured to output `predicted_label`, `probability`, `labels`, and `probabilities`.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;&quot;dog&quot;,0.6,&quot;['cat', 'dog', 'fish']&quot;,&quot;[0.1, 0.6, 0.3]&quot;&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;&quot;dog&quot;,0.6,&quot;['cat', 'dog', 'fish']&quot;,&quot;[0.1, 0.6, 0.3]\n&quot;&quot;cat&quot;,0.7,&quot;['cat', 'dog', 'fish']&quot;,&quot;[0.7, 0.2, 0.1]&quot;&quot;</td>
</tr>
</tbody>
</table>

For the previous example, the SageMaker Clarify processing job can be configured in the following ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.
• Set the label parameter of the predictor configuration to 0 to extract the predicted label.

• Set the parameter to 2 to extract the predicted labels, and set probability to 3 to extract the corresponding probabilities. The SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value. Referring to the previous example of a single record, the model predicts three labels: cat, dog, and fish, with corresponding probabilities of 0.1, 0.6, and 0.3. Based on these probabilities, the predicted label is dog, as it has the highest probability value of 0.6.

• Set probability to 3 to extract the probabilities. If label_headers is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label header with the highest probability value.

For feature importance analysis, the previous example can be configured as follows.

• Set probability to 3 extract the probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels. If the customer doesn’t specify label_headers, then the predicted labels will be used as label headers in the analysis report.

**Endpoint Response is in JSON Lines format**

If the response payload is in JSON Lines format (MIME type: application/jsonlines), the SageMaker Clarify processing job deserializes each line as JSON. It then extracts predictions from the deserialized data using JMESPath expressions provided in analysis configuration. The lines in the response payload must match the records in the request payload. The following tables shows examples of response data in different formats. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

The following sections show example endpoint responses in JSON Lines formats.

**Endpoint response is in JSON Lines format and contains probability only**

The following table is an example endpoint response that only outputs the probability value (score).

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;score&quot;:0.6}'</td>
</tr>
</tbody>
</table>
For the previous example, set the analysis configuration parameter `probability` to JMESPath expression "score" to extract its value.

### Endpoint response is in JSON Lines format and contains predicted label only

The following table is an example endpoint response that only outputs the predicted label.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;prediction&quot;:1}'</td>
</tr>
</tbody>
</table>
| Two records              | '{"prediction":1}""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""""
|                          | "prediction":0}'                                 |

For the previous example, set the `label` parameter of the predictor configuration to JMESPath expression `prediction`. Then, the SageMaker Clarify processing job can extract the predicted labels for bias analysis. For more information, see Configure the Analysis.

### Endpoint response is in JSON Lines format and contains predicted label and probability

The following table is an example endpoint response that outputs the predicted label and its score.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;prediction&quot;:1,&quot;score&quot;:0.6}'</td>
</tr>
</tbody>
</table>
| Two records              | '{"prediction":1,"score":0.6}
|                          | "prediction":0,"score":0.3}'                    |
For the previous example, set the label parameter of the predictor configuration to JMESPath expression "prediction" to extract the predicted labels. Set probability to JMESPath expression "score" to extract the probability. For more information, see Configure the Analysis.

Endpoint response is in JSON Lines format and contains predicted labels and probabilities (multiclass)

The following table is an example endpoint response from a multiclass model that outputs the following:

- A list of predicted labels.
- Probabilities, and the selected predicted label and its probability.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6,&quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.1,0.6,0.3]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6,&quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.1,0.6,0.3]}\n{&quot;predicted_label&quot;:&quot;cat&quot;,&quot;probability&quot;:0.7,&quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.7,0.2,0.1]}'</td>
</tr>
</tbody>
</table>

For the previous example, the SageMaker Clarify processing job can be configured in several ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.

- Set the label parameter of the predictor configuration to JMESPath expression "predicted_label" to extract the predicted label.
- Set the parameter to JMESPath expression "predicted_labels" to extract the predicted labels. Set probability to JMESPath expression "probabilities" to extract their probabilities. The SageMaker Clarify job automatically determine the predicted label by identifying the label with the highest probability value.
Set probability to JMESPath expression "probabilities" to extract their probabilities. If label_headers is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value.

For feature importance analysis, do the following.

Set probability to the JMESPath expression "probabilities" to extract their probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels.

**Endpoint Response is in JSON format**

If the response payload is in JSON format (MIME type: application/json), the SageMaker Clarify processing job deserializes the entire payload as JSON. It then extracts predictions from the deserialized data using JMESPath expressions provided in the analysis configuration. The records in the response payload must match the records in the request payload.

The following sections show example endpoint responses in JSON formats. The sections contain tables with examples of response data in different formats and for different problem types. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

**Endpoint response is in JSON format and contains probability only**

The following table is an example response from an endpoint that only outputs the probability value (score).

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'[0.6]'</td>
</tr>
<tr>
<td>Two records</td>
<td>'[0.6,0.3]'</td>
</tr>
</tbody>
</table>

For the previous example, there is no line break in the response payload. Instead, a single JSON object contains a list of scores, one for each record in the request. Set the analysis configuration parameter probability to JMESPath expression "[*]" to extract the value.
Endpoint response is in JSON format and contains predicted label only

The following table is an example response from an endpoint that only outputs the predicted label.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predicted_labels&quot;:[1]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predicted_labels&quot;:[1,0]}'</td>
</tr>
</tbody>
</table>

Set the label parameter of the predictor configuration to JMESPath expression "predicted_labels", and then the SageMaker Clarify processing job can extract the predicted labels for bias analysis.

Endpoint response is JSON format and contains predicted label and probability

The following table is an example response from an endpoint that outputs the predicted label and its score.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predictions&quot;:[{&quot;label&quot;:1,&quot;score&quot;:0.6}]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predictions&quot;:[{&quot;label&quot;:1,&quot;score&quot;:0.6},{&quot;label&quot;:0,&quot;score&quot;:0.3}]}'</td>
</tr>
</tbody>
</table>

For the previous example, set the label parameter of the predictor configuration to the JMESPath expression "predictions[*].label" to extract the predicted labels. Set probability to JMESPath expression "predictions[*].score" to extract the probability.

Endpoint response is in JSON format and contains predicted labels and probabilities (multiclass)

The following table is an example response from an endpoint that from a multiclass model that outputs the following:
- A list of predicted labels.
- Probabilities, and the selected predicted label and its probability.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'[[&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6, &quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.1,0.6,0.3]]]'</td>
</tr>
<tr>
<td>Two records</td>
<td>'[[&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6, &quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.1,0.6,0.3]],&quot;predicted_label&quot;: &quot;cat&quot;,&quot;probability&quot;:0.7,&quot;predicted_labels&quot;:[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;:[0.7,0.2,0.1]]]'</td>
</tr>
</tbody>
</table>

The SageMaker Clarify processing job can be configured in several ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.

- Set the `label` parameter of the `predictor` configuration to JMESPath expression `"[*].predicted_label"` to extract the predicted label.
- Set the parameter to JMESPath expression `"[*].predicted_labels"` to extract the predicted labels. Set `probability` to JMESPath expression `"[*].probabilities"` to extract their probabilities. The SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest proximity value.
- Set `probability` to JMESPath expression `"[*].probabilities"` to extract their probabilities. If `label_headers` is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value.

For feature importance analysis, set `probability` to JMESPath expression `"[*].probabilities"` to extract their probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels.
Pre-check endpoint request and response for tabular data

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests and responses to make sure that both are compliant with the requirements in the Endpoint requests for tabular data section and the Endpoint response for tabular data section. If your model container supports batch requests, you can start with a single record request, and then try two or more records.

The following commands show how to request a response using the AWS CLI. The AWS CLI is pre-installed in SageMaker Studio Classic, and SageMaker Notebook instances. If you must to install the AWS CLI, follow this installation guide.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name $ENDPOINT_NAME \
  --content-type $CONTENT_TYPE \
  --accept $ACCEPT_TYPE \
  --body $REQUEST_DATA \
  $CLI_BINARY_FORMAT \
  /dev/stderr 1>/dev/null
```

The parameters are defined, as follows.

- `$ENDPOINT_NAME` – The name of the endpoint.
- `$CONTENT_TYPE` – The MIME type of the request (model container input).
- `$ACCEPT_TYPE` – The MIME type of the response (model container output).
- `$REQUEST_DATA` – The requested payload string.
- `$CLI_BINARY_FORMAT` – The format of the command line interface (CLI) parameter. For AWS CLI v1, this parameter should remain blank. For v2, this parameter should be set to `--cli-binary-format raw-in-base64-out`.

**Note**

AWS CLI v2 passes binary parameters as base64-encoded strings by default.

The following request and response examples to and from the endpoint use AWS CLI v1.
Endpoint request and response in CSV format

In the following code example, the request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-sagemaker-xgboost-model \
   --content-type text/csv \
   --accept text/csv \
   --body '1,2,3,4' \
   /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.6
```

In the following code example, the request consists of two records, and the response includes their probabilities, which are separated by a comma.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-sagemaker-xgboost-model \
   --content-type text/csv \
   --accept text/csv \
   --body $'1,2,3,4\n5,6,7,8' \
   /dev/stderr 1>/dev/null
```

From the previous code example, the "content" expression in the --body tells the command to interpret '\n' in the content as a line break. The response output follows.

```
0.6,0.3
```

In the following code example, the request consists of two records, the response includes their probabilities, separated with a line break.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-1 \
   --content-type text/csv \
   --accept text/csv \
   --body $'1,2,3,4\n5,6,7,8' \
   /dev/stderr 1>/dev/null
```
From the previous code example, the response output follows.

```
0.6
0.3
```

In the following code example, the request consists of a single record, and the response is probability values from a multiclass model containing three classes.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
  --body '1,2,3,4' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.1,0.6,0.3
```

In the following code example, the request consists of two records, and the response includes their probability values from a multiclass model containing three classes.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8'$ \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.1,0.6,0.3
0.2,0.5,0.3
```

In the following code example, the request consists of two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-2 \
```
---content-type text/csv \
--accept text/csv \
--body $'1,2,3,4\n5,6,7,8' \ 
/dev/stderr 1>/dev/null

From the previous code example, the response output follows.

1,0.6
0,0.3

In the following code example, the request consists of two records and the response includes label headers and probabilities.

aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-csv-3 \ 
--content-type text/csv \
--accept text/csv \ 
--body $'1,2,3,4\n5,6,7,8' \ 
/dev/stderr 1>/dev/null

From the previous code example, the response output follows.

"['cat','dog','fish'],[0.1,0.6,0.3]"
"['cat','dog','fish'],[0.2,0.5,0.3]"

Endpoint request and response in JSON Lines format

In the following code example, the request consists of a single record and the response is its probability value.

aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines \ 
--content-type application/jsonlines \ 
--accept application/jsonlines \ 
--body '{"features":["This is a good product",5]}' \ 
/dev/stderr 1>/dev/null

From the previous code example, the response output follows.

{"score":0.6}
In the following code example, the request contains two records, and the response includes predicted label and probability.

```bash
aws sagemaker-runtime invoke-endpoint
    --endpoint-name test-endpoint-jsonlines-2
    --content-type application/jsonlines
    --accept application/jsonlines
    --body '${"features":[1,2,3,4]
             "features":[5,6,7,8]}'
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```json
{"predicted_label":1,"probability":0.6}
{"predicted_label":0,"probability":0.3}
```

In the following code example, the request contains two records, and the response includes label headers and probabilities.

```bash
aws sagemaker-runtime invoke-endpoint
    --endpoint-name test-endpoint-jsonlines-3
    --content-type application/jsonlines
    --accept application/jsonlines
    --body '${"data":{"features":[1,2,3,4]}}
            "data":{"features":[5,6,7,8]}}'
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```json
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}
```

**Endpoint request and response in mixed formats**

In the following code example, the request is in CSV format and the response is in JSON Lines format.

```bash
aws sagemaker-runtime invoke-endpoint
    --endpoint-name test-endpoint-csv-in-jsonlines-out
    --content-type text/csv
    --accept application/jsonlines
    --body $'1,2,3,4
            5,6,7,8'
```

Configure a SageMaker Clarify Processing Job
From the previous code example, the response output follows.

```json
{"probability":0.6}
{"probability":0.3}
```

In the following code example, the request is in JSON Lines format and the response is in CSV format.

```bash
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-jsonlines-in-csv-out \
   --content-type application/jsonlines \
   --accept text/csv \
   --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}'
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.6
0.3
```

In the following code example, the request is in CSV format and the response is in JSON format.

```bash
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-in-jsonlines-out \
   --content-type text/csv \
   --accept application/jsonlines \
   --body "$'1,2,3,4\n5,6,7,8'"
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```json
{"predictions":[{"label":1,"score":0.6},{"label":0,"score":0.3}]}
```

**Image data**

A SageMaker Clarify processing job provides support for explaining images. This topic provides the data format requirements for image data. For more information, see [computer vision](#).
**Image dataset prerequisites**

An image dataset contains one or more image files. To identify an input dataset to the SageMaker Clarify processing job, set either a `ProcessingInput` named `dataset` or the analysis configuration `dataset_uri` parameter to an Amazon S3 URI prefix of your image files.

The supported image file formats and file extensions are listed in the following table.

<table>
<thead>
<tr>
<th>Image format</th>
<th>File extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>JPEG</td>
<td>jpg, jpeg</td>
</tr>
<tr>
<td>PNG</td>
<td>png</td>
</tr>
</tbody>
</table>

Set the analysis configuration `dataset_type` parameter to `application/x-image`. Because the type is not a specific image file format, the `content_type` will be used to decide the image file format and extension.

The SageMaker Clarify processing job loads each image file to a 3-dimensional NumPy array for further processing. The three dimensions include height, width, and RGB values of each pixel.

**Endpoint request for image data**

The SageMaker Clarify processing job converts the raw RGB data of an image into a compatible image format, such as JPEG. It does this before it sends the data to the endpoint for predictions. The supported image formats are as follows.

<table>
<thead>
<tr>
<th>Data Format</th>
<th>MIME type</th>
<th>File extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>JPEG</td>
<td>image/jpeg</td>
<td>jpg, jpeg</td>
</tr>
<tr>
<td>PNG</td>
<td>image/png</td>
<td>png</td>
</tr>
<tr>
<td>NPY</td>
<td>application/x-npy</td>
<td>All above</td>
</tr>
</tbody>
</table>

Specify the data format of the request payload by using the analysis configuration parameter `content_type`. If the `content_type` is not provided, the data format defaults to `image/jpeg`. 
Endpoint response for image data

Upon receiving the response of an inference endpoint invocation, the SageMaker Clarify processing job deserializes response payload and then extracts the predictions from it.

Image classification problem

The data format of the response payload should be specified by the analysis configuration parameter accept_type. If accept_type is not provided, the data format defaults to application/json. The supported formats are the same as those described in the Endpoint response for tabular data in the tabular data section.

See Inference with the Image Classification Algorithm for an example of a SageMaker built-in image classification algorithm that accepts a single image and then returns an array of probability values (scores), each for a class.

As shown in the following table, when the content_type parameter is set to application/jsonlines, the response is a JSON object.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image</td>
<td>'{&quot;prediction&quot;:[0.1,0.6,0.3]}'</td>
</tr>
</tbody>
</table>

In the previous example, set the probability parameter to JMESPath expression "prediction" to extract the scores.

When the content_type is set to application/json, the response is a JSON object, as shown in the following table.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image</td>
<td>'[0.1,0.6,0.3]'</td>
</tr>
</tbody>
</table>

In the previous example, set probability to JMESPath expression "[*]" to extract all the elements of the array. In the previous example, [0.1, 0.6, 0.3] is extracted. Alternatively, if you skip
setting the probability configuration parameter, then all the elements of the array are also extracted. This is because the entire payload is deserialized as the predictions.

### Object detection problem

The analysis configuration accept_type defaults to application/json and the only supported format is the Object Detection Inference Format. For more information about response formats, see [Response Formats](#).

The following table is an example response from an endpoint that outputs an array. Each element of the array is an array of values containing the class index, the confidence score, and the bounding box coordinates of the detected object.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image (one object)</td>
<td>'[[4.0, 0.8641945540949988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244]]'</td>
</tr>
<tr>
<td>Single image (two objects)</td>
<td>'[[4.0, 0.8641945540949988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244],[0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475]]'</td>
</tr>
</tbody>
</table>

The following table is an example response from an endpoint that outputs a JSON object with a key referring to the array. Set the analysis configuration probability to the key "prediction" to extract the values.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image (one object)</td>
<td>'{&quot;prediction&quot;:[[4.0, 0.8641945540949988, 0.3088374733924866, 0.07030484080314636]]}'</td>
</tr>
</tbody>
</table>

Configure a SageMaker Clarify Processing Job
### Pre-check endpoint request and response for image data

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests and responses. Make sure that both are compliant with the requirements in the **Endpoint request for image data** section and **Endpoint response for image data** section.

The following are two code examples showing how to send requests and examine the responses for both image classification and object detection problems.

#### Image classification problem

The following example code instructs an endpoint to read a PNG file and then classifies it.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-image-classification \
  --content-type "image/png" \
  --accept "application/json" \
  --body fileb://./test.png \
  /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
[0.1, 0.6, 0.3]
```
Object detection problem

The following example code instructs an endpoint to read a JPEG file and then detects the objects in it.

```
aws sagemaker-runtime invoke-endpoint
   --endpoint-name test-endpoint-sagemaker-object-detection
   --content-type "image/jpg"
   --accept "application/json"
   --body fileb://./test.jpg
   /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
{"prediction":[[4.0, 0.8641945540904998, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244], [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475], [4.0, 0.32643985450267792, 0.034883320331573486, 0.6318609714508057, 0.5967587828636169], [8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051, 0.8985623121261597], [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702, 0.39093565940856934, 0.9574796557426453]]}
```

Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

To analyze your data and models for bias and explainability using SageMaker Clarify, you must configure a SageMaker Clarify processing job. This guide shows how to configure the job inputs, outputs, resources, and analysis configuration using the SageMaker Python SDK API `SageMakerClarifyProcessor`.

The API acts as a high-level wrapper of the SageMaker `CreateProcessingJob` API. It hides many of the details that are involved in setting up a SageMaker Clarify processing job. The details to set up a job include retrieving the SageMaker Clarify container image URI and generating the analysis configuration file. The following steps show you how to configure, initialize and launch a SageMaker Clarify processing job.

Configure a SageMaker Clarify processing job using the API

1. Define the configuration objects for each portion of the job configuration. These portions can include the following:
The configuration objects for a SageMaker Clarify processing job vary for different types of data formats and use cases. Configuration examples for tabular data in CSV and JSON Lines format, natural language processing (NLP), and computer vision problems are provided in the following sections.

2. Create a SageMakerClarifyProcessor object and initialize it with parameters that specify the job resources. These resources include parameters such as the number of compute instances to use.

The following code example shows how to create a SageMakerClarifyProcessor object and instruct it to use one ml.c4.xlarge compute instance to do the analysis.

```python
from sagemaker import clarify

clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=session,
)
```

3. Call the specific run method of the SageMakerClarifyProcessor object with the configuration objects for your use case to launch the job. These run methods include the following:

- run_pre_training_bias
- run_post_training_bias
- run_bias
- run_explainability
- run_bias_and_explainability

This SageMakerClarifyProcessor handles several tasks behind the scenes. These tasks include retrieving the SageMaker Clarify container image universal resource identifier (URI),
composing an analysis configuration file based on the provided configuration objects, uploading the file to an Amazon S3 bucket, and configuring the SageMaker Clarify processing job.

The following expandable sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs). The sections show feature importance for these data types:

- Tabular datasets in CSV format or JSON Lines format
- Natural language processing (NLP) datasets
- Computer vision datasets

A guide to run parallel SageMaker Clarify processing jobs with distributed training using Spark follows the expandable sections.

**Analyze tabular data in CSV format**

The following examples show how to configure bias analysis and explainability analysis for a tabular dataset in CSV format. In these examples, the incoming dataset has four feature columns and one binary label column, Target. The contents of the dataset are as follows. A label value of 1 indicates a positive outcome.

<table>
<thead>
<tr>
<th>Target, Age, Gender, Income, Occupation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 25, 0, 2, 850, 2</td>
</tr>
<tr>
<td>1, 36, 0, 6, 585, 0</td>
</tr>
<tr>
<td>1, 22, 1, 1, 759, 1</td>
</tr>
<tr>
<td>0, 48, 0, 3, 446, 1</td>
</tr>
</tbody>
</table>

This DataConfig object specifies the input dataset and where to store the output. The s3_data_input_path parameter can either be a URI of a dataset file or an Amazon S3 URI prefix. If you provide a S3 URI prefix, the SageMaker Clarify processing job recursively collects all Amazon S3 files located under the prefix. The value for s3_output_path should be an S3 URI prefix to hold the analysis results. The following code example shows how to specify a data configuration for the previous sample input dataset.

```python
data_config = clarify.DataConfig(
    s3_data_input_path=dataset_s3_uri,
    dataset_type='text/csv',
)```
How to compute all pre-training bias metrics for a CSV dataset

The following code sample shows how to configure a BiasConfig object to measure bias of the previous sample input towards samples with a Gender value of 0.

```python
bias_config = clarify.BiasConfig(
    label_values_or_threshold=[1],
    facet_name='Gender',
    facet_values_or_threshold=[0],
)
```

The following code example shows how to use a run statement to launch a SageMaker Clarify processing job that computes all pre-training bias metrics for an input dataset.

```python
clarify_processor.run_pre_training_bias(
    data_config=data_config,
    data_bias_config=bias_config,
    methods="all",
)
```

Alternatively, you can choose which metrics to compute by assigning a list of pre-training bias metrics to the methods parameter. For example, replacing methods="all" with methods=["CI", "DPL"] instructs the SageMaker Clarify Processor to compute only Class Imbalance and Difference in Proportions of Labels.

How to compute all post-training bias metrics for a CSV dataset

You can compute pre-training bias metrics prior to training. However, to compute post-training bias metrics, you must have a trained model. The following example output is from a binary classification model that outputs data in CSV format. In this example output, each row contains two columns. The first column contains the predicted label, and the second column contains the probability value for that label.

```
0, 0.028986845165491
1, 0.825382471084594
...```
In the following example configuration, the ModelConfig object instructs the job to deploy the SageMaker model to an ephemeral endpoint. The endpoint uses one ml.m4.xlarge inference instance. Because the parameter content_type and accept_type are not set, they automatically use the value of the parameter dataset_type, which is text/csv.

```python
model_config = clarify.ModelConfig(
    model_name=your_model,
    instance_type='ml.m4.xlarge',
    instance_count=1,
)
```

The following configuration example uses a ModelPredictedLabelConfig object with a label index of 0. This instructs the SageMaker Clarify processing job to locate the predicted label in the first column of the model output. The Processing job uses zero-based indexing in this example.

```python
predicted_label_config = clarify.ModelPredictedLabelConfig(
    label=0,
)
```

Combined with the previous configuration example, the following code example launches a SageMaker Clarify processing job to compute all the post-training bias metrics.

```python
clarify_processor.run_post_training_bias(
    data_config=data_config,
    data_bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predicted_label_config,
    methods="all",
)
```

Similarly, you can choose which metrics to compute by assigning a list of post-training bias metrics to the methods parameter. For example, replace methods="all" with methods=["DPPL", "DI"] to compute only Difference in Positive Proportions in Predicted Labels and Disparate Impact.

**How to compute all bias metrics for a CSV dataset**

The following configuration example shows how to run all pre-training and post-training bias metrics in one SageMaker Clarify processing job.
clarify_processor.run_bias(
    data_config=data_config,
    bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predicted_label_config,
    pre_training_methods="all",
    post_training_methods="all",
)

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio Classic to detect bias, see Fairness and Explainability with SageMaker Clarify.

**How to compute SHAP values for a CSV dataset**

SageMaker Clarify provides feature attributions using the KernelSHAP algorithm. SHAP analysis requires the probability value or score instead of predicted label, so this ModelPredictedLabelConfig object has probability index 1. This instructs the SageMaker Clarify processing job to extract the probability score from the second column of the model output (using zero-based indexing).

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability=1,
)
```

The SHAPConfig object provides SHAP analysis parameters. In this example, the SHAP baseline parameter is omitted and the value of the num_clusters parameter is 1. This instructs the SageMaker Clarify Processor to compute one SHAP baseline sample based on clustering the input dataset. If you want to choose the baseline dataset, see SHAP Baselines for Explainability.

```python
shap_config = clarify.SHAPConfig(
    num_clusters=1,
)
```

The following code example launches a SageMaker Clarify processing job to compute SHAP values.

```python
clarify_processor.run_explainability(
    data_config=data_config,
    model_config=model_config,
    model_scores=probability_config,
    explainability_config=shap_config,
)
```
For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio Classic to compute SHAP values, see Fairness and Explainability with SageMaker Clarify.

**How to compute partial dependence plots (PDPs) for a CSV dataset**

PDPs show the dependence of the predicted target response on one or more input features of interest while holding all other features constant. An upward sloping line, or curve in the PDP, indicates that the relationship between the target and input feature(s) is positive, and the steepness indicates the strength of the relationship. A downward sloping line or curve indicates that if an input feature decreases, the target variable increases. Intuitively, you can interpret the partial dependence as the response of the target variable to each input feature of interest.

The following configuration example is for using a PDPConfig object to instruct the SageMaker Clarify processing job to compute the importance of the Income feature.

```python
pdp_config = clarify.PDPConfig(
    features=['Income'],
    grid_resolution=10,
)
```

In the previous example, the `grid_resolution` parameter divides the range of the Income feature values into 10 buckets. The SageMaker Clarify processing job will generate PDPs for Income split into 10 segments on the x-axis. The y-axis will show the marginal impact of Income on the target variable.

The following code example launches a SageMaker Clarify processing job to compute PDPs.

```python
clarify_processor.run_explainability(
    data_config=data_config,
    model_config=model_config,
    model_scores=probability_config,
    explainability_config=pdp_config,
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio Classic to compute PDPs, see Explainability with SageMaker Clarify - Partial Dependence Plots (PDP).
Amazon SageMaker

Developer Guide

How to compute both SHAP values and PDPs for a CSV dataset
You can compute both SHAP values and PDPs in a single SageMaker Clarify processing job. In the
following conﬁguration example, the top_k_features parameter of a new PDPConfig object
is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the 2 features
that have the largest global SHAP values.
shap_pdp_config = clarify.PDPConfig(
top_k_features=2,
grid_resolution=10,
)

The following code example launches a SageMaker Clarify processing job to compute both SHAP
values and PDPs.
clarify_processor.run_explainability(
data_config=data_config,
model_config=model_config,
model_scores=probability_config,
explainability_config=[shap_config, shap_pdp_config],
)

Analyze tabular data in JSON Lines format
The following examples show how to conﬁgure bias analysis and explainability analysis for a
tabular dataset in >SageMaker JSON Lines dense format. See JSONLINES Request Format for more
information. In these examples, the incoming dataset has the same data as the previous section,
but they're in the JSON Lines format. Each line is a valid JSON object. The key Features points to
an array of feature values, and the key Label points to the ground truth label.
{"Features":[25,0,2850,2],"Label":0}
{"Features":[36,0,6585,0],"Label":1}
{"Features":[22,1,1759,1],"Label":1}
{"Features":[48,0,3446,1],"Label":0}
...

In the following conﬁguration example, the DataConfig object speciﬁes the input dataset and
where to store the output. The features parameter is set to the JMESPath expression Features so
that the SageMaker Clarify processing job can extract the array of features from each record. The
Run SageMaker Clarify Processing Jobs

5334


label parameter is set to JMESPath expression Label so that the SageMaker Clarify processing job can extract the ground truth label from each record.

```python
data_config = clarify.DataConfig(
    s3_data_input_path=jsonl_dataset_s3_uri,
    dataset_type='application/jsonlines',
    headers=['Age', 'Gender', 'Income', 'Occupation', 'Target'],
    label='Label',
    features='Features',
    s3_output_path=clarify_job_output_s3_uri,
)
```

You must have a trained model to compute post-training bias metrics or feature importance. The following example is from a binary classification model that outputs JSON Lines data in the example's format. Each row of the model output is a valid JSON object. The key `predicted_label` points to the predicted label, and the key `probability` points to the probability value.

```json
{"predicted_label":0,"probability":0.0289868451654911}
{"predicted_label":1,"probability":0.8253824710845944}
...
```

In the following configuration example, a ModelConfig object instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. The endpoint uses one `ml.m4.xlarge` inference instance.

```python
model_config = clarify.ModelConfig(
    model_name=your_model,
    instance_type='ml.m4.xlarge',
    instance_count=1,
    content_template='{"Features":$features}',
)
```

In previous configuration example, the parameter `content_type` and `accept_type` are not set. Therefore, they automatically use the value of the `dataset_type` parameter of the DataConfig object, which is `application/jsonlines`. The SageMaker Clarify processing job uses the `content_template` parameter to compose the model input by replacing the `$features` placeholder by an array of features.
The following example configuration shows how to set the label parameter of the ModelPredictedLabelConfig object to the JMESPath expression `predicted_label`. This will extract the predicted label from the model output.

```python
predicted_label_config = clarify.ModelPredictedLabelConfig(
    label='predicted_label',
)
```

The following example configuration shows how to set the probability parameter of the ModelPredictedLabelConfig object to the JMESPath expression `probability`. This will extract the score from the model output.

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability='probability',
)
```

To compute bias metrics and feature importance for datasets in JSON Lines format, use the same run statements and configuration objects as the previous section for CSV datasets. You can run a SageMaker Clarify processing job in SageMaker Studio Classic to detect bias and compute feature importance. For instructions and an example notebook, see Fairness and Explainability with SageMaker Clarify (JSON Lines Format).

**Analyze tabular data for NLP explainability**

SageMaker Clarify supports explanations for natural language processing (NLP) models. These explanations help you understand which sections of text are the most important for your model predictions. You can explain either the model prediction for a single instance of the input dataset, or model predictions from the baseline dataset. To understand and visualize a model’s behavior, you can specify multiple levels of granularity. To do this, define the length of the text segment, such as its tokens, sentences, paragraphs.

SageMaker Clarify NLP explainability is compatible with both classification and regression models. You can also use SageMaker Clarify to explain your model’s behavior on multi-modal datasets that contain text, categorical, or numerical features. NLP explainability for multi-modal datasets can help you understand how important each feature is to the model’s output. SageMaker Clarify supports 62 languages and can handle text which includes multiple languages.

The following example shows an analysis configuration file for computing feature importance for NLP. In this example, the incoming dataset is a tabular dataset in CSV format, with one binary label column and two feature columns.
The following configuration example shows how to specify an input dataset in CSV format and output data path using the DataConfig object.

```python
nlp_data_config = clarify.DataConfig(
    s3_data_input_path=nlp_dataset_s3_uri,
    dataset_type='text/csv',
    headers=['Target', 'Rating', 'Comments'],
    label='Target',
    s3_output_path=clarify_job_output_s3_uri,
)
```

The following example output was created from a binary classification model trained on the previous input dataset. The classification model accepts CSV data, and it outputs a single score in between 0 and 1.

```
0.491656005382537
0.569582343101501
...
```

The following example shows how to configure the ModelConfig object to deploy a SageMaker model. In this example, an ephemeral endpoint deploys the model. This endpoint uses one ml.g4dn.xlarge inference instance equipped with a GPU, for accelerated inferencing.

```python
nlp_model_config = clarify.ModelConfig(
    model_name=your_nlp_model_name,
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
)
```

The following example shows how to configure the ModelPredictedLabelConfig object to locate the probability (score) in the first column with an index of 0.

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability=0,
)
The following example SHAP configuration shows how to run a token-wise explainability analysis using a model and an input dataset in the English language.

```python
text_config = clarify.TextConfig(
    language='english',
    granularity='token',
)

nlp_shap_config = clarify.SHAPConfig(
    baseline=[[4, '[MASK]']],
    num_samples=100,
    text_config=text_config,
)
```

In the previous example, the `TextConfig` object activates the NLP explainability analysis. The `granularity` parameter indicates that the analysis should parse tokens. In English, each token is a word. For other languages, see the [spaCy documentation for tokenization](https://spacy.io/usage/linguistic-features/tokenization), which SageMaker Clarify uses for NLP processing. The previous example also shows how to use an average Rating of 4 to set an in-place SHAP baseline instance. A special mask token `[MASK]` is used to replace a token (word) in Comments.

In the previous example, if the instance is 2, "Flavor needs work", set the baseline to an average Rating of 4 with the following baseline.

```python
4, '[MASK]' 
```

In the previous example, the SageMaker Clarify explainer iterates through each token and replaces it with the mask, as follows.

```plaintext
2,"[MASK] needs work"
4,"Flavor [MASK] work"
4,"Flavor needs [MASK]"
```

Then, the SageMaker Clarify explainer will send each line to your model for predictions. This is so that the explainer learns the predictions with and without the masked words. The SageMaker Clarify explainer then uses this information to compute the contribution of each token.
The following code example launches a SageMaker Clarify processing job to compute SHAP values.

```python
clarify_processor.run_explainability(
    data_config=nlp_data_config,
    model_config=nlp_model_config,
    model_scores=probability_config,
    explainability_config=nlp_shap_config,
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio Classic for NLP explainability analysis, see [Explaining Text Sentiment Analysis Using SageMaker Clarify](#).

### Analyze image data for computer vision explainability

SageMaker Clarify generates heat maps that provide insights into how your computer vision models classify and detect objects in your images.

In the following configuration example, the input dataset consists of JPEG images.

```python
cv_data_config = clarify.DataConfig(
    s3_data_input_path=cv_dataset_s3_uri,
    dataset_type="application/x-image",
    s3_output_path=clarify_job_output_s3_uri,
)
```

In the previous configuration example, the DataConfig object contains an `s3_data_input_path` set to an S3 URI prefix. The SageMaker Clarify processing job recursively collects all image files located under the prefix.

### How to explain an image classification model

The SageMaker Clarify processing job explains images using the KernelSHAP algorithm, which treats the image as a collection of super pixels. Given a dataset consisting of images, the processing job outputs a dataset of images where each image shows the heat map of the relevant super pixels.

The following configuration example shows how to configure an explainability analysis using a SageMaker image classification model. See [Image Classification - MXNet](#) for more information.

```python
ic_model_config = clarify.ModelConfig(
```
In the previous configuration example, a model named `your_cv_ic_model`, has been trained to classify the animals on input JPEG images. The `ModelConfig` object in the previous example instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. For accelerated inferencing, the endpoint uses one `ml.p2.xlarge` inference instance equipped with a GPU.

After a JPEG image is sent to an endpoint, the endpoint classifies it and returns a list of scores. Each score is for a category. The `ModelPredictedLabelConfig` object provides the name of each category, as follows.

```python
ic_prediction_config = clarify.ModelPredictedLabelConfig(
    label_headers=['bird', 'cat', 'dog'],
)
```

An example output for the previous input of `[bird', 'cat', 'dog']` could be `0.3, 0.6, 0.1`, where `0.3` represents the confidence score for classifying an image as a bird.

The following example SHAP configuration shows how to generate explanations for an image classification problem. It uses an `ImageConfig` object to activate the analysis.

```python
ic_image_config = clarify.ImageConfig(
    model_type="IMAGE_CLASSIFICATION",
    num_segments=20,
    segment_compactness=5,
)

ic_shap_config = clarify.SHAPConfig(
    num_samples=100,
    image_config=ic_image_config,
)
```

SageMaker Clarify extracts features using the Simple Linear Iterative Clustering (SLIC) method from scikit-learn library for image segmentation. The previous configuration example, the
model_type parameter, indicates the type of image classification problem. The parameter num_segments estimates how many approximate number of segments will be labeled in the input image. The number of segments is then passed to the slic n_segments parameter.

Each segment of the image is considered a super-pixel, and local SHAP values are computed for each segment. The parameter segment_compactness determines the shape and size of the image segments that are generated by the scikit-image slic method. The sizes and shapes of the image segments are then passed to the slic compactness parameter.

The following code example launches a SageMaker Clarify processing job to generate heat maps for your images. Positive heat map values show that the feature increased the confidence score of detecting the object. Negative values indicate that the feature decreased the confidence score.

```python
clarify_processor.run_explainability(
    data_config=cv_data_config,
    model_config=ic_model_config,
    model_scores=ic_prediction_config,
    explainability_config=ic_shap_config,
)
```

For a sample notebook that uses SageMaker Clarify to classify images and explain its classification, see [Explaining Image Classification with SageMaker Clarify](#).

**How to explain an object detection model**

A SageMaker Clarify processing job can detect and classify objects in an image and then provide an explanation for the detected object. The process for explanation is as follows.

1. Image objects are first categorized into one of the classes in a specified collection. For example, if an object detection model can recognize cat, dog and fish, then these three classes are in a collection. This collection is specified by the label_headers parameter as follows.

   ```python
clarify.ModelPredictedLabelConfig(
    label_headers=object_categories,
  )
```

2. The SageMaker Clarify processing job produces a confidence score for each object. A high confidence score indicates that it belongs to one of the classes in a specified collection. The SageMaker Clarify processing job also produces the coordinates of a bounding box that delimits
the object. For more information about confidence scores and bounding boxes, see Response Formats.

3. SageMaker Clarify then provides an explanation for the detection of an object in the image scene. It uses the methods described in the How to explain an image classification model section.

In the following configuration example, a SageMaker object detection model `your_cv_od_model` is trained on JPEG images to identify the animals on them.

```python
od_model_config = clarify.ModelConfig(
    model_name='your_cv_od_model',
    instance_type='ml.p2.xlarge',
    instance_count=1,
    content_type='image/jpeg',
    accept_type='application/json',
)
```

The `ModelConfig` object in the previous configuration example instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. For accelerated imaging, this endpoint uses one `ml.p2.xlarge` inference instance equipped with a GPU.

In the following example configuration, the `ModelPredictedLabelConfig` object provides the name of each category for classification.

```python
ic_prediction_config = clarify.ModelPredictedLabelConfig(
    label_headers=['bird', 'cat', 'dog'],
)
```

The following example SHAP configuration shows how to generate explanations for an object detection.

```python
od_image_config = clarify.ImageConfig(
    model_type='OBJECT_DETECTION',
    num_segments=20,
    segment_compactness=5,
    max_objects=5,
    iou_threshold=0.5,
    context=1.0,
)
od_shap_config = clarify.SHAPConfig(
```
num_samples=100,
    image_config=image_config,
)

In the previous example configuration, the ImageConfig object activates the analysis. The model_type parameter indicates that the type of problem is object detection. For a detailed description of the other parameters, see Configure the Analysis.

The following code example launches a SageMaker Clarify processing job to generate heat maps for your images. Positive heat map values show that the feature increased the confidence score of detecting the object. Negative values indicate that the feature decreased the confidence score.

clarify_processor.run_explainability(
    data_config=cv_data_config,
    model_config=od_model_config,
    model_scores=od_prediction_config,
    explainability_config=od_shap_config,
)

For a sample notebook that uses SageMaker Clarify to detect objects in an image and explain its predictions, see Explaining object detection models with Amazon SageMaker Clarify.

**How to run parallel SageMaker Clarify processing jobs**

When working with large datasets, you can use Apache Spark to increase the speed of your SageMaker Clarify processing jobs. Spark is a unified analytics engine for large-scale data processing. When you request more than one instance per SageMaker Clarify processor, SageMaker Clarify uses the distributed computing capabilities from Spark.

The following configuration example shows how to use SageMakerClarifyProcessor to create a SageMaker Clarify processor with 5 compute instances. To run any jobs associated with the SageMakerClarifyProcessor, SageMaker Clarify using Spark distributed processing.

from sagemaker import clarify

spark_clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=5,
    instance_type='ml.c5.xlarge',
)
If you set the `save_local_shap_values` parameter of `SHAPConfig` to True, the SageMaker Clarify processing job saves the local SHAP value as multiple part files in the job output location.

To associate the local SHAP values to the input dataset instances, use the `joinsource` parameter of `DataConfig`. If you add more compute instances, we recommend that you also increase the `instance_count` of `ModelConfig` for the ephemeral endpoint. This prevents Spark workers' concurrent inference requests from overwhelming the endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint-to-processing instances.

**Get Analysis Results**

This topic shows how to get analysis results that SageMaker Clarify generates. After the SageMaker Clarify processing job is finished, you can download the output files to inspect, or visualize the results in SageMaker Studio Classic.

The SageMaker Clarify processing job output directory contains the following files:

- `analysis.json` – A file that contains bias metrics and feature importance in JSON format.
- `report.ipynb` – A static notebook that contains code to help you visualize bias metrics and feature importance.
- `explanations_shap/out.csv` – A directory that is created and contains automatically generated files based on your specific analysis configurations. For example, if you activate the `save_local_shap_values` parameter, then per-instance local SHAP values will be saved to the `explanations_shap` directory. As another example, if your analysis configuration does not contain a value for the SHAP baseline parameter, the SageMaker Clarify explainability job computes a baseline by clustering the input dataset. It then saves the generated baseline to the directory.

The following sections provide detailed information about the schema and the report that's generated by bias analysis, SHAP analysis, computer vision explainability analysis, and partial dependence plots (PDPs) analysis. If the configuration analysis contains parameters to compute multiple analyses, then the results are aggregated into one analysis and one report file.

**Topics**

- [Bias analysis](#)
- [SHAP analysis](#)
- [Computer vision (CV) explainability analysis](#)
Partial dependence plots (PDPs) analysis

Bias analysis

Amazon SageMaker Clarify uses the terminology documented in Amazon SageMaker Clarify Terms for Bias and Fairness to discuss bias and fairness.

Schema for the analysis file

The analysis file is in JSON format and is organized into two sections: pre-training bias metrics and post-training bias metrics. The parameters for pre-training and post-training bias metrics are as follows.

- **pre_training_bias_metrics** – Parameters for pre-training bias metrics. For more information, see Measure Pre-training Bias and Configure the Analysis.
  - **label** – The ground truth label name defined by the `label` parameter of the analysis configuration.
  - **label_value_or_threshold** – A string containing the label values or interval defined by the `label_values_or_threshold` parameter of the analysis configuration. For example, if value 1 is provided for binary classification problem, then the string will be 1. If multiple values [1, 2] are provided for multi-class problem, then the string will be 1, 2. If a threshold 40 is provided for regression problem, then the string will be an internal like (40, 68] in which 68 is the maximum value of the label in the input dataset.
  - **facets** – The section contains several key-value pairs, where the key corresponds to the facet name defined by the `name_or_index` parameter of the facet configuration, and the value is an array of facet objects. Each facet object has the following members:
    - **value_or_threshold** – A string containing the facet values or interval defined by the `value_or_threshold` parameter of the facet configuration.
    - **metrics** – The section contains an array of bias metric elements, and each bias metric element has the following attributes:
      - **name** – The short name of the bias metric. For example, CI.
      - **description** – The full name of the bias metric. For example, Class Imbalance (CI).
      - **value** – The bias metric value, or JSON null value if the bias metric is not computed for a particular reason. The values ±∞ are represented as strings ∞ and -∞ respectively.
      - **error** – An optional error message that explains why the bias metric was not computed.
• **post_training_bias_metrics** – The section contains the post-training bias metrics and it follows a similar layout and structure to the pre-training section. For more information, see [Measure Post-training Data and Model Bias](#).

The following is an example of an analysis configuration that will calculate both pre-training and post-training bias metrics.

```json
{
    "version": "1.0",
    "pre_training_bias_metrics": {
        "label": "Target",
        "label_value_or_threshold": "1",
        "facets": {
            "Gender": [ {
                "value_or_threshold": "0",
                "metrics": [ {
                    "name": "CDDL",
                    "description": "Conditional Demographic Disparity in Labels (CDDL)",
                    "value": -0.06
                }, {
                    "name": "CI",
                    "description": "Class Imbalance (CI)",
                    "value": 0.6
                }, ...
            ]
        ]
    },
    "post_training_bias_metrics": {
        "label": "Target",
        "label_value_or_threshold": "1",
        "facets": {
            "Gender": [ {
                "value_or_threshold": "0",
                "metrics": [ {
                    "name": "AD",
                    "description": "Accuracy Difference (AD)",
                    "value": ...
                }, ...
            ]
        ]
    }
}
```
Bias analysis report

The bias analysis report includes several tables and diagrams that contain detailed explanations and descriptions. These include, but are not limited to, the distribution of label values, the distribution of facet values, high-level model performance diagram, a table of bias metrics, and their descriptions. For more information about bias metrics and how to interpret them, see the Learn How Amazon SageMaker Clarify Helps Detect Bias.

SHAP analysis

SageMaker Clarify processing jobs use the Kernel SHAP algorithm to compute feature attributions. The SageMaker Clarify processing job produces both local and global SHAP values. These help to determine the contribution of each feature towards model predictions. Local SHAP values represent the feature importance for each individual instance, while global SHAP values aggregate the local SHAP values across all instances in the dataset. For more information about SHAP values and how to interpret them, see Feature Attributions that Use Shapley Values.

Schema for the SHAP analysis file

Global SHAP analysis results are stored in the explanations section of the analysis file, under the kernel_shap method. The different parameters of the SHAP analysis file are as follows:

- **explanations** – The section of the analysis file that contains the feature importance analysis results.
- **kernal_shap** – The section of the analysis file that contains the global SHAP analysis result.
• **global_shap_values** – A section of the analysis file that contains several key-value pairs. Each key in the key-value pair represents a feature name from the input dataset. Each value in the key-value pair corresponds to the feature's global SHAP value. The global SHAP value is obtained by aggregating the per-instance SHAP values of the feature using the `agg_method` configuration. If the `use_logit` configuration is activated, then the value is calculated using the logistic regression coefficients, which can be interpreted as log-odds ratios.

• **expected_value** – The mean prediction of the baseline dataset. If the `use_logit` configuration is activated, then the value is calculated using the logistic regression coefficients.

• **global_top_shap_text** – (For NLP explainability analysis). A section of the analysis file that includes a set of key-value pairs. SageMaker Clarify processing jobs aggregate the SHAP values of each token and then select the top tokens based on their global SHAP values. The `max_top_tokens` configuration defines the number of tokens to be selected.

Each of the selected top tokens has a key-value pair. The key in the key-value pair corresponds to a top token’s text feature name. Each value in the key-value pair is the global SHAP values of the top token. For an example of a `global_top_shap_text` key-value pair, see the output that follows.

The following is example output from the SHAP analysis of a tabular dataset.

```json
{
  "version": "1.0",
  "explanations": {
    "kernel_shap": {
      "Target": {
        "global_shap_values": {
          "Age": 0.022486410860333206,
          "Gender": 0.007381025261958729,
          "Income": 0.006843906804137847,
          "Occupation": 0.006843906804137847,
          ...
        },
        "expected_value": 0.508233428001
      }
    }
  }
}
```
The following is example output from the SHAP analysis of a text dataset. The output corresponding to the column Comments is an example of output that is generated after analysis of a text feature.

```json
{
    "version": "1.0",
    "explanations": {
        "kernel_shap": {
            "Target": {
                "global_shap_values": {
                    "Rating": 0.022486410860333206,
                    "Comments": 0.058612104851485144,
                    ...
                },
                "expected_value": 0.46700941970297033,
                "global_top_shap_text": {
                    "charming": 0.04127962903247833,
                    "brilliant": 0.02450240786522321,
                    "enjoyable": 0.024093569652715457,
                    ...
                }
            }
        }
    }
}
```

**Schema for the generated baseline file**

When a SHAP baseline configuration is not provided, the SageMaker Clarify processing job generates a baseline dataset. SageMaker Clarify uses a distance-based clustering algorithm to generate a baseline dataset from clusters created from the input dataset. The resulting baseline dataset is saved in a CSV file, located at `explanations_shap/baseline.csv`. This output file contains a header row and several instances based on the `num_clusters` parameter that is specified in the analysis configuration. The baseline dataset only consists of feature columns. An example of a baseline created by clustering the input dataset follows.

<table>
<thead>
<tr>
<th>Age, Gender, Income, Occupation</th>
</tr>
</thead>
<tbody>
<tr>
<td>35, 0, 2883, 1</td>
</tr>
<tr>
<td>40, 1, 6178, 2</td>
</tr>
</tbody>
</table>

Get Analysis Results
Schema for local SHAP values from tabular dataset explainability analysis

For tabular datasets, if a single compute instance is used, the SageMaker Clarify processing job saves the local SHAP values to a CSV file named explanations_shap/out.csv. If you use multiple compute instances, local SHAP values are saved to several CSV files in the explanations_shap directory.

An output file containing local SHAP values has a row containing the local SHAP values for each column that is defined by the headers. The headers follow the naming convention of Feature_Label where the feature name is appended by an underscore, followed by the name of your target variable.

For multi-class problems, the feature names in the header vary first, then labels. For example, two features F1, F2, and two classes L1 and L2, in headers are F1_L1, F2_L1, F1_L2, and F2_L2. If the analysis configuration contains a value for the joinsource_name_or_index parameter, then the key column used in the join is appended to the end of the header name. This allows mapping of the local SHAP values to instances of the input dataset. An example of an output file containing SHAP values follows.

```
Age_Target,Gender_Target,Income_Target,Occupation_Target
0.003937908,0.001388849,0.00242389,0.00274234
-0.0052784,0.017144491,0.004480645,-0.017144491
...
```

Schema for local SHAP values from NLP explainability analysis

For NLP explainability analysis, if a single compute instance is used, the SageMaker Clarify processing job saves local SHAP values to a JSON Lines file named explanations_shap/out.jsonl. If you use multiple compute instances, the local SHAP values are saved to several JSON Lines files in the explanations_shap directory.

Each file containing local SHAP values has several data lines, and each line is a valid JSON object. The JSON object has the following attributes:

- **explanations** – The section of the analysis file that contains an array of Kernel SHAP explanations for a single instance. Each element in the array has the following members:
  - **feature_name** – The header name of the features provided by the headers configuration.
• **data_type** – The feature type inferred by the SageMaker Clarify processing job. Valid values for text features include numerical, categorical, and free_text (for text features).

• **attributions** – A feature-specific array of attribution objects. A text feature can have multiple attribution objects, each for a unit defined by the granularity configuration. The attribution object has the following members:
  
  • **attribution** – A class-specific array of probability values.
  
  • **description** – (For text features) The description of the text units.
  
  • **partial_text** – The portion of the text explained by the SageMaker Clarify processing job.
  
  • **start_idx** – A zero-based index to identify the array location indicating the beginning of the partial text fragment.

The following is an example of a single line from a local SHAP values file, beautified to enhance its readability.

```json
{
  "explanations": [
    {
      "feature_name": "Rating",
      "data_type": "categorical",
      "attributions": [
        {
          "attribution": [0.00342270632248735]
        }
      ]
    },
    {
      "feature_name": "Comments",
      "data_type": "free_text",
      "attributions": [
        {
          "attribution": [0.005260534499999983],
          "description": {
            "partial_text": "It's",
            "start_idx": 0
          }
        },
        {
          "attribution": [0.00424190349999996],
          "description": {

```
SHAP analysis report

The SHAP analysis report provides a bar chart of a maximum of 10 top global SHAP values. The following chart example shows the SHAP values for the top 4 features.
Computer vision (CV) explainability analysis

SageMaker Clarify computer vision explainability takes a dataset consisting of images and treats each image as a collection of super pixels. After analysis, the SageMaker Clarify processing job outputs a dataset of images where each image shows the heat map of the super pixels.

The following example shows an input speed limit sign on the left and a heat map shows the magnitude of SHAP values on the right. These SHAP values were calculated by an image recognition Resnet-18 model that is trained to recognize German traffic signs. The German Traffic Sign Recognition Benchmark (GTSRB) dataset is provided in the paper Man vs. computer: Benchmarking machine learning algorithms for traffic sign recognition. In the example output, large positive values indicate that the super pixel has a strong positive correlation with the model prediction. Large negative values indicate that the super pixel has a strong negative correlation with the model prediction. The larger the absolute value of the SHAP value shown in the heat map, the stronger the relationship between the super pixel and model prediction.
Partial dependence plots (PDPs) analysis

Partial dependence plots show the dependence of the predicted target response on a set of input features of interest. These are marginalized over the values of all other input features and are referred to as the complement features. Intuitively, you can interpret the partial dependence as the target response, which is expected as a function of each input feature of interest.

Schema for the analysis file

The PDP values are stored in the explanations section of the analysis file under the pdp method. The parameters for explanations are as follows:

- **explanations** – The section of the analysis files that contains feature importance analysis results.
- **pdp** – The section of the analysis file that contains an array of PDP explanations for a single instance. Each element of the array has the following members:
  - **feature_name** – The header name of the features provided by the headers configuration.
  - **data_type** – The feature type inferred by the SageMaker Clarify processing job. Valid values for data_type include numerical and categorical.
  - **feature_values** – Contains the values present in the feature. If the data_type inferred by SageMaker Clarify is categorical, feature_values contains all of the unique values that the feature could be. If the data_type inferred by SageMaker Clarify is numerical, feature_values contains a list of the central value of generated buckets. The
The grid_resolution parameter determines the number of buckets used to group the feature column values.

- **data_distribution** – An array of percentages, where each value is the percentage of instances that a bucket contains. The grid_resolution parameter determines the number of buckets. The feature column values are grouped into these buckets.

- **model_predictions** – An array of model predictions, where each element of the array is an array of predictions that corresponds to one class in the model's output.

**label_headers** – The label headers provided by the label_headers configuration.

- **error** – An error message generated if the PDP values are not computed for a particular reason. This error message replaces the content contained in the feature_values, data_distributions, and model_predictions fields.

The following is example output from an analysis file containing a PDP analysis result.

```json
{
  "version": "1.0",
  "explanations": {
    "pdp": [

**PDP analysis report**

You can generate an analysis report containing a PDP chart for each feature. The PDP chart plots feature_values along the x-axis, and it plots model_predictions along the y-axis. For multi-
class models, `model_predictions` is an array, and each element of this array corresponds to one of the model prediction classes.

The following is an example of PDP chart for the feature Age. In the example output, the PDP shows the number of feature values that are grouped into buckets. The number of buckets is determined by `grid_resolution`. The buckets of feature values are plotted against model predictions. In this example, the higher feature values have the same model prediction values.

**pdp for Age**
Number of unique grid points: 10

![PDP chart for Age](image)

**Troubleshoot SageMaker Clarify Processing Jobs**

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

**Note**

The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. A common reason for errors is that parameters
are either missing or not valid. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

Topics

- **Processing job fails to finish**
- **Processing job is taking too long to run**
- **Processing job finishes without results and you get a CloudWatch warning message**
- **Error message for invalid analysis configuration**
- **Bias metric computation fails for several or all metrics**
- **Mismatch between analysis config and dataset/model input/output**
- **Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error**
- **Execution role is invalid**
- **Failed to download data**
- **Could not connect to SageMaker**

**Processing job fails to finish**

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
  clarify_processor.jobs[-1].describe()
  ```
- Run the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```
Processing job is taking too long to run

If your processing job is taking too long to run, use the following ways to find the root cause.

Check to see if your resource configuration is sufficient to handle your computing load. To speed up your job, try the following:

- Use a larger instance type. SageMaker Clarify queries the model repeatedly, and a larger instance can significantly reduce your computation time. For a list of available instances, their memory sizes, bandwidth, and other performance details, see Amazon SageMaker Pricing.

- Add more instances. SageMaker Clarify can use multiple instances to explain multiple input data points in parallel. To enable parallel computing, set your instance_count to more than 1 when you call SageMakerClarifyProcessor. For more information, see How to run parallel SageMaker Clarify processing jobs. If you increase your instance count, monitor the performance of your endpoint to check that it can deploy the increased load. For more information, see Capture data from real-time endpoint.

- If you're computing SHapley Additive exPlanations (SHAP) values, reduce the num_samples parameter in your analysis configuration file. The number of samples directly affects the following:
  - The size of the synthetic datasets that are sent to your endpoint
  - Job runtime

  Reducing the number of samples can also lead to reduced accuracy in estimating SHAP values. For more information, see Configure the Analysis.

Processing job finishes without results and you get a CloudWatch warning message

If the processing job finishes but no results are found, the CloudWatch logs produce a warning message that says Signal 15 received, cleaning up. This warning indicates that the job was stopped either because a customer request called the StopProcessingJob API, or that the job ran out of the allotted time for its completion. In the latter case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase it as needed.
Error message for invalid analysis configuration

- If you get the error message Unable to load analysis configuration as JSON., this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.

- If you get the error message Analysis configuration schema validation error., this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the analysis configuration file. For more information, see Configure the Analysis.

Bias metric computation fails for several or all metrics

If you receive one of the following error messages No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values. or Predicted Label Column series data type is not the same as Label Column series., try the following:

- Check that the correct dataset is being used.
- Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
- Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the DataType. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
- In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
- For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

Mismatch between analysis config and dataset/model input/output

- Check that the baseline format in the analysis config is the same as dataset format.
- If you receive the error message Could not convert string to float., check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
• If you receive the error message Unable to locate the facet, or Headers must contain label, or Headers in config do not match with the number of columns in the dataset, or Feature names not found, check that the headers match the columns.

• If you receive the error message Data must contain features, check the content template for JSON Lines and compare it with the dataset sample if available.

**Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error**

If you receive the error message Fallback to per-record prediction because of model error, this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

**Execution role is invalid**

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

**Failed to download data**

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

**Could not connect to SageMaker**

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify virtual private cloud (VPC) configuration.

**Sample notebooks**

The following sections contain notebooks to help you get started using SageMaker Clarify, to use it for special tasks, including those inside a distributed job, and for computer vision.
Getting started

The following sample notebooks show how to use SageMaker Clarify to get started with explainability and model bias tasks. These tasks include creating a processing job, training a machine learning (ML) model, and monitoring model predictions:

- **Explainability and bias detection with Amazon SageMaker Clarify** – Use SageMaker Clarify to create a processing job to detect bias and explain model predictions.

- **Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify** – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

- How to **read a dataset in JSON Lines format** into a SageMaker Clarify processing job.

- **Mitigate Bias, train another unbiased model, and put it in the model registry** – Use Synthetic Minority Over-sampling Technique (SMOTE) and SageMaker Clarify to mitigate bias, train another model, then put the new model into the model registry. This sample notebook also shows how to place the new model artifacts, including data, code and model metadata, into the model registry. This notebook is part of a series that shows how to integrate SageMaker Clarify into a SageMaker pipeline that is described in the [Architect and build the full machine learning lifecycle with AWS](#) blog post.

Special cases

The following notebooks show you how to use a SageMaker Clarify for special cases including inside your own container and for natural language processing tasks:

- **Fairness and Explainability with SageMaker Clarify (Bring Your Own Container)** – Build your own model and container that can integrate with SageMaker Clarify to measure bias and generate an explainability analysis report. This sample notebook also introduces key terms and shows you how to access the report through SageMaker Studio Classic.

- **Fairness and Explainability with SageMaker Clarify Spark Distributed Processing** – Use distributed processing to run a SageMaker Clarify job that measures the pre-training bias of a dataset and the post-training bias of a model. This sample notebook also shows you how to obtain an explanation for the importance of the input features on the model output, and access the explainability analysis report through SageMaker Studio Classic.

- **Explainability with SageMaker Clarify - Partial Dependence Plots (PDP)** – Use SageMaker Clarify to generate PDPs and access a model explainability report.
• **Explaining text sentiment analysis using SageMaker Clarify Natural language processing (NLP) explainability** – Use SageMaker Clarify for text sentiment analysis.

• Use computer vision (CV) explainability for **image classification** and **object detection**.

These notebooks have been verified to run in Amazon SageMaker Studio Classic. If you need instructions on how to open a notebook in Studio Classic, see [Create or Open an Amazon SageMaker Studio Classic Notebook](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**.

## Detect Pre-training Data Bias

Algorithmic bias, discrimination, fairness, and related topics have been studied across disciplines such as law, policy, and computer science. A computer system might be considered biased if it discriminates against certain individuals or groups of individuals. The machine learning models powering these applications learn from data and this data could reflect disparities or other inherent biases. For example, the training data may not have sufficient representation of various demographic groups or may contain biased labels. The machine learning models trained on datasets that exhibit these biases could end up learning them and then reproduce or even exacerbate those biases in their predictions. The field of machine learning provides an opportunity to address biases by detecting them and measuring them at each stage of the ML lifecycle. You can use Amazon SageMaker Clarify to determine whether data used for training models encodes any bias.

Bias can be measured before training and after training, and monitored against baselines after deploying models to endpoints for inference. Pre-training bias metrics are designed to detect and measure bias in the raw data before it is used to train a model. The metrics used are model-agnostic because they do not depend on any model outputs. However, there are different concepts of fairness that require distinct measures of bias. Amazon SageMaker Clarify provides bias metrics to quantify various fairness criteria.

For additional information about bias metrics, see [Learn How Amazon SageMaker Clarify Helps Detect Bias](#) and [Fairness Measures for Machine Learning in Finance](#).

## Amazon SageMaker Clarify Terms for Bias and Fairness

SageMaker Clarify uses the following terminology to discuss bias and fairness.
Feature

An individual measurable property or characteristic of a phenomenon being observed, contained in a column for tabular data.

Label

Feature that is the target for training a machine learning model. Referred to as the observed label or observed outcome.

Predicted label

The label as predicted by the model. Also referred to as the predicted outcome.

Sample

An observed entity described by feature values and label value, contained in a row for tabular data.

Dataset

A collection of samples.

Bias

An imbalance in the training data or the prediction behavior of the model across different groups, such as age or income bracket. Biases can result from the data or algorithm used to train your model. For instance, if an ML model is trained primarily on data from middle-aged individuals, it may be less accurate when making predictions involving younger and older people.

Bias metric

A function that returns numerical values indicating the level of a potential bias.

Bias report

A collection of bias metrics for a given dataset, or a combination of a dataset and a model.

Positive label values

Label values that are favorable to a demographic group observed in a sample. In other words, designates a sample as having a positive result.

Negative label values

Label values that are unfavorable to a demographic group observed in a sample. In other words, designates a sample as having a negative result.
**Group variable**

Categorical column of the dataset that is used to form subgroups for the measurement of Conditional Demographic Disparity (CDD). Required only for this metric with regards to Simpson’s paradox.

**Facet**

A column or feature that contains the attributes with respect to which bias is measured.

**Facet value**

The feature values of attributes that bias might favor or disfavor.

**Predicted probability**

The probability, as predicted by the model, of a sample having a positive or negative outcome.

---

**Sample Notebooks**

Amazon SageMaker Clarify provides the following sample notebook for bias detection:

- [Explainability and bias detection with Amazon SageMaker Clarify](#) – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Classic Notebook](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**.

**Topics**

- [Measure Pre-training Bias](#)
- [Generate Reports for Bias in Pre-training Data in SageMaker Studio](#)

**Measure Pre-training Bias**

Measuring bias in ML models is a first step to mitigating bias. Each measure of bias corresponds to a different notion of fairness. Even considering simple concepts of fairness leads to many different measures applicable in various contexts. For example, consider fairness with respect to age, and, for simplicity, that middle-aged and rest of the age groups are the two relevant demographics,
referred to as *facets*. In the case of an ML model for lending, we may want small business loans to be issued to equal numbers of both demographics. Or, when processing job applicants, we may want to see equal numbers of members of each demographic hired. However, this approach may assume that equal numbers of both age groups apply to these jobs, so we may want to condition on the number that apply. Further, we may want to consider not whether equal numbers apply, but whether we have equal numbers of qualified applicants. Or, we may consider fairness to be an equal acceptance rate of qualified applicants across both age demographics, or, an equal rejection rate of applicants, or both. You might use datasets with different proportions of data on the attributes of interest. This imbalance can conflate the bias measure you choose. The models might be more accurate in classifying one facet than in the other. Thus, you need to choose bias metrics that are conceptually appropriate for the application and the situation.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet *a* and for a disfavored facet *d*. These labels *y* are referred to as *observed labels* to distinguish them from the *predicted labels* *y'* that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- **labels:**
  - *y* represents the *n* observed labels for event outcomes in a training dataset.
  - *y'* represents the predicted labels for the *n* observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
    - $n'^{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
    - $n'^{(0)}$ is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
  - *facet* *a* – The feature value that defines a demographic that bias favors.
• \( n_a \) is the number of observed labels for the favored facet value: \( n_a = n_a^{(1)} + n_a^{(0)} \) the sum of the positive and negative observed labels for the value facet \( a \).

• \( n'_a \) is the number of predicted labels for the favored facet value: \( n'_a = n'_a^{(1)} + n'_a^{(0)} \) the sum of the positive and negative predicted outcome labels for the facet value \( a \). Note that \( n'_a = n_a \).

• facet \( d \) – The feature value that defines a demographic that bias disfavors.

• \( n_d \) is the number of observed labels for the disfavored facet value: \( n_d = n_d^{(1)} + n_d^{(0)} \) the sum of the positive and negative observed labels for the facet value \( d \).

• \( n'_d \) is the number of predicted labels for the disfavored facet value: \( n'_d = n'_d^{(1)} + n'_d^{(0)} \) the sum of the positive and negative predicted labels for the facet value \( d \). Note that \( n'_d = n_d \).

• probability distributions for outcomes of the labeled facet data outcomes:

  • \( P_a(y) \) is the probability distribution of the observed labels for facet \( a \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( a \) labeled with positive outcomes to the total number, \( P_a(y^1) = n_a^{(1)}/n_a \), and the ratio of the number of samples with negative outcomes to the total number, \( P_a(y^0) = n_a^{(0)}/n_a \).

  • \( P_d(y) \) is the probability distribution of the observed labels for facet \( d \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( d \) labeled with positive outcomes to the total number, \( P_d(y^1) = n_d^{(1)}/n_d \), and the ratio of the number of samples with negative outcomes to the total number, \( P_d(y^0) = n_d^{(0)}/n_d \).

Models trained on data biased by demographic disparities might learn and even exacerbate them. To identify bias in the data before expending resources to train models on it, SageMaker Clarify provides data bias metrics that you can compute on raw datasets before training. All of the pretraining metrics are model-agnostic because they do not depend on model outputs and so are valid for any model. The first bias metric examines facet imbalance, but not outcomes. It determines the extent to which the amount of training data is representative across different facets, as desired for the application. The remaining bias metrics compare the distribution of outcome labels in various ways for facets \( a \) and \( d \) in the data. The metrics that range over negative values can detect negative bias. The following table contains a cheat sheet for quick guidance and links to the pretraining bias metrics.
## Pre-training Bias Metrics

<table>
<thead>
<tr>

</table>

- Positive values indicate a outcomes where facet $d$ is rejected more than accepted.
- Near zero indicates no demographic disparity on average.
- Negative values indicate a outcomes where facet $a$ is rejected more than accepted.

For additional information about bias metrics, see [Fairness Measures for Machine Learning in Finance](#).

• **Conditional Demographic Disparity (CDD)**

**Class Imbalance (CI)**

Class imbalance (CI) bias occurs when a facet value $d$ has fewer training samples when compared with another facet $a$ in the dataset. This is because models preferentially fit the larger facets at the expense of the smaller facets and so can result in a higher training error for facet $d$. Models are also at higher risk of overfitting the smaller data sets, which can cause a larger test error for facet $d$. Consider the example where a machine learning model is trained primarily on data from middle-aged individuals (facet $a$), it might be less accurate when making predictions involving younger and older people (facet $d$).

The formula for the (normalized) facet imbalance measure:

$$CI = \frac{n_a - n_d}{n_a + n_d}$$

Where $n_a$ is the number of members of facet $a$ and $n_d$ the number for facet $d$. Its values range over the interval \([-1, 1]\).

- Positive CI values indicate the facet $a$ has more training samples in the dataset and a value of 1 indicates the data only contains members of the facet $a$.
- Values of CI near zero indicate a more equal distribution of members between facets and a value of zero indicates a perfectly equal partition between facets and represents a balanced distribution of samples in the training data.
- Negative CI values indicate the facet $d$ has more training samples in the dataset and a value of -1 indicates the data only contains members of the facet $d$.
- CI values near either of the extremes values of -1 or 1 are very imbalanced and are at a substantial risk of making biased predictions.

If a significant facet imbalance is found to exist among the facets, you might want to rebalance the sample before proceeding to train models on it.

**Difference in Proportions of Labels (DPL)**

The difference in proportions of labels (DPL) compares the proportion of observed outcomes with positive labels for facet $d$ with the proportion of observed outcomes with positive labels of facet $a$ in a training dataset. For example, you could use it to compare the proportion of middle-aged individuals (facet $a$) and other age groups (facet $d$) approved for financial loans. Machine learning
models try to mimic the training data decisions as closely as possible. So a machine learning model trained on a dataset with a high DPL is likely to reflect the same imbalance in its future predictions.

The formula for the difference in proportions of labels is as follows:

$$DPL = (q_a - q_d)$$

Where:

- $q_a = n_a^{(1)}/n_a$ is the proportion of facet $a$ who have an observed label value of 1. For example, the proportion of a middle-aged demographic who get approved for loans. Here $n_a^{(1)}$ represents the number of members of facet $a$ who get a positive outcome and $n_a$ the is number of members of facet $a$.

- $q_d = n_d^{(1)}/n_d$ is the proportion of facet $d$ who have an observed label value of 1. For example, the proportion of people outside the middle-aged demographic who get approved for loans. Here $n_d^{(1)}$ represents the number of members of the facet $d$ who get a positive outcome and $n_d$ the is number of members of the facet $d$.

If DPL is close enough to 0, then we say that demographic parity has been achieved.

For binary and multicategory facet labels, the DPL values range over the interval (-1, 1). For continuous labels, we set a threshold to collapse the labels to binary.

- Positive DPL values indicate that facet $a$ is has a higher proportion of positive outcomes when compared with facet $d$.

- Values of DPL near zero indicate a more equal proportion of positive outcomes between facets and a value of zero indicates perfect demographic parity.

- Negative DPL values indicate that facet $d$ has a higher proportion of positive outcomes when compared with facet $a$.

Whether or not a high magnitude of DPL is problematic varies from one situation to another. In a problematic case, a high-magnitude DPL might be a signal of underlying issues in the data. For example, a dataset with high DPL might reflect historical biases or prejudices against age-based demographic groups that would be undesirable for a model to learn.

**Kullback-Leibler Divergence (KL)**

The Kullback-Leibler divergence (KL) measures how much the observed label distribution of facet $a$, $P_a(y)$, diverges from distribution of facet $d$, $P_d(y)$. It is also known as the relative entropy of $P_a(y)$.
with respect to $P_d(y)$ and quantifies the amount of information lost when moving from $P_a(y)$ to $P_d(y)$.

The formula for the Kullback-Leibler divergence is as follows:

$$KL(P_a \parallel P_d) = \sum_y P_a(y) \cdot \log[P_a(y)/P_d(y)]$$

It is the expectation of the logarithmic difference between the probabilities $P_a(y)$ and $P_d(y)$, where the expectation is weighted by the probabilities $P_a(y)$. This is not a true distance between the distributions as it is asymmetric and does not satisfy the triangle inequality. The implementation uses natural logarithms, giving KL in units of nats. Using different logarithmic bases gives proportional results but in different units. For example, using base 2 gives KL in units of bits.

For example, assume that a group of applicants for loans have a 30% approval rate (facet $d$) and that the approval rate for other applicants (facet $a$) is 80%. The Kullback-Leibler formula gives you the label distribution divergence of facet $a$ from facet $d$ as follows:

$$KL = 0.8 \cdot \ln(0.8/0.3) + 0.2 \cdot \ln(0.2/0.7) = 0.53$$

There are two terms in the formula here because labels are binary in this example. This measure can be applied to multiple labels in addition to binary ones. For example, in a college admissions scenario, assume an applicant may be assigned one of three category labels: $y_i = \{y_0, y_1, y_2\} = \{\text{rejected}, \text{waitlisted}, \text{accepted}\}$.

Range of values for the KL metric for binary, multicategory, and continuous outcomes is $[0, +\infty)$.

- Values near zero mean the outcomes are similarly distributed for the different facets.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

**Jensen-Shannon Divergence (JS)**

The Jensen-Shannon divergence (JS) measures how much the label distributions of different facets diverge from each other entropically. It is based on the Kullback-Leibler divergence, but it is symmetric.

The formula for the Jensen-Shannon divergence is as follows:

$$JS = \frac{1}{2} \cdot [KL(P_a \parallel P) + KL(P_d \parallel P)]$$

Where $P = \frac{1}{2}(P_a + P_d)$, the average label distribution across facets $a$ and $d$. 
The range of JS values for binary, multicategory, continuous outcomes is \([0, \ln(2))\).

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

This metric indicates whether there is a big divergence in one of the labels across facets.

**L_p-norm (LP)**

The L_p-norm (LP) measures the p-norm distance between the facet distributions of the observed labels in a training dataset. This metric is non-negative and so cannot detect reverse bias.

The formula for the L_p-norm is as follows:

\[
L_p(P_a, P_d) = \left( \sum ||P_a - P_d||^p \right)^{1/p}
\]

Where the p-norm distance between the points \(x\) and \(y\) is defined as follows:

\[
L_p(x, y) = (|x_1-y_1|^p + |x_2-y_2|^p + \ldots + |x_n-y_n|^p)^{1/p}
\]

The 2-norm is the Euclidean norm. Assume you have an outcome distribution with three categories, for example, \(y_i = \{y_0, y_1, y_2\} = \{\text{accepted, waitlisted, rejected}\}\) in a college admissions multicategory scenario. You take the sum of the squares of the differences between the outcome counts for facets \(a\) and \(d\). The resulting Euclidean distance is calculated as follows:

\[
L_2(P_a, P_d) = \left[ (n_a^{(0)} - n_d^{(0)})^2 + (n_a^{(1)} - n_d^{(1)})^2 + (n_a^{(2)} - n_d^{(2)})^2 \right]^{1/2}
\]

Where:

- \(n_a^{(i)}\) is number of the \(i\)th category outcomes in facet \(a\): for example \(n_a^{(0)}\) is number of facet \(a\) acceptances.
- \(n_d^{(i)}\) is number of the \(i\)th category outcomes in facet \(d\): for example \(n_d^{(2)}\) is number of facet \(d\) rejections.

The range of LP values for binary, multicategory, and continuous outcomes is \([0, \sqrt{2})\), where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.
Total Variation Distance (TVD)

The total variation distance data bias metric (TVD) is half the $L_1$-norm. The TVD is the largest possible difference between the probability distributions for label outcomes of facets $a$ and $d$. The $L_1$-norm is the Hamming distance, a metric used compare two binary data strings by determining the minimum number of substitutions required to change one string into another. If the strings were to be copies of each other, it determines the number of errors that occurred when copying. In the bias detection context, TVD quantifies how many outcomes in facet $a$ would have to be changed to match the outcomes in facet $d$.

The formula for the Total variation distance is as follows:

$$\text{TVD} = \frac{1}{2} L_1(P_a, P_d)$$

For example, assume you have an outcome distribution with three categories, $y_i = \{y_0, y_1, y_2\} = \{\text{accepted, waitlisted, rejected}\}$, in a college admissions multicategory scenario. You take the differences between the counts of facets $a$ and $d$ for each outcome to calculate TVD. The result is as follows:

$$L_1(P_a, P_d) = |n_a^{(0)} - n_d^{(0)}| + |n_a^{(1)} - n_d^{(1)}| + |n_a^{(2)} - n_d^{(2)}|$$

Where:

- $n_a^{(i)}$ is number of the $i$th category outcomes in facet $a$: for example $n_a^{(0)}$ is number of facet $a$ acceptances.
- $n_d^{(i)}$ is number of the $i$th category outcomes in facet $d$: for example $n_d^{(2)}$ is number of facet $d$ rejections.

The range of TVD values for binary, multicategory, and continuous outcomes is $[0, 1)$, where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

Kolmogorov-Smirnov (KS)

The Kolmogorov-Smirnov bias metric (KS) is equal to the maximum divergence between labels in the distributions for facets $a$ and $d$ of a dataset. The two-sample KS test implemented by SageMaker Clarify complements the other measures of label imbalance by finding the most imbalanced label.
The formula for the Kolmogorov-Smirnov metric is as follows:

$$KS = \max(|P_a(y) - P_d(y)|)$$

For example, assume a group of applicants (facet $a$) to college are rejected, waitlisted, or accepted at 40%, 40%, 20% respectively and that these rates for other applicants (facet $d$) are 20%, 10%, 70%. Then the Kolmogorov-Smirnov bias metric value is as follows:

$$KS = \max(|0.4-0.2|, |0.4-0.1|, |0.2-0.7|) = 0.5$$

This tells us the maximum divergence between facet distributions is 0.5 and occurs in the acceptance rates. There are three terms in the equation because labels are multiclass of cardinality three.

The range of LP values for binary, multicategory, and continuous outcomes is $[0, +1]$, where:

- Values near zero indicate the labels were evenly distributed between facets in all outcome categories. For example, both facets applying for a loan got 50% of the acceptances and 50% of the rejections.
- Values near one indicate the labels for one outcome were all in one facet. For example, facet $a$ got 100% of the acceptances and facet $d$ got none.
- Intermittent values indicate relative degrees of maximum label imbalance.

**Conditional Demographic Disparity (CDD)**

The demographic disparity metric (DD) determines whether a facet has a larger proportion of the rejected outcomes in the dataset than of the accepted outcomes. In the binary case where there are two facets, men and women for example, that constitute the dataset, the disfavored one is labelled facet $d$ and the favored one is labelled facet $a$. For example, in the case of college admissions, if women applicants comprised 46% of the rejected applicants and comprised only 32% of the accepted applicants, we say that there is demographic disparity because the rate at which women were rejected exceeds the rate at which they are accepted. Women applicants are labelled facet $d$ in this case. If men applicants comprised 54% of the rejected applicants and 68% of the accepted applicants, then there is not a demographic disparity for this facet as the rate of rejection is less than the rate of acceptance. Men applicants are labelled facet $a$ in this case.

The formula for the demographic disparity for the less favored facet $d$ is as follows:

$$DD_d = n_d^{(0)}/n^{(0)} - n_d^{(1)}/n^{(1)} = P_d R(y^0) - P_d A(y^1)$$
Where:

- \( n_a^{(0)} + n_d^{(0)} \) is the total number of rejected outcomes in the dataset for the favored facet \( a \) and disadvantaged facet \( d \).
- \( n_a^{(1)} + n_d^{(1)} \) is the total number of accepted outcomes in the dataset for the favored facet \( a \) and disadvantaged facet \( d \).
- \( P^R_d(y_0) \) is the proportion of rejected outcomes (with value 0) in facet \( d \).
- \( P^A_d(y_1) \) is the proportion of accepted outcomes (value 1) in facet \( d \).

For the college admission example, the demographic disparity for women is \( DD_d = 0.46 - 0.32 = 0.14 \). For men \( DD_a = 0.54 - 0.68 = -0.14 \).

A conditional demographic disparity (CDD) metric that conditions DD on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. The statistics for this case were used in the example calculations of DD. However, when departmental subgroups were examined, women were shown to have higher admission rates than men when conditioned by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgrouped acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDD metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities (\( DD_i \)) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity is as follows:

\[
CDD = \frac{1}{n} \sum_i n_i \cdot DD_i
\]

Where:

- \( \sum_i n_i = n \) is the total number of observations and \( n_i \) is the number of observations for each subgroup.
- \( DD_i = n_i^{(0)}/n^{(0)} - n_i^{(1)}/n^{(1)} = P_i^R(y_0) - P_i^A(y_1) \) is the demographic disparity for the \( i \)th subgroup.
The demographic disparity for a subgroup \( (DD_i) \) are the difference between the proportion of rejected outcomes and the proportion of accepted outcomes for each subgroup.

The range of DD values for binary outcomes for the full dataset \( DD_d \) or for its conditionalized subgroups \( DD_i \) is \([-1, +1]\).

- +1: when there no rejections in facet \( a \) or subgroup and no acceptances in facet \( d \) or subgroup
- Positive values indicate there is a demographic disparity as facet \( d \) or subgroup has a greater proportion of the rejected outcomes in the dataset than of the accepted outcomes. The higher the value the less favored the facet and the greater the disparity.
- Negative values indicate there is not a demographic disparity as facet \( d \) or subgroup has a larger proportion of the accepted outcomes in the dataset than of the rejected outcomes. The lower the value the more favored the facet.
- -1: when there are no rejections in facet \( d \) or subgroup and no acceptances in facet \( a \) or subgroup

If you don't condition on anything then CDD is zero if and only if DPL is zero.

This metric is useful for exploring the concepts of direct and indirect discrimination and of objective justification in EU and UK non-discrimination law and jurisprudence. For additional information, see Why Fairness Cannot Be Automated. This paper also contains the relevant data and analysis of the Berkeley admissions case that shows how conditionalizing on departmental admission rate subgroups illustrates Simpson's paradox.

**Generate Reports for Bias in Pre-training Data in SageMaker Studio**

SageMaker Clarify is integrated with Amazon SageMaker Data Wrangler, which can help you identify bias during data preparation without having to write your own code. Data Wrangler provides an end-to-end solution to import, prepare, transform, featurize, and analyze data with Amazon SageMaker Studio. For an overview of the Data Wrangler data prep workflow, see Prepare ML Data with Amazon SageMaker Data Wrangler.

You specify attributes of interest, such as gender or age, and SageMaker Clarify runs a set of algorithms to detect the presence of bias in those attributes. After the algorithm runs, SageMaker Clarify provides a visual report with a description of the sources and severity of possible bias so that you can plan steps to mitigate. For example, in a financial dataset that contains few examples of business loans to one age group as compared to others, SageMaker flags the imbalance so that you can avoid a model that disfavors that age group.
To analyze and report on data bias

To get started with Data Wrangler, see Get Started with Data Wrangler.

1. In Amazon SageMaker Studio Classic, from the Home menu in the left panel, navigate to the Data node, then choose Data Wrangler. This opens the Data Wrangler landing page in Studio Classic.

2. Choose the + Import data button to create a new flow.

3. In your flow page, from the Import tab, choose Amazon S3, navigate to your Amazon S3 bucket, find your dataset, then choose Import.

4. After you have imported your data, on the flow graph in the Data flow tab, choose the + sign to the right of the Data types node.

5. Choose Add analysis.

6. On the Create Analysis page, choose Bias Report for the Analysis type.

7. Configure the bias report by providing a report Name, the column to predict and whether it is a value or threshold, the column to analyze for bias (the facet) and whether it is a value or threshold.

8. Continue configuring the bias report by choosing the bias metrics.
9. Choose **Check for bias** to generate and view the bias report. Scroll down to view all of the reports.
10. Choose the caret to the right of each bias metric description to see documentation that can help you interpret the significance of the metric values.

11. To view a table summary of the bias metric values, choose the **Table** toggle. To save the report, choose **Save** in the lower-right corner of the page. You can see the report on the flow graph in the **Data flow** tab. Double-click on the report to open it.

**Detect Post-training Data and Model Bias**

Post-training bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet $d$, experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by post-training bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see [Amazon SageMaker Clarify Terms for Bias and Fairness](#).
For additional information about post-training bias metrics, see Learn How Amazon SageMaker Clarify Helps Detect Bias and Fairness Measures for Machine Learning in Finance.

**Measure Post-training Data and Model Bias**

Amazon SageMaker Clarify provides eleven post-training data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet $a$ and for a disfavored facet $d$. These labels $y$ are referred to as observed labels to distinguish them from the predicted labels $y'$ that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- **labels:**
  - $y$ represents the $n$ observed labels for event outcomes in a training dataset.
  - $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - $n^{(1)}_a$ is the number of observed labels for positive outcomes (acceptances).
    - $n^{(1)}_d$ is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - $n^{(0)}_a$ is the number of observed labels for negative outcomes (rejections).
    - $n^{(0)}_d$ is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
• facet \(a\) – The feature value that defines a demographic that bias favors.

  • \(n_a\) is the number of observed labels for the favored facet value: \(n_a = n_a^{(1)} + n_a^{(0)}\) the sum of the positive and negative observed labels for the value facet \(a\).

  • \(n_a'\) is the number of predicted labels for the favored facet value: \(n_a' = n_a'^{(1)} + n_a'^{(0)}\) the sum of the positive and negative predicted outcome labels for the facet value \(a\). Note that \(n_a' = n_a\).

• facet \(d\) – The feature value that defines a demographic that bias disfavors.

  • \(n_d\) is the number of observed labels for the disfavored facet value: \(n_d = n_d^{(1)} + n_d^{(0)}\) the sum of the positive and negative observed labels for the facet value \(d\).

  • \(n_d'\) is the number of predicted labels for the disfavored facet value: \(n_d' = n_d'^{(1)} + n_d'^{(0)}\) the sum of the positive and negative predicted labels for the facet value \(d\). Note that \(n_d' = n_d\).

• probability distributions for outcomes of the labeled facet data outcomes:

  • \(P_a(y)\) is the probability distribution of the observed labels for facet \(a\). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \(a\) labeled with positive outcomes to the total number, \(P_a(y^1) = n_a^{(1)}/n_a\), and the ratio of the number of samples with negative outcomes to the total number, \(P_a(y^0) = n_a^{(0)}/n_a\).

  • \(P_d(y)\) is the probability distribution of the observed labels for facet \(d\). For binary labeled data, this distribution is given by the number of samples in facet \(d\) labeled with positive outcomes to the total number, \(P_d(y^1) = n_d^{(1)}/n_d\), and the ratio of the number of samples with negative outcomes to the total number, \(P_d(y^0) = n_d^{(0)}/n_d\).

The following table contains a cheat sheet for quick guidance and links to the post-training bias metrics.

**Post-training bias metrics**

<table>
<thead>
<tr>
<th>Post-training bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Difference in Positive Proportions in Predicted Labels (DPPL)</strong></td>
<td>Measures the difference in the proportion of positive predictions between the favored facet (a) and the disfavored facet (d).</td>
<td>Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias?</td>
<td>Range for normalized binary &amp; multiclass facet labels: [-1, +1] Range for continuous labels: (-∞, +∞)</td>
</tr>

**Difference in Positive Proportions in Predicted Labels (DPPL)**

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions \( (y' = 1) \) for facet \( a \) and the proportion of positive predictions \( (y' = 1) \) for facet \( d \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), it might be biased against facet \( d \). In this example, you must determine whether the 10% difference is material to a case for bias.

A comparison of difference in proportions of labels (DPL), a measure of pre-training bias, with DPPL, a measure of post-training bias, assesses whether bias in positive proportions that are initially present in the dataset changes after training. If DPPL is larger than DPL, then bias in positive proportions increased after training. If DPPL is smaller than DPL, the model did not increase bias in positive proportions after training. Comparing DPL against DPPL does not guarantee that the model reduces bias along all dimensions. For example, the model may still be biased when considering other metrics such as **Counterfactual Fliptest (FT)** or **Accuracy Difference (AD)**. For more information about bias detection, see the blog post Learn how Amazon SageMaker Clarify helps detect bias. See **Difference in Proportions of Labels (DPL)** for more information about DPL.

The formula for the DPPL is:

\[
DPPL = q'_a - q'_d
\]

Where:

- \( q'_a = \frac{n'_a}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a \) represents the number of members of facet \( a \) who get a positive predicted outcome of value 1 and \( n_a \) the is number of members of facet \( a \).
- \( q'_d = \frac{n'_d}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d \)
represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

If DPPL is close enough to 0, it means that post-training demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((-\infty, +\infty)\).

- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \).

  This is referred to as positive bias.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.

- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.

**Disparate Impact (DI)**

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions \((y' = 1)\) for facet \( d \) over the proportion of positive predictions \((y' = 1)\) for facet \( a \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), then \( DI = .5/.6 = 0.8 \), which indicates a positive bias and an adverse impact on the other aged group represented by facet \( d \).

The formula for the ratio of proportions of the predicted labels:

\[
DI = \frac{q'_d}{q'_a}
\]

Where:

- \( q'_a = n'_a(1)/n_a \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \)
represents the number of members of facet $a$ who get a positive predicted outcome and $n_a$ the is number of members of facet $a$.

- $q'_d = n'_d(1)/n_d$ is the predicted proportion of facet $d$ a who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here $n'_d(1)$ represents the number of members of facet $d$ who get a positive predicted outcome and $n_d$ the is number of members of facet $d$.

For binary, multicategory facet, and continuous labels, the DI values range over the interval $[0, \infty)$.

- Values less than 1 indicate that facet $a$ has a higher proportion of predicted positive outcomes than facet $d$. This is referred to as positive bias.

- A value of 1 indicates demographic parity.

- Values greater than 1 indicate that facet $d$ has a higher proportion of predicted positive outcomes than facet $a$. This is referred to as negative bias.

**Difference in Conditional Acceptance (DCAcc)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels $y'$) for a certain facet as compared to what was observed in the training dataset (labels $y$). For example, if there were more acceptances (a positive outcome) observed in the training dataset for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were approved favoring the middle-aged group.

The formula for the difference in conditional acceptance:

$$\text{DCAcc} = c_a - c_d$$

Where:

- $c_a = n'_a(1)/n'_a(1)$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $a$ to the predicted number of positive outcome (acceptances) for facet $a$.

- $c_d = n'_d(1)/n'_d(1)$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $d$ to the predicted number of predicted positive outcomes (acceptances) for facet $d$. 

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet \(a\)) and 50 people from other age groups (facet \(d\)) who applied for loans, where the model recommended that 60 from facet \(a\) and 30 from facet \(d\) be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet \(a\) and 20 from facet \(d\) were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested \((70/60 = 1.17)\) and granted loans to 33% more from other age groups than the observed labels suggested \((20/30 = 0.67)\). The calculation of the DCAcc value gives the following:

\[
\text{DCAcc} = \frac{70}{60} - \frac{20}{30} = \frac{1}{2}
\]

The positive value indicates that there is a potential bias against the middle-aged facet \(a\) with a lower acceptance rate as compared with the other facet \(d\) than the observed data (taken as unbiased) indicate is the case.

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet \(a\)) and 50 people from other age groups (facet \(d\)) who applied for loans, where the model recommended that 60 from facet \(a\) and 30 from facet \(d\) be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet \(a\) and 40 from facet \(d\) were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested \((50/60 = 0.83)\), and granted loans to 33% more from other age groups than the observed labels suggested \((40/30 = 1.33)\). The calculation of the DCAcc value gives the following:

\[
\text{DCAcc} = \frac{50}{60} - \frac{40}{30} = -1/2
\]

The negative value indicates that there is a potential bias against facet \(d\) with a lower acceptance rate as compared with the middle-aged facet \(a\) than the observed data (taken as unbiased) indicate is the case.

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the
predictions $y'$ by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of $y'$. The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is $(-\infty, +\infty)$.

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is higher than the same ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $a$. The larger the difference of the ratios, the more extreme the apparent bias.

- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is the similar to the ratio for facet $d$. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.

- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is less than that ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Conditional Rejection (DCR)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels $y'$) to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels $y$). For example, if there were more observed rejections (a negative outcome) for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were rejected that favored the middle-aged group over other groups.

The formula for the difference in conditional acceptance:

$$DCR = r_d - r_a$$

Where:
• $r_d = n_d (0)/ n_d (0)$ is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet $d$ to the predicted number of negative outcome (rejections) for facet $d$.
• $r_a = n_a (0)/ n_a (0)$ is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet $a$ to the predicted number of negative outcome of value 0 (rejections) for facet $a$.

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were rejected. In other words, the model rejected 17% more loans from the middle aged facet than the observed labels in the training data suggested ($50/60 = 0.83$), and rejected 33% fewer loans from other age groups than the observed labels suggested ($40/30 = 1.33$). The DCR value quantifies this difference in the ratio of observed to predicted rejection rates between the facets. The positive value indicates that there is a potential bias favoring the middle aged group with lower rejection rates as compared with other groups than the observed data (taken as unbiased) indicate is the case.

\[
DCR = 40/30 - 50/60 = 1/2
\]

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were rejected. In other words, the model rejected 17% fewer loans from the middle aged facet than the observed labels in the training data suggested ($70/60 = 1.17$), and rejected 33% more loans from other age groups than the observed labels suggested ($20/30 = 0.67$). The negative value indicates that there is a potential bias favoring facet $a$ with lower rejection rates as compared with the middle-aged facet $a$ than the observed data (taken as unbiased) indicate is the case.

\[
DCR = 20/30 - 70/60 = -1/2
\]

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is $(-\infty, +\infty)$. 
Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is greater than that ratio for facet $a$. These values indicate a possible bias against the qualified applicants from facet $a$. The larger the value of DCR metric, the more extreme the apparent bias.

Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet $a$ is similar to the ratio for facet $d$. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.

Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is less than that ratio for facet $a$. These values indicate a possible bias against the qualified applicants from facet $d$. The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

**Specificity difference (SD)**

The specificity difference (SD) is the difference in specificity between the favored facet $a$ and disfavored facet $d$. Specificity measures how often the model correctly predicts a negative outcome ($y' = 0$). Any difference in these specificities is a potential form of bias.

Specificity is perfect for a facet if all of the $y=0$ cases are correctly predicted for that facet. Specificity is greater when the model minimizes false positives, known as a Type I error. For example, the difference between a low specificity for lending to facet $a$, and high specificity for lending to facet $d$, is a measure of bias against facet $d$.

The following formula is for the difference in the specificity for facets $a$ and $d$.

$$SD = \frac{TN_d}{TN_d + FP_d} - \frac{TN_a}{TN_a + FP_a} = TNR_d - TNR_a$$

The following variables used to calculate SD are defined as follows:

- $TN_d$ are the true negatives predicted for facet $d$.
- $FP_d$ are the false positives predicted for facet $d$.
- $TN_a$ are the true negatives predicted for facet $a$.
- $FP_a$ are the false positives predicted for facet $a$.
- $TNR_a = \frac{TN_a}{TN_a + FP_a}$ is the true negative rate, also known as the specificity, for facet $a$.
- $TNR_d = \frac{TN_d}{TN_d + FP_d}$ is the true negative rate, also known as the specificity, for facet $d$. 

For example, consider the following confusion matrices for facets $a$ and $d$.

**Confusion matrix for the favored facet $a$**

<table>
<thead>
<tr>
<th>Class $a$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

**Confusion matrix for the disfavored facet $d$**

<table>
<thead>
<tr>
<th>Class $d$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the specificity difference is $SD = \frac{18}{18+5} - \frac{20}{20+10} = 0.7826 - 0.6667 = 0.1159$, which indicates a bias against facet $d$.

The range of values for the specificity difference between facets $a$ and $d$ for binary and multiclass classification is $[-1, +1]$. This metric is not available for the case of continuous labels. Here is what different values of $SD$ imply:

- Positive values are obtained when there is higher specificity for facet $d$ than for facet $a$. This suggests that the model finds less false positives for facet $d$ than for facet $a$. A positive value indicates bias against facet $d$.
- Values near zero indicate that the specificity for facets that are being compared is similar. This suggests that the model finds a similar number of false positives in both of these facets and is not biased.
- Negative values are obtained when there is higher specificity for facet $a$ than for facet $d$. This suggests that the model finds more false positives for facet $a$ than for facet $d$. A negative value indicates bias against facet $a$. 

Detect Post-training Data and Model Bias
Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet \( a \) and disfavored facet \( d \). Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the \( y=1 \) cases are correctly predicted as \( y'=1 \) for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets \( a \) and \( d \)) that should qualify for loans are detected correctly by the model? If the recall rate is high for lending to facet \( a \), but low for lending to facet \( d \), the difference provides a measure of this bias against the group belonging to facet \( d \).

The formula for difference in the recall rates for facets \( a \) and \( d \):

\[
RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d
\]

Where:

- \( TP_a \) are the true positives predicted for facet \( a \).
- \( FN_a \) are the false negatives predicted for facet \( a \).
- \( TP_d \) are the true positives predicted for facet \( d \).
- \( FN_d \) are the false negatives predicted for facet \( d \).
- \( TPR_a = \frac{TP_a}{TP_a + FN_a} \) is the recall for facet \( a \), or its true positive rate.
- \( TPR_d = \frac{TP_d}{TP_d + FN_d} \) is the recall for facet \( d \), or its true positive rate.

For example, consider the following confusion matrices for facets \( a \) and \( d \).

Confusion Matrix for the Favored Facet \( a \)

<table>
<thead>
<tr>
<th>Class ( a ) predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>
Confusion Matrix for the Disfavored Facet d

<table>
<thead>
<tr>
<th>Class d predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is $RD = 65/70 - 20/27 = 0.93 - 0.74 = 0.19$ which indicates a bias against facet $d$.

The range of values for the recall difference between facets $a$ and $d$ for binary and multicategory classification is $[-1, +1]$. This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

Difference in Acceptance Rates (DAR)

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$DAR = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}$$
Where:

- TP\(_a\) are the true positives predicted for facet \(a\).
- FP\(_a\) are the false positives predicted for facet \(a\).
- TP\(_d\) are the true positives predicted for facet \(d\).
- FP\(_d\) are the false positives predicted for facet \(d\).

For example, suppose the model accepts 70 middle-aged applicants (facet \(a\)) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet \(d\)) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then DAR = 35/70 - 40/100 = 0.10, which indicates a potential bias against qualified people from the second age group (facet \(d\)).

The range of values for DAR for binary, multicategory facet, and continuous labels is [-1, +1].

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet \(a\) is larger than the same ratio for facet \(d\). These values indicate a possible bias against the disfavored facet \(d\) caused by the occurrence of relatively more false positives in facet \(d\). The larger the difference in the ratios, the more extreme the apparent bias.

- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets \(a\) and \(d\) have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.

- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet \(d\) is larger than the ratio facet \(a\). These values indicate a possible bias against the favored facet \(a\) caused by the occurrence of relatively more false positives in facet \(a\). The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets \(a\) and \(d\). This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that
are identified as such by the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$DRR = \frac{TN_d}{TN_d + FN_d} - \frac{TN_a}{TN_a + FN_a}$$

The components for the previous DRR equation are as follows.

- $TN_d$ are the true negatives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TP_a$ are the true negatives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.

For example, suppose the model rejects 100 middle-aged applicants (facet $a$) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model rejects 50 applicants from other age demographics (facet $d$) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then $DRR = 40/50 - 80/100 = 0$, so no bias is indicated.

The range of values for DRR for binary, multicategory facet, and continuous labels is $[-1, +1]$.

- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $d$ is larger than the same ratio for facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false negatives in facet $a$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets $a$ and $d$ have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $a$ is larger than the ratio facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.
Accuracy Difference (AD)

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet $a$) than for another age-based demographic (facet $d$), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet $a$, $ACC_a$, minus that for facet $d$, $ACC_d$:

$$AD = ACC_a - ACC_d$$

Where:

- $ACC_a = (TP_a + TN_a)/(TP_a + TN_a + FP_a + FN_a)$
  - $TP_a$ are the true positives predicted for facet $a$
  - $TN_a$ are the true negatives predicted for facet $a$
  - $FP_a$ are the false positives predicted for facet $a$
  - $FN_a$ are the false negatives predicted for facet $a$
- $ACC_d = (TP_d + TN_d)/(TP_d + TN_d + FP_d + FN_d)$
  - $TP_d$ are the true positives predicted for facet $d$
  - $TN_d$ are the true negatives predicted for facet $d$
  - $FP_d$ are the false positives predicted for facet $d$
  - $FN_d$ are the false negatives predicted for facet $d$

For example, suppose a model approves loans to 70 applicants from facet $a$ of 100 and rejected the other 30. 10 should not have been offered the loan ($FP_a$) and 60 were approved that should have been rejected ($FN_a$).
have been (TP<sub>a</sub>). 20 of the rejections should have been approved (FN<sub>a</sub>) and 10 were correctly rejected (TN<sub>a</sub>). The accuracy for facet <i>a</i> is as follows:

\[
\text{ACC}_a = \frac{60 + 10}{60 + 10 + 20 + 10} = 0.7
\]

Next, suppose a model approves loans to 50 applicants from facet <i>d</i> of 100 and rejected the other 50. 10 should not have been offered the loan (FP<sub>a</sub>) and 40 were approved that should have been (TP<sub>a</sub>). 40 of the rejections should have been approved (FN<sub>a</sub>) and 10 were correctly rejected (TN<sub>a</sub>). The accuracy for facet <i>a</i> is determined as follows:

\[
\text{ACC}_d = \frac{40 + 10}{40 + 10 + 40 + 10} = 0.5
\]

The accuracy difference is thus AD = ACC<sub>a</sub> - ACC<sub>d</sub> = 0.7 - 0.5 = 0.2. This indicates there is a bias against facet <i>d</i> as the metric is positive.

The range of values for AD for binary and multicategory facet labels is [-1, +1].

- Positive values occur when the prediction accuracy for facet <i>a</i> is greater than that for facet <i>d</i>. It means that facet <i>d</i> suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet <i>d</i>.
- Values near zero occur when the prediction accuracy for facet <i>a</i> is similar to that for facet <i>d</i>.
- Negative values occur when the prediction accuracy for facet <i>d</i> is greater than that for facet <i>a</i>. It means that facet <i>a</i> suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet <i>a</i>.

**Treatment Equality (TE)**

The treatment equality (TE) is the difference in the ratio of false negatives to false positives between facets <i>a</i> and <i>d</i>. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

\[
\text{TE} = \frac{\text{FN}_d}{\text{FP}_d} - \frac{\text{FN}_a}{\text{FP}_a}
\]

Where:
- FN\(_d\) are the false negatives predicted for facet \(d\).
- FP\(_d\) are the false positives predicted for facet \(d\).
- FN\(_a\) are the false negatives predicted for facet \(a\).
- FP\(_a\) are the false positives predicted for facet \(a\).

Note the metric becomes unbounded if FP\(_a\) or FP\(_d\) is zero.

For example, suppose that there are 100 loan applicants from facet \(a\) and 50 from facet \(d\). For facet \(a\), 8 were wrongly denied a loan (FN\(_a\)) and another 6 were wrongly approved (FP\(_a\)). The remaining predictions were true, so TP\(_a\) + TN\(_a\) = 86. For facet \(d\), 5 were wrongly denied (FN\(_d\)) and 2 were wrongly approved (FP\(_d\)). The remaining predictions were true, so TP\(_d\) + TN\(_d\) = 43. The ratio of false negatives to false positives equals 8/6 = 1.33 for facet \(a\) and 5/2 = 2.5 for facet \(d\). Hence TE = 2.5 - 1.33 = 1.167, even though both facets have the same accuracy:

\[
\text{ACC}_a = \frac{(86)}{(86 + 8 + 6)} = 0.86
\]
\[
\text{ACC}_d = \frac{(43)}{(43 + 5 + 2)} = 0.86
\]

The range of values for differences in conditional rejection for binary and multicategory facet labels is \((-\infty, +\infty)\). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false negatives to false positives for facet \(d\) is greater than that for facet \(a\).
- Values near zero occur when the ratio of false negatives to false positives for facet \(a\) is similar to that for facet \(d\).
- Negative values occur when the ratio of false negatives to false positives for facet \(d\) is less than that for facet \(a\).

\[\text{Note}\]

A previous version stated that the Treatment Equality metric is computed as FP\(_a\) / FN\(_a\) - FP\(_d\) / FN\(_d\) instead of FN\(_d\) / FP\(_d\) - FN\(_a\) / FP\(_a\). While either of the versions can be used. For more information, see Fairness measures for Machine Learning in Finance.
Conditional Demographic Disparity in Predicted Labels (CDDPL)

The demographic disparity metric (DDPL) determines whether facet $d$ has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pre-training CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range $(-1,+1)$.

The formula for the demographic disparity predictions for labels of facet $d$ is as follows:

$$DDPL_d = \frac{n'_d(0)}{n'_d(0)} - \frac{n'_d(1)}{n'_d(1)} = P_d^R(y'_0) - P_d^A(y'_1)$$

Where:

- $n'_d(0) = n'_a(0) + n'_d(0)$ is the number of predicted rejected labels for facets $a$ and $d$.
- $n'_d(1) = n'_a(1) + n'_d(1)$ is the number of predicted accepted labels for facets $a$ and $d$.
- $P_d^R(y'_0)$ is the proportion of predicted rejected labels (value 0) in facet $d$.
- $P_d^A(y'_1)$ is the proportion of predicted accepted labels (value 1) in facet $d$.

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson’s paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels ($DDPL_i$) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

$$CDDPL = \frac{1}{n} \cdot \sum_i n_i \cdot DDPL_i$$

Where:
• $\sum_i n_i = n$ is the total number of observations and $n_i$ is the number of observations for each subgroup.

• $\text{DDPL}_i = n_i^{(0)} / n^{(0)} - n_i^{(1)} / n^{(1)} = P_i^R(y_i^0) - P_i^A(y_i^1)$ is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels ($\text{DDPL}_i$) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is $[-1,+1]$.

• $+1$: when there are no predicted rejection labels for facet $a$ or subgroup and no predicted acceptances for facet $d$ or subgroup.

• Positive values indicate there is a demographic disparity in predicted labels as facet $d$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.

• Values near zero indicate there is no demographic disparity on average.

• Negative values indicate there is a demographic disparity in predicted labels as facet $a$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.

• $-1$: when there are no predicted rejection labels for facet $d$ or subgroup and no predicted acceptances for facet $a$ or subgroup.

**Counterfactual Fliptest (FT)**

The fliptest is an approach that looks at each member of facet $d$ and assesses whether similar members of facet $a$ have different model predictions. The members of facet $a$ are chosen to be k-nearest neighbors of the observation from facet $d$. We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual fliptest is the difference in the cardinality of two sets divided by the number of members of facet $d$:

$$FT = (F^+ - F^-)/n_d$$

Where:
• $F^+ = \text{is the number of disfavored facet } d \text{ members with an unfavorable outcome whose nearest neighbors in favored facet } a \text{ received a favorable outcome.}$

• $F^- = \text{is the number of disfavored facet } d \text{ members with a favorable outcome whose nearest neighbors in favored facet } a \text{ received an unfavorable outcome.}$

• $n_d \text{ is the sample size of facet } d.$

The range of values for the counterfactual flitpest for binary and multicategory facet labels is $[-1, +1].$ For continuous labels, we set a threshold to collapse the labels to binary.

• Positive values occur when the number of unfavorable counterfactual flitpest decisions for the disfavored facet $d$ exceeds the favorable ones.

• Values near zero occur when the number of unfavorable and favorable counterfactual flitpest decisions balance out.

• Negative values occur when the number of unfavorable counterfactual flitpest decisions for the disfavored facet $d$ is less than the favorable ones.

**Generalized entropy (GE)**

The generalized entropy index (GE) measures the inequality in benefit $b$ for the predicted label compared to the observed label. A benefit occurs when a false positive is predicted. A false positive occurs when a negative observation ($y=0$) has a positive prediction ($y'\neq 0$). A benefit also occurs when the observed and predicted labels are the same, also known as a true positive and true negative. No benefit occurs when a false negative is predicted. A false negative occurs when a positive observation ($y=1$) is predicted to have a negative outcome ($y'\neq 0$). The benefit $b$ is defined, as follows.

$$b = y' - y + 1$$

Using this definition, a false positive receives a benefit $b$ of 2, and a false negative receives a benefit of 0. Both a true positive and a true negative receive a benefit of 1.

The GE metric is computed following the [Generalized Entropy Index](https://en.wikipedia.org/wiki/Generalized_entropy) (GE) with the weight alpha set to 2. This weight controls the sensitivity to different benefit values. A smaller alpha means an increased sensitivity to smaller values.
The following variables used to calculate GE are defined as follows:

- \( b_i \) is the benefit received by the \( i^{th} \) data point.
- \( b' \) is the mean of all benefits.

GE can range from 0 to 0.5, where values of zero indicate no inequality in benefits across all data points. This occurs either when all inputs are correctly predicted or when all the predictions are false positives. GE is undefined when all predictions are false negatives.

**Note**

The metric GE does not depend on a facet value being either favored or disfavored.

---

**Model Explainability**

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed.

- To obtain explanations for your datasets and models, see [Use SageMaker Clarify to explain and detect bias](#).
- To obtain explanations in real-time from a SageMaker endpoint, see [Online Explainability with SageMaker Clarify](#).

Transparency about how ML models arrive at their predictions is also critical to consumers and regulators. They need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach. You can
use this to understand why a model made a prediction after training, and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value, from the field of cooperative game theory, that assigns each feature an importance value for a particular prediction.

Clarify produces partial dependence plots (PDPs) that show the marginal effect features have on the predicted outcome of a machine learning model. Partial dependence helps explain target response given a set of input features. It also supports both computer vision (CV) and natural language processing (NLP) explainability using the same Shapley Values (SHAP) algorithm as used for tabular data explanations.

What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- Why did the model predict a negative outcome such as a loan rejection for a given applicant?
- How does the model make predictions?
- Why did the model make an incorrect prediction?
- Which features have the largest influence on the behavior of the model?

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, for example in the case of ML modeling of images, the baseline might be implicit, where an image whose pixels are all the same color can serves as a baseline.

**Sample Notebooks**

Amazon SageMaker Clarify provides the following sample notebook for model explainability:
• **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

• **Explaining Image Classification with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models classify images.

• **Explaining object detection models with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models detect objects.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Classic Notebook](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**.

**Topics**

• **Feature Attributions that Use Shapley Values**

• **SHAP Baselines for Explainability**

**Feature Attributions that Use Shapley Values**

SageMaker Clarify provides feature attributions based on the concept of **Shapley value**. You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model’s predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the *game* and the features included in the model as the *players*. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either *dropping* that feature from the model or *dropping* all other features from the model. However, this approach does not take
into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given \( d \) features, there are \( 2^d \) such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature \( f \), consider the marginal contribution of including \( f \) in all feature combinations (and associated models) that do not contain \( f \), and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of \( d \), say 50 features, it is computationally prohibitive and impractical to train \( 2^d \) possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses Shapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see [A Unified Approach to Interpreting Model Predictions](#).

**SHAP Baselines for Explainability**

Explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines. Therefore, your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either uninformative or informative. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature, is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a
particular applicant was accepted as compared to a baseline acceptances based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

### Use SageMaker Clarify explainability with SageMaker Autopilot

Autopilot uses tools provided by Amazon SageMaker Clarify to help provide insights into how machine learning (ML) models make predictions. These tools can help ML engineers, product managers, and other internal stakeholders understand model characteristics. To trust and interpret decisions made on model predictions, both consumers and regulators rely on transparency in machine learning in order.

The Autopilot explanatory functionality uses a model-agnostic feature attribution approach. This approach determines the contribution of individual features or inputs to the model's output, providing insights into the relevance of different features. You can use it to understand why a model made a prediction after training, or use it to provide per-instance explanation during inference. The implementation includes a scalable implementation of SHAP (Shapley Additive Explanations). This implementation is based on the concept of a Shapley value from cooperative game theory, which assigns each feature an importance value for a particular prediction.

You can use SHAP explanations for the following: auditing and meeting regulatory requirements, building trust in the model, supporting human decision-making, or debugging and improving model performance.

For additional information on Shapely values and baselines, see [SHAP Baselines for Explainability](#).

For a guide to the Amazon SageMaker Clarify documentation, see [Guide to the SageMaker Clarify Documentation](#).
Use governance to document and track model performance

Model governance is a framework that gives systematic visibility into machine learning (ML) model development, validation, and usage. Amazon SageMaker provides purpose-built ML governance tools for managing control access, activity tracking, and reporting across the ML lifecycle.

Manage least-privilege permissions for ML practitioners using Amazon SageMaker Role Manager, create detailed model documentation using Amazon SageMaker Model Cards, and gain visibility into your models with centralized dashboards using Amazon SageMaker Model Dashboard.

Amazon SageMaker Role Manager

With Amazon SageMaker Role Manager, administrators can define user permissions with least-privilege permissions for common machine learning activities. Use Amazon SageMaker Role Manager to build and manage persona-based IAM roles specific to your business needs.

For more information, see Amazon SageMaker Role Manager.

Amazon SageMaker Model Cards

Use Amazon SageMaker Model Cards to document, retrieve, and share essential model information from conception to deployment. With model cards, model risk managers, data scientists, and ML engineers can create an immutable record of intended model uses, risk ratings, training details, evaluation results, and more.

For more information, see Amazon SageMaker Model Cards.

Amazon SageMaker Model Dashboard

Amazon SageMaker Model Dashboard is a pre-built, visual overview of all the models in your account. SageMaker Model Dashboard integrates valuable information from Amazon SageMaker Model Monitor, Transform Jobs, Endpoints, ML Lineage Tracking and Amazon CloudWatch so you can access high-level model information and track model performance in one unified view.

For more information, see Amazon SageMaker Model Dashboard.
Amazon SageMaker Model Cards

Use Amazon SageMaker Model Cards to document critical details about your machine learning (ML) models in a single place for streamlined governance and reporting.

Catalog details such as the intended use and risk rating of a model, training details and metrics, evaluation results and observations, and additional call-outs such as considerations, recommendations, and custom information. By creating model cards, you can do the following:

• Provide guidance on how a model should be used.
• Support audit activities with detailed descriptions of model training and performance.
• Communicate how a model is intended to support business goals.

Model cards provide prescriptive guidance on what information to document and include fields for custom information. After creating a model card, you can export it to a PDF or download it to share with relevant stakeholders. Any edits other than an approval status update made to a model card result in additional model card versions in order to have an immutable record of model changes.

Topics

• Prerequisites
• Intended uses of a model
• Risk ratings
• Model card JSON schema
• Create a model card
• Manage model cards
• Cross-account support for Amazon SageMaker Model Cards
• Use model cards through the low-level APIs
• Model card FAQs

Prerequisites

To get started with Amazon SageMaker Model Cards, you must have permission to create, edit, view, and export model cards.
**Intended uses of a model**

Specifying the intended uses of a model helps ensure that model developers and users have the information they need to train or deploy the model responsibly. The intended uses of a model should describe the scenarios in which the model is appropriate to use as well as the scenarios in which the model is not recommended to use.

We recommend including:

- The general purpose of the model
- Use cases for which the model was intended
- Use cases for which the model was not intended
- Assumptions made when developing the model

The intended uses of a model go beyond technical details and describe how a model should be used in production, the scenarios in which it is appropriate to use a model, and additional considerations such as the type of data to use with the model or any assumptions made during development.

**Risk ratings**

Developers create ML models for use cases with varying levels of risk. For example, a model that approves loan applications might be a higher risk model than one that detects the category of an email. Given the varied risk profiles of a model, model cards provide a field for you to categorize a model's risk rating.

This risk rating can be unknown, low, medium, or high. Use these risk rating fields to label unknown, low, medium, or high-risk models and help your organization comply with any existing rules about putting certain models into production.

**Model card JSON schema**

Evaluation details for a model card must be provided in JSON format. If you have existing JSON format evaluation reports generated by SageMaker Clarify or SageMaker Model Monitor, upload them to Amazon S3 and provide an S3 URI to automatically parse evaluation metrics. For more information and sample reports, see the example metrics folder in the Amazon SageMaker Model Governance - Model Cards example notebook.
When creating a model card using the SageMaker Python SDK, model content must be in the model card JSON schema and provided as a string. Provide model content similar to the following example.

**Model card JSON schema sample file**

```json
{
    "$schema": "http://json-schema.org/draft-07/schema#",
    "$id": "http://json-schema.org/draft-07/schema#",

Create a model card

You can create an Amazon SageMaker Model Card using either the SageMaker console or the SageMaker Python SDK. You can also use the API operations directly. For more information about the API operations, see Use model cards through the low-level APIs.

Create a model card using the SageMaker console

Go to the Amazon SageMaker console. In the navigation pane, under Governance, choose Model cards. On the upper right-hand corner, choose Create model card.

Go through the four steps in the Create model card prompt to document details about your model.

Step 1: Enter model details and intended use

If your model is an AWS resource, specify the exact model name in this field to auto-populate model details. To browse existing model names, see Models in the Amazon SageMaker console. Each unique model name can have only one associated model card.

If your model is not an AWS resource, provide a unique name for your model. To add a model as an AWS resource, see Create a model in the Amazon SageMaker Developer Guide. Alternatively, you can add your model as a model package using SageMaker Marketplace or SageMaker Model Registry.
For more information on intended uses, see Intended uses of a model. For more information on risk ratings, see Risk ratings.

Step 2: Enter training details

Add any training details, training observations, datasets, hyperparameters, and details about the model's objective function to the model card.

The objective function in a model card can be any function that is optimized during training. This can include, but is not limited to, cost functions, loss functions, or objective metrics. In this section, document the objective function that is most critical to training your model.

We recommend that you catalog the following attributes of your objective function:

- Optimization direction
- Metric
- Description

For example, you might minimize (optimization direction) cross entropy loss (metric) for a binary classification problem (description) or maximize likelihood for logistic regression. Additionally, you can provide notes about why you chose this objective function over others.

Step 3: Enter evaluation details

If you have existing evaluation reports generated by SageMaker Clarify or Model Monitor, either provide an S3 URI for those reports or upload them manually to add them to the model card.

For more information on SageMaker Clarify, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability.

For more information on monitoring drift in model quality metrics using Model Monitor, see Monitor model quality.

To add your own evaluation report, choose Generic model card evaluation. All model card evaluation reports must be in the Model card JSON schema.

Step 4: Enter additional details

Add custom model card detail fields for any additional information that you want to address on your model card. For example, you might include the custom field Line of business with a value of Personal finance.
**Save model card**

After reviewing the information in your model card, choose **Save** in the lower right-hand corner to save your model card.

**Create a model card using the SageMaker Python SDK**

Before creating a model card, you must first define the content of your model card. When using the SageMaker Python SDK, model content consists of a model overview, training details, intended uses, evaluation details, and additional information.

You can create model cards for:

- Models that are hosted within SageMaker
- Model packages (models) within the SageMaker Model Registry
- Models that are hosted or registered outside of SageMaker

You can also create model cards without associating any models to them.

We recommend adding the models that you've trained to the SageMaker Model Registry. The model registry helps you catalog models and track model versions. When you create a model card, the information about the model from the model registry automatically populates the model card. You can edit the model card or add information to it after you create it.

For information about using the model registry, see [Register and Deploy Models with Model Registry](#). For information about creating a model card from a model registry, see [Create a model card for your model in the SageMaker Model Registry](#).

### Note

To use model cards with the SageMaker Python SDK, you first need to establish a SageMaker Session. For more information, see [Session](#) in the SageMaker Python SDK API reference.

To create a model card for models that aren't in the SageMaker Model Registry, see [Create a model that isn't in the model registry](#).
Create a model that isn't in the model registry

Use the information in the following sections to create a model card for a model that you haven't added to the model registry.

**Step 1: Define model overview**

Define an overview of your model.

```python
model_overview = ModelOverview.from_model_name(
    model_name=model_name,
    sagemaker_session=sagemaker_session,
    model_description="A-description-of-your-model",
    problem_type="Problem-type", # For example, "Binary Classification"
    algorithm_type="Algorithm-type", # For example, "Logistic Regression"
    model_creator="Name-of-model-creator",
    model_owner="Name-of-model-owner",
)
```

If your model is an AWS resource, then overview information such as the model ARN, inference container URI, and the S3 location of model artifacts is automatically retrievable. Print the associated AWS metadata with the following commands:

```python
print(model_overview.model_id)
print(model_overview.inference_environment.container_image)
print(model_overview.model_artifact)
```

**Step 2: Define training details**

To define your model's training details, you must first define its objective function.

```python
objective_function = ObjectiveFunction(
    function=Function(
        function=ObjectiveFunctionEnum.MINIMIZE,
        facet=FacetEnum.LOSS,
    ),
    notes="An-explanation-about-objective-function",
)
```

Next, you can define your training details using your existing model overview, session, and objective function. Add any training observations here.
training_details = TrainingDetails.from_model_overview(
    model_overview=model_overview,
    sagemaker_session=sagemaker_session,
    objective_function=objective_function,
    training_observations="Model-training-observations",
)

Once again, if your model is an AWS resource, certain training details are autopopulated. Print the training job ARN, training container URI, and training metrics with the following commands:

print(training_details.training_job_details.training_arn)
print(training_details.training_job_details.training_environment.container_image)
print([{"name": i.name, "value": i.value} for i in training_details.training_job_details.training_metrics])

Define evaluation details

To define your model's evaluation details, you must first define one or more metric groups to describe metrics used for any evaluation jobs.

my_metric_group = MetricGroup(
    name="binary classification metrics",
    metric_data=[Metric(name="accuracy", type=MetricTypeEnum.NUMBER, value=0.5)]
)

Next, you can define your evaluation details using evaluation metrics and datasets for each evaluation job. Add any evaluation observations here and give your evaluation job a unique name.

evaluation_details = [
    EvaluationJob(
        name="Example-evaluation-job",
        evaluation_observation="Evaluation-observations",
        datasets="s3://path/to/evaluation/data",
        metric_groups=[my_metric_group],
    )
]

If you have existing evaluation reports generated by SageMaker Clarify or SageMaker Model Monitor, upload them to Amazon S3 and provide an S3 URI to automatically parse evaluation
metrics. To add your own generic model card evaluation report, provide a report in the evaluation results JSON format.

```python
report_type = "clarify_bias.json"
example_evaluation_job.add_metric_group_from_json(
    f"example_metrics/{report_type}"), EvaluationMetricTypeEnum.CLARIFY_BIAS
)
```

**Step 3: Define intended uses**

Define the intended uses of the model, including the general purpose of the model and the use cases for which it was intended. It is also recommended to include any factors that potentially affect this model's efficacy in a particular use case and your organization's risk rating of the model. For more information, see Intended uses of a model and Risk ratings.

```python
intended_uses = IntendedUses(
    purpose_of_model="Purpose-of-the-model",
    intended_uses="The-intended-uses-of-this-model",
    factors_affecting_model_efficiency="Any-factors-effecting-model-efficacy",
    risk_rating=RiskRatingEnum.LOW,
    explanations_for_risk_rating="Explanation-for-low-risk-rating",
)
```

**Define additional information**

Lastly, you can add additional custom information to your model card. You can document any ethical considerations, caveats, and recommendations about the model. You can also add any custom details that you would like in the form of key-value pairs.

```python
additional_information = AdditionalInformation(
    ethical_considerations="Any-ethical-considerations",
    caveats_and_recommendations="Any-caveats-and-recommendations",
    custom_details={"custom details1": "details-value"},
)
```

**Step 4: Create model card**

Name your model card, define a model card, and then use that definition to create a model card using the SageMaker Python SDK.

```python
model_card_name = "my-model-card"
```
Create a model card for your model in the SageMaker Model Registry

Before you begin creating a model card, make sure that you've created a model package group and a model package. For more information about using model registry, see Register and Deploy Models with Model Registry.

⚠️ Important

You must have permissions to use the operations in SageMaker Model Registry. We recommend using AmazonSageMakerModelRegistryFullAccess AWS managed policy. For more information about the managed policy, see AWS Managed Policies for Model Registry.

Use the SageMaker Python SDK to create a model card for a model package within the SageMaker Model Registry. A model package is a model that you've trained. When you create a model card, Amazon SageMaker Model Cards automatically imports the data from the model package into the model card.

When you create a model card for a model package, Amazon SageMaker Model Card uses the DescribeModelPackage operation to add the data from the model package to the model card. The following are examples of the fields that can be imported from a model package into a model card:

- ModelDataUrl
- ModelPackageDescription
- ModelPackageGroupName
- ModelPackageStatus
Use the following code to define the model package and create a model card from it:

```python
mp_details = ModelPackage.from_model_package_arn(
    model_package_arn="example_model_package_arn",
    sagemaker_session=sagemaker_session,
)

model_card_name = "example-model-card"
my_card = ModelCard(
    name=model_card_name,
    status=ModelCardStatusEnum.status,
    model_package_details=mp_details,
    sagemaker_session=sagemaker_session,
)
my_card.create()
```

For `status`, you're specifying the approval status of the model card. If you don't specify a status, SageMaker Model Cards uses the default value of DRAFT. If you don't specify a SageMaker session, SageMaker Model Cards uses the default SageMaker session.

You must specify a name for the model and the Amazon Resource Name (ARN) of the model package. For information about getting the Amazon Resource Name (ARN) for the model package, see [View the Details of a Model Version (Boto3)](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#sagemaker.ModelPackage.from_model_package_arn).

The model card that you've created from the model package might have information that is either missing or inaccurate. You can add information to the model card or edit it. For more information about managing your model cards, see [Manage model cards](https://docs.aws.amazon.com/sagemaker/latest/dg/model-card-management.html).

SageMaker Model Registry supports versioning of your model packages. You can version your model package and create a model card for each version. The information from model cards of preceding versions carry over to model cards created from subsequent versions. For example, you could have version 1, version 2, and version 3 of a model package. Suppose you've already created a model card for version 1, but you haven't created one for version 2. If you create a model card for version 3, Amazon SageMaker Model Cards automatically carries over the information from the model card for version 1 to the model card for version 3.
Note

You can also create model cards for model packages that don't use versioning. However, most machine learning workflows involve multiple versions of the same model, so we recommend doing the following:

1. Creating a version for each model package
2. Creating a model card for each version of the model package

Manage model cards

After you've created a model card, you can manage them. Managing model cards include the following actions:

- Editing a model card
- Deleting a model card
- Exporting a model card to a PDF

You can manage using either the Amazon SageMaker console or the SageMaker Python SDK.

Manage model cards using the console

Use the information in the following sections to manage your model cards with the Amazon SageMaker console.

Edit a model card

To edit a model card, navigate to the model card of your choice by selecting its name in the Amazon SageMaker Model Card console and choose Edit.

After you save a model card, you cannot edit the name of that model card. After you save a model card version, you cannot update that version of the model card. Any edits that you need to make are saved as a subsequent version in order to have an immutable record of model changes.

To view different versions of the model card, choose Actions, Select version, and then choose the version that you want to view.
Export a model card

Follow these steps to export a model card.

1. Go to the Amazon SageMaker Model Card console.
2. Choose the name of the model card you want to export.
3. In the model card overview, choose Actions and then Export PDF.
4. Enter an S3 URI or browse available S3 buckets for your model card PDF.
5. If your model card exports successfully, you can either choose Download PDF in the resulting banner or download your PDF directly from Amazon S3.

Delete a model card

Follow these steps to permanently delete one or more model cards.

1. Go to the Amazon SageMaker Model Cards console.
2. Check the box to the left of the name of the card(s) you want to delete.
3. Choose Delete in the upper right-hand corner.
4. Confirm your request to permanently delete one or more cards.

You can also delete a model card when viewing the model card overview in the console by choosing Actions and then Delete model card.

Manage model cards using the SageMaker Python SDK

Use the information in the following sections to manage your model cards with the Amazon SageMaker Python SDK.

Use model cards through the SageMaker Python SDK

You can create an Amazon SageMaker Model Card programmatically through the SageMaker Python SDK. For more information see Amazon SageMaker Model Cards in the SageMaker Python SDK API reference.

Edit a model card

You can edit a model card using the model_card.update() method. Updating a model card creates a new model card version in order to have an immutable record of model changes. You cannot update the name of a model card.
Export a model card

Specify an S3 output path and export your model card PDF to it with the following commands:

```python
s3_output_path = f"s3://{bucket}/{prefix}/export"
pdf_s3_url = my_card.export_pdf(s3_output_path=s3_output_path).delete()
```

Delete a model card

Permanently delete a model card with the following command:

```python
my_card.delete()
```

Sample notebooks

For more information on working with model cards through the SageMaker Python SDK, see the Amazon SageMaker Model Governance - Model Card example notebook.

Cross-account support for Amazon SageMaker Model Cards

Use cross-account support in Amazon SageMaker Model Cards to share model cards between AWS accounts. The account where the model cards are created is the model card account. Users in the model card account share them with the shared accounts. The users in a shared account can update the model cards or create PDFs of them.

Users in the model card account share their model cards through AWS Resource Access Manager (AWS RAM). AWS RAM helps you share resources across AWS accounts. For an introduction to AWS RAM, see What is AWS Resource Access Manager?

The following is the process to share model cards:

1. A user in the model card account sets up the cross-account model card sharing using AWS Resource Access Manager.
2. If the model cards are encrypted with AWS KMS keys, the user setting up model sharing must also provide users in the shared account with AWS KMS permissions.
3. A user in the shared account accepts the invite to the resource share.
4. A user in the shared account provides the other users with permissions to access the model cards.

If you're a user in the model card account, see the following sections:

- Set up cross-account model card sharing
- Set up AWS KMS permissions for the shared account
- Get responses to your resource share invitation

If you're a user in the shared account, see Set up IAM user permissions in the shared account about setting up permissions for yourself and the other users in the account.

**Set up cross-account model card sharing**

Use AWS Resource Access Manager (AWS RAM) to grant users in your AWS account access to view or update model cards created in a different AWS account.

To set up model card sharing, you must create a resource share. A resource share specifies:

- The resources being shared
- Who or what has access to the resources
- Managed permissions for the resources

For more information about resource shares, see Terms and concepts for AWS RAM. We recommend taking the time to understand AWS RAM conceptually before you go through the process of creating a resource share.

⚠️ **Important**

You must have permissions to create a resource share. For more information about permissions, see How AWS RAM works with IAM.

For procedures to create a resource share and additional information about them, see Create a resource share.

When you go through the procedure of creating a resource share, you specify sagemaker:ModelCard as the resource type. You must also specify the Amazon Resource
Number (ARN) of the AWS RAM resource-based policy. You can specify either the default policy or the policy that has additional permissions to create a PDF of the model card.

With the default `AWSRAMPermissionSageMakerModelCards` resource-based policy, the users in the shared account have permissions to do the following operations:

- `DescribeModelCard`
- `ListModelCardVersions`
- `UpdateModelCard`

With the `AWSRAMPermissionSageMakerModelCardsAllowExport` resource-based policy, the users in the shared account have permissions to do all of the preceding actions. They also have permissions to create a model card export job and describe it through the following operations:

- `CreateModelCardExportJob`
- `DescribeModelCardExportJob`

The users in the shared account can create an export job to generate a PDF of a model card. They can also describe an export job that has been created to find the PDF's Amazon S3 URI.

Model cards and export jobs are resources. The model card account owns the export jobs created by a user in the shared account. For example, a user in account A shares model card X with shared account B. A user in account B creates export job Y for model card X that stores the output in an Amazon S3 location that the user in account B specifies. Even though account B created export job Y, it belongs to account A.

Each AWS account has resource quotas. For information about quotas related to model cards, see Amazon SageMaker endpoints and quotas.

**Set up AWS KMS permissions for the shared account**

If the model cards that you're sharing have been encrypted with AWS Key Management Service keys, you also need to share the access to the keys with the shared account. Otherwise, the users in the shared account can't view, update, or export the model cards. For an overview of AWS KMS, see AWS Key Management Service.

To provide AWS KMS permissions to users in the shared account, update your key policy with the following statement:
The preceding statement provides users in the shared account with `kms:Decrypt` and `kms:GenerateDataKey` permissions. With `kms:Decrypt`, users can decrypt the model cards. With `kms:GenerateDataKey`, users can encrypt the model cards that they update or the PDFs that they create.

**Get responses to your resource share invitation**

After you've created a resource share, the shared accounts that you've specified in the resource share receive an invitation to join it. They must accept the invite to access the resources.

For information about accepting a resource share invite, see [Using shared AWS resources](#) in the *AWS Resource Access Manager User Guide*. 

---

```
{
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::shared-account-id::role/example-IAM-role"
        ]
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt",
    ],
    "Resource": "arn:aws:kms:AWS-Region-of-model-card-account:model-card-account-id:key/AWS KMS-key-id"
    "Condition": {
        "Bool": {"kms:GrantIsForAWSResource": true },
        "StringEquals": {
            "kms:ViaService": [
                "sagemaker.AWS-Region.amazonaws.com",
                "s3.AWS-Region.amazonaws.com"
            ],
        },
        "StringLike": {
        }
    }
}
```
Set up IAM user permissions in the shared account

The following information assumes that you've accepted the resource share invitation from the model card account. For more information about accepting a resource share invitation, see Using shared AWS resources.

You and the other users in your account use an IAM role to access the model cards shared from the model card account. Use the following template to change the policy of the IAM role. You can modify the template for your own use case.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker:DescribeModelCard",
            "sagemaker:UpdateModelCard",
            "sagemaker:CreateModelCardExportJob",
            "sagemaker:ListModelCardVersions",
            "sagemaker:DescribeModelCardExportJob"
         ],
         "Resource": [
         ]
      },
      {
         "Effect": "Allow",
         "Action": "s3:PutObject",
         "Resource": "arn:aws:s3:::Amazon-S3-bucket-storing-the-pdf-of-the-model-card/model-card-name/*"
      }
   ]
}
```

To access model cards encrypted using AWS KMS, you must provide users in your account with the following AWS KMS permissions.
Use model cards through the low-level APIs

You can create an Amazon SageMaker Model Card directly through the SageMaker API or the AWS Command Line Interface (AWS CLI).

**Note**

When creating a model card with the low-level APIs, the content must be in the model card JSON schema and provided as a string. For more information, see [Model card JSON schema](#).

**SageMaker API**

Use the following SageMaker API commands to work with Amazon SageMaker Model Cards:

- **CreateModelCard**
- **DescribeModelCard**
- **ListModelCards**
- **ListModelCardVersions**
- **UpdateModelCard**
- **CreateModelCardExportJob**
- **DescribeModelCardExportJob**
- **ListModelCardExportJobs**
- **DeleteModelCard**
AWS CLI

Use the following AWS CLI commands to work with Amazon SageMaker Model Cards:

- `create-model-card`
- `describe-model-card`
- `list-model-cards`
- `list-model-card-versions`
- `update-model-card`
- `create-model-card-export-job`
- `describe-model-card-export-job`
- `list-model-card-export-jobs`
- `delete-model-card`

Model card FAQs

Refer to the following FAQ items for answers to commonly asked questions about Amazon SageMaker Model Card.

Q. What is model risk?

A: You can use models for a variety of business applications ranging from predicting cyber attacks and approving loan applications to detecting the category of an email. Each of these applications assumes a different level of risk. For example, incorrectly detecting a cyber attack has much greater business impact than incorrectly categorizing an email. Given these varied risk profiles of a model, you can use model cards to provide a risk rating of low, medium, or high for a model. If you don’t know the risk of your model, you can set the status to unknown. Customers are responsible for assigning the risk profile for each model. Based on the risk rating, organizations may have different rules in place for deploying those models to production. For more information, see `Risk ratings`.

Q. What is the intended use of a model?

The intended use of a model describes how you should use the model in your production applications. This goes beyond technical requirements like the type of instance to which you should deploy a model and instead refers to the types of applications to create with the model, the scenarios in which you can expect a reasonable performance from the model, or the type of data to
use with the model. We recommend providing this information in the model card for better model governance. You can define a kind of model specification in the intended use field and ensure that model developers and consumers follow this specification while training and deploying their models. For more information, see Intended uses of a model.

Q. Does SageMaker autopopulate information in my model card?

When you use the SageMaker Python SDK or the AWS console to create your model card, SageMaker autopopulates details about your SageMaker trained model in the card. This includes details about how the model was trained along with all the model details returned by the describe-model API call.

Q. Can I customize a model card?

Amazon SageMaker Model Cards have a defined structure to them that cannot be modified. This structure gives you guidance on what information should be captured in a model card. While you cannot change the structure of the model card, there is some flexibility introduced through custom properties in the Additional information section of the model card.

Q. Can I edit a model card once it is created?

Model cards have versions associated with them. A given model version is immutable across all attributes other than the model card status. If you make any other changes to the model card, such as evaluation metrics, description, or intended uses, SageMaker creates a new version of the model card to reflect the updated information. This is to ensure that a model card, once created, cannot be tampered with.

Q. Can I create model cards for models that were not trained using SageMaker?

A: Yes. You can create model cards for models not trained in SageMaker, but no information is automatically populated in the card. You must supply all the information needed in the model card for non-SageMaker models.

Q. Can I export or share model cards?

A: Yes. You can export each version of a model card to a PDF, downloaded, and share it.

Q. Do I need to register my model in the Model Registry to use model cards?

A: No. You can use model cards independently of the Model Registry.
Q. What is the difference between model cards and Model Registry?

A: Model cards are intended to provide organizations with a mechanism to document as much detail about their model as they like by following SageMaker’s prescriptive guidance along with providing their own custom information. You can introduce model cards at the very start of the ML process and use them to define the business problem that the model should solve and any considerations to think about while using the model. After a model is trained, you can populate the model card associated with that model with information about the model and how it was trained. Model cards are associated with models and are immutable once associated with a model. This ensures that the model card is the single source of truth for all the information related to a model, including how it was trained and how it should be used.

The Model Registry is a catalog that stores metadata about your models. Each entry in the model registry corresponds to a unique model version. That model version contains information about the model such as where the model artifacts are stored in Amazon S3, what container is needed to deploy the model, and custom metadata that should be attached to the model.

Q. Are model card versions related to model versions in the Model Registry?

A: Model card versions and model versions are different entities in SageMaker. Each update to a model card results in a new version of that card. Model versions correspond to incrementally trained models that are registered in the Model Registry. A model card version may be linked to a specific model version in the Model Registry by way of the model ID field in the model card, but this is not necessary.

Q. Are model cards integrated with SageMaker Model Monitor?

A: No. You can upload the performance metrics computed by SageMaker Model Monitor to the model card by uploading a metrics file to Amazon S3 and linking that to the card, but there is no native integration between Model Monitor and model cards. Model dashboards are integrated with Model Monitor. For more information on model dashboards, see Amazon SageMaker Model Dashboard.

Amazon SageMaker Model Dashboard

Amazon SageMaker Model Dashboard is a centralized portal, accessible from the SageMaker console, where you can view, search, and explore all of the models in your account. You can track which models are deployed for inference and if they are used in batch transform jobs or hosted on endpoints. If you set up monitors with Amazon SageMaker Model Monitor, you can also track...
the performance of your models as they make real-time predictions on live data. You can use the
dashboard to find models that violate thresholds you set for data quality, model quality, bias and
explainability. The dashboard's comprehensive presentation of all your monitor results helps you
quickly identify models that don't have these metrics configured.

The Model Dashboard aggregates model-related information from several SageMaker features. In
addition to the services provided in Model Monitor, you can view model cards, visualize workflow
lineage, and track your endpoint performance. You no longer have to sort through logs, query
in notebooks, or access other AWS services to collect the data you need. With a cohesive user
experience and integration into existing services, SageMaker's Model Dashboard provides an out-
of-the-box model governance solution to help you ensure quality coverage across all your models.

Prerequisites

To use the Model Dashboard, you should have one or more models in your account. You can train
models using Amazon SageMaker or import models you've trained elsewhere. To create a model in
SageMaker, you can use the CreateModel API. For more information, see CreateModel. You can
also use SageMaker-provided ML environments, such as Amazon SageMaker Studio Classic, which
provides project templates that set up model training and deployment for you. For information
about how to get started with Studio Classic, see Amazon SageMaker Studio Classic.

While this is not a mandatory prerequisite, customers gain the most value out of the dashboard
if they set up model monitoring jobs using SageMaker Model Monitor for models deployed to
endpoints. For prerequisites and instructions on how to use SageMaker Model Monitor, see Monitor
data and model quality.

Model Dashboard elements

The Model Dashboard view extracts high-level details from each model to provide a comprehensive
summary of every model in your account. If your model is deployed for inference, the dashboard
helps you track the performance of your model and endpoint in real time.

Important details to highlight in this page include:

- **Risk rating**: A user-specified parameter from the model card with a **low**, **medium**, or **high** value.
  The model card's risk rating is a categorical measure of the business impact of the model's
  predictions. Models are used for a variety of business applications, each of which assumes
  a different level of risk. For example, incorrectly detecting a cyber attack has much greater
  business impact than incorrectly categorizing an email. If you don't know the model risk, you can
  set it to **unknown**. For information about Amazon SageMaker Model Cards see Model Cards.
Model Monitor alerts: Model Monitor alerts are a primary focus of the Model Dashboard, and reviewing the existing documentation on the various monitors provided by SageMaker is a helpful way to get started. For an in-depth explanation of the SageMaker Model Monitor feature and sample notebooks, see Monitor data and model quality.

The Model Dashboard displays Model Monitor status values by the following monitor types:

- **Data Quality**: Compares live data to training data. If they diverge, your model's inferences may no longer be accurate. For additional details about the Data Quality monitor, see Monitor data quality.

- **Model Quality**: Compares the predictions that the model makes with the actual Ground Truth labels that the model attempts to predict. For additional details about the Model Quality monitor, see Monitor model quality.

- **Bias Drift**: Compares the distribution of live data to training data, which can also cause inaccurate predictions. For additional details about the Bias Drift monitor, see Monitor Bias Drift for Models in Production.

- **Feature Attribution Drift**: Also known as explainability drift. Compares the relative rankings of your features in training data versus live data, which could also be a result of bias drift. For additional details about the Feature Attribution Drift monitor, see Monitor Feature Attribution Drift for Models in Production.

Each Model Monitor status is one of the following values:

- **None**: No monitor is scheduled

- **Inactive**: A monitor was scheduled, but it was deactivated

- **OK**: A monitor is scheduled and is active, and has not encountered the necessary number of violations in recent model monitor executions to raise an alert

- **Time and date**: An active monitor raised an alert at the specified time and date

- **Endpoint**: The endpoints which host your model for real-time inference. Within the Model Dashboard, you can select the endpoint column to view performance metrics such as CPU, GPU, disk, and memory utilization of your endpoints in real time to help you track the performance of your compute instances.

- **Batch transform job**: The most recent batch transform job that ran using this model. This column helps you determine if a model is actively used for batch inference.

- **Model details**: Each entry in the dashboard links to a model details page where you can delve deeper into an individual model. You can access the model's lineage graph, which visualizes the workflow from data preparation to deployment, and metadata for each step. You can also create
and view the model card, review alert details and history, assess the performance of your real-time endpoints, and access other infrastructure-related details.

**View Model Monitor schedules and alerts**

Using the Python SDK, you can create a model monitor for data quality, model quality, bias drift, or feature attribution drift. For more information about using SageMaker Model Monitor, see Monitor data and model quality. The Model Dashboard populates information from all the monitors you create on all your models in your account. You can track the status of each monitor, which indicates whether your monitor is running as expected or failed due to an internal error. You can also activate or deactivate any monitor in the model details page itself. For instructions about how to view scheduled monitors for a model, see View scheduled monitors. For instructions about how to activate or deactivate model monitors, see Activate or deactivate a model monitor.

A properly-configured and actively-running model monitor might raise alerts, in which case the monitoring executions produce violation reports. For details about how alerts work and how to view alert results, history, and links to job reports for debug, see View and edit alerts.

**View scheduled monitors**

To view a model’s scheduled monitors, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the scheduled monitors you want to view.
5. View the scheduled monitors in the Monitor schedule section. You can review the status for each monitor in the Status schedule column, which is one of the following values:

   - **Failed**: The monitoring schedule failed due to a problem with the configuration or settings (such as incorrect user permissions).
   - **Pending**: The monitor is in the process of becoming scheduled.
   - **Stopped**: The schedule is stopped by the user.
   - **Scheduled**: The schedule is created and runs at the frequency you specified.
Activate or deactivate a model monitor

To activate or deactivate a model monitor, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the alert you want to modify.
5. Choose the radio box next to the monitor schedule of the alert you want to modify.
6. (optional) Choose Deactivate monitor schedule if you want to deactivate your monitor schedule.
7. (optional) Choose Activate monitor schedule if you want to activate your monitor schedule.

View and edit alerts

The Model Dashboard displays alerts you configured in Amazon CloudWatch. You can modify the alert criteria within the dashboard itself. The alert criteria depend upon two parameters:

- **Datapoints to alert**: Within the evaluation period, how many execution failures raise an alert.
- **Evaluation period**: The number of most recent monitoring executions to consider when evaluating alert status.

The following image shows an example scenario of a series of Model Monitor executions in which we set a hypothetical Evaluation period of 3 and a Datapoints to alert value of 2. After every monitoring execution, the number of failures are counted within the Evaluation period of 3. If the number of failures meets or exceeds the Datapoints to alert value 2, the monitor raises an alert and remains in alert status until the number of failures within the Evaluation period becomes less than 2 in subsequent iterations. In the image, the evaluation windows are red when the monitor raises an alert or remains in alert status, and green otherwise.

Note that even if the evaluation window size has not reached the Evaluation period of 3, as shown in the first 2 rows of the image, the monitor still raises an alert if the number of failures meets or exceeds the Datapoints to alert value of 2.
Within the monitor details page, you can view your alert history, edit existing alert criteria, and view job reports to help you debug alert failures. For instructions about how to view alert history or job reports for failed monitoring executions, see View alert history or job reports. For instructions about how to edit alert criteria, see Edit alert criteria.

View alert history or job reports

To view alert history or job reports of failed executions, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the alert history you want to view.
5. In the Schedule name column, select the monitor name of the alert history you want to view.
6. To view alert history, select the Alert history tab.
7. (optional) To view job reports of monitoring executions, complete the following steps:
1. In the **Alert history** tab, choose **View executions** for the alert you want to investigate.

2. In the **Execution history** table, choose **View report** of the monitoring execution you want to investigate.

   **The report displays the following information:**

   - **Feature**: The user-defined ML feature monitored
   - **Constraint**: The specific check within the monitor
   - **Violation details**: Information about why the constraint was violated

**Edit alert criteria**

**To edit an alert in the Model Dashboard, complete the following steps:**

1. Open the [SageMaker console](https://console.aws.amazon.com/sagemaker/home)

2. Choose **Governance** in the left panel.

3. Choose **Model Dashboard**.

4. In the **Models** section of the Model Dashboard, select the model name of the alert you want to modify.

5. Choose the radio box next to the monitor schedule of the alert you want to modify.

6. Choose **Edit Alert** in the **Monitor schedule** section.

7. (optional) Change **Datapoints to alert** if you want to change the number of failures within the **Evaluation period** that initiate an alert.

8. (optional) Change **Evaluation period** if you want to change the number of most recent monitoring executions to consider when evaluating alert status.

**View a model lineage graph**

When you train a model, Amazon SageMaker creates a visualization of your entire ML workflow from data preparation to deployment. This visualization is called a model lineage graph and uses entities to represent individual steps in your workflow. For example, a basic model lineage graph might have an entity representing your training set, which is associated with an entity representing your training job, which is associated with another entity representing your model.
In addition, the graph stores information about each step in your workflow. With this information, you can recreate any step in the workflow or track model and dataset lineage. For example, SageMaker Lineage stores the S3 URI of your input data sources with each job so you can perform further analysis of the data sources for compliance verification.

While the model lineage graph can help you view the steps in individual workflows, there are many other capabilities that you can leverage using the AWS SDK. For example, with the AWS SDK you can create or query your entities. For more information about the full set of features in SageMaker Lineage and example notebooks, see Amazon SageMaker ML Lineage Tracking.

**Introduction to entities**

Amazon SageMaker automatically creates tracking entities for SageMaker jobs, models, model packages, and endpoints if the data is available. For a basic workflow, suppose you train a model using a dataset. SageMaker automatically generates a lineage graph with three entities:

- **Dataset**: A type of artifact, which is an entity representing a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action.

- **TrainingJob**: A type of trial component, which is an entity representing processing, training, and transform jobs.

- **Model**: Another type of artifact. Like the **Dataset** artifact, a **Model** is a URI addressable object. In this case, it is an output of the **TrainingJob** trial component.

Your model lineage graph expands quickly if you add additional steps to your workflow, such as data preprocessing or postprocessing, if you deploy your model to an endpoint, or if you include your model in a model package, among many other possibilities. For the complete list of SageMaker entities, see Amazon SageMaker ML Lineage Tracking.

**Entity properties**

Each node in the graph displays the entity type, but you can choose the vertical ellipsis to the right of the entity type to see specific details related to your workflow. In our previous barebones lineage graph, you can choose the vertical ellipsis next to **DataSet** to see specific values for the following properties (common to all artifact entities):

- **Name**: The name of your dataset.

- **Source URI**: The Amazon S3 location of your dataset.
For the TrainingJob entity, you can see the specific values for the following properties (common to all TrialComponent entities):

- **Name**: The name of the training job.
- **Job ARN**: The Amazon Resource Name (ARN) of your training job.

For the **Model** entity, you see the same properties as listed for **DataSet** since they are both artifact entities. For a list of the entities and their associated properties, see [Lineage Tracking Entities](#).

**Entity queries**

Amazon SageMaker automatically generates graphs of lineage entities as you use them. However if you are running many iterations of an experiment and don't want to view every lineage graph, the AWS SDK can help you perform queries across all your workflows. For example, you can query your lineage entities for all the processing jobs that use an endpoint. Or, you can see all the downstream trails that use an artifact. For a list of all the queries you can perform, see [Querying Lineage Entities](#).

**View a model's lineage graph**

To view the lineage graph for a model, complete the following steps:

1. Open the [SageMaker console](#).
2. Choose **Governance** in the left panel.
3. Choose **Model Dashboard**.
4. In the **Models** section of the Model Dashboard, select the model name of the lineage graph you want to view.
5. Choose **View lineage** in the **Model Overview** section.

**View Endpoint Status**

If you want to use your trained model to perform inference on live data, you deploy your model to a real-time endpoint. To ensure appropriate latency of your predictions, you want to make sure the instances that host your model are running efficiently. Model Dashboard's endpoint monitoring feature displays real-time information about your endpoint configuration and helps you track endpoint performance with metrics.

**Monitor settings**
The Model Dashboard links to existing SageMaker endpoint details pages which display real-time graphs of metrics you can select in Amazon CloudWatch. Within your dashboard, you can track these metrics as your endpoint is handling real-time inference requests. Some metrics you can select are the following:

- **CpuUtilization**: The sum of each individual CPU core's utilization, with each ranging from 0%–100%.
- **MemoryUtilization**: The percentage of memory used by the containers on an instance, ranging from 0%–100%.
- **DiskUtilization**: The percentage of disk space used by the containers on an instance, ranging from 0%–100%.

For the complete list of metrics you can view in real time, see [Monitor Amazon SageMaker with Amazon CloudWatch](#).

**Runtime settings**

Amazon SageMaker supports automatic scaling (auto scaling) for your hosted models. Auto scaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, auto scaling brings more instances online. When the workload decreases, auto scaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using. You can customize the following runtime settings in the Model Dashboard:

- **Update weights**: Change the amount of workload assigned to each instance with numerical weighting. For more information about instance weighting during auto scaling, see [Configure instance weighting for Amazon EC2 Auto Scaling](#).
- **Update instance count**: Change the number of total instances that can service your workload when it increases.

For more information about endpoint runtime settings, see [CreateEndpointConfig](#).

**Endpoint configuration settings**

Endpoint configuration settings display the settings you specified when you created the endpoint. These settings inform SageMaker which resources to provision for your endpoint. Some settings included are the following:
• **Data capture**: You can choose to capture information about your endpoint's inputs and outputs. For example, you may want to sample incoming traffic to see if the results correlate to training data. You can customize your sampling frequency, the format of the stored data, and Amazon S3 location of stored data. For more information about setting up your data capture configuration, see [Capture data](#).

• **Production variants**: See the previous discussion in Runtime settings.

• **Async invocation configuration**: If your endpoint is asynchronous, this section includes the maximum number of concurrent requests sent by the SageMaker client to the model container, the Amazon S3 location of your success and failure notifications, and the output location of your endpoint outputs. For more information about asynchronous outputs, see [Create, invoke, and update an Asynchronous Endpoint](#).

• **Encryption key**: You can enter your encryption key if you want to encrypt your outputs.

For more information about endpoint configuration settings, see [CreateEndpointConfig](#).

### View status and configuration for an endpoint

**To view the status and configuration for a model's endpoint, complete the following steps:**

1. Open the [SageMaker console](#).
2. Choose **Governance** in the left panel.
3. Choose **Model Dashboard**.
4. In the **Models** section of the Model Dashboard, select the model name of the endpoint you want to view.
5. Select the endpoint name in the **Endpoints** section.

### Model Dashboard FAQ

Refer to the following FAQ topics for answers to commonly asked questions about Amazon SageMaker Model Dashboard.

**Q. What is Model Dashboard?**

Amazon SageMaker Model Dashboard is a centralized repository of all models created in your account. The models are generally the outputs of SageMaker training jobs, but you can also import
models trained elsewhere and host them on SageMaker. Model Dashboard provides a single interface for IT administrators, model risk managers, and business leaders to track all deployed models and aggregates data from multiple AWS services to provide indicators about how your models are performing. You can view details about model endpoints, batch transform jobs, and monitoring jobs for additional insights into model performance. The dashboard’s visual display helps you quickly identify which models have missing or inactive monitors so you can ensure all models are periodically checked for data drift, model drift, bias drift, and feature attribution drift. Lastly, the dashboard’s ready access to model details helps you dive deep so you can access logs, infrastructure-related information, and resources to help you debug monitoring failures.

**Q. What are the prerequisites to use Model Dashboard?**

You should have one or more models created in SageMaker, either trained on SageMaker or externally trained. While this is not a mandatory prerequisite, you gain the most value from the dashboard if you set up model monitoring jobs via Amazon SageMaker Model Monitor for models deployed to endpoints.

**Q. Who should use Model Dashboard?**

Model risk managers, ML practitioners, data scientists and business leaders can get a comprehensive overview of models using the Model Dashboard. The dashboard aggregates and displays data from Amazon SageMaker Model Cards, Endpoints and Model Monitor services to display valuable information such as model metadata from the model card and model registry, endpoints where the models are deployed, and insights from model monitoring.

**Q. How do I use Model Dashboard?**

Model Dashboard is available out of the box with Amazon SageMaker and does not require any prior configuration. However, if you have set up model monitoring jobs using SageMaker Model Monitor and Clarify, you use Amazon CloudWatch to configure alerts that raise a flag in the dashboard when model performance deviates from an acceptable range. You can create and add new model cards to the dashboard, and view all the monitoring results associated with endpoints. Model Dashboard currently does not support cross-account models.

**Q. What is Amazon SageMaker Model Monitor?**

With Amazon SageMaker Model Monitor, you can select the data you want to monitor and analyze without writing any code. SageMaker Model Monitor lets you select data, such as prediction output, from a menu of options and captures metadata such as timestamp, model name, and endpoint
so you can analyze model predictions. You can specify the sampling rate of data capture as a percentage of overall traffic in the case of high volume real-time predictions. This data is stored in your own Amazon S3 bucket. You can also encrypt this data, configure fine-grained security, define data retention policies, and implement access control mechanisms for secure access.

**Q. What types of model monitors does SageMaker support?**

SageMaker Model Monitor provides the following types of model monitors:

- **Data Quality**: Monitor drift in data quality.
- **Model Quality**: Monitor drift in model quality metrics, such as accuracy.
- **Bias Drift for Models in Production**: Monitor bias in your model's predictions by comparing the distribution of training and live data.
- **Feature Attribution Drift for Models in Production**: Monitor drift in feature attribution by comparing the relative rankings of features in training and live data.

**Q. What inference methods does SageMaker Model Monitor support?**

Model Monitor currently supports endpoints that host a single model for real-time inference and does not support monitoring of multi-model endpoints.

**Q. How can I get started with SageMaker Model Monitor?**

You can use the following resources to get started with model monitoring:

- [Data quality monitor example notebook](#)
- [Model quality monitor example notebook](#)
- [Bias drift monitor example notebook](#)
- [Feature attribution drift monitor example notebook](#)

For more examples of model monitoring, see the GitHub repository [amazon-sagemaker-examples](#).

**Q. How does Model Monitor work?**

Amazon SageMaker Model Monitor automatically monitors machine learning models in production, using rules to detect drift in your model. Model Monitor notifies you when quality issues arise through alerts. To learn more, see [How Model Monitor Works](#).
Q. When and how do you bring your own container (BYOC) for Model Monitor?

Model Monitor computes model metrics and statistics on tabular data only. For use cases other than tabular datasets, such as images or text, you can bring your own containers (BYOC) to monitor your data and models. For example, you can use BYOC to monitor an image classification model that takes images as input and outputs a label. To learn more about container contracts, see Bring Your Own Containers.

Q. Where can I find examples of BYOC for Model Monitor?

You can find helpful BYOC examples in the following links:

- Monitor data and model quality
- GitHub example repository
- Bring Your Own Containers
- Detecting data drift in NLP using BYOC Model Monitor
- Detecting and analyzing incorrect predictions in CV

Q. How do I integrate Model Monitor with SageMaker Pipelines?

For details about how to integrate Model Monitor and SageMaker Pipelines, see Amazon SageMaker Pipelines now integrates with SageMaker Model Monitor and SageMaker Clarify.

For an example, see the GitHub sample notebook SageMaker Pipelines integration with Model Monitor and Clarify.

Q. Are there any performance concerns using DataCapture?

When turned on, data capture occurs asynchronously on the SageMaker endpoints. To prevent impact to inference requests, DataCapture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% to ensure DataCapture continues capturing requests.
Use Docker containers to build models

Amazon SageMaker makes extensive use of *Docker containers* for build and runtime tasks. SageMaker provides pre-built Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases. For information about how to bring your own containers for use with Amazon SageMaker Studio Classic, see *Bring your own SageMaker image*.

**Topics**

- Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker
- Docker Container Basics
- Use Pre-built SageMaker Docker images
- Adapting your own Docker container to work with SageMaker
- Create a container with your own algorithms and models
- Examples and More Information: Use Your Own Algorithm or Model
- Troubleshooting your Docker containers

**Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker**

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. Your level of engagement with containers depends on your use case.

**Use cases for using pre-built Docker containers with SageMaker**

Consider the following use cases when using containers with SageMaker:

- **Pre-built SageMaker algorithm** – Use the image that comes with the built-in algorithm. See *Use Amazon SageMaker Built-in Algorithms or Pre-trained Models* for more information.
- **Custom model with pre-built SageMaker container** – If you train or deploy a custom model, but use a framework that has a pre-built SageMaker container including TensorFlow and PyTorch, choose one of the following options:
• If you don’t need a custom package, and the container already includes all required packages: Use the pre-built Docker image associated with your framework. For more information, see Use Pre-built SageMaker Docker images.

• If you need a custom package installed into one of the pre-built containers: Confirm that the pre-built Docker image allows a requirements.txt file, or extend the pre-built container based on the following use cases.

**Use cases for extending a pre-built Docker container**

The following are use cases for extending a pre-built Docker container:

• **You can’t import the dependencies** – Extend the pre-built Docker image associated with your framework. See Extend a Pre-built Container for more information.

• **You can’t import the dependencies in the pre-built container and the pre-built container supports requirements.txt** – Add all the required dependencies in requirements.txt. The following frameworks support using requirements.txt.
  - TensorFlow
  - Chainer
  - Sci-kit learn
  - PyTorch
  - Apache MXNet

**Use case for building your own container**

If you build or train a custom model and require custom framework that does not have a pre-built image, build a custom container.

The following decision tree illustrates the information in the previous three lists: Use cases for using pre-built Docker containers with SageMaker; Use cases for extending a pre-built Docker container; Use case for building your own container.
As a customer use case example, to train and deploy a TensorFlow model, refer to the previous sections of Use cases to decide which container that you need. The following are considerations that you can make to choose your container:

- A TensorFlow model is a custom model.
- Because a TensorFlow model is going to be built in the TensorFlow framework, use the TensorFlow pre-built framework container to train and host the model.
- If you require custom packages in either your `entrypoint` script or `inference script`, either extend the pre-built container or use a `requirements.txt` file to install dependencies at runtime.

After you determine the type of container that you need, the following information provides details about the previously listed options.

- **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy
these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK. You can do that by specifying the algorithm or framework version when creating your Estimator. The available built-in algorithms are itemized and described in the Use Amazon SageMaker Built-in Algorithms or Pre-trained Models topic. For more information about the available frameworks, see ML Frameworks and Languages. For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get started topic.

- **Use pre-built SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and pre-built Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks that are currently supported by SageMaker, see Prebuilt SageMaker Docker Images for Deep Learning. For information about the scikit-learn and SparkML pre-built container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML. For more information about using frameworks with the Amazon SageMaker Python SDK, see their respective topics in Machine Learning Frameworks and Languages.

- **Extend a pre-built SageMaker container image.** If you would like to extend a pre-built SageMaker algorithm or model Docker image, you can modify the SageMaker image to satisfy your needs. For an example, see Extending our PyTorch containers.

- **Adapt an existing container image:** If you would like to adapt a pre-existing container image to work with SageMaker, you must modify the Docker container to enable either the SageMaker Training or Inference toolkit. For an example that shows how to build your own containers to train and host an algorithm, see Bring Your Own R Algorithm.

### Docker Container Basics

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see Docker overview.
The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

**SageMaker Functions**

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used. While you don't need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

**Containers with SageMaker Studio**

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you must create your Docker container following the steps in [Bring your own SageMaker image](#).

**Use Pre-built SageMaker Docker images**

Amazon SageMaker provides containers for its built-in algorithms and pre-built Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the pre-built SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

For the Docker registry path and other parameters for each of the Amazon SageMaker provided algorithms and Deep Learning Containers (DLC), see [Docker Registry Paths and Example Code](#).

**Note**

For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see [SageMaker RL Containers](#).

**Topics**

- [Prebuilt SageMaker Docker Images for Deep Learning](#)
- [Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML](#)
- [Train a Deep Graph Network](#)
Prebuilt SageMaker Docker Images for Deep Learning

Amazon SageMaker provides prebuilt Docker images that include deep learning frameworks and other dependencies needed for training and inference. For a complete list of the prebuilt Docker images managed by SageMaker, see Docker Registry Paths and Example Code.

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>
<td>PyTorch</td>
<td>Using PyTorch with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>

Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Fine-tuning and deploying a BERTopic model on SageMaker with your own scripts and dataset, by extending existing PyTorch containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.
Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.

<table>
<thead>
<tr>
<th>Library</th>
<th>Prebuilt Docker Image Source Code</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>scikit-learn</td>
<td><a href="#">SageMaker Scikit-learn Containers</a></td>
<td><a href="#">Using Scikit-learn with the Amazon SageMaker Python SDK</a></td>
</tr>
<tr>
<td>Spark ML</td>
<td><a href="#">SageMaker Spark ML Serving Containers</a></td>
<td><a href="#">SparkML Python SDK Documentation</a></td>
</tr>
</tbody>
</table>

For more information and links to github repositories, see Use Scikit-learn with Amazon SageMaker and Use SparkML Serving with Amazon SageMaker.

Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark ML:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>`
For example, 746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:1.2-1-cpu-py3

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>`

For example, 341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4

For account IDs and AWS Region names, see Docker Registry Paths and Example Code.

Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available sagemaker-sparkml-serving image in the ca-central-1 Region:

```
aws \\
  ecr describe-images \\
  --region ca-central-1 \\
  --region-id 341280168497 \\
  --repository-name sagemaker-sparkml-serving
```

Train a Deep Graph Network

In this overview, you learn how to get started with a deep graph network by using one of the DGL containers in Amazon Elastic Container Registry (Amazon ECR). You can also see links to practical examples for deep graph networks.

What Is a Deep Graph Network?

Deep graph networks refer to a type of neural network that is trained to solve graph problems. A deep graph network uses an underlying deep learning framework like PyTorch or MXNet. The potential for graph networks in practical AI applications is highlighted in the Amazon SageMaker tutorials for Deep Graph Library (DGL). Examples for training models on graph datasets include social networks, knowledge bases, biology, and chemistry.
Several examples are provided using Amazon SageMaker's deep learning containers that are preconfigured with DGL. If you have special modules you want to use with DGL, you can also build your own container. The examples involve heterographs, which are graphs that have multiple types of nodes and edges, and draw on a variety of applications across disparate scientific fields, such as bioinformatics and social network analysis. DGL provides a wide array of graph neural network implementations for different types models. Some of the highlights include:

- Graph convolutional network (GCN)
- Relational graph convolutional network (R-GCN)
- Graph attention network (GAT)
• Deep generative models of graphs (DGMG)
• Junction tree neural network (JTNN)

Get Started

DGL is available as a deep learning container in Amazon ECR. You can select deep learning containers when you write your estimator function in an Amazon SageMaker notebook. You can also craft your own custom container with DGL by following the Bring Your Own Container guide. The easiest way to get started with a deep graph network uses one of the DGL containers in Amazon ECR.

Note

Backend framework support is limited to PyTorch and MXNet.

Setup

If you are using Amazon SageMaker Studio, you need to clone the examples repository first. If you are using a notebook instance, you can find the examples by choosing the SageMaker icon at bottom of the left toolbar.

To clone the Amazon SageMaker SDK and notebook examples repository

1. From the JupyterLab view in Amazon SageMaker, go to the File Browser at the top of the left toolbar. From the File Browser panel, you can see a new navigation at the top of the panel.
2. Choose the icon on the far right to clone a Git repository.
3. Add the repository URL: https://github.com/awslabs/amazon-sagemaker-examples.git
4. Browse the newly added folder and its contents. The DGL examples are stored in the sagemaker-python-sdk folder.

Run a Graph Network Training Example

To train a deep graph network

1. From the JupyterLab view in Amazon SageMaker, browse the example notebooks and look for DGL folders. Several files may be included to support an example. Examine the README for any prerequisites.
2. Run the .ipynb notebook example.
3. Find the estimator function, and note the line where it is using an Amazon ECR container for DGL and a specific instance type. You may want to update this to use a container in your preferred Region.
4. Run the function to launch the instance and use the DGL container for training a graph network. Charges are incurred for launching this instance. The instance self-terminates when the training is complete.

Examples

An example of knowledge graph embedding (KGE) is provided. It uses the Freebase dataset, a knowledge base of general facts. An example use case would be to graph the relationships of persons and predict their nationality.

An example implementation of a graph convolutional network (GCN) shows how you can train a graph network to predict toxicity. A physiology dataset, Tox21, provides toxicity measurements for how substances affect biological responses.

Another GCN example shows you how to train a graph network on a scientific publications bibliography dataset, known as Cora. You can use it to find relationships between authors, topics, and conferences.

The last example is a recommender system for movie reviews. It uses a graph convolutional matrix completion (GCMC) network trained on the MovieLens datasets. These datasets consist of movie titles, genres, and ratings by users.

Use a Deep Learning Container with DGL

The following example uses preconfigured deep learning containers. This is the easiest to try since it works out of the box on Amazon SageMaker.

- Semi-supervised classification of a knowledge base using a GCN

Bring Your Own Container with DGL

The following examples enable you to bring your own container (BYOC). Read the BYOC guide and familiarize yourself with that process before trying these. Configuration is required.

- Molecular property prediction of toxicity using a GCN
• **Recommender system for movies using a GCMC implementation**

---

## Extend a Pre-built Container

If a pre-built SageMaker container doesn't fulfill all of your requirements, you can extend the existing image to accommodate your needs. Even if there is direct support for your environment or framework, you may want to add additional functionality or configure your container environment differently. By extending a pre-built image, you can leverage the included deep learning libraries and settings without having to create an image from scratch. You can extend the container to add libraries, modify settings, and install additional dependencies.

The following tutorial shows how to extend a pre-built SageMaker image and publish it to Amazon ECR.

### Topics

- **Requirements to Extend a Pre-built Container**
- **Extend SageMaker Containers to Run a Python Script**

## Requirements to Extend a Pre-built Container

To extend a pre-built SageMaker image, you need to set the following environment variables within your Dockerfile. For more information on environment variables with SageMaker containers, see the [SageMaker Training Toolkit GitHub repo](https://github.com/aws/sagemaker-training-toolkit).

- **SAGEMAKER_SUBMIT_DIRECTORY**: The directory within the container in which the Python script for training is located.
- **SAGEMAKER_PROGRAM**: The Python script that should be invoked and used as the entry point for training.

You can also install additional libraries by including the following in your Dockerfile:

```
RUN pip install <library>
```

The following tutorial shows how to use these environment variables.
Extend SageMaker Containers to Run a Python Script

In this tutorial, you learn how to extend the SageMaker PyTorch container with a Python file that uses the CIFAR-10 dataset. By extending the SageMaker PyTorch container, you utilize the existing training solution made to work with SageMaker. This tutorial extends a training image, but the same steps can be taken to extend an inference image. For a full list of the available images, see Available Deep Learning Containers Images.

To run your own training model using the SageMaker containers, build a Docker container through a SageMaker Notebook instance.

**Step 1: Create an SageMaker Notebook Instance**

1. Open the [SageMaker console](#).
2. In the left navigation pane, choose **Notebook**, choose **Notebook instances**, and then choose **Create notebook instance**.
3. On the **Create notebook instance** page, provide the following information:
   a. For **Notebook instance name**, enter **RunScriptNotebookInstance**.
   b. For **Notebook Instance type**, choose **ml.t2.medium**.
   c. In the **Permissions and encryption** section, do the following:
      i. For **IAM role**, choose **Create a new role**.
      ii. On the **Create an IAM role** page, choose **Specific S3 buckets**, specify an Amazon S3 bucket named **sagemaker-run-script**, and then choose **Create role**.

        SageMaker creates an IAM role named AmazonSageMaker-
        ExecutionRole-**YYYYMMDDTHHmmSS**, such as AmazonSageMaker-
        ExecutionRole-20190429T110788. Note that the execution role naming
        convention uses the date and time when the role was created, separated by a T.
   d. For **Root Access**, choose **Enable**.
   e. Choose **Create notebook instance**.
4. On the **Notebook instances** page, the **Status** is **Pending**. It can take a few minutes for Amazon CloudWatch Internet Monitor to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see Extend a Pre-built Container.
CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

**Step 2: Create and Upload the Dockerfile and Python Training Scripts**

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.

2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```bash
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

The Dockerfile script performs the following tasks:
- FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04 – Downloads the SageMaker PyTorch base image. You can replace this with any SageMaker base image you want to bring to build containers.

- ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code – Sets /opt/ml/code as the training script directory.

- COPY cifar10.py /opt/ml/code/cifar10.py – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- ENV SAGEMAKER_PROGRAM cifar10.py – Sets your cifar10.py training script as the entrypoint script.

d. On the left directory navigation pane, the text file name might automatically be named untitled.txt. To rename the file, right-click the file, choose Rename, rename the file as Dockerfile without the .txt extension, and then press Ctrl+s or Command+s to save the file.

3. Create or upload a training script cifar10.py in the docker_test_folder. You can use the following example script for this exercise.

```python
import ast
import argparse
import logging
import os

import torch
import torch.distributed as dist
import torch.nn as nn
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision
import torchvision.models
import torchvision.transforms as transforms
import torch.nn.functional as F

logger=logging.getLogger(__name__)
logger.setLevel(logging.DEBUG)
```

Extend a Pre-built Container
```python
classes=('plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'ship', 'truck')

# https://github.com/pytorch/tutorials/blob/master/beginner_source/blitz/cifar10_tutorial.py#L118
class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1=nn.Conv2d(3, 6, 5)
        self.pool=nn.MaxPool2d(2, 2)
        self.conv2=nn.Conv2d(6, 16, 5)
        self.fc1=nn.Linear(16 * 5 * 5, 120)
        self.fc2=nn.Linear(120, 84)
        self.fc3=nn.Linear(84, 10)

    def forward(self, x):
        x=self.pool(F.relu(self.conv1(x)))
        x=self.pool(F.relu(self.conv2(x)))
        x=x.view(-1, 16 * 5 * 5)
        x=F.relu(self.fc1(x))
        x=F.relu(self.fc2(x))
        x=self.fc3(x)
        return x

def _train(args):
    is_distributed=len(args.hosts) > 1 and args.dist_backend is not None
    logger.debug("Distributed training - {}".format(is_distributed))

    if is_distributed:
        # Initialize the distributed environment.
        world_size=len(args.hosts)
        os.environ['WORLD_SIZE']=str(world_size)
        host_rank=args.hosts.index(args.current_host)
        dist.init_process_group(backend=args.dist_backend, rank=host_rank,
                                world_size=world_size)
        logger.info("\'Initialized the distributed environment: \'{0}\\' backend on {} nodes. .format(
                            args.dist_backend,
                            dist.get_world_size()) + 'Current host rank is {}. Using cuda: {}. Number of gpus: {}".format(0)
```
dist.get_rank(), torch.cuda.is_available(), args.num_gpus))

criterion=nn.CrossEntropyLoss().to(device)
optimizer=torch.optim.SGD(model.parameters(), lr=args.lr,
    momentum=args.momentum)

for epoch in range(0, args.epochs):
    running_loss=0.0
    for i, data in enumerate(train_loader):
        # get the inputs
        inputs, labels=data
        inputs, labels=inputs.to(device), labels.to(device)

        # zero the parameter gradients
        optimizer.zero_grad()
# forward + backward + optimize
outputs=model(inputs)
loss=criterion(outputs, labels)
loss.backward()
optimizer.step()

# print statistics
running_loss += loss.item()
if i % 2000 == 1999:  # print every 2000 mini-batches
    print('[%d, %5d] loss: %.3f' %
          (epoch + 1, i + 1, running_loss / 2000))
running_loss=0.0
print('Finished Training')
return _save_model(model, args.model_dir)

def _save_model(model, model_dir):
    logger.info("Saving the model.")
    path=os.path.join(model_dir, 'model.pth')
    # recommended way from http://pytorch.org/docs/master/notes/serialization.html
    torch.save(model.cpu().state_dict(), path)

def model_fn(model_dir):
    logger.info('model_fn')
    device="cuda" if torch.cuda.is_available() else "cpu"
    model=Net()
    if torch.cuda.device_count() > 1:
        logger.info("Gpu count: {}".format(torch.cuda.device_count()))
        model=nn.DataParallel(model)

    with open(os.path.join(model_dir, 'model.pth'), 'rb') as f:
        model.load_state_dict(torch.load(f))
    return model.to(device)

if __name__ == '__main__':
    parser=argparse.ArgumentParser()

    parser.add_argument('--workers', type=int, default=2, metavar='W',
            help='number of data loading workers (default: 2)')
    parser.add_argument('--epochs', type=int, default=2, metavar='E',
            help='number of total epochs to run (default: 2)')
Step 3: Build the Container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose conda_pytorch_p39 in the Notebook section.

2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```
   % cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```
   ! pwd
   ```

   output: /home/ec2-user/SageMaker/docker_test_folder
3. Log in to Docker to access the base container:

```bash
! aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
```

4. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

```bash
! docker build -t pytorch-extended-container-test .
```

The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

**Note**

If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

```bash
unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
```

Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the -f flag. For example, if you named your Dockerfile Dockerfile-text.txt, run the following command:

```bash
! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
```

**Step 4: Test the Container**

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose Notebook in conda_pytorch_p39 framework. The rest of the code snippets must run from the Jupyter notebook instance.

2. Download the CIFAR-10 dataset.

```python
import torch
import torchvision
```
import torchvision.transforms as transforms

def _get_transform():
    return transforms.Compose(
        [transforms.ToTensor(),
         transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

def get_train_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    trainset=torchvision.datasets.CIFAR10(root=data_dir, train=True, download=True, transform=transform)
    return torch.utils.data.DataLoader(trainset, batch_size=4, shuffle=True, num_workers=2)

def get_test_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    testset=torchvision.datasets.CIFAR10(root=data_dir, train=False, download=True, transform=transform)
    return torch.utils.data.DataLoader(testset, batch_size=4, shuffle=False, num_workers=2)

trainloader=get_train_data_loader('/tmp/pytorch-example/cifar-10-data')
testloader=get_test_data_loader('/tmp/pytorch-example/cifar-10-data')

3. **Set role to the role used to create your Jupyter notebook. This is used to configure your SageMaker Estimator.**

```python
from sagemaker import get_execution_role
role=get_execution_role()
```

4. **Paste the following example script into the notebook code cell to configure a SageMaker Estimator using your extended container.**

```python
from sagemaker.estimator import Estimator
hyperparameters={'epochs': 1}
estimator=Estimator(
    image_uri='pytorch-extended-container-test',
    role=role,
```
5. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

**Step 5: Push the Container to Amazon Elastic Container Registry (Amazon ECR)**

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.

Run the following command lines in a notebook cell.

```bash
%%sh

# Specify an algorithm name
algorithm_name=pytorch-extended-container-test
account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]; then
  aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Log into Docker
```
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the docker image locally with the image name and then push it to ECR # with the full name.

docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}

2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

client=boto3.client('sts')
account=client.get_caller_identity()]['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="pytorch-extended-container-test"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)

ecr_image
# This should return something like
# 12-digits-of-your-account.dkr.ecr.us-east-2.amazonaws.com/tf-2.2-test:latest

3. Use the ecr_image retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker PyTorch estimator.

```python
import sagemaker

from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator=Estimator(extend a Pre-built Container
2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

client=boto3.client('sts')
account=client.get_caller_identity()]['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="pytorch-extended-container-test"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)

ecr_image
# This should return something like
# 12-digits-of-your-account.dkr.ecr.us-east-2.amazonaws.com/tf-2.2-test:latest

3. Use the ecr_image retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker PyTorch estimator.

```python
import sagemaker

from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator=Estimator(extend a Pre-built Container

```python
image_uri=ecr_image,
role=get_execution_role(),
base_job_name='pytorch-extended-container-test',
instance_count=1,
instance_type='ml.p2.xlarge'
)

# start training
estimator.fit()

# deploy the trained model
predictor=estimator.deploy(1, instance_type)
```

### Step 6: Clean up Resources

To clean up resources when done with the Get Started example

1. Open the [SageMaker console](https://console.aws.amazon.com/sagemaker/home?region), choose the notebook instance **RunScriptNotebookInstance**, choose **Actions**, and choose **Stop**. It can take a few minutes for the instance to stop.

2. After the instance **Status** changes to **Stopped**, choose **Actions**, choose **Delete**, and then choose **Delete** in the dialog box. It can take a few minutes for the instance to be deleted. The notebook instance disappears from the table when it has been deleted.

3. Open the [Amazon S3 console](https://console.aws.amazon.com/s3/home) and delete the bucket that you created for storing model artifacts and the training dataset.

4. Open the [IAM console](https://console.aws.amazon.com/iam/home) and delete the IAM role. If you created permission policies, you can delete them, too.

---

**Note**

The Docker container shuts down automatically after it has run. You don't need to delete it.

---

### Adapting your own Docker container to work with SageMaker

You can adapt an existing Docker image to work with SageMaker. You may need to use an existing, external Docker image with SageMaker when you have a container that satisfies feature or safety
requirements that are not currently supported by a pre-built SageMaker image. There are two toolkits that allow you to bring your own container and adapt it to work with SageMaker:

- SageMaker Training Toolkit
- SageMaker Inference Toolkit

The following topics show how to adapt your existing image using the SageMaker Training and Inference toolkits:

Topics
- Individual Framework Libraries
- Using the SageMaker Training and Inference Toolkits
- Adapting your own training container
- Adapting Your Own Inference Container

Individual Framework Libraries

In addition to the SageMaker Training Toolkit and SageMaker Inference Toolkit, SageMaker also provides toolkits specialized for TensorFlow, MXNet, PyTorch, and Chainer. The following table provides links to the GitHub repositories that contain the source code for each framework and their respective serving toolkits. The instructions linked are for using the Python SDK to run training algorithms and host models on SageMaker. The functionality for these individual libraries is included in the SageMaker Training Toolkit and SageMaker Inference Toolkit.

<table>
<thead>
<tr>
<th>Framework</th>
<th>Toolkit Source Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td><a href="#">SageMaker TensorFlow Training</a></td>
</tr>
<tr>
<td></td>
<td><a href="#">SageMaker TensorFlow Serving</a></td>
</tr>
<tr>

<td><a href="#">SageMaker MXNet Inference</a></td>
</tr>
<tr>
<td>PyTorch</td>
<td><a href="#">SageMaker PyTorch Training</a></td>
</tr>
<tr>
<td></td>
<td><a href="#">SageMaker PyTorch Inference</a></td>
</tr>
</tbody>
</table>
Using the SageMaker Training and Inference Toolkits

The SageMaker Training and SageMaker Inference toolkits implement the functionality that you need to adapt your containers to run scripts, train algorithms, and deploy models on SageMaker. When installed, the library defines the following for users:

- The locations for storing code and other resources.
- The entry point that contains the code to run when the container is started. Your Dockerfile must copy the code that needs to be run into the location expected by a container that is compatible with SageMaker.
- Other information that a container needs to manage deployments for training and inference.

SageMaker Toolkits Containers Structure

When SageMaker trains a model, it creates the following file folder structure in the container's /opt/ml directory.

```
/opt/ml
### input
#   ### config
#   #   ### hyperparameters.json
#   #   ### resourceConfig.json
#   ### data
#       ### <channel_name>
#           ### <input data>
### model
#
### code
#
### output
#
### failure
```
When you run a model training job, the SageMaker container uses the /opt/ml/input/ directory, which contains the JSON files that configure the hyperparameters for the algorithm and the network layout used for distributed training. The /opt/ml/input/ directory also contains files that specify the channels through which SageMaker accesses the data, which is stored in Amazon Simple Storage Service (Amazon S3). The SageMaker containers library places the scripts that the container will run in the /opt/ml/code/ directory. Your script should write the model generated by your algorithm to the /opt/ml/model/ directory. For more information, see Use Your Own Training Algorithms.

When you host a trained model on SageMaker to make inferences, you deploy the model to an HTTP endpoint. The model makes real-time predictions in response to inference requests. The container must contain a serving stack to process these requests.

In a hosting or batch transform container, the model files are located in the same folder to which they were written during training.

```
/opt/ml/model
#
### <model files>
```

For more information, see Use your own inference code.

**Single Versus Multiple Containers**

You can either provide separate Docker images for the training algorithm and inference code or you can use a single Docker image for both. When creating Docker images for use with SageMaker, consider the following:

- Providing two Docker images can increase storage requirements and cost because common libraries might be duplicated.

- In general, smaller containers start faster for both training and hosting. Models train faster and the hosting service can react to increases in traffic by automatically scaling more quickly.

- You might be able to write an inference container that is significantly smaller than the training container. This is especially common when you use GPUs for training, but your inference code is optimized for CPUs.

- SageMaker requires that Docker containers run without privileged access.
• Both Docker containers that you build and those provided by SageMaker can send messages to the Stdout and Stderr files. SageMaker sends these messages to Amazon CloudWatch logs in your AWS account.

For more information about how to create SageMaker containers and how scripts are executed inside them, see the SageMaker Training Toolkit and SageMaker Inference Toolkit repositories on GitHub. They also provide lists of important environmental variables and the environmental variables provided by SageMaker containers.

Adapting your own training container

To run your own training model, build a Docker container using the Amazon SageMaker Training Toolkit through an Amazon SageMaker notebook instance.

**Step 1: Create a SageMaker notebook instance**

2. In the left navigation pane, choose **Notebook**, choose **Notebook instances**, and then choose **Create notebook instance**.
3. On the **Create notebook instance** page, provide the following information:
   a. For **Notebook instance name**, enter **RunScriptNotebookInstance**.
   b. For **Notebook Instance type**, choose **ml.t2.medium**.
   c. In the **Permissions and encryption** section, do the following:
      i. For **IAM role**, choose **Create a new role**. This opens a new window.
      ii. On the **Create an IAM role** page, choose **Specific S3 buckets**, specify an Amazon S3 bucket named **sagemaker-run-script**, and then choose **Create role**.

      SageMaker creates an IAM role named **AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS**. For example, **AmazonSageMaker-ExecutionRole-20190429T110788**. Note that the execution role naming convention uses the date and time at which the role was created, separated by a T.
   d. For **Root Access**, choose **Enable**.
   e. Choose **Create notebook instance**.
4. On the **Notebook instances** page, the **Status** is **Pending**. It can take a few minutes for Amazon SageMaker to launch a machine learning compute instance—in this case, it launches
a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see `CreateNotebookInstance`.

5. Click on the Name of the notebook you just created. This opens a new page.

6. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: `arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788`

7. After the status of the notebook instance changes to InService, choose Open JupyterLab.

**Step 2: Create and upload the Dockerfile and Python training scripts**

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name `docker_test_folder`.

2. Create a Dockerfile text file in the `docker_test_folder` directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
#Download an open source TensorFlow Docker image
FROM tensorflow/tensorflow:latest-gpu-jupyter

# Install sagemaker-training toolkit that contains the common functionality necessary to create a container compatible with SageMaker and the Python SDK.
RUN pip3 install sagemaker-training

# Copies the training code inside the container
COPY train.py /opt/ml/code/train.py

# Defines train.py as script entrypoint
ENV SAGEMAKER_PROGRAM train.py
```

The Dockerfile script performs the following tasks:
- **FROM tensorflow/tensorflow:latest-gpu-jupyter** – Downloads the latest TensorFlow Docker base image. You can replace this with any Docker base image you want to bring to build containers, as well as with AWS pre-built container base images.

- **RUN pip install sagemaker-training** – Installs [SageMaker Training Toolkit](https://docs.aws.amazon.com/sagemaker/latest/dg/training-toolkit.html) that contains the common functionality necessary to create a container compatible with SageMaker.

- **COPY train.py /opt/ml/code/train.py** – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- **ENV SAGEMAKER_PROGRAM train.py** – Takes your training script `train.py` as the entrypoint script copied in the `/opt/ml/code` folder of the container. This is the only environmental variable that you must specify when you build your own container.

**d.** On the left directory navigation pane, the text file name might automatically be named `untitled.txt`. To rename the file, right-click the file, choose **Rename**, rename the file as `Dockerfile` without the `.txt` extension, and then press Ctrl+s or Command+s to save the file.

3. **Upload a training script `train.py` to the `docker_test_folder`**. You can use the following example script to create a model that reads handwritten digits trained on the MNIST dataset for this exercise.

```python
import tensorflow as tf
import os

mnist = tf.keras.datasets.mnist

(x_train, y_train), (x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

model = tf.keras.models.Sequential([
    tf.keras.layers.Flatten(input_shape=(28, 28)),
    tf.keras.layers.Dense(128, activation='relu'),
    tf.keras.layers.Dropout(0.2),
    tf.keras.layers.Dense(10, activation='softmax')
])

model.compile(optimizer='adam',
              loss='sparse_categorical_crossentropy',
              metrics=['accuracy'])
```

---

Adapting your own training container
Step 3: Build the container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose the latest version of conda_tensorflow2 in the Notebook section.

2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```bash
   cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```bash
   ! pwd
   ```

   Output: /home/ec2-user/SageMaker/docker_test_folder

3. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```bash
   ! docker build -t tf-custom-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

   **Note**

   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```bash
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```
Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the -f flag. For example, if you named your Dockerfile as Dockerfile-text.txt, run the following command:

```
! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
```

**Step 4: Test the container**

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose the latest version of conda_tensorflow2 in the Notebook section.

2. Paste the following example script into the notebook code cell to configure a SageMaker Estimator.

```python
import sagemaker
from sagemaker.estimator import Estimator

estimator = Estimator(image_uri='tf-custom-container-test',
                      role=sagemaker.get_execution_role(),
                      instance_count=1,
                      instance_type='local')

estimator.fit()
```

In the preceding code example, sagemaker.get_execution_role() is specified to the role argument to automatically retrieve the role set up for the SageMaker session. You can also replace it with the string value of the IAM role ARN number you used when you configured the notebook instance. The ARN should look like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'.

3. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.
Step 5: Push the container to Amazon Elastic Container Registry (Amazon ECR)

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs. If you want to use a private Docker registry instead of Amazon ECR, see Push your training container to a private registry.

Run the following command lines in a notebook cell.

```bash
%%sh

# Specify an algorithm name
algorithm_name=tf-custom-container-test

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
```
Note

This bash shell script may raise a permission issue similar to the following error message:

```
denied: User: [ARN] is not authorized to perform: ecr:InitiateLayerUpload on resource:
arn:aws:ecr:us-east-1:[id]:repository/tf-custom-container-test
```

If this error occurs, you need to attach the `AmazonEC2ContainerRegistryFullAccess` policy to your IAM role. Go to the IAM console, choose Roles from the left navigation pane, look up the IAM role you used for the Notebook instance. Under the Permission tab, choose the Attach policies button, and search the `AmazonEC2ContainerRegistryFullAccess` policy. Mark the check box of the policy, and choose Add permissions to finish.

2. Run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'

byoc_image_uri = '{}.dkr.ecr.{}.{}.{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

byoc_image_uri
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/sagemaker-byoc-test:latest
```
3. Use the ecr_image retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker estimator with the byoc_image_uri and initiates a training job on an Amazon EC2 instance.

**SageMaker Python SDK v1**

```python
import sagemaker
from sagemaker import get_execution_role, estimator

estimator = estimator(image_uri=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.g4dn.xlarge')

#train your model
estimator.fit()
```

**SageMaker Python SDK v2**

```python
import sagemaker
from sagemaker import get_execution_role, estimator

estimator = estimator(image_uri=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.g4dn.xlarge')

#train your model
estimator.fit()
```

4. If you want to deploy your model using your own container, refer to [Adapting Your Own Inference Container](#). You can also use an AWS framework container that can deploy a TensorFlow model. To deploy the example model to read handwritten digits, enter the following example script into the same notebook that you used to train your model in the previous sub-step to obtain the image URIs (universal resource identifiers) needed for deployment, and deploy the model.
import boto3
import sagemaker

#obtain image uris
from sagemaker import image_uris
container = image_uris.retrieve(framework='tensorflow', region='us-west-2', version='2.11.0',
                               image_scope='inference', instance_type='ml.g4dn.xlarge')

# create the model entity, endpoint configuration and endpoint
predictor = estimator.deploy(1, instance_type='ml.g4dn.xlarge', image_uri=container)

Test your model using a sample handwritten digit from the MNIST dataset using the following code example.

# Retrieve an example test dataset to test
import numpy as np
import matplotlib.pyplot as plt
from keras.datasets import mnist

# Load the MNIST dataset and split it into training and testing sets
(x_train, y_train), (x_test, y_test) = mnist.load_data()
# Select a random example from the training set
example_index = np.random.randint(0, x_train.shape[0])
example_image = x_train[example_index]
example_label = y_train[example_index]

# Print the label and show the image
print(f"Label: {example_label}")
plt.imshow(example_image, cmap='gray')
plt.show()

Convert the test handwritten digit into a form that TensorFlow can ingest and make a test prediction.

from sagemaker.serializers import JSONSerializer
data = {"instances": example_image.tolist()}
predictor.serializer=JSONSerializer()  # update the predictor to use the JSONSerializer
predictor.predict(data)  # make the prediction
For a full example that shows how to test a custom container locally and push it to an Amazon ECR image, see the Building Your Own TensorFlow Container example notebook.

Tip

To profile and debug training jobs to monitor system utilization issues (such as CPU bottlenecks and GPU underutilization) and identify training issues (such as overfitting, overtraining, exploding tensors, and vanishing gradients), use Amazon SageMaker Debugger. For more information, see Use Debugger with Custom Training Containers.

Step 6: Clean up resources

To clean up resources when done with the get started example

1. Open the SageMaker console, choose the notebook instance RunScriptNotebookInstance, choose Actions, and choose Stop. It can take a few minutes for the instance to stop.
2. After the instance Status changes to Stopped, choose Actions, choose Delete, and then choose Delete in the dialog box. It can take a few minutes for the instance to be deleted. The notebook instance disappears from the table when it has been deleted.
3. Open the Amazon S3 console and delete the bucket that you created for storing model artifacts and the training dataset.
4. Open the IAM console and delete the IAM role. If you created permission policies, you can delete them, too.

Note

The Docker container shuts down automatically after it has run. You don't need to delete it.

Blogs and Case Studies

The following blogs discuss case studies about using custom training containers in Amazon SageMaker.

• Why bring your own container to Amazon SageMaker and how to do it right, Medium (January 20th, 2023)
Adapt your training job to access images in a private Docker registry

You can use a private Docker registry instead of an Amazon Elastic Container Registry (Amazon ECR) to host your images for SageMaker Training. The following instructions show you how to create a Docker registry, configure your virtual private cloud (VPC) and training job, store images, and give SageMaker access to the training image in the private docker registry. These instructions also show you how to use a Docker registry that requires authentication for a SageMaker training job.

Create and store your images in a private Docker registry

Create a private Docker registry to store your images. Your registry must:

- use the Docker Registry HTTP API protocol
- be accessible from the same VPC specified in the VpcConfig parameter in the CreateTrainingJob API. Input VpcConfig when you create your training job.
- secured with a TLS certificate from a known public certificate authority.

For more information about creating a Docker registry, see Deploy a registry server.

Configure your VPC and SageMaker training job

SageMaker uses a network connection within your VPC to access images in your Docker registry. To use the images in your Docker registry for training, the registry must be accessible from an Amazon VPC in your account. For more information, see Use a Docker registry that requires authentication for training.

You must also configure your training job to connect to the same VPC to which your Docker registry has access. For more information, see Configure a Training Job for Amazon VPC Access.

Create a training job using an image from your private Docker registry

To use an image from your private Docker registry for training, use the following guide to configure your image, configure and create a training job. The code examples that follow use the AWS SDK for Python (Boto3) client.

1. Create a training image configuration object and input Vpc the TrainingRepositoryAccessMode field as follows.

```python
training_image_config = {
```
Note

If your private Docker registry requires authentication, you must add a `TrainingRepositoryAuthConfig` object to the training image configuration object. You must also specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides access credentials to SageMaker using the `TrainingRepositoryCredentialsProviderArn` field of the `TrainingRepositoryAuthConfig` object. For more information, see the example code structure below.

```python
training_image_config = {
    'TrainingRepositoryAccessMode': 'Vpc',
    'TrainingRepositoryAuthConfig': {
        'TrainingRepositoryCredentialsProviderArn':
            'arn:aws:lambda:Region:Acct:function:FunctionName'
    }
}
```

For information about how to create the Lambda function to provide authentication, see [Use a Docker registry that requires authentication for training](#).

2. Use a Boto3 client to create a training job and pass the correct configuration to the `create_training_job` API. The following instructions show you how to configure the components and create a training job.

a. Create the `AlgorithmSpecification` object that you want to pass to `create_training_job`. Use the training image configuration object that you created in the previous step, as shown in the following code example.

```python
algorithm_specification = {
    'TrainingImage': 'myteam.myorg.com/docker-local/my-training-image:<IMAGE-TAG>',
    'TrainingImageConfig': training_image_config,
    'TrainingInputMode': 'File'
}
```
b. Specify the name of the training job and role that you want to pass to `create_training_job`, as shown in the following code example.

```python
training_job_name = 'private-registry-job'
execution_role_arn = 'arn:aws:iam::123456789012:role/SageMakerExecutionRole'
```

c. Specify a security group and subnet for the VPC configuration for your training job. Your private Docker registry must allow inbound traffic from the security groups that you specify, as shown in the following code example.

```python
vpc_config = {
    'SecurityGroupIds': ['sg-0123456789abcdef0'],
    'Subnets': ['subnet-0123456789abcdef0', 'subnet-0123456789abcdef1']
}
```

**Note**

If your subnet is not in the same VPC as your private Docker registry, you must set up a networking connection between the two VPCs. See [Connect VPCs using VPC peering](#) for more information.

d. Specify the resource configuration, including machine learning compute instances and storage volumes to use for training, as shown in the following code example.

```python
resource_config = {
    'InstanceType': 'ml.m4.xlarge',
    'InstanceCount': 1,
    'VolumeSizeInGB': 10,
}
```

e. Specify the input and output data configuration, where the training dataset is stored, and where you want to store model artifacts, as shown in the following code example.

```python
input_data_config = [
```
f. Specify the maximum number of seconds that a model training job can run as shown in the following code example.

```python
ing stopping_condition = {
    'MaxRuntimeInSeconds': 1800
}
```

g. Finally, create the training job using the parameters you specified in the previous steps as shown in the following code example.

```python
import boto3
sm = boto3.client('sagemaker')
try:
    resp = sm.create_training_job(
        TrainingJobName=training_job_name,
        AlgorithmSpecification=algorithmSpecification,
        RoleArn=execution_role_arn,
        InputDataConfig=input_data_config,
        OutputDataConfig=output_data_config,
        ResourceConfig=resource_config,
        VpcConfig=vpc_config,
        StoppingCondition=stopping_condition
    )
except Exception as e:
    print(f'error calling CreateTrainingJob operation: {e}')
```
Use a SageMaker estimator to run a training job

You can also use an estimator from the SageMaker Python SDK to handle the configuration and running of your SageMaker training job. The following code examples show how to configure and run an estimator using images from a private Docker registry.

1. Import the required libraries and dependencies, as shown in the following code example.

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator

session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

2. Provide a Uniform Resource Identifier (URI) to your training image, security groups and subnets for the VPC configuration for your training job, as shown in the following code example.

```python
image_uri = "myteam.myorg.com/docker-local/my-training-image:<IMAGE-TAG>"
security_groups = ["sg-0123456789abcdef0"]
subnets = ["subnet-0123456789abcdef0", "subnet-0123456789abcdef0"]
```

For more information about `security_group_ids` and `subnets`, see the appropriate parameter description in the Estimators section of the SageMaker Python SDK.

**Note**

SageMaker uses a network connection within your VPC to access images in your Docker registry. To use the images in your Docker registry for training, the registry must be accessible from an Amazon VPC in your account.

3. Optionally, if your Docker registry requires authentication, you must also specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides access credentials to SageMaker. The following code example shows how to specify the ARN.
For more information about using images in a Docker registry requiring authentication, see **Use a Docker registry that requires authentication for training** below.

4. Use the code examples from the previous steps to configure an estimator, as shown in the following code example.

```python
# The training repository access mode must be 'Vpc' for private docker registry jobs
training_repository_access_mode = "Vpc"

# Specify the instance type, instance count you want to use
instance_type="ml.m5.xlarge"
instance_count=1

# Specify the maximum number of seconds that a model training job can run
max_run_time = 1800

# Specify the output path for the model artifacts
output_path = "s3://your-output-bucket/your-output-path"

estimator = Estimator(
    image_uri=image_uri,
    role=role,
    subnets=subnets,
    security_group_ids=security_groups,
    training_repository_access_mode=training_repository_access_mode,
    training_repository_credentials_provider_arn=training_repository_credentials_provider_arn,
    # remove this line if auth is not needed
    instance_type=instance_type,
    instance_count=instance_count,
    output_path=output_path,
    max_run=max_run_time
)
```

5. Start your training job by calling `estimator.fit` with your job name and input path as parameters, as shown in the following code example.

```python
input_path = "s3://your-input-bucket/your-input-path"
job_name = "your-job-name"
```
Use a Docker registry that requires authentication for training

If your Docker registry requires authentication, you must create an AWS Lambda function that provides access credentials to SageMaker. Then, create a training job and provide the ARN of this Lambda function inside the `create_training_job` API. Lastly, you can optionally create an interface VPC endpoint so that your VPC can communicate with your Lambda function without sending traffic over the internet. The following guide shows how to create a Lambda function, assign it the correct role and create an interface VPC endpoint.

Create the Lambda function

Create an AWS Lambda function that passes access credentials to SageMaker and returns a response. The following code example creates the Lambda function handler, as follows.

```python
def handler(event, context):
    response = {
        "Credentials": {
            "Username": "username",
            "Password": "password"
        }
    }
    return response
```

The type of authentication used to set up your private Docker registry determines the contents of the response returned by your Lambda function as follows.

- If your private Docker registry uses basic authentication, the Lambda function will return the username and password needed in order to authenticate to the registry.

- If your private Docker registry uses bearer token authentication, the username and password are sent to your authorization server, which then returns a bearer token. This token is then used to authenticate to your private Docker registry.
Note

If you have more than one Lambda functions for your registries in the same account, and the execution role is the same for your training jobs, then training jobs for registry one would have access to the Lambda functions for other registries.

Grant the correct role permission to your Lambda function

The IAMrole that you use in the create_training_job API must have permission to call an AWS Lambda function. The following code example shows how to extend permissions policy of an IAM role to call myLambdaFunction.

```
{
   "Effect": "Allow",
   "Action": [
      "lambda:InvokeFunction"
   ],
   "Resource": [
      "arn:aws:lambda:*:*:function:*myLambdaFunction*"
   ]
}
```

For information about editing a role permissions policy, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

Note

An IAM role with an attached AmazonSageMakerFullAccess managed policy has permission to call any Lambda function with "SageMaker" in its name.

Create an interface VPC endpoint for Lambda

If you create an interface endpoint, your Amazon VPC can communicate with your Lambda function without sending traffic over the internet. For more information, see Configuring interface VPC endpoints for Lambda in the AWS Lambda Developer Guide.

After your interface endpoint is created, SageMaker training will call your Lambda function by sending a request through your VPC to lambda.region.amazonaws.com. If you select
Enable DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, you must map lambda.region.amazonaws.com, to your Lambda interface endpoint.

Adapting Your Own Inference Container

If none of the Amazon SageMaker pre-built inference containers suffice for your situation, you can build your own Docker container and use it inside SageMaker for training and inference. For more information and an example of how to build your own Docker container for training and inference with SageMaker, see Building your own algorithm container.

You can also use the SageMaker Inference Toolkit to adapt your container to work with SageMaker hosting. The following guide shows you how to use the SageMaker Inference Toolkit to adapt your inference container.

Using the SageMaker inference toolkit

To adapt your container to work with SageMaker hosting, create the inference code in one or more Python script files and use a Dockerfile that imports the inference toolkit.

The inference code for the inference toolkit should include an inference handler, a handler service, and an entrypoint. In this example, they are stored as three separate Python files. All three of these Python files must be in the same directory as your Dockerfile.

For an example Jupyter notebook that shows a complete example of extending a container by using the SageMaker inference toolkit, see Amazon SageMaker Multi-Model Endpoints using your own algorithm container.

Step 1: Create an Inference Handler

The SageMaker inference toolkit is built on the multi-model server (MMS). MMS expects a Python script that implements the following functions:

- Load the model.
- Pre-process input data.
- Get predictions from the model.
- Process the output data in a model handler.

Optionally, you can use the context argument in the functions you implement to access additional serving information, such as a GPU ID or the batch size. If you are using multiple
GPUs, you must specify the context argument in the predict_fn function to select a GPU for prediction. For more information about the context argument and how to use it, see the examples in The SageMaker PyTorch Model Server in the SageMaker Python SDK.

The model_fn Function

The model_fn function loads your model. There are default implementations for the model_fn function, named default_model_fn, on the SageMaker PyTorch and MXNet Inference toolkits. The default implementation loads models saved using torchscript, of the form .pt or .pth. If your model requires custom methods to load, or you want to perform extra steps when loading your model, you must implement the model_fn function. The following simple example shows an implementation of a model_fn function that loads a PyTorch model:

```python
def model_fn(self, model_dir):
    import torch

    logger.info('model_fn')
    device = "cuda" if torch.cuda.is_available() else "cpu"
    with open(os.path.join(model_dir, 'model.pth'), 'rb') as f:
        model = torch.jit.load(f)
    return model.to(device)
```

The input Function

The input_fn pre-processes input data. Specifically, the input_fn function is responsible for deserializing your input data so that it can be passed to your model. It takes input data and content type as parameters, and returns deserialized data. The SageMaker inference toolkit provides a default implementation that deserializes the following content types:

- JSON
- CSV
- Numpy array
- NPZ

If your model requires a different content type, or you want to preprocess your input data before sending it to the model, you must implement the input_fn function. The following example shows a simple implementation of the input_fn function.

```python
from sagemaker_inference import content_types, decoder
```
def input_fn(self, input_data, content_type):
    """A default input_fn that can handle JSON, CSV and NPZ formats.
    Args:
        input_data: the request payload serialized in the content_type format
        content_type: the request content_type
    Returns: input_data deserialized into torch.FloatTensor or
torch.cuda.FloatTensor depending if cuda is available.
    """
    return decoder.decode(input_data, content_type)

The predict_fn Function

The predict_fn function is responsible for getting predictions from the model. It takes the model
and the data returned from input_fn as parameters, and returns the prediction. There is no
default implementation for the predict_fn. You must implement it yourself. The following is a
simple implementation of the predict_fn function for a PyTorch model.

def predict_fn(self, data, model):
    """A default predict_fn for PyTorch. Calls a model on data deserialized in
    input_fn.
    Runs prediction on GPU if cuda is available.
    Args:
        data: input data (torch.Tensor) for prediction deserialized by input_fn
        model: PyTorch model loaded in memory by model_fn
    Returns: a prediction
    """
    return model(data)

The output_fn Function

The output_fn function processes the output data in a model handler. A model handler contains
functions that are defined at the model level. The output_fn function is responsible for serializing
the data that the predict_fn function returns as a prediction. The SageMaker inference toolkit
implements a default output_fn function that serializes Numpy arrays, JSON, and CSV. If your
model outputs any other content type, or you want to perform other post-processing of your data
before sending it to the user, you must implement your own output_fn function. The following
shows a simple output_fn function for a PyTorch model.
from sagemaker_inference import encoder
def output_fn(self, prediction, accept):
    """A default output_fn for PyTorch. Serializes predictions from predict_fn to
    JSON, CSV or NPY format.

    Args:
        prediction: a prediction result from predict_fn
        accept: type which the output data needs to be serialized

    Returns: output data serialized
    """
    return encoder.encode(prediction, accept)

Step 2: Implement a Handler Service

The handler service implements initialize and handle methods, and is run by the model
server. The initialize method is invoked when the model server starts, and the handle method
is invoked for all incoming inference requests to the model server. For more information, see
Custom Service in the Multi-model server documentation. The following is an example of a handler
service for a PyTorch model server.

class HandlerService(DefaultHandlerService):
    """Handler service that is executed by the model server.
    Determines specific default inference handlers to use based on model being used.
    This class extends `DefaultHandlerService`, which define the following:
    - The `handle` method is invoked for all incoming inference requests to the
      model server.
    - The `initialize` method is invoked at model server start up.
    Based on: https://github.com/awslabs/mxnet-model-server/blob/master/docs/
    custom_service.md
    """
    def __init__(self):
        transformer = Transformer(default_inference_handler=DefaultPytorchInferenceHandler())
        super(HandlerService, self).__init__(transformer=transformer)
Step 3: Implement an Entrypoint

An entrypoint starts the model server by invoking the handler service. Specify the location of the entrypoint in your Dockerfile. The following is an example of an entrypoint.

```python
from sagemaker_inference import model_server
model_server.start_model_server(handler_service=HANDLER_SERVICE)
```

Step 4: Write a Dockerfile

Write a Dockerfile. For a full example of a Dockerfile for an inference container, see [Dockerfile](#). In your Dockerfile, copy the model handler from Step 2 and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following is an example of the lines you can add to your Dockerfile to copy the model handler and specify the entrypoint.

```bash
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/entrypoint.py"]
```

Step 5: Build and Register Your Container

Last, build your container and register it. The following shell script from the sample notebook builds the container and uploads it to an Amazon ECR repository in your AWS account.

```
# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel
```

Note

SageMaker hosting supports using inference containers that are stored in repositories other than Amazon ECR. For information, see [Use a Private Docker Registry for Real-Time Inference Containers](#).

The following shell script shows how to build and register a container.

```
%%sh

# The name of our algorithm
classification=algorithm_name=demo-sagemaker-multimodel
```

Adapting Your Own Inference Container
cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1

if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null

# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the Docker image locally with the image name and then push it to ECR
# with the full name.

docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}

You can now use this container to deploy endpoints in SageMaker.

**Additional Information**

For an example of how to deploy an endpoint in SageMaker, see [Amazon SageMaker Multi-Model Endpoints using your own algorithm container](#).

For an introductory tutorial about deploying a model to a real-time inference endpoint, see [Deploy a Machine Learning Model to a Real-Time Inference Endpoint](#).

For information about how to deploy a custom Docker image in SageMaker in an API gateway, see [Creating a machine learning-powered REST API with Amazon API Gateway mapping templates and Amazon SageMaker](#).
Create a container with your own algorithms and models

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. The following sections show how to create Docker containers with your training and inference algorithms for use with SageMaker.

Topics

• **Use Your Own Training Algorithms**
• **Use your own inference code**

Use Your Own Training Algorithms

This section explains how Amazon SageMaker interacts with a Docker container that runs your custom training algorithm. Use this information to write training code and create a Docker image for your training algorithms.

Topics

• [How Amazon SageMaker Runs Your Training Image](#)
• [How Amazon SageMaker Provides Training Information](#)
• [Run Training with EFA](#)
• [How Amazon SageMaker Signals Algorithm Success and Failure](#)
• [How Amazon SageMaker Processes Training Output](#)

How Amazon SageMaker Runs Your Training Image

You can use a custom entrypoint script to automate infrastructure to train in a production environment. If you pass your entrypoint script into your Docker container, you can also run it as a standalone script without rebuilding your images. SageMaker processes your training image using a Docker container entrypoint script.

This section shows you how to use a custom entrypoint without using the training toolkit. If you want to use a custom entrypoint but are unfamiliar with how to manually configure a Docker container, we recommend that you use the [SageMaker training toolkit library](#) instead. For more information about how to use the training toolkit, see [Adapting your own training container](#).
By default, SageMaker looks for a script called `train` inside your container. You can also manually provide your own custom entrypoint by using the `ContainerArguments` and `ContainerEntrypoint` parameters of the `AlgorithmSpecification` API.

You have the following two options to manually configure your Docker container to run your image:

- Use the `CreateTrainingJob` API and a Docker container with an entrypoint instruction contained inside of it.
- Use the `CreateTrainingJob` API, and pass your training script from outside of your Docker container.

If you pass your training script from outside your Docker container, you don’t need to rebuild the Docker container when you update your script. You can also use several different scripts to run in the same container.

Your entrypoint script should contain training code for your image. If you use the optional `source_dir` parameter inside an `estimator`, it should reference the relative Amazon S3 path to the folder containing your entrypoint script. You can reference multiple files using the `source_dir` parameter. If you do not use `source_dir`, you can specify the entrypoint using the `entry_point` parameter. For an example of a custom entrypoint script that contains an estimator, see [Bring Your Own Model with SageMaker Script Mode](#).

**Run a training job with an entrypoint script bundled inside the Docker container**

SageMaker can run an entrypoint script bundled inside your Docker container.

- By default, Amazon SageMaker runs the following container.

  ```bash
docker run image train
  ```

- SageMaker overrides any default `CMD` statements in a container by specifying the `train` argument after the image name. In your Docker container, use the following `exec` form of the `ENTRYPOINT` instruction.

  ```bash
ENTRYPOINT ["executable", "param1", "param2", ...]
  ```

  The following example shows how to specify a python entrypoint instruction called `k-means-algorithm.py`. 

---

Use Your Own Training Algorithms
ENTRYPOINT ["python", "k-means-algorithm.py"]

The exec form of the ENTRYPOINT instruction starts the executable directly, not as a child of /bin/sh. This enables it to receive signals like SIGTERM and SIGKILL from SageMaker APIs. The following conditions apply when using the SageMaker APIs.

- The CreateTrainingJob API has a stopping condition that directs SageMaker to stop model training after a specific time.
- The following shows the StopTrainingJob API. This API issues the equivalent of the docker stop, with a 2-minute timeout command to gracefully stop the specified container.
  
  ```bash
docker stop -t 120
  ```

  The command attempts to stop the running container by sending a SIGTERM signal. After the 2-minute timeout, the API sends SIGKILL and forcibly stops the containers. If the container handles the SIGTERM gracefully and exits within 120 seconds from receiving it, no SIGKILL is sent.

  If you want access to the intermediate model artifacts after SageMaker stops the training, add code to handle saving artifacts in your SIGTERM handler.

- If you plan to use GPU devices for model training, make sure that your containers are nvidia-docker compatible. Include only the CUDA toolkit on containers; don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.
- You can't use the tini initializer as your entrypoint script in SageMaker containers because it gets confused by the train and serve arguments.
- /opt/ml and all subdirectories are reserved by SageMaker training. When building your algorithm’s Docker image, make sure that you don't place any data that's required by your algorithm in this directory. Because if you do, the data may no longer be visible during training.

To bundle your shell or Python scripts inside your Docker image, or to provide the script in an Amazon S3 bucket or by using the AWS Command Line Interface (CLI), continue to the following section.

**Bundle your shell script in a Docker container**

If you want to bundle a custom shell script inside your Docker image, use the following steps.
1. Copy your shell script from your working directory to inside your Docker container. The following code snippet copies a custom entarypoint script `custom_entrypoint.sh` from the current working directory to a Docker container located in `mydir`. The following example assumes that the base Docker image has Python installed.

```
FROM <base-docker-image>:<tag>

# Copy custom entarypoint from current dir to /mydir on container
COPY ./custom_entrypoint.sh /mydir/
```

2. Build and push a Docker container to the Amazon Elastic Container Registry (Amazon ECR) by following the instructions at [Pushing a Docker image](https://docs.aws.amazon.com/AmazonECR/latest/userguide/pushing-image.html) in the Amazon ECR User Guide.

3. Launch the training job by running the following AWS CLI command.

```
aws --region <your-region> sagemaker create-training-job
  --training-job-name <your-training-job-name>
  --role-arn <your-execution-role-arn>
  --algorithm-specification '{
      "TrainingInputMode": "File",
      "TrainingImage": "<your-ecr-image>",
      "ContainerEntrypoint": ["/bin/sh"],
      "ContainerArguments": ["/mydir/custom_entrypoint.sh"]
    }'
  --output-data-config '{"S3OutputPath": "s3://custom-entrypoint-output-bucket/"}]
  --resource-config '{"VolumeSizeInGB": 10,"InstanceCount": 1,"InstanceType": "ml.m5.2xlarge"}
  --stopping-condition '{"MaxRuntimeInSeconds": 180}'
```

### Bundle your Python script in a Docker container

To bundle a custom Python script inside your Docker image, use the following steps.

1. Copy your Python script from your working directory to inside your Docker container. The following code snippet copies a custom entarypoint script `custom_entrypoint.py` from the current working directory to a Docker container located in `mydir`.

```
FROM <base-docker-image>:<tag>

# Copy custom entarypoint from current dir to /mydir on container
COPY ./custom_entrypoint.py /mydir/
```

2. Launch the training job by running the following AWS CLI command.
Run a training job with an entrypoint script outside the Docker container

You can use your own Docker container for training and pass in an entrypoint script from outside the Docker container. There are some benefits to structuring your entrypoint script outside the container. If you update your entrypoint script, you don’t need to rebuild the Docker container. You can also use several different scripts to run in the same container.

Specify the location of your training script using the `ContainerEntrypoint` and `ContainerArguments` parameters of the `AlgorithmSpecification` API. These entrypoints and arguments behave in the same manner as Docker entrypoints and arguments. The values in these parameters override the corresponding `ENTRYPOINT` or `CMD` provided as part of the Docker container.

When you pass your custom entrypoint script to your Docker training container, the inputs that you provide determine the behavior of the container.

- For example, if you provide only `ContainerEntrypoint`, the request syntax using the `CreateTrainingJob` API is as follows.

```json
{
   "AlgorithmSpecification": {
      "ContainerEntrypoint": ["string"],
      "..."
   }
}
```

Then, the SageMaker training backend runs your custom entrypoint as follows.

```bash
docker run --entrypoint <ContainerEntrypoint> image
```
Note

If `ContainerEntrypoint` is provided, the SageMaker training backend runs the image with the given entrypoint and overrides the default `ENTRYPOINT` in the image.

- If you provide only `ContainerArguments`, SageMaker assumes that the Docker container contains an entrypoint script. The request syntax using the `CreateTrainingJob` API is as follows.

```json
{
    "AlgorithmSpecification": {
        "ContainerArguments": ["arg1", "arg2"],
        ...
    }
}
```

The SageMaker training backend runs your custom entrypoint as follows.

```
docker run image <ContainerArguments>
```

- If you provide both the `ContainerEntrypoint` and `ContainerArguments`, then the request syntax using the `CreateTrainingJob` API is as follows.

```json
{
    "AlgorithmSpecification": {
        "ContainerEntrypoint": ["string"],
        "ContainerArguments": ["arg1", "arg2"],
        ...
    }
}
```

The SageMaker training backend runs your custom entrypoint as follows.

```
docker run --entrypoint <ContainerEntrypoint> image <ContainerArguments>
```

You can use any supported `InputDataConfig` source in the `CreateTrainingJob` API to provide an entrypoint script to run your training image.
Provide your entrypoint script in an Amazon S3 bucket

To provide a custom entrypoint script using an S3 bucket, use the S3DataSource parameter of the `DataSource` API to specify the location of the script. If you use the S3DataSource parameter, the following are required.

- The `InputMode` must be of the type `File`.
- The `S3DataDistributionType` must be `FullyReplicated`.

The following example has a script called `custom_entrypoint.sh` placed in a path to an S3 bucket `s3://<bucket-name>/<bucket prefix>/custom_entrypoint.sh`.

```bash
#!/bin/bash
echo "Running custom_entrypoint.sh"
echo "Hello you have provided the following arguments: " "$@
```

Next, you must set the configuration of the input data channel to run a training job. Do this either by using the AWS CLI directly or with a JSON file.

Configure the input data channel using AWS CLI with a JSON file

To configure your input data channel with a JSON file, use AWS CLI as shown in the following code structure. Ensure that all of the following fields use the request syntax defined in the `CreateTrainingJob` API.

```json
// run-my-training-job.json
{
  "AlgorithmSpecification": {
    "ContainerEntrypoint": "/bin/sh",
    "ContainerArguments": ["/opt/ml/input/data/<your_channel_name>/custom_entrypoint.sh"],
    ... 
  },
  "InputDataConfig": [
    {
      "ChannelName": "<your_channel_name>",
      "DataSource": {
        "S3DataSource": {
          "S3DataDistributionType": "FullyReplicated",
          "S3DataType": "S3Prefix",
          
```
Next, run the AWS CLI command to launch the training job from the JSON file as follows.

```bash
aws sagemaker create-training-job --cli-input-json file://run-my-training-job.json
```

**Configure the input data channel using AWS CLI directly**

To configure your input data channel without a JSON file, use the following AWS CLI code structure.

```bash
aws --region <your-region> sagemaker create-training-job \
--training-job-name <your-training-job-name> \
--role-arn <your-execution-role-arn> \
--algorithm-specification '{ \
    "TrainingInputMode": "File", \
    "TrainingImage": "<your-ecr-image>", \
    "ContainerEntrypoint": ["/bin/sh"], \
    "ContainerArguments": ["/opt/ml/input/data/<your_channel_name>/custom_entrypoint.sh"]}' \
--input-data-config '{[ \
    "ChannelName": "<your_channel_name>", \
    "DataSource": { \
        "S3DataSource": { \
            "S3DataType": "S3Prefix", \
            "S3Uri": "s3://<bucket-name>/<bucket_prefix>", \
            "S3DataDistributionType": "FullyReplicated"}}}" \
--output-data-config '{"S3OutputPath": "s3://custom-entrypoint-output-bucket/"}' \
--resource-config '{"VolumeSizeInGB": 10,"InstanceCount": 1,"InstanceType": "ml.m5.2xlarge"}' \
--stopping-condition '{"MaxRuntimeInSeconds": 180}'
```

**How Amazon SageMaker Provides Training Information**

This section explains how SageMaker makes training information, such as training data, hyperparameters, and other configuration information, available to your Docker container.
When you send a `CreateTrainingJob` request to SageMaker to start model training, you specify the Amazon Elastic Container Registry (Amazon ECR) path of the Docker image that contains the training algorithm. You also specify the Amazon Simple Storage Service (Amazon S3) location where training data is stored and algorithm-specific parameters. SageMaker makes this information available to the Docker container so that your training algorithm can use it. This section explains how we make this information available to your Docker container. For information about creating a training job, see `CreateTrainingJob`. For more information on the way that SageMaker containers organize information, see [Using the SageMaker Training and Inference Toolkits](#).

### Topics

- Hyperparameters
- Environment Variables
- Input Data Configuration
- Training Data
- Distributed Training Configuration

### Hyperparameters

SageMaker makes the hyperparameters in a `CreateTrainingJob` request available in the Docker container in the `/opt/ml/input/config/hyperparameters.json` file.

The following is an example of a hyperparameter configuration in `hyperparameters.json` to specify the `num_round` and `eta` hyperparameters in the `CreateTrainingJob` operation for XGBoost.

```json
{
    "num_round": "128",
    "eta": "0.001"
}
```

For a complete list of hyperparameters that can be used for the SageMaker built-in XGBoost algorithm, see [XGBoost Hyperparameters](#).

The hyperparameters that you can tune depend on the algorithm that you are training. For a list of hyperparameters available for a SageMaker built-in algorithm, find them listed in **Hyperparameters** under the algorithm link in [Use Amazon SageMaker Built-in Algorithms or Pre-trained Models](#).
Environment Variables

SageMaker sets the following environment variables in your container:

- TRAINING_JOB_NAME – Specified in the TrainingJobName parameter of the CreateTrainingJob request.
- TRAINING_JOB_ARN – The Amazon Resource Name (ARN) of the training job returned as the TrainingJobArn in the CreateTrainingJob response.
- All environment variables specified in the Environment parameter in the CreateTrainingJob request.

Input Data Configuration

SageMaker makes the data channel information in the InputDataConfig parameter from your CreateTrainingJob request available in the /opt/ml/input/config/inputdataconfig.json file in your Docker container.

For example, suppose that you specify three data channels (train, evaluation, and validation) in your request. SageMaker provides the following JSON:

```json
{
  "train" : {
    "ContentType": "trainingContentType",
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"},
  "evaluation" : {
    "ContentType": "evalContentType",
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"},
  "validation" : {
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"}
}
```

Note

SageMaker provides only relevant information about each data channel (for example, the channel name and the content type) to the container, as shown in the previous example.
S3DistributionType will be set as FullyReplicated if you specify EFS or FSxLustre as input data sources.

Training Data

The TrainingInputMode parameter in the AlgorithmSpecification of the CreateTrainingJob request specifies how the training dataset is made available to your container. The following input modes are available.

• **File mode**

  If you use File mode as your TrainingInputMode value, SageMaker sets the following parameters in your container.

  • Your TrainingInputMode parameter is written to inputdataconfig.json as "File".
  • Your data channel directory is written to /opt/ml/input/data/channel_name.

  If you use File mode, SageMaker creates a directory for each channel. For example, if you have three channels named training, validation, and testing, SageMaker makes the following three directories in your Docker container:

  • /opt/ml/input/data/training
  • /opt/ml/input/data/validation
  • /opt/ml/input/data/testing

  File mode also supports the following data sources.

  • Amazon Simple Storage Service (Amazon S3)
  • Amazon Elastic File System (Amazon EFS)
  • Amazon FSx for Lustre

  **Note**

  Channels that use file system data sources such as Amazon EFS and Amazon FSx must use File mode. In this case, the directory path provided in the channel is mounted at /opt/ml/input/data/channel_name.

• **FastFile mode**
If you use FastFile mode as your TrainingInputNodeParameter, SageMaker sets the following parameters in your container.

- Similar to File mode, in FastFile mode, your TrainingInputMode parameter is written to inputdataconfig.json as "File".
- Your data channel directory is written to /opt/ml/input/data/channel_name.

FastFile mode supports the following data sources.

- Amazon S3

If you use FastFile mode, the channel directory is mounted with read-only permission.

Historically, File mode preceded FastFile mode. To ensure backwards compatibility, algorithms that support File mode can also seamlessly work with FastFile mode as long as the TrainingInputMode parameter is set to File in inputdataconfig.json.

Note

Channels that use FastFile mode must use a S3DataType of "S3Prefix". FastFile mode presents a folder view that uses the forward slash (/) as the delimiter for grouping Amazon S3 objects into folders. S3Uri prefixes must not correspond to a partial folder name. For example, if an Amazon S3 dataset contains s3://my-bucket/train-01/data.csv, then neither s3://my-bucket/train nor s3://my-bucket/train-01 are allowed as S3Uri prefixes.

A trailing forward slash is recommended to define a channel corresponding to a folder. For example, the s3://my-bucket/train-01/ channel for the train-01 folder. Without the trailing forward slash, the channel would be ambiguous if there existed another folder s3://my-bucket/train-011/ or file s3://my-bucket/train-01.txt/.

Pipe mode

- TrainingInputMode parameter written to inputdataconfig.json: "Pipe"
- Data channel directory in the Docker container: /opt/ml/input/data/channel_name_epoch_number
- Supported data sources: Amazon S3
You need to read from a separate pipe for each channel. For example, if you have three channels named training, validation, and testing, you need to read from the following pipes:

- /opt/ml/input/data/training_0, /opt/ml/input/data/training_1, ...
- /opt/ml/input/data/validation_0, /opt/ml/input/data/validation_1, ...
- /opt/ml/input/data/testing_0, /opt/ml/input/data/testing_1, ...

Read the pipes sequentially. For example, if you have a channel called training, read the pipes in this sequence:

1. Open /opt/ml/input/data/training_0 in read mode and read it to end-of-file (EOF) or, if you are done with the first epoch, close the pipe file early.
2. After closing the first pipe file, look for /opt/ml/input/data/training_1 and read it until you have completed the second epoch, and so on.

If the file for a given epoch doesn't exist yet, your code may need to retry until the pipe is created. There is no sequencing restriction across channel types. For example, you can read multiple epochs for the training channel and only start reading the validation channel when you are ready. Or, you can read them simultaneously if your algorithm requires that.

For an example of a Jupyter notebook that shows how to use Pipe mode when bringing your own container, see Bring your own pipe-mode algorithm to Amazon SageMaker.

### Distributed Training Configuration

If you're performing distributed training with multiple containers, SageMaker makes information about all containers available in the /opt/ml/input/config/resourceconfig.json file.

To enable inter-container communication, this JSON file contains information for all containers. SageMaker makes this file available for both File and Pipe mode algorithms. The file provides the following information:

- **current_host**—The name of the current container on the container network. For example, algo-1. Host values can change at any time. Don't write code with specific values for this variable.
- **hosts**—The list of names of all containers on the container network, sorted lexicographically. For example, ["algo-1", "algo-2", "algo-3"] for a three-node cluster. Containers can
use these names to address other containers on the container network. Host values can change at any time. Don't write code with specific values for these variables.

- **network_interface_name**—The name of the network interface that is exposed to your container. For example, containers running the Message Passing Interface (MPI) can use this information to set the network interface name.

- Do not use the information in `/etc/hostname` or `/etc/hosts` because it might be inaccurate.

- Hostname information may not be immediately available to the algorithm container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.

The following is an example file on node 1 in a three-node cluster:

```json
{
    "current_host": "algo-1",
    "hosts": ["algo-1","algo-2","algo-3"],
    "network_interface_name":"eth1"
}
```

## Run Training with EFA

SageMaker provides integration with EFA devices to accelerate High Performance Computing (HPC) and machine learning applications. This integration allows you to leverage an EFA device when running your distributed training jobs. You can add EFA integration to an existing Docker container that you bring to SageMaker. The following information outlines how to configure your own container to use an EFA device for your distributed training jobs.

### Prerequisites

Your container must satisfy the [SageMaker Training container specification](https://sagemaker.readthedocs.io/en/stable/)

### Install EFA and required packages

Your container must download and install the EFA software. This allows your container to recognize the EFA device, and provides compatible versions of Libfabric and Open MPI.

Any tools like MPI and NCCL must be installed and managed inside the container to be used as part of your EFA-enabled training job. For a list of all available EFA versions, see [Verify the EFA installer using a checksum](https://sagemaker.readthedocs.io/en/stable/). The following example shows how to modify the Dockerfile of your EFA-enabled container to install EFA, MPI, OFI, NCCL, and NCCL-TEST.
Note

When using PyTorch with EFA on your container, the NCCL version of your container should match the NCCL version of your PyTorch installation. To verify the PyTorch NCCL version, use the following command:

torch.cuda.nccl.version()

ARG OPEN_MPI_PATH=/opt/amazon/openmpi/
ENV NCCL_VERSION=2.7.8
ENV EFA_VERSION=1.30.0
ENV BRANCH_OFI=1.1.1

##########################################################################
## EFA and MPI SETUP
RUN cd $HOME \\
   && curl -0 https://s3-us-west-2.amazonaws.com/aws-efa-installer/aws-efa-installer-
   ${EFA_VERSION}.tar.gz \\
   && tar -xf aws-efa-installer-${EFA_VERSION}.tar.gz \\
   && cd aws-efa-installer \\
   && ./efa_installer.sh -y --skip-kmod -g \\

ENV PATH="$OPEN_MPI_PATH/bin:$PATH"
ENV LD_LIBRARY_PATH="$OPEN_MPI_PATH/lib/:$LD_LIBRARY_PATH"

##########################################################################
## NCCL, OFI, NCCL-TEST SETUP
RUN cd $HOME \\
   && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \\
   && cd nccl \\
   && make -j64 src.build BUILDDIR=/usr/local \\

RUN apt-get update && apt-get install -y autoconf
RUN cd $HOME \\
   && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \\
   && cd aws-ofi-nccl \\
   && ./autogen.sh \\
   && ./configure --with-libfabric=/opt/amazon/efa \\
      --with-mpi=/opt/amazon/openmpi \\
      --with-cuda=/usr/local/cuda \\

Considerations when creating your container

The EFA device is mounted to the container as /dev/infiniband/uverbs0 under the list of devices accessible to the container. On P4d instances, the container has access to 4 EFA devices. The EFA devices can be found in the list of devices accessible to the container as:

- /dev/infiniband/uverbs0
- /dev/infiniband/uverbs1
- /dev/infiniband/uverbs2
- /dev/infiniband/uverbs3

To get information about hostname, peer hostnames, and network interface (for MPI) from the resourceconfig.json file provided to each container instances, see Distributed Training Configuration. Your container handles regular TCP traffic among peers through the default Elastic Network Interfaces (ENI), while handling OFI (kernel bypass) traffic through the EFA device.

Verify that your EFA device is recognized

To verify that the EFA device is recognized, run the following command from within your container.

```
/opt/amazon/efa/bin/fi_info -p efa
```

Your output should look similar to the following.

```
provider: efa
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-rdm
  version: 2.0
  type: FI_EP_RDM
```
Running a training job with EFA

Once you've created an EFA-enabled container, you can run a training job with EFA using a SageMaker Estimator the same way as you would with any other Docker image. For more information on registering your container and using it for training, see Adapting Your Own Training Container.

How Amazon SageMaker Signals Algorithm Success and Failure

A training algorithm indicates whether it succeeded or failed using the exit code of its process.

A successful training execution should exit with an exit code of 0 and an unsuccessful training execution should exit with a non-zero exit code. These will be converted to Completed and Failed in the TrainingJobStatus returned by DescribeTrainingJob. This exit code convention is standard and is easily implemented in all languages. For example, in Python, you can use `sys.exit(1)` to signal a failure exit, and simply running to the end of the main routine will cause Python to exit with code 0.

In the case of failure, the algorithm can write a description of the failure to the failure file. See next section for details.

How Amazon SageMaker Processes Training Output

As your algorithm runs in a container, it generates output including the status of the training job and model and output artifacts. Your algorithm should write this information to the following files, which are located in the container's /output directory. Amazon SageMaker processes the information contained in this directory as follows:
Use your own inference code

You can use Amazon SageMaker to interact with Docker containers and run your own inference code in one of two ways:

- To use your own inference code with a persistent endpoint to get one prediction at a time, use SageMaker hosting services.
- To use your own inference code to get predictions for an entire dataset, use SageMaker batch transform.

Use Your Own Inference Code with Hosting Services

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for hosting services. Use this information to write inference code and create a Docker image.
Topics

- How SageMaker Runs Your Inference Image
- How SageMaker Loads Your Model Artifacts
- How Your Container Should Respond to Inference Requests
- How Your Container Should Respond to Health Check (Ping) Requests
- Use a Private Docker Registry for Real-Time Inference Containers

How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For model inference, SageMaker runs the container as:

  ```
  docker run image serve
  ```

  SageMaker overrides default CMD statements in a container by specifying the serve argument after the image name. The serve argument overrides arguments that you provide with the CMD command in the Dockerfile.

- SageMaker expects all containers to run with root users. Create your container so that it uses only root users. When SageMaker runs your container, users that do not have root-level access can cause permissions issues.

- We recommend that you use the exec form of the ENTRYPOINT instruction:

  ```
  ENTRYPOINT ["executable", "param1", "param2"]
  ```

  For example:

  ```
  ENTRYPOINT ["python", "k_means_inference.py"]
  ```
The exec form of the ENTRYPOINT instruction starts the executable directly, not as a child of /bin/sh. This enables it to receive signals like SIGTERM and SIGKILL from the SageMaker API operations, which is a requirement.

For example, when you use the `CreateEndpoint` API to create an endpoint, SageMaker provisions the number of ML compute instances required by the endpoint configuration, which you specify in the request. SageMaker runs the Docker container on those instances.

If you reduce the number of instances backing the endpoint (by calling the `UpdateEndpointWeightsAndCapacities` API), SageMaker runs a command to stop the Docker container on the instances that are being terminated. The command sends the SIGTERM signal, then it sends the SIGKILL signal thirty seconds later.

If you update the endpoint (by calling the `UpdateEndpoint` API), SageMaker launches another set of ML compute instances and runs the Docker containers that contain your inference code on them. Then it runs a command to stop the previous Docker containers. To stop a Docker container, command sends the SIGTERM signal, then it sends the SIGKILL signal 30 seconds later.

- SageMaker uses the container definition that you provided in your `CreateModel` request to set environment variables and the DNS hostname for the container as follows:
  
  - It sets environment variables using the `ContainerDefinition.Environment` string-to-string map.
  - It sets the DNS hostname using the `ContainerDefinition.ContainerHostname`.

- If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your `CreateEndpointConfig` request), make sure that your containers are
nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

• You can't use the tini initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

How SageMaker Loads Your Model Artifacts

In your CreateModel API request, you can use either the ModelDataUrl or S3DataSource parameter to identify the S3 location where model artifacts are stored. SageMaker copies your model artifacts from the S3 location to the /opt/ml/model directory for use by your inference code. Your container has read-only access to /opt/ml/model. Do not write to this directory.

The ModelDataUrl must point to a tar.gz file. Otherwise, SageMaker won't download the file.

If you trained your model in SageMaker, the model artifacts are saved as a single compressed tar file in Amazon S3. If you trained your model outside SageMaker, you need to create this single compressed tar file and save it in a S3 location. SageMaker decompresses this tar file into /opt/ml/model directory before your container starts.

For deploying large models, we recommend that you follow Deploying uncompressed models.

How Your Container Should Respond to Inference Requests

To obtain inferences, the client application sends a POST request to the SageMaker endpoint. SageMaker passes the request to the container, and returns the inference result from the container to the client.

For more information about the inference requests that your container will receive, see the following actions in the Amazon SageMaker API Reference:

• InvokeEndpoint
• InvokeEndpointAsync
• InvokeEndpointWithResponseStream

Requirements for inference containers

To respond to inference requests, your container must meet the following requirements:
• SageMaker strips all POST headers except those supported by InvokeEndpoint. SageMaker might add additional headers. Inference containers must be able to safely ignore these additional headers.

• To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the /invocations and /ping endpoints.

• A customer's model containers must accept socket connection requests within 250 ms.

• A customer's model containers must respond to requests within 60 seconds. The model itself can have a maximum processing time of 60 seconds before responding to the /invocations. If your model is going to take 50-60 seconds of processing time, the SDK socket timeout should be set to be 70 seconds.

Example invocation functions

The following examples demonstrate how the code in your container can process inference requests. These examples handle requests that client applications send by using the InvokeEndpoint action.

FastAPI

FastAPI is a web framework for building APIs with Python.

```python
from fastapi import FastAPI, status, Request, Response
...
app = FastAPI()
...
@app.post('/invocations')
async def invocations(request: Request):
    # model() is a hypothetical function that gets the inference output:
    model_resp = await model(Request)

    response = Response(
        content=model_resp,
        status_code=status.HTTP_200_OK,
        media_type="text/plain",
    )
    return response
...
```

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint.
Flask

Flask is a framework for developing web applications with Python.

```python
import flask
...  app = flask.Flask(__name__) ...
@app.route('/invocations', methods=['POST'])
def invoke(request):
    # model() is a hypothetical function that gets the inference output:
    resp_body = model(request)
    return flask.Response(resp_body, mimetype='text/plain')
```

In this example, the `invoke` function handles the inference request that SageMaker sends to the `/invocations` endpoint.

**Example invocation functions for streaming requests**

The following examples demonstrate how the code in your inference container can process streaming inference requests. These examples handle requests that client applications send by using the InvokeEndpointWithResponseStream action.

When a container handles a streaming inference request, it returns the model's inference as a series of parts incrementally as the model generates them. Client applications start receiving responses immediately when they're available. They don't need to wait for the model to generate the entire response. You can implement streaming to support fast interactive experiences, such as chatbots, virtual assistants, and music generators.

**FastAPI**

FastAPI is a web framework for building APIs with Python.

```python
from starlette.responses import StreamingResponse
from fastapi import FastAPI, status, Request
...  app = FastAPI()
...
@app.post('/invocations')
```
async def invocations(request: Request):
    # Streams inference response using HTTP chunked encoding
    async def generate():
        # model() is a hypothetical function that gets the inference output:
        yield await model(Request)
        yield "\n"

    response = StreamingResponse(
        content=generate(),
        status_code=status.HTTP_200_OK,
        media_type="text/plain",
    )
    return response

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint. To stream the response, the example uses the StreamingResponse class from the Starlette framework.

Flask

Flask is a framework for developing web applications with Python.

```python
import flask
...
app = flask.Flask(__name__)
...
@app.route('/invocations', methods=["POST"])
def invocations(request):
    # Streams inference response using HTTP chunked encoding

    def generate():
        # model() is a hypothetical function that gets the inference output:
        yield model(request)
        yield "\n"
    return flask.Response(
        flask.stream_with_context(generate()), mimetype='text/plain')

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint. To stream the response, the example uses the flask.stream_with_context function from the Flask framework.
How Your Container Should Respond to Health Check (Ping) Requests

SageMaker launches new inference containers in the following situations:

- Responding to `CreateEndpoint`, `UpdateEndpoint`, and `UpdateEndpointWeightsAndCapacities` API calls
- Security patching
- Replacing unhealthy instances

Soon after container startup, SageMaker starts sending periodic GET requests to the `/ping` endpoint.

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the `/invocations` endpoint.

If the container does not begin to pass health checks by consistently responding with 200s during the 8 minutes after startup, the new instance launch fails. This causes `CreateEndpoint` to fail, leaving the endpoint in a failed state. The update requested by `UpdateEndpoint` isn't completed, security patches aren't applied, and unhealthy instances aren't replaced.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on `/ping` attempts is 2 seconds.

Use a Private Docker Registry for Real-Time Inference Containers

Amazon SageMaker hosting enables you to use images stored in Amazon ECR to build your containers for real-time inference by default. Optionally, you can build containers for real-time inference from images in a private Docker registry. The private registry must be accessible from an Amazon VPC in your account. Models that you create based on the images stored in your private Docker registry must be configured to connect to the same VPC where the private Docker registry is accessible. For information about connecting your model to a VPC, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC.

Your Docker registry must be secured with a TLS certificate from a known public certificate authority (CA).
**Note**

Your private Docker registry must allow inbound traffic from the security groups you specify in the VPC configuration for your model, so that SageMaker hosting is able to pull model images from your registry. SageMaker can pull model images from DockerHub if there's a path to the open internet inside your VPC.

- [Store Images in a Private Docker Registry other than Amazon Elastic Container Registry](#)
- [Use an Image from a Private Docker Registry for Real-time Inference](#)
- [Allow SageMaker to authenticate to a private Docker registry](#)
- [Create the Lambda function](#)
- [Give your execution role permission to Lambda](#)
- [Create an interface VPC endpoint for Lambda](#)

---

**Store Images in a Private Docker Registry other than Amazon Elastic Container Registry**

To use a private Docker registry to store your images for SageMaker real-time inference, create a private registry that is accessible from your Amazon VPC. For information about creating a Docker registry, see [Deploy a registry server](#) in the Docker documentation. The Docker registry must comply with the following:

- The registry must be a [Docker Registry HTTP API V2](#) registry.
- The Docker registry must be accessible from the same VPC that you specify in the VpcConfig parameter that you specify when you create your model.

**Use an Image from a Private Docker Registry for Real-time Inference**

When you create a model and deploy it to SageMaker hosting, you can specify that it use an image from your private Docker registry to build the inference container. Specify this in the ImageConfig object in the PrimaryContainer parameter that you pass to a call to the [create_model](#) function.
To use an image stored in your private Docker registry for your inference container

1. Create the image configuration object and specify a value of Vpc for the RepositoryAccessMode field.

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc'
   }
   ```

2. If your private Docker registry requires authentication, add a RepositoryAuthConfig object to the image configuration object. For the RepositoryCredentialsProviderArn field of the RepositoryAuthConfig object, specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides credentials that allows SageMaker to authenticate to your private Docker Registry. For information about how to create the Lambda function to provide authentication, see Allow SageMaker to authenticate to a private Docker registry.

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc',
       'RepositoryAuthConfig': {
           'RepositoryCredentialsProviderArn':
               'arn:aws:lambda:Region:Acct:function:FunctionName'
       }
   }
   ```

3. Create the primary container object that you want to pass to create_model, using the image configuration object that you created in the previous step.

   Provide your image in digest form. If you provide your image using the :latest tag, there is a risk that SageMaker pulls a newer version of the image than intended. Using the digest form ensures that SageMaker pulls the intended image version.

   ```python
   primary_container = {
       'ContainerHostname': 'ModelContainer',
       'Image': 'myteam.myorg.com/docker-local/my-inference-image:<IMAGE-TAG>',
       'ImageConfig': image_config
   }
   ```

4. Specify the model name and the execution role that you want to pass to create_model.

   ```python
   model_name = 'vpc-model'
   ```
5. Specify one or more security groups and subnets for the VPC configuration for your model. Your private Docker registry must allow inbound traffic from the security groups that you specify. The subnets that you specify must be in the same VPC as your private Docker registry.

```python
vpc_config = {
    'SecurityGroupIds': ['sg-0123456789abcdef0'],
    'Subnets': ['subnet-0123456789abcdef0', 'subnet-0123456789abcdef1']
}
```

```python
import boto3
sm = boto3.client('sagemaker')
```

7. Create the model by calling `create_model`, using the values you specified in the previous steps for the `PrimaryContainer` and `VpcConfig` parameters.

```python
try:
    resp = sm.create_model(
        ModelName=model_name,
        PrimaryContainer=primary_container,
        ExecutionRoleArn=execution_role_arn,
        VpcConfig=vpc_config,
    )
except Exception as e:
    print(f'error calling CreateModel operation: {e}')
else:
    print(resp)
```

8. Finally, call `create_endpoint_config` and `create_endpoint` to create the hosting endpoint, using the model that you created in the previous step.

```python
endpoint_config_name = 'my-endpoint-config'
sm.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            'VariantName': 'MyVariant',
            'ModelName': model_name,
            'InitialInstanceCount': 1,
        }
    ],
)
```
Allow SageMaker to authenticate to a private Docker registry

To pull an inference image from a private Docker registry that requires authentication, create an AWS Lambda function that provides credentials, and provide the Amazon Resource Name (ARN) of the Lambda function when you call `create_model`. When SageMaker runs `create_model`, it calls the Lambda function that you specified to get credentials to authenticate to your Docker registry.

Create the Lambda function

Create an AWS Lambda function that returns a response with the following form:

```python
def handler(event, context):
    response = {
        "Credentials": {"Username": "username", "Password": "password"}
    }
    return response
```

Depending on how you set up authentication for your private Docker registry, the credentials that your Lambda function returns can mean either of the following:

- If you set up your private Docker registry to use basic authentication, provide the sign-in credentials to authenticate to the registry.
- If you set up your private Docker registry to use bearer token authentication, the sign-in credentials are sent to your authorization server, which returns a Bearer token that can then be used to authenticate to the private Docker registry.
Give your execution role permission to Lambda

The execution role that you use to call `create_model` must have permissions to call AWS Lambda functions. Add the following to the permissions policy of your execution role.

```json
{
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda::*::*:function:*myLambdaFunction*"
    ]
}
```

Where `myLambdaFunction` is the name of your Lambda function. For information about editing a role permissions policy, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

Note

An execution role with the AmazonSageMakerFullAccess managed policy attached to it has permission to call any Lambda function with SageMaker in its name.

Create an interface VPC endpoint for Lambda

Create an interface endpoint so that your Amazon VPC can communicate with your AWS Lambda function without sending traffic over the internet. For information about how to do this, see Configuring interface VPC endpoints for Lambda in the AWS Lambda Developer Guide.

SageMaker hosting sends a request through your VPC to `lambda.region.amazonaws.com`, to call your Lambda function. If you choose Private DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, make sure to map `lambda.region.amazonaws.com` to your Lambda interface endpoint.
Use Your Own Inference Code with Batch Transform

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for batch transform. Use this information to write inference code and create a Docker image.

Topics

- How SageMaker Runs Your Inference Image
- How SageMaker Loads Your Model Artifacts
- How Containers Serve Requests
- How Your Container Should Respond to Inference Requests
- How Your Container Should Respond to Health Check (Ping) Requests

How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For batch transforms, SageMaker invokes the model on your behalf. SageMaker runs the container as:

  
  docker run image serve

  The input to batch transforms must be of a format that can be split into smaller files to process in parallel. These formats include CSV, JSON, JSON Lines, TFRecord and RecordIO.

  SageMaker overrides default CMD statements in a container by specifying the serve argument after the image name. The serve argument overrides arguments that you provide with the CMD command in the Dockerfile.

- We recommend that you use the exec form of the ENTRYPOINT instruction:

  
  ENTRYPOINT ["executable", "param1", "param2"]

  For example:
• SageMaker sets environment variables specified in `CreateModel` and `CreateTransformJob` on your container. Additionally, the following environment variables are populated:

  • `SAGEMAKER_BATCH` is set to `true` when the container runs batch transforms.

  • `SAGEMAKER_MAX_PAYLOAD_IN_MB` is set to the largest size payload that is sent to the container via HTTP.

  • `SAGEMAKER_BATCH_STRATEGY` is set to `SINGLE_RECORD` when the container is sent a single record per call to invocations and `MULTI_RECORD` when the container gets as many records as will fit in the payload.

  • `SAGEMAKER_MAX_CONCURRENT_TRANSFORMS` is set to the maximum number of invocations requests that can be opened simultaneously.

  Note
  The last three environment variables come from the API call made by the user. If the user doesn’t set values for them, they aren’t passed. In that case, either the default values or the values requested by the algorithm (in response to the `/execution-parameters`) are used.

• If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your `CreateTransformJob` request), make sure that your containers are nvidia-docker compatible. Don’t bundle NVIDIA drivers with the image. For more information about nvidia-docker, see [NVIDIA/nvidia-docker](https://github.com/NVIDIA/nvidia-docker).

• You can’t use the `init` initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

**How SageMaker Loads Your Model Artifacts**

In a `CreateModel` request, container definitions include the `ModelDataUrl` parameter, which identifies the location in Amazon S3 where model artifacts are stored. When you use SageMaker
to run inferences, it uses this information to determine from where to copy the model artifacts. It copies the artifacts to the /opt/ml/model directory in the Docker container for use by your inference code.

The ModelDataUrl parameter must point to a tar.gz file. Otherwise, SageMaker can't download the file. If you train a model in SageMaker, it saves the artifacts as a single compressed tar file in Amazon S3. If you train a model in another framework, you need to store the model artifacts in Amazon S3 as a compressed tar file. SageMaker decompresses this tar file and saves it in the /opt/ml/model directory in the container before the batch transform job starts.

How Containers Serve Requests

Containers must implement a web server that responds to invocations and ping requests on port 8080. For batch transforms, you have the option to set algorithms to implement execution-parameters requests to provide a dynamic runtime configuration to SageMaker. SageMaker uses the following endpoints:

- ping—Used to periodically check the health of the container. SageMaker waits for an HTTP 200 status code and an empty body for a successful ping request before sending an invocations request. You might use a ping request to load a model into memory to generate inference when invocations requests are sent.

- (Optional) execution-parameters—Allows the algorithm to provide the optimal tuning parameters for a job during runtime. Based on the memory and CPUs available for a container, the algorithm chooses the appropriate MaxConcurrentTransforms, BatchStrategy, and MaxPayloadInMB values for the job.

Before calling the invocations request, SageMaker attempts to invoke the execution-parameters request. When you create a batch transform job, you can provide values for the MaxConcurrentTransforms, BatchStrategy, and MaxPayloadInMB parameters. SageMaker determines the values for these parameters using this order of precedence:

1. The parameter values that you provide when you create the CreateTransformJob request.
2. The values that the model container returns when SageMaker invokes the execution-parameters endpoint>
3. The default parameter values, listed in the following table.
### Parameter Default Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxConcurrentTransforms</td>
<td>1</td>
</tr>
<tr>
<td>BatchStrategy</td>
<td>MULTI_RECORD</td>
</tr>
<tr>
<td>MaxPayloadInMB</td>
<td>6</td>
</tr>
</tbody>
</table>

The response for a GET execution-parameters request is a JSON object with keys for `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` parameters. This is an example of a valid response:

```json
{
  "MaxConcurrentTransforms": 8,
  "BatchStrategy": "MULTI_RECORD",
  "MaxPayloadInMB": 6
}
```

How Your Container Should Respond to Inference Requests

To obtain inferences, Amazon SageMaker sends a POST request to the inference container. The POST request body contains data from Amazon S3. Amazon SageMaker passes the request to the container, and returns the inference result from the container, saving the data from the response to Amazon S3.

To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the `/invocations` endpoint. The inference request timeout and max retries can be configured through `ModelClientConfig`.

How Your Container Should Respond to Health Check (Ping) Requests

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the `/invocations` endpoint.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on `/ping` attempts is 2 seconds.
Examples and More Information: Use Your Own Algorithm or Model

The following Jupyter notebooks and added information show how to use your own algorithms or pretrained models from an Amazon SageMaker notebook instance. For links to the GitHub repositories with the prebuilt Dockerfiles for the TensorFlow, MXNet, Chainer, and PyTorch frameworks and instructions on using the AWS SDK for Python (Boto3) estimators to run your own training algorithms on SageMaker Learner and your own models on SageMaker hosting, see Prebuilt SageMaker Docker Images for Deep Learning

Setup

1. Create a SageMaker notebook instance. For instructions on how to create and access Jupyter notebook instances, see Amazon SageMaker Notebook Instances.
2. Open the notebook instance you created.
3. Choose the SageMaker Examples tab for a list of all SageMaker example notebooks.
4. Open the sample notebooks from the Advanced Functionality section in your notebook instance or from GitHub using the provided links. To open a notebook, choose its Use tab, then choose Create copy.

Host models trained in Scikit-learn

To learn how to host models trained in Scikit-learn for making predictions in SageMaker by injecting them into first-party k-means and XGBoost containers, see the following sample notebooks.

- kmeansBringYourOwnModel
- xgboostBringYourOwnModel

Package TensorFlow and Scikit-learn models for use in SageMaker

To learn how to package algorithms that you have developed in TensorFlow and scikit-learn frameworks for training and deployment in the SageMaker environment, see the following notebooks. They show you how to build, register, and deploy your own Docker containers using Dockerfiles.
Train and deploy a neural network on SageMaker

To learn how to train a neural network locally using MXNet or TensorFlow, and then create an endpoint from the trained model and deploy it on SageMaker, see the following notebooks. The MXNet model is trained to recognize handwritten numbers from the MNIST dataset. The TensorFlow model is trained to classify irises.

- mxnet_mnist_byom
- tensorflow_BYOM_iris

Training using pipe mode

To learn how to use a Dockerfile to build a container that calls the train.py script and uses pipe mode to custom train an algorithm, see the following notebook. In pipe mode, the input data is transferred to the algorithm while it is training. This can decrease training time compared to using file mode.

- pipe_bring_your_own

Bring your own R model

To learn how to use add a custom R image to build and train a model in a AWS SMS notebook, see the following blog post. This blog post uses a sample R Dockerfile from a library of SageMaker Studio Classic Custom Image Samples.

- Bringing your own R environment to Amazon SageMaker Studio Classic

Extend a pre-built PyTorch container Image

To learn how to extend a prebuilt SageMaker PyTorch container image when you have additional functional requirements for your algorithm or model that the prebuilt Docker image doesn’t support, see the following notebook.

- BERTtopic_extending_container
Train and debug training jobs on a custom container

To learn how to train and debug training jobs using SageMaker Debugger, see the following notebook. A training script provided through this example uses the TensorFlow Keras ResNet 50 model and the CIFAR10 dataset. A Docker custom container is built with the training script and pushed to Amazon ECR. While the training job is running, Debugger collects tensor outputs and identifies debugging problems. With smdebug client library tools, you can set a smdebug trial object that calls the training job and debugging information, check the training and Debugger rule status, and retrieve tensors saved in an Amazon S3 bucket to analyze training issues.

- build_your_own_container_with_debugger

Troubleshooting your Docker containers

The following are common errors that you might run into when using Docker containers with SageMaker. Each error is followed by a solution to the error.

- **Error: SageMaker has lost the Docker daemon.**

  To fix this error, restart Docker using the following command.

  ```sh
  sudo service docker restart
  ```

- **Error: The /tmp directory of your Docker container has run out of space.**

  Docker containers use the / and /tmp partitions to store code. These partitions can fill up easily when using large code modules in local mode. The SageMaker Python SDK supports specifying a custom temp directory for your local mode root directory to avoid this issue.

  To specify the custom temp directory in the EBS volume storage, create a file at the following path `~/.sagemaker/config.yaml` and add the following configuration. The directory that you specify as `container_root` must already exist. The SageMaker Python SDK will not try to create it.

  ```yaml
  local:
    container_root: /home/ec2-user/SageMaker/temp
  ```
With this configuration, local mode uses the /temp directory and not the default /tmp directory.
Configure security in Amazon SageMaker

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon SageMaker, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using SageMaker. The following topics show you how to configure SageMaker to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your SageMaker resources.

**Topics**

- [Access Control](#)
- [Data Protection in Amazon SageMaker](#)
- [Identity and Access Management for Amazon SageMaker](#)

Access Control

Amazon SageMaker Studio notebooks and SageMaker notebook instances differ in their runtime environments. The following topics describe how to control root access to these notebooks.

Topics

- Access control and SageMaker Studio notebooks
- Control root access to a SageMaker notebook instance

Access control and SageMaker Studio notebooks

Amazon SageMaker Studio uses filesystem and container permissions for access control and isolation of Studio users and notebooks. This is one of the major differences between Studio notebooks and SageMaker notebook instances. This topic describes how permissions are set up to avoid security threats, what SageMaker does by default, and how the customer can customize the permissions. For more information about Studio notebooks and their runtime environment, see Use Amazon SageMaker Studio Classic Notebooks.

SageMaker app permissions

A run-as user is a POSIX user/group which is used to run the JupyterServer app and KernelGateway apps inside the container.

The run-as user for the JupyterServer app is sagemaker-user (1000) by default. This user has sudo permissions to enable the installation of dependencies such as yum packages.

The run-as user for the KernelGateway apps is root (0) by default. This user is able to install dependencies using pip/apt-get/conda.

Due to user remapping, neither user is able to access resources or make changes to the host instance.

User remapping

SageMaker performs user-remapping to map a user inside the container to a user on the host instance outside the container. The range of user IDs (0 - 65535) in the container are mapped to non-privileged user IDs above 65535 on the instance. For example, sagemaker-user (1000) inside the container might map to user (200001) on the instance, where the number in parentheses is
the user ID. If the customer creates a new user/group inside the container, it won't be privileged on the host instance regardless of the user/group ID. The root user of the container is also mapped to a non-privileged user on the instance. For more information, see Isolate containers with a user namespace.

Note

Files created by the user sagemaker-user may look like they are owned by sagemaker-studio (uid 65534). This is a side effect of a fast app creation mode where SageMaker container images are pre-pulled, allowing applications to start in under a minute. If your application requires the file owner uid and the process owner uid to match, ask the customer service to remove your account number from the image pre-pull feature.

Custom image permissions

Customers can bring their own custom SageMaker images. These images can specify a different run-as user/group to launch the KernelGateway app. The customer can implement fine grained permission control inside the image, for example, to disable root access or perform other actions. The same user remapping applies here. For more information, see Bring your own SageMaker image.

Container isolation

Docker keeps a list of default capabilities that the container can use. SageMaker doesn't add additional capabilities. SageMaker adds specific route rules to block requests to Amazon EFS and the instance metadata service (IMDS) from the container. Customers can't change these route rules from the container. For more information, see Runtime privilege and Linux capabilities.

App metadata access

Metadata used by running apps are mounted to the container with read-only permission. Customers aren't able to modify this metadata from the container. For the available metadata, see Get Studio Classic Notebook and App Metadata.

User isolation on EFS

When you onboard to Studio, SageMaker creates an Amazon Elastic File System (EFS) volume for your domain that is shared by all Studio users in the domain. Each user gets their own private
home directory on the EFS volume. This home directory is used to store the user's notebooks, Git repositories, and other data. To prevent other users in the domain from accessing the user's data, SageMaker creates a globally unique user ID for the user's profile and applies it as a POSIX user/group ID for the user's home directory.

**EBS access**

An Amazon Elastic Block Store (Amazon EBS) volume is attached to the host instance and shared across all images. It's used for the root volume of the notebooks and stores temporary data that's generated inside the container. The storage isn't persisted when the instance running the notebooks is deleted. The root user inside the container can't access the EBS volume.

**IMDS access**

Due to security concerns, access to the Amazon Elastic Compute Cloud (Amazon EC2) Instance Metadata Service (IMDS) is unavailable in SageMaker Studio. For more information on IMDS, see Instance metadata and user data.

**Control root access to a SageMaker notebook instance**

By default, when you create a notebook instance, users that log into that notebook instance have root access. Data science is an iterative process that might require the data scientist to test and use different software tools and packages, so many notebook instance users need to have root access to be able to install these tools and packages. Because users with root access have administrator privileges, users can access and edit all files on a notebook instance with root access enabled.

If you don't want users to have root access to a notebook instance, when you call CreateNotebookInstance or UpdateNotebookInstance operations, set the RootAccess field to Disabled. You can also disable root access for users when you create or update a notebook instance in the Amazon SageMaker console. For information, see Step 1: Create an Amazon SageMaker Notebook Instance.

**Note**

Lifecycle configurations need root access to be able to set up a notebook instance. Because of this, lifecycle configurations associated with a notebook instance always run with root access even if you disable root access for users.
Note

For security reasons, Rootless Docker is installed on root-disabled notebook instances instead of regular Docker. For more information, see Run the Docker daemon as a non-root user (Rootless mode)

Data Protection in Amazon SageMaker

The AWS shared responsibility model applies to data protection in Amazon SageMaker. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon SageMaker or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used
for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Protect Data at Rest Using Encryption

To protect your Amazon SageMaker Studio notebooks and SageMaker notebook instances, along with your model-building data and model artifacts, SageMaker encrypts the notebooks, as well as output from Training and Batch Transform jobs. SageMaker encrypts these by default using the AWS Managed Key for Amazon S3. This AWS Managed Key for Amazon S3 cannot be shared for cross-account access. For cross-account access, specify your customer managed key while creating SageMaker resources so that it can be shared for cross-account access. For data output to Amazon S3 Express One Zone, the data is encrypted with server-side encryption with Amazon S3 managed keys (SSE-S3). For more information on AWS KMS, see What is AWS Key Management Service?.

Topics

- Studio notebooks
- Notebook instances, SageMaker jobs, and Endpoints
- SageMaker geospatial capabilities

Studio notebooks

In Amazon SageMaker Studio, your SageMaker Studio notebooks and data can be stored in the following locations:

- An S3 bucket – When you onboard to Studio and enable shareable notebook resources, SageMaker shares notebook snapshots and metadata in an Amazon Simple Storage Service (Amazon S3) bucket.
- An EFS volume – When you onboard to Studio, SageMaker attaches an Amazon Elastic File System (Amazon EFS) volume to your domain for storing your Studio notebooks and data files. The EFS volume persists after the domain is deleted.
• An EBS volume – When you open a notebook in Studio, an Amazon Elastic Block Store (Amazon EBS) is attached to the instance that the notebook runs on. The EBS volume persists for the duration of the instance.

SageMaker uses the AWS Key Management Service (AWS KMS) to encrypt the S3 bucket and both volumes. By default, it uses a KMS key managed in an AWS service account. For more control, you can specify your own customer managed key when you onboard to Studio or through the SageMaker API. For more information, see Amazon SageMaker Domain overview and CreateDomain.

In the CreateDomain API, you use the S3KmsKeyId parameter to specify the customer managed key for shareable notebooks. You use the KmsKeyId parameter to specify the customer managed key for the EFS and EBS volumes. The same customer managed key is used for both volumes. The customer managed key for shareable notebooks can be the same customer managed key as used for the volumes or a different customer managed key.

Notebook instances, SageMaker jobs, and Endpoints

To encrypt the machine learning (ML) storage volume that is attached to notebooks, processing jobs, training jobs, hyperparameter tuning jobs, batch transform jobs, and endpoints, you can pass an AWS KMS key to SageMaker. If you don't specify a KMS key, SageMaker encrypts storage volumes with a transient key and discards it immediately after encrypting the storage volume. For notebook instances, if you don't specify a KMS key, SageMaker encrypts both OS volumes and ML data volumes with a system-managed KMS key.

You can use an AWS managed AWS KMS key to encrypt all instance OS volumes. You can encrypt all ML data volumes for all SageMaker instances with a AWS KMS key that you specify. ML storage volumes are mounted as follows:

• Notebooks - /home/ec2-user/SageMaker
• Processing - /opt/ml/processing and /tmp/
• Training - /opt/ml/ and /tmp/
• Batch - /opt/ml/ and /tmp/
• Endpoints - /opt/ml/ and /tmp/

Processing, batch transform, and training job containers and their storage are ephemeral in nature. When the job completes, output is uploaded to Amazon S3 using AWS KMS encryption with an
optional AWS KMS key that you specify and the instance is torn down. If an AWS KMS Key is not provided in the job request, SageMaker uses the default AWS KMS key for Amazon S3 for your role's account. If the output data is stored in Amazon S3 Express One Zone, it is encrypted with server-side encryption with Amazon S3 managed keys (SSE-S3).

**Note**

The key policy for an AWS Managed Key for Amazon S3 cannot be edited, so cross-account permissions cannot be granted for these key policies. If the output Amazon S3 bucket for the request is from another account, specify your own AWS KMS Customer Key in the job request and ensure that the job's execution role has permissions to encrypt data with it.

**Important**

Sensitive data that needs to be encrypted with a KMS key for compliance reasons should be stored in the ML storage volume or in Amazon S3, both of which can be encrypted using a KMS key you specify.

When you open a notebook instance, SageMaker saves it and any files associated with it in the SageMaker folder in the ML storage volume by default. When you stop a notebook instance, SageMaker creates a snapshot of the ML storage volume. Any customizations to the operating system of the stopped instance, such as installed custom libraries or operating system level settings, are lost. Consider using a lifecycle configuration to automate customizations of the default notebook instance. When you terminate an instance, the snapshot and the ML storage volume are deleted. Any data that you need to persist beyond the lifespan of the notebook instance should be transferred to an Amazon S3 bucket.

**Note**

Certain Nitro-based SageMaker instances include local storage, depending on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't use a KMS key on an instance type with local storage. For a list of instance types that support local instance storage, see [Instance Store Volumes](#). For more information about storage volumes on Nitro-based instances, see [Amazon EBS and NVMe on Linux Instances](#).
SageMaker geospatial capabilities

You can protect your data at rest using encryption for SageMaker geospatial.

Server-Side Encryption with Amazon SageMaker geospatial owned key (Default)

Amazon SageMaker geospatial capabilities encrypts all your data, including computational results from your EarthObservationJobs and VectorEnrichmentJobs along with all your service metadata. There is no data that is stored within Amazon SageMaker unencrypted. It uses a default AWS owned key to encrypt all your data.

Server-Side Encryption with KMS Keys Stored in AWS Key Management Service (SSE-KMS)

Amazon SageMaker geospatial capabilities supports encryption using a customer-owned KMS key. For more information, see Use AWS KMS Permissions for Amazon SageMaker geospatial capabilities.

Protecting Data in Transit with Encryption

All internetwork data in transit supports TLS 1.2 encryption. We recommend that you use TLS 1.3.

With Amazon SageMaker, machine learning (ML) model artifacts and other system artifacts are encrypted in transit and at rest. Requests to the SageMaker API and console are made over a secure (SSL) connection. You pass AWS Identity and Access Management roles to SageMaker to provide permissions to access resources on your behalf for training and deployment.

Some intranetwork data in transit (inside the service platform) is unencrypted. This includes:

- Command and control communications between the service control plane and training job instances (not customer data).
- Communications between nodes in distributed processing jobs (intranetwork).
- Communications between nodes in distributed training jobs (intranetwork).

There are no inter-node communications for batch processing.

You can choose to encrypt communication between nodes in a training cluster.
For use cases in the healthcare sector, the best practice for security is to encrypt communication between the nodes.

For information about how to encrypt communication, see the next topic at Protect Communications Between ML Compute Instances in a Distributed Training Job.

Encrypting inter-container traffic can increase training time, especially if you use distributed deep learning algorithms. For affected algorithms, this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

FIPS validated endpoints are available for the SageMaker API and request router for hosted models (runtime). For information about FIPS compliant endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Protect Communications with RStudio on Amazon SageMaker

RStudio on Amazon SageMaker provides encryption for all communications that involve SageMaker components. However, the previous version did not support encryption between the RStudioServerPro and RSession apps.

RStudio released version 2022.02.2-485.pro2 in April 2022. This version supports encryption between RStudioServerPro and RSession apps to enable end-to-end encryption. The version upgrade, however, is not completely backward compatible. As a result, you must update all of your RStudioServerPro and RSession apps. For information about how to update your apps, see Upgrade the RStudio Version.

Protect Communications Between ML Compute Instances in a Distributed Training Job

By default, Amazon SageMaker runs training jobs in an Amazon Virtual Private Cloud (Amazon VPC) to help keep your data secure. You can add another level of security to protect your training containers and data by configuring a private VPC. Distributed ML frameworks and algorithms
usually transmit information that is directly related to the model, such as weights, not the training dataset. When performing distributed training, you can further protect data that is transmitted between instances. This can help you to comply with regulatory requirements. To do this, use inter-container traffic encryption.

### Note

For use cases in the healthcare sector, the best practice for security is to encrypt communication between the nodes.

Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. Enabling inter-container traffic encryption doesn't affect training jobs with a single compute instance. However, for training jobs with several compute instances, the effect on training time depends on the amount of communication between compute instances. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

You can enable inter-container traffic encryption for training jobs or hyperparameter tuning jobs. You can use SageMaker APIs or console to enable inter-container traffic encryption.

For information about running training jobs in a private VPC, see [Give SageMaker Training Jobs Access to Resources in Your Amazon VPC](#).

### Enable Inter-container Traffic Encryption (API)

Before enabling inter-container traffic encryption on training or hyperparameter tuning jobs with APIs, add inbound and outbound rules to your private VPC's security group.

**To enable inter-container traffic encryption (API)**

1. Add the following inbound and outbound rules in the security group for your private VPC:

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port Range</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>500</td>
<td>Self Security Group ID</td>
</tr>
<tr>
<td>ESP</td>
<td>50</td>
<td>Self Security Group ID</td>
</tr>
</tbody>
</table>
2. When you send a request to the `CreateTrainingJob` or `CreateHyperParameterTuningJob` API, specify `True` for the `EnableInterContainerTrafficEncryption` parameter.

### Note

For the ESP 50 protocol, the AWS Security Group Console might display the port range as "All". However, Amazon EC2 ignores the specified port range because it is not applicable for the ESP 50 IP protocol.

---

**Enable Inter-container Traffic Encryption (Console)**

**Enable Inter-container Traffic Encryption in a Training Job**

**To enable inter-container traffic encryption in a training job**

2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you have created.
5. Choose **Enable inter-container traffic encryption**.

After you enable inter-container traffic encryption, finish creating the training job. For more information, see [Step 4: Train a Model](#).

**Enable Inter-container Traffic Encryption in a Hyperparameter Tuning Job**

**To enable inter-container traffic encryption in a hyperparameter tuning job**

2. In the navigation pane, choose **Training**, then choose **Hyperparameter tuning jobs**.
3. Choose **Create hyperparameter tuning job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you created.
5. Choose **Enable inter-container traffic encryption**.
After enabling inter-container traffic encryption, finish creating the hyperparameter tuning job. For more information, see Configure and Launch a Hyperparameter Tuning Job.

**Key Management**

Customers can specify AWS KMS keys, including bring your own keys (BYOK), to use for envelope encryption with Amazon S3 input/output buckets and machine learning (ML) Amazon EBS volumes. ML volumes for notebook instances and for processing, training, and hosted model Docker containers can be optionally encrypted by using AWS KMS customer-owned keys. All instance OS volumes are encrypted with an AWS-managed AWS KMS key.

---

**Note**

Certain Nitro-based instances include local storage, dependent on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't request a VolumeKmsKeyId when using an instance type with local storage.

For a list of instance types that support local instance storage, see Instance Store Volumes.

For more information about local instance storage encryption, see SSD Instance Store Volumes.

For more information about storage volumes on nitro-based instances, see Amazon EBS and NVMe on Linux Instances.

---

For information about AWS KMS keys see What is AWS Key Management Service? in the AWS Key Management Service Developer Guide.

**Internetwork Traffic Privacy**

This topic describes how Amazon SageMaker secures connections from the service to other locations.

Internetwork communications support TLS 1.2 encryption between all components and clients. We recommend TLS 1.3.

Instances can be connected to Customer VPC, providing access to S3 VPC endpoints or customer repositories. Internet egress can be managed through this interface by the customer if service platform internet egress is disabled for notebooks. For training and hosting, egress through the service platform is not available when connected to the customer's VPC.
By default, API calls made to published endpoints traverse the public network to the request router. SageMaker supports Amazon Virtual Private Cloud interface endpoints powered by AWS PrivateLink for private connectivity between the customer's VPC and the request router to access hosted model endpoints. For information about Amazon VPC, see Connect to SageMaker Within your VPC.

Identity and Access Management for Amazon SageMaker

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use SageMaker resources. IAM is an AWS service that you can use with no additional charge.

- Troubleshooting Amazon SageMaker Identity and Access

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in SageMaker.

Service user – If you use the SageMaker service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more SageMaker features to do your work, you might need additional permissions. Understanding how access is managed can
help you request the right permissions from your administrator. If you cannot access a feature in SageMaker, see [Troubleshooting Amazon SageMaker Identity and Access](#).

**Service administrator** – If you're in charge of SageMaker resources at your company, you probably have full access to SageMaker. It's your job to determine which SageMaker features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with SageMaker, see [How Amazon SageMaker Works with IAM](#).

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to SageMaker. To view example SageMaker identity-based policies that you can use in IAM, see [Amazon SageMaker Identity-Based Policy Examples](#).

## Authenticating with Identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the [AWS Sign-In User Guide](#).

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the [IAM User Guide](#).

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

IAM Users and Groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier
to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

**IAM Roles**

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
• **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

• **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the [IAM User Guide](#).

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the [IAM User Guide](#).

To learn whether to use IAM roles or IAM users, see [When to create an IAM role (instead of a user)](#) in the [IAM User Guide](#).

### Managing Access Using Policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the [IAM User Guide](#).
Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-Based Policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as **inline policies** or **managed policies**. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

**Resource-Based Policies**

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM **role trust policies** and Amazon S3 **bucket policies**. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.
Access Control Lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other Policy Types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.
Multiple Policy Types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

How Amazon SageMaker Works with IAM

Before you use IAM to manage access to SageMaker, you should understand what IAM features are available to use with SageMaker. To get a high-level view of how SageMaker and other AWS services work with IAM, see AWS Services That Work with IAM in the IAM User Guide.

Topics

• SageMaker Identity-Based Policies

SageMaker Identity-Based Policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. SageMaker supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the IAM User Guide.

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in SageMaker use the following prefix before the action: sagemaker:. For example, to grant someone permission to run a SageMaker training job with the SageMaker CreateTrainingJob API operation, you include the sagemaker:CreateTrainingJob action in
their policy. Policy statements must include either an Action or NotAction element. SageMaker
defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```json
"Action": [
    "sagemaker:action1",
    "sagemaker:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin
with the word Describe, include the following action:

```json
"Action": "sagemaker:Describe*"
```

To see a list of SageMaker actions, see Actions, resources, and condition keys for Amazon SageMaker in the Service Authorization Reference.

Resources

SageMaker does not support specifying resource ARNs in a policy.

Condition Keys

Administrators can use AWS JSON policies to specify who has access to what. That is, which
principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement
is in effect. The Condition element is optional. You can create conditional expressions that use
condition operators, such as equals or less than, to match the condition in the policy with values in
the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single
Condition element, AWS evaluates them using a logical AND operation. If you specify multiple
values for a single condition key, AWS evaluates the condition using a logical OR operation. All of
the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant
an IAM user permission to access a resource only if it is tagged with their IAM user name. For more
information, see IAM policy elements: variables and tags in the IAM User Guide.
AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

SageMaker defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

SageMaker supports a number of service-specific condition keys that you can use for fine-grained access control for the following operations:

- CreateProcessingJob
- CreateTrainingJob
- CreateModel
- CreateEndpointConfig
- CreateTransformJob
- CreateHyperParameterTuningJob
- CreateLabelingJob
- CreateNotebookInstance
- UpdateNotebookInstance

To see a list of SageMaker condition keys, see Condition keys for Amazon SageMaker in the IAM User Guide. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon SageMaker.

For examples of using SageMaker condition keys, see the following: Control Creation of SageMaker Resources with Condition Keys.

Examples

To view examples of SageMaker identity-based policies, see Amazon SageMaker Identity-Based Policy Examples.

SageMaker Resource-Based Policies

SageMaker does not support resource-based policies.
Authorization Based on SageMaker Tags

You can attach tags to SageMaker resources or pass tags in a request to SageMaker. To control access based on tags, you provide tag information in the condition element of a policy using the `sagemaker:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. For more information about tagging SageMaker resources, see Control Access to SageMaker Resources by Using Tags.

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Control Access to SageMaker Resources by Using Tags.

SageMaker IAM Roles

An IAM role is an entity within your AWS account that has specific permissions.

Using Temporary Credentials with SageMaker

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as `AssumeRole` or `GetFederationToken`.

SageMaker supports using temporary credentials.

Service-Linked Roles

SageMaker partially supports service-linked roles. Service-linked roles are currently available for SageMaker Studio Classic and SageMaker training jobs.

Service Roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

SageMaker supports service roles.

Choosing an IAM Role in SageMaker

When you create a notebook instance, processing job, training job, hosted endpoint, or batch transform job resource in SageMaker, you must choose a role to allow SageMaker to access SageMaker on your behalf. If you have previously created a service role or service-linked role, then SageMaker provides you with a list of roles to choose from. It's important to choose a role that
allows access to the AWS operations and resources you need. For more information, see SageMaker Roles.

Amazon SageMaker Identity-Based Policy Examples

By default, IAM users and roles don't have permission to create or modify SageMaker resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. To learn how to attach policies to an IAM user or group, see Adding and Removing IAM Identity Permissions in the IAM User Guide.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the IAM User Guide.

Topics

- Policy Best Practices
- Using the SageMaker Console
- Allow Users to View Their Own Permissions
- Control Creation of SageMaker Resources with Condition Keys
- Control Access to the SageMaker API by Using Identity-based Policies
- Limit Access to SageMaker API and Runtime Calls by IP Address
- Limit Access to a Notebook Instance by IP Address
- Control Access to SageMaker Resources by Using Tags
- Provide Permissions for Tagging SageMaker Resources Upon Creation

Policy Best Practices

Identity-based policies determine whether someone can create, access, or delete SageMaker resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies
that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

**Using the SageMaker Console**

To access the Amazon SageMaker console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the SageMaker resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won’t function as intended for entities (users or roles) with that policy.

To ensure that those entities can still use the SageMaker console, also attach the following AWS managed policy to the entities. For more information, see Adding Permissions to a User in the IAM User Guide:
You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

**Permissions Required to Use the Amazon SageMaker Console**

The permissions reference table lists the Amazon SageMaker API operations and shows the required permissions for each operation. For more information about Amazon SageMaker API operations, see [Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference](#).

To use the Amazon SageMaker console, you need to grant permissions for additional actions. Specifically, the console needs permissions that allow the `ec2` actions to display subnets, VPCs, and security groups. Optionally, the console needs permission to create execution roles for tasks such as `CreateNotebook`, `CreateTrainingJob`, and `CreateModel`. Grant these permissions with the following permissions policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SageMakerApis",
         "Effect": "Allow",
         "Action": [
            "sagemaker:*"
         ],
         "Resource": "*"
      },
      {
         "Sid": "VpcConfigurationForCreateForms",
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeVpcs",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups"
         ],
         "Resource": "*"
      }
   ]
}
```
],
"Resource": "*
},
{
  "Sid": "KmsKeysForCreateForms",
  "Effect": "Allow",
  "Action": [
    "kms:DescribeKey",
    "kms:ListAliases"
  ],
  "Resource": "*"
},
{
  "Sid": "AccessAwsMarketplaceSubscriptions",
  "Effect": "Allow",
  "Action": [
    "aws-marketplace:ViewSubscriptions"
  ],
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": [
    "codecommit:BatchGetRepositories",
    "codecommit:CreateRepository",
    "codecommit:GetRepository",
    "codecommit:ListRepositories",
    "codecommit:ListBranches",
    "secretsmanager:CreateSecret",
    "secretsmanager:DescribeSecret",
    "secretsmanager:ListSecrets"
  ],
  "Resource": "*"
},
{
  "Sid": "ListAndCreateExecutionRoles",
  "Effect": "Allow",
  "Action": [
    "iam:ListRoles",
    "iam:CreateRole",
    "iam:CreatePolicy",
    "iam:AttachRolePolicy"
  ],
  "Resource": "*
}
Permissions Required to Use the Amazon SageMaker Ground Truth Console

To use the Amazon SageMaker Ground Truth console, you need to grant permissions for additional resources. Specifically, the console needs permissions for the AWS Marketplace to view subscriptions, Amazon Cognito operations to manage your private workforce, Amazon S3 actions for access to your input and output files, and AWS Lambda actions to list and invoke functions. Grant these permissions with the following permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "GroundTruthConsole",
            "Effect": "Allow",
            "Action": [
                "aws-marketplace:DescribeListings",
                "aws-marketplace:ViewSubscriptions"
            ],
            "Resource": "*"
        }
    ]
}
```
Permissions Required to Use the Amazon Augmented AI (Preview) Console

To use the Augmented AI console, you need to grant permissions for additional resources. Grant these permissions with the following permissions policy:
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "sagemaker:*Algorithm",
          "sagemaker:*Algorithms",
          "sagemaker:*App",

Allow Users to View Their Own Permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"],
            "Condition": {
                "StringEquals": {
                }
            }
        }
    ]
}
```
Control Creation of SageMaker Resources with Condition Keys

Control fine-grained access to allow the creation of SageMaker resources by using SageMaker-specific condition keys. For information about using condition keys in IAM policies, see [IAM JSON Policy Elements: Condition](https://docs.aws.amazon.com/iam/latest/userguide/service-policy-elements-condition.html) in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users_policies_service-credentials.html).

The condition keys, along with related API actions, and links to relevant documentation are listed in [Condition Keys for SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/iam-policy-examples.html#condition-keys) in the [IAM User Guide](https://docs.aws.amazon.com/iam/latest/userguide/service-policy-elements-condition.html).

The following examples show how to use the SageMaker condition keys to control access.

Control Access to SageMaker Resources by Using File System Condition Keys

SageMaker training provides a secure infrastructure for the training algorithm to run in, but for some cases you may want increased defense in depth. For example, you minimize the risk of running untrusted code in your algorithm, or you have specific security mandates in your organization. For these scenarios, you can use the service-specific condition keys in the Condition element of an IAM policy to scope down the user to specific file systems, directories, access modes (read-write, read-only) and security groups.

Topics

- **Restrict an IAM User to Specific Directories and Access Modes**
- **Restrict a User to a Specific File System**

Restrict an IAM User to Specific Directories and Access Modes

The policy below restricts a user to the `/sagemaker/xgboost-dm/train` and `/sagemaker/xgboost-dm/validation` directories of an EFS file system to `ro` (read-only) AccessMode:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AccessToElasticFileSystem",  
            "Effect": "Allow",  
            "Action": [  
                "sagemaker:CreateTrainingJob",  
                "sagemaker:CreateHyperParameterTuningJob"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "sagemaker:FileSystemId": "fs-12345678",  
                    "sagemaker:FileSystemAccessMode": "ro"  
                }  
            }  
        }  
    ]  
}
```

⚠️ **Note**

When a directory is allowed, all of its subdirectories are also accessible by the training algorithm. POSIX permissions are ignored.
Restrict a User to a Specific File System

To prevent a malicious algorithm using a user space client from accessing any file system directly in your account, you can restrict networking traffic by allowing ingress from a specific security group. In the following example, the user can only use the specified security group to access the file system:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToElasticFileSystemValidation",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:FileSystemId": "fs-12345678",
          "sagemaker:FileSystemAccessMode": "ro",
          "sagemaker:FileSystemType": "EFS",
          "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/validation"
        }
      }
    }
  ]
}
```
Although the above example can restrict an algorithm to a specific file system, it does not prevent an algorithm from accessing any directory within that file system using the user space client. To mitigate this, you can:

- Ensure that the file system only contains data that you trust your users to access
- Create an IAM role that restricts your users to launching training jobs with algorithms from approved ECR repositories

For more information on how to use roles with SageMaker, see [SageMaker Roles](#).

**Restrict Training to a Specific VPC**

Restrict an AWS user to creating training jobs from within a Amazon VPC. When a training job is created within a VPC, you can use VPC flow logs to monitor all traffic to and from the training cluster. For information about using VPC flow logs, see [VPC Flow Logs](#) in the Amazon Virtual Private Cloud User Guide.

The following policy enforces that a training job is created by a user calling [CreateTrainingJob](#) from within a VPC:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:FileSystemId": "fs-12345678",
                    "sagemaker:FileSystemAccessMode": "ro",
                    "sagemaker:FileSystemType": "FSxLustre",
                    "sagemaker:FileSystemDirectoryPath": "/fsx/sagemaker/xgboost/train"
                },
                "ForAllValues:StringEquals": {
                    "sagemaker:VpcSecurityGroupIds": [
                        "sg-12345678"
                    ]
                }
            }
        }
    ]
}
```
Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows

Amazon SageMaker Ground Truth and Amazon Augmented AI work teams fall into one of three 
workforce types: public (with Amazon Mechanical Turk), private, and vendor. To restrict user access to a specific work team using one of these types or the work team ARN, use the `sagemaker:WorkteamType` and/or the `sagemaker:WorkteamArn` condition keys. For the `sagemaker:WorkteamType` condition key, use string condition operators. For the `sagemaker:WorkteamArn` condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the `sagemaker:WorkteamType` and `sagemaker:WorkteamArn` condition keys with appropriate condition operators and valid condition values.

The following example uses the `sagemaker:WorkteamType` condition key with the StringEquals condition operator to restrict access to a public work team. It accepts condition...
values in the following format: `workforcetype-crowd`, where `workforcetype` can equal `public`, `private`, or `vendor`.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "RestrictWorkteamType",
         "Effect": "Deny",
         "Action": "sagemaker:CreateLabelingJob",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "sagemaker:WorkteamType": "public-crowd"
            }
         }
      }
   ]
}
```

The following policies show how to restrict access to a public work team using the `sagemaker:WorkteamArn` condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the `ArnLike` condition operator. The second shows how to use it with the `ArnEquals` condition operator and the work team ARN.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "RestrictWorkteamType",
         "Effect": "Deny",
         "Action": "sagemaker:CreateLabelingJob",
         "Resource": "*",
         "Condition": {
            "ArnLike": {
               "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/**"
            }
         }
      }
   ]
}
```
Enforce Encryption of Input Data

The following policy restricts a user to specify a AWS KMS key to encrypt input data when creating training, hyperparameter tuning, and labeling jobs by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceEncryption",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateTrainingJob", "sagemaker:CreateHyperParameterTuningJob", "sagemaker:CreateLabelingJob", "sagemaker:CreateFlowDefinition"],
         "Resource": "/*
         "ArnEquals": {
            "sagemaker:VolumeKmsKey": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
         }
      }
   ]
}
```
Enforce Encryption of Notebook Instance Storage Volume

The following policy restricts a user to specify an AWS KMS key to encrypt the attached storage volume when creating or updating a notebook instance by using the `sagemaker:VolumeKmsKey` condition key:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceEncryption",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateNotebookInstance"],
         "Resource": "*",
         "Condition": {
            "ArnLike": {
               "sagemaker:VolumeKmsKey": "*key/volume-kms-key-12345"
            }
         }
      }
   ]
}
```

Enforce Network Isolation for Training Jobs

The following policy restricts a user to enable network isolation when creating training jobs by using the `sagemaker:NetworkIsolation` condition key:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceIsolation",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateTrainingJob"],
         "Resource": "*",
         "Condition": {
            "ArnLike": {
               "sagemaker:NetworkIsolation": "*key/network-isolation-12345"
            }
         }
      }
   ]
}
```
"Effect": "Allow",
"Action": [
    "sagemaker:CreateTrainingJob",
    "sagemaker:CreateHyperParameterTuningJob"
],
"Resource": "*",
"Condition": {
    "Bool": {
        "sagemaker:NetworkIsolation": "true"
    }
}
}

Enforce a Specific Instance Type for Training Jobs

The following policy restricts a user to use a specific instance type when creating training jobs by using the `sagemaker:InstanceTypes` condition key:

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceInstanceType",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "sagemaker:InstanceTypes": ["ml.c5.*"]
                }
            }
        }
    ]
}

Identity-Based Policy Examples
Enforce a Specific EI Accelerator for Training Jobs

The following policy restricts a user to use a specific elastic inference (EI) accelerator, if an accelerator is provided, when creating or updating notebook instances and when creating endpoint configurations by using the `sagemaker:AcceleratorTypes` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceAcceleratorType",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateNotebookInstance",
            "sagemaker:UpdateNotebookInstance",
            "sagemaker:CreateEndpointConfig"
         ],
         "Resource": "*",
         "Condition": {
            "ForAllValues:StringEquals": {
               "sagemaker:AcceleratorTypes": ["ml.eia1.medium"]
            }
         }
      }
   ]
}
```

Enforce Disabling Internet Access and Root Access for Creating Notebook Instances

You can disable both internet access and root access to notebook instances to help make them more secure. For information about controlling root access to a notebook instance, see Control root access to a SageMaker notebook instance. For information about disabling internet access for a notebook instance, see Connect a Notebook Instance in a VPC to External Resources.

The following policy requires a user to disable network access when creating instance, and disable root access when creating or updating a notebook instance.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DisablingInternetAccess",
         "Effect": "Deny",
         "Action": [
            "sagemaker:CreateNotebookInstance",
            "sagemaker:UpdateNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "NotIpAddress": {
               "Address": "*",
               "Protocol": "TCP",
               "Port": 80
            }
         }
      },
      {
         "Sid": "DisablingRootAccess",
         "Effect": "Deny",
         "Action": [
            "sagemaker:CreateNotebookInstance",
            "sagemaker:UpdateNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "NotPrincipal": {
               "Arn": "*",
               "Effect": "Allow",
               "Action": [
                  "sts:AssumeRole"
               ]
            }
         }
      }
   ]
}
```
Control Access to the SageMaker API by Using Identity-based Policies

To control access to SageMaker API calls and calls to SageMaker hosted endpoints, use identity-based IAM policies.

Topics

- [Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC](#)
Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC

If you set up an interface endpoint in your VPC, individuals outside the VPC can still connect to the SageMaker API and runtime over the internet unless you attach an IAM policy that restricts access to calls coming from within the VPC to all users and groups that have access to your SageMaker resources. For information about creating a VPC interface endpoint for the SageMaker API and runtime, see Connect to SageMaker Within your VPC.

⚠️ Important
If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the SageMaker API or runtime.

🔍 Note
This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
  "Id": "api-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableAPIAccess",
      "Effect": "Allow",
      "Action": ["sagemaker:*"],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:SourceVpc": "vpc-111bbaaa"
        }
      }
    }
  ]
}
```
If you want to restrict access to the API to only calls made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
   "Id": "api-example-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnableAPIAccess",
         "Effect": "Allow",
         "Action": ["sagemaker:CreatePresignedNotebookInstanceUrl"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "aws:sourceVpce": [
                  "vpce-111bbccc",
                  "vpce-111bbddd"
               ]
            }
         }
      }
   ]
}
```

**Limit Access to SageMaker API and Runtime Calls by IP Address**

To allow access to SageMaker API calls and runtime invocations only from IP addresses in a list that you specify, attach an IAM policy that denies access to the API unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the API or runtime. For information about creating IAM policies, see [Creating IAM Policies](#) in the *AWS Identity and Access Management User Guide*. To specify the list of IP addresses that you want to have access to the API call, use the `IpAddress` condition operator and the `aws:SourceIP` condition context key. For information about IAM condition operators, see [IAM Identity-Based Policy Examples](#)
For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to the CreateTrainingJob only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker:CreateTrainingJob",
            "Resource": "*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": [
                        "192.0.2.0/24",
                        "203.0.113.0/24"
                    ]
                }
            }
        }
    ]
}
```

Limit Access to a Notebook Instance by IP Address

To allow access to a notebook instance only from IP addresses in a list that you specify, attach an IAM policy that denies access to CreatePresignedNotebookInstanceUrl unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the notebook instance. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the notebook instance, use the IpAddress condition operator and the aws:SourceIP condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to a notebook instance only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```
The policy restricts access to both the call to CreatePresignedNotebookInstanceUrl and to the URL that the call returns. The policy also restricts access to opening a notebook instance in the console and is enforced for every HTTP request and WebSocket frame that attempts to connect to the notebook instance.

Note

Using this method to filter by IP address is incompatible when connecting to SageMaker through a VPC interface endpoint. For information about restricting access to a notebook instance when connecting through a VPC interface endpoint, see Connect to a Notebook Instance Through a VPC Interface Endpoint.

Control Access to SageMaker Resources by Using Tags

Specify tags within an IAM policy to control access to groups of SageMaker resources. Use tags to implement attribute based access control (ABAC). Using tags helps you partition access to resources to specific groups of users. You can have one team with access to one group of resources and a different team with access to another set of resources. You can provide ResourceTag conditions in IAM policies to provide access for each group.
Tag-based policies don't work to restrict the following API calls:

- DeleteImageVersion
- DescribeImageVersion
- ListAlgorithms
- ListCodeRepositories
- ListCompilationJobs
- ListEndpointConfigs
- ListEndpoints
- ListFlowDefinitions
- ListHumanTaskUis
- ListHyperparameterTuningJobs
- ListLabelingJobs
- ListLabelingJobsForWorkteam
- ListModelPackages
- ListModels
- ListNotebookInstanceLifecycleConfigs
- ListNotebookInstances
- ListSubscribedWorkteams
- ListTags
- ListProcessingJobs
- ListTrainingJobs
- ListTrainingJobsForHyperParameterTuningJob
- ListTransformJobs
- ListWorkteams
- Search

A simple example can help you understand how you can use tags to partition resources. Suppose that you've defined two different IAM groups, named DevTeam1 and DevTeam2, in your AWS
account. You've created 10 notebook instances as well. You're using 5 of the notebook instances for one project. You're using the other 5 for a second project. You can provide DevTeam1 with permissions to make API calls on the notebook instances that you're using for the first project. You can provide DevTeam2 to make API calls on notebook instances used for the second project.

The following procedure provides a simple example that helps you understand the concept of adding tags. You can use it to implement the solution described in the preceding paragraph.

**To control access to API calls (example)**

1. Add a tag with the key `Project` and value `A` to the notebook instances used for the first project. For information about adding tags to SageMaker resources, see `AddTags`.
2. Add a tag with the key `Project` and value `B` to the notebook instances used for the second project.
3. Create an IAM policy with a `ResourceTag` condition that denies access to the notebook instances used for the second project, and attach that policy to DevTeam1. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of `Project` and a value of `B`:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "sagemaker:*",
         "Resource": "*"
       },
       {
         "Effect": "Deny",
         "Action": "sagemaker:*",
         "Resource": "*",
         "Condition": {
           "StringEquals": {
             "sagemaker:ResourceTag/Project": "B"
           }
         }
       },
       {
         "Effect": "Deny",
         "Action": ["sagemaker:AddTags",
                     "sagemaker:GetNotebookInstanceMetrics",
                     "sagemaker:ListNotebookInstances",
                     "sagemaker:ListNotebookInstanceTypes",
                     "sagemaker:DeleteNotebookInstance",
                     "sagemaker:DescribeNotebookInstance",
                     "sagemaker:UpdateNotebookInstance",
                     "sagemaker:StopNotebookInstance",
                     "sagemaker:StartNotebookInstance",
                     "sagemaker:CreateNotebookInstance"
                   ],
         "Resource": "*",
         "Condition": {
           "StringEquals": {
             "sagemaker:ResourceTag/Project": "B"
           }
         }
       }
     ]
   }
   ```
For information about creating IAM policies and attaching them to identities, see [Controlling Access Using Policies](https://docs.aws.amazon.com/IAM/latest/userguide/access-policy-reference.html) in the *AWS Identity and Access Management User Guide*.

4. Create an IAM policy with a ResourceTag condition that denies access to the notebook instances used for the first project, and attach that policy to DevTeam2. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of `Project` and a value of `A`:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:*",
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": "sagemaker:*",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:ResourceTag/Project": "A"
        }
      }
    },
    {
      "Effect": "Deny",
      "Action": ["sagemaker:AddTags", "sagemaker:DeleteTags"],
      "Resource": "*"
    }
  ]
}
```
Provide Permissions for Tagging SageMaker Resources Upon Creation

There are many Amazon SageMaker operations that let your users specify tags when you create a resource. Use resource tags to implement attributed based access control (ABAC). Using tags helps you partition access to resources to specific groups of users. You can have one team with access to one group of resources and a different team with access to another set of resources. You can provide `ResourceTag` conditions in IAM policies to provide access for each group.

You must give your users access to the permissions that they're using to create the resource. For users that need to create a processing job, you must give them access to `sagemaker:CreateProcessingJob` within the policy. If your users are tagging the resources that they create, you must also give tagging permissions.

⚠️ **Important**

You can only give your users permissions to add tags to resources that they create. They can't add tags to resources that have already been created. The following are operations where you can't give them resources to add tags:

- DeleteImageVersion
- DescribeImageVersion
- ListAlgorithms
- ListCodeRepositories
- ListCompilationJobs
- ListEndpointConfigs
- ListEndpoints
- ListFlowDefinitions
- ListHumanTaskUis
- ListHyperparameterTuningJobs
- ListLabelingJobs
- ListLabelingJobsForWorkteam
- ListModelPackages
- ListModels
You can control access to the operations that the user can tag or the tags that they can use. You can specify permissions for the following use cases:

- Adding permissions to tag the resources created using any operation and permissions to use any tag
- Adding permissions to tag the resources created using specific operations and permissions to use any tag
- Adding permissions to tag the resources created using any operation and permissions to specific tags
- Adding permissions to tag the resources created using specific operations and permissions to specific tags

Permissions for any operation and any tag

Add the following statement to an IAM policy to grant your users permissions to add any tag for any operation.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:Create*"
            ]
        }
    ]
}
```
Permissions for a specific operation with specific tags

The following statement gives the user permission to add the cc123 tag to resources created using the CreateModel operation. You can modify the statement to suit your own needs and add it to the IAM policy attached to the role of your users.

```json
{
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [ "sagemaker:CreateModel"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "aws:RequestTag/cost-center": [ "cc123" ]
            },
            "ForAnyValue:StringEquals": {
               "aws:TagKeys": [ "purpose" ]
            }
         }
      }
   ]
}
```
Permissions for a specific operation and any tag

The following statement gives your users permissions to add any tag to resources created using the CreateModel operation.

```json
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["sagemaker:CreateModel"],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": ["sagemaker:AddTags"],
      "Condition": {
        "String": {
          "sagemaker:TaggingAction": ["CreateModel"]
        }
      }
    }
  ]
}
```
Cross-Service Confused Deputy Prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, the confused deputy problem can arise due to cross-service impersonation. Cross-service impersonation can occur when one service (the calling service) invokes another service (the called service) and leverages the called service's elevated permissions to act on resources the calling service has no authorization to access. To prevent unauthorized access through the confused deputy problem, AWS provides tools to help secure your data across services. These tools help you control the permissions granted to service principals, limiting their access to only the resources in your account that are required. By carefully managing the access privileges of service principals, you can help mitigate the risk of services improperly accessing data or resources to which they should not have permissions.

Read on for general guidance or navigate to an example for a specific SageMaker feature:

Topics

- Limit Permissions With Global Condition Keys
- SageMaker Edge Manager
- SageMaker Images
- SageMaker Inference
- SageMaker Batch Transform Jobs
- SageMaker Marketplace
- SageMaker Neo
- SageMaker Pipelines
- SageMaker Processing Jobs
- SageMaker Studio
- SageMaker Training Jobs
Limit Permissions With Global Condition Keys

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition keys in resource policies to limit the permissions to the resource that Amazon SageMaker gives another service. If you use both global condition keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:sagemaker::*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition keys in SageMaker to prevent the confused deputy problem.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "sagemaker.amazonaws.com"
    },
    # Specify an action and resource policy for another service
    "Action": "service:ActionName",
    "Resource": [
      "arn:aws:service:::ResourceName/*"
    ],
    "Condition": {
      " ArnLike": {
        "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:*"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```
The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Edge Manager created by account number 123456789012 in the `us-west-2` Region.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": { "Service": "sagemaker.amazonaws.com" },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
            }
        }
    }
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific packaging job to further limit permissions.

**SageMaker Images**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Images. Use this template with either `Image` or `ImageVersion`. This example uses an ImageVersion record ARN with the account number 123456789012. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": { "Service": "sagemaker.amazonaws.com" },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
            }
        }
    }
}
```
Do not replace the `aws:SourceArn` in this template with the full ARN of a specific image or image version. The ARN must be in the format provided above and specify either `image` or `image-version`. The partition placeholder should designate either an AWS commercial partition (`aws`) or an AWS in China partition (`aws-cn`), depending on where the image or image version is running. Similarly, the region placeholder in the ARN can be any valid Region where SageMaker images are available.

**SageMaker Inference**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker real-time, serverless, and asynchronous inference. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": { "Service": "sagemaker.amazonaws.com" },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
            }
        }
    }
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific model or endpoint. The ARN must be in the format provided above. The asterisk in the ARN template does not stand for wildcard and should not be changed.
SageMaker Batch Transform Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker batch transform jobs created by account number 123456789012 in the us-west-2 Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                }
            }
        }
    ]
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific batch transform job to further limit permissions.

SageMaker Marketplace

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Marketplace resources created by account number 123456789012 in the us-west-2 Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "marketplacecatalog.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                }
            }
        }
    ]
}
```
Do not replace the `aws:SourceArn` in this template with the full ARN of a specific algorithm or model package. The ARN must be in the format provided above. The asterisk in the ARN template does stand for wildcard and covers all training jobs, models, and batch transform jobs from validation steps, as well as algorithm and model packages published to SageMaker Marketplace.

**SageMaker Neo**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Neo compilation jobs created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
            "ArnLike": {
            }
         }
      }
   ]
}
```
You can replace the `aws:SourceArn` in this template with the full ARN of one specific compilation job to further limit permissions.

**SageMaker Pipelines**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Pipelines using pipeline execution records from one or more pipelines. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:pipeline/mypipeline/*"
                }
            }
        }
    ]
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific pipeline execution. The ARN must be in the format provided above. The `partition` placeholder should designate either an AWS commercial partition (`aws`) or an AWS in China partition (`aws-cn`), depending on where the pipeline is running. Similarly, the `region` placeholder in the ARN can be any valid Region where SageMaker Pipelines is available.

The asterisk in the ARN template does stand for wildcard and covers all pipeline executions of a pipeline named `mypipeline`. If you want to allow the `AssumeRole` permissions for all pipelines in account `123456789012` rather than one specific pipeline, then the `aws:SourceArn` would be `arn:aws:sagemaker:*:123456789012:pipeline/*`.  

*Cross-Service Confused Deputy Prevention*  

5630
SageMaker Processing Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker processing jobs created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
            "ArnLike": {
            }
         }
      }
   ]
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific processing job to further limit permissions.

SageMaker Studio

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Studio created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
            "ArnLike": {
            }
         }
      }
   ]
}
```
Do not replace the `aws:SourceArn` in this template with the full ARN of a specific Studio application, user profile, or domain. The ARN must be in the format provided in the previous example. The asterisk in the ARN template does not stand for wildcard and should not be changed.

### SageMaker Training Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker training jobs created by account number 123456789012 in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
            "ArnLike": {
            }
         }
      }
   ]
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific training job to further limit permissions.
SageMaker Roles

Amazon SageMaker performs operations on your behalf using other AWS services. You must grant SageMaker permissions to use these services and the resources they act upon. You grant SageMaker these permissions using an AWS Identity and Access Management (IAM) execution role. For more information on IAM roles, see IAM roles.

To create and use an execution role, you can use the following procedures.

Create execution role

Use the following procedure to create an execution role with the IAM managed policy, AmazonSageMakerFullAccess, attached. If your use case requires more granular permissions, use other sections on this page to create an execution role that meets your business needs. You can create an execution role using the SageMaker console or the AWS CLI.

Important

The IAM managed policy, AmazonSageMakerFullAccess, used in the following procedure only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to add an additional policy to an execution role to grant it access to other Amazon S3 buckets and objects, see Add Additional Amazon S3 Permissions to a SageMaker Execution Role.

Note

You can create an execution role directly when you create a SageMaker domain or a notebook instance.

- For information on how to create a SageMaker domain, see Custom onboarding to Amazon SageMaker Domain using IAM Identity Center.
- For information on how to create a notebook instance, see Step 1: Create an Amazon SageMaker Notebook Instance.
To create a new execution role from the SageMaker console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles and then choose Create role.
3. Keep AWS service as the Trusted entity type and then use the down arrow to find SageMaker in Use cases for other AWS services.
4. Choose SageMaker – Execution and then choose Next.
5. The IAM managed policy, AmazonSageMakerFullAccess, is automatically attached to the role. To see the permissions included in this policy, choose the plus (+) sign next to the policy name. Choose Next.
6. Enter a Role name and a Description.
7. (Optional) Add additional permissions and tags to the role.
8. Choose Create role.
9. On the Roles section of the IAM console, find the role you just created. If needed, use the text box to search for the role using the role name.
10. On the role summary page, make note of the ARN.

To create a new execution role from the AWS CLI

Before you create an execution role using the AWS CLI, make sure to update and configure it by following the instructions in AWS CLI Prerequisites, then continue with the instructions in Onboard from the AWS CLI.

Once you have created an execution role, you can associate it with a SageMaker domain, a user profile, or with a Jupyter notebook instance.

- To learn about how to associate an execution role with an existing SageMaker domain, see Edit Domain settings.
- To learn about how to associate an execution role with an existing user profile, see Add and Remove User Profiles.
- To learn about how to associate an execution role with an existing notebook instance, see Update a Notebook Instance.

You can also pass the ARN of an execution role to your API call. For example, using Amazon SageMaker Python SDK, you can pass the ARN of your execution role to an estimator. In the code
sample that follows, we create an estimator using the XGBoost algorithm container and pass the ARN of the execution role as a parameter. For the full example on GitHub, see Customer Churn Prediction with XGBoost.

```python
import sagemaker, boto3
from sagemaker import image_uris

sess = sagemaker.Session()
region = sess.boto_region_name
bucket = sess.default_bucket()
prefix = "sagemaker/DEMO-xgboost-churn"
container = sagemaker.image_uris.retrieve("xgboost", region, "1.7-1")

xgb = sagemaker.estimator.Estimator(
    container,
    execution-role-ARN,  # Add this parameter
    instance_count=1,
    instance_type="ml.m4.xlarge",
    output_path="s3://{}/{}//output".format(bucket, prefix),
    sagemaker_session=sess,
)

...  
```

Add Additional Amazon S3 Permissions to a SageMaker Execution Role

When you use a SageMaker feature with resources in Amazon S3, such as input data, the execution role you specify in your request (for example CreateTrainingJob) is used to access these resources.

If you attach the IAM managed policy, AmazonSageMakerFullAccess, to an execution role, that role has permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. It also has permission to perform the following actions on any Amazon S3 resource:

```json
"s3:CreateBucket",
"s3:GetBucketLocation",
"s3:ListBucket",
"s3:ListAllMyBuckets",
"s3:GetBucketCors",
"s3:PutBucketCors"
```
To give an execution role permissions to access one or more specific buckets in Amazon S3, you can attach a policy similar to the following to the role. This policy grants an IAM role permission to perform all actions that AmazonSageMakerFullAccess allows but restricts this access to the buckets `DOC-EXAMPLE-BUCKET1` and `DOC-EXAMPLE-BUCKET2`. Refer to the security documentation for the specific SageMaker feature you are using to learn more about the Amazon S3 permissions required for that feature.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
                "s3:AbortMultipartUpload"
            ],
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*",
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:GetBucketLocation",
                "s3:ListBucket",
                "s3:ListAllMyBuckets",
                "s3:GetBucketCors",
                "s3:PutBucketCors"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET1",
                          "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/"
            ]
        }
    ]
}
```
Get execution role

You can use the SageMaker console or the AWS CLI to retrieve the ARN of the execution role attached to a SageMaker domain, a user profile, or a notebook instance.

- To find the ARN of the IAM execution role attached to a SageMaker domain, see View and Edit Domains.
- To find the ARN of the IAM execution role attached to a user profile, see View User Profiles and User Profile Details.
- To find the ARN of the IAM execution role attached to a notebook instance:
  1. Open the IAM console at https://console.aws.amazon.com/iam/.
  2. On the left navigation pane, choose Notebook then Notebook instances.
  3. From the list of notebooks, select the notebook that you want to view.
  4. The ARN is in the Permissions and encryption section.

Alternatively, Amazon SageMaker Python SDK users can retrieve the ARN of the execution role attached to their user profile or a notebook instance by running the following code:

```python
import sagemaker
sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

⚠️ Note

The execution role is available only when running a notebook within SageMaker. If you run `get_execution_role` in a notebook not on SageMaker, expect a "region" error.
Passing Roles

Actions like passing a role between services are a common function within SageMaker. You can find more details on Actions, Resources, and Condition Keys for SageMaker in the IAM User Guide.

You pass the role (iam:PassRole) when making these API calls: CreateAutoMLJob, CreateCompilationJob, CreateDomain, CreateFeatureGroup, CreateFlowDefinition, CreateHyperParameterTuningJob, CreateImage, CreateLabelingJob, CreateModel, CreateMonitoringSchedule, CreateNotebookInstance, CreateProcessingJob, CreateTrainingJob, CreateUserProfile, RenderUiTemplate, and UpdateImage.

You attach the following trust policy to the IAM role which grants SageMaker principal permissions to assume the role, and is the same for all of the execution roles:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

The permissions that you need to grant to the role vary depending on the API that you call. The following sections explain these permissions.

⚠️ Note

Instead of managing permissions by crafting a permission policy, you can use the AWS-managed AmazonSageMakerFullAccess permission policy. The permissions in this policy are fairly broad, to allow for any actions you might want to perform in SageMaker. For a listing of the policy including information about the reasons for adding many of the permissions, see AWS managed policy: AmazonSageMakerFullAccess. If you prefer to create custom policies and manage permissions to scope the permissions only to the actions you need to perform with the execution role, see the following topics.
Important

If you’re running into issues, see Troubleshooting Amazon SageMaker Identity and Access.

For more information about IAM roles, see IAM Roles in the IAM User Guide.

Topics

• CreateAutoMLJob API: Execution Role Permissions
• CreateDomain API: Execution Role Permissions
• CreateImage and UpdateImage APIs: Execution Role Permissions
• CreateNotebookInstance API: Execution Role Permissions
• CreateHyperParameterTuningJob API: Execution Role Permissions
• CreateProcessingJob API: Execution Role Permissions
• CreateTrainingJob API: Execution Role Permissions
• CreateModel API: Execution Role Permissions
• SageMaker geospatial capabilities roles

CreateAutoMLJob API: Execution Role Permissions

For an execution role that you can pass in a CreateAutoMLJob API request, you can attach the following minimum permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iam:PassRole"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "iam:PassedToService": "sagemaker.amazonaws.com"
            }
         }
      }
   ]
}
```
If you specify a private VPC for your AutoML job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
  ],
  "Resource": "*"
}
```
"ec2:DescribeVpcs",
"ec2:DescribeDhcpOptions",
"ec2:DescribeSubnets",
"ec2:DescribeSecurityGroups"
]}
}

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}

If you specify a KMS key in the output configuration of your AutoML job, add the following permissions:

{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}

If you specify a volume KMS key in the resource configuration of your AutoML job, add the following permissions:

{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant"
  ]
}

CreateDomain API: Execution Role Permissions

The execution role for domains with IAM Identity Center and the user/execution role for IAM domains need the following permissions when you pass an AWS KMS customer managed key as the
KmsKeyId in the CreateDomain API request. The permissions are enforced during the CreateApp API call.

For an execution role that you can pass in the CreateDomain API request, you can attach the following permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": ["kms:CreateGrant", "kms:DescribeKey"],
           "Resource": "arn:aws:kms:region:account-id:key/kms-key-id"
       }
   ]
}
```

Alternatively, if the permissions are specified in a KMS policy, you can attach the following policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Sid": "Allow use of the key",
           "Effect": "Allow",
           "Principal": {
               "AWS": [
                    "arn:aws:iam::account-id:role/ExecutionRole"
               ]
           },
           "Action": ["kms:CreateGrant", "kms:DescribeKey"],
           "Resource": "*
       }
   ]
}
```
CreateImage and UpdateImage APIs: Execution Role Permissions

For an execution role that you can pass in a CreateImage or UpdateImage API request, you can attach the following permission policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchGetImage",
        "ecr:GetDownloadUrlForLayer"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```

CreateNotebookInstance API: Execution Role Permissions

The permissions that you grant to the execution role for calling the CreateNotebookInstance API depend on what you plan to do with the notebook instance. If you plan to use it to invoke SageMaker APIs and pass the same role when calling the CreateTrainingJob and CreateModel APIs, attach the following permissions policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```
"Effect": "Allow",
"Action": [
  "sagemaker:*",
  "ecr:GetAuthorizationToken",
  "ecr:GetDownloadUrlForLayer",
  "ecr:BatchGetImage",
  "ecr:BatchCheckLayerAvailability",
  "ecr:SetRepositoryPolicy",
  "ecr:CompleteLayerUpload",
  "ecr:BatchDeleteImage",
  "ecr:UploadLayerPart",
  "ecr:DeleteRepositoryPolicy",
  "ecr:InitiateLayerUpload",
  "ecr:DeleteRepository",
  "ecr:PutImage",
  "ecr:CreateRepository",
  "cloudwatch:PutMetricData",
  "cloudwatch:GetMetricData",
  "cloudwatch:GetMetricStatistics",
  "cloudwatch:ListMetrics",
  "logs:CreateLogGroup",
  "logs:CreateLogStream",
  "logs:DescribeLogStreams",
  "logs:PutLogEvents",
  "logs:GetLogEvents",
  "s3:CreateBucket",
  "s3:ListBucket",
  "s3:GetBucketLocation",
  "s3:GetObject",
  "s3:PutObject",
  "s3:DeleteObject",
  "robomaker:CreateSimulationApplication",
  "robomaker:DescribeSimulationApplication",
  "robomaker:DeleteSimulationApplication",
  "robomaker:CreateSimulationJob",
  "robomaker:DescribeSimulationJob",
  "robomaker:CancelSimulationJob",
  "ec2:CreateVpcEndpoint",
  "ec2:DescribeRouteTables",
  "elasticfilesystem:DescribeMountTargets"
],
"Resource": "*
}
To tighten the permissions, limit them to specific Amazon S3 and Amazon ECR resources, by restricting "Resource": "*", as follows:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:*",
                "ecr:GetAuthorizationToken",
                "cloudwatch:PutMetricData",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:PutLogEvents",
                "logs:GetLogEvents"
            ],
            "Resource": [
                "arn:aws:codecommit:*:*:*sagemaker*",
                "arn:aws:codecommit:*:*:*SageMaker*",
                "arn:aws:codecommit:*:*:*Sagemaker*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "sagemaker.amazonaws.com"
                }
            }
        }
    ]
}
```
"Resource": "*",
},
{
  "Effect": "Allow",
  "Action": [
    "iam:PassRole"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "iam:PassedToService": "sagemaker.amazonaws.com"
    }
  }
},
{
  "Effect": "Allow",
  "Action": [
    "s3:ListBucket"
  ],
  "Resource": [
    "arn:aws:s3:::inputbucket"
  ]
},
{
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:DeleteObject"
  ],
  "Resource": [
    "arn:aws:s3:::inputbucket/object1",
    "arn:aws:s3:::outputbucket/path",
    "arn:aws:s3:::inputbucket/object2",
    "arn:aws:s3:::inputbucket/object3"
  ]
},
{
  "Effect": "Allow",
  "Action": [
    "ecr:BatchCheckLayerAvailability",
    "ecr:GetDownloadUrlForLayer",
    "ecr:BatchGetImage"
  ]
}
If you plan to access other resources, such as Amazon DynamoDB or Amazon Relational Database Service, add the relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- **Scope the s3:ListBucket permission to the specific bucket that you specify as**  
  `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.

- **Scope s3:GetObject, s3:PutObject, and s3:DeleteObject permissions as follows:**
  - Scope to the following values that you specify in a `CreateTrainingJob` request:
    - `InputDataConfig.DataSource.S3DataSource.S3Uri`
    - `OutputDataConfig.S3OutputPath`
  - Scope to the following values that you specify in a `CreateModel` request:
    - `PrimaryContainer.ModelDataUrl`
    - `SupplementalContainers.ModelDataUrl`

- **Scope ecr permissions as follows:**
  - Scope to the `AlgorithmSpecification.TrainingImage` value that you specify in a `CreateTrainingJob` request.
  - Scope to the `PrimaryContainer.Image` value that you specify in a `CreateModel` request.

The `cloudwatch` and `logs` actions are applicable for "
" resources. For more information, see

CreateHyperParameterTuningJob API: Execution Role Permissions

For an execution role that you can pass in a CreateHyperParameterTuningJob API request, you can attach the following permission policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [ 
    {
      "Effect": "Allow",
      "Action": [ 
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    }
  ]
}
```

Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3, Amazon ECR, and Amazon CloudWatch Logs resources:

```
{
  "Version": "2012-10-17",
  "Statement": [ 
    {
      "Effect": "Allow",
      "Action": [ 
        "cloudwatch:PutMetricData",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    }
  ]
}
```
{ "Effect": "Allow",
"Action": [ "s3:ListBucket"
],
"Resource": [ "arn:aws:s3:::inputbucket"
]
},
{
"Effect": "Allow",
"Action": [ "s3:GetObject",
"s3:PutObject"
],
"Resource": [ "arn:aws:s3:::inputbucket/object",
"arn:aws:s3:::outputbucket/path"
]
},
{
"Effect": "Allow",
"Action": [ "ecr:BatchCheckLayerAvailability",
"ecr:GetDownloadUrlForLayer",
"ecr:BatchGetImage"
],
"Resource": "arn:aws:ecr:region::repository/my-repo"
},
{
"Effect": "Allow",
"Action": [ "logs:CreateLogStream",
"logs:PutLogEvents",
"logs:CreateLogGroup",
"logs:DescribeLogStreams"
],
"Resource": "arn:aws:logs:*:*:log-group:/aws/sagemaker/TrainingJobs*"
} }
If the training container associated with the hyperparameter tuning job needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateHyperParameterTuningJob` request:
  
  
  InputDataConfig.DataSource.S3DataSource.S3Uri

  OutputDataConfig.S3OutputPath

- Scope Amazon ECR permissions to the registry path `(AlgorithmSpecification.TrainingImage)` that you specify in a `CreateHyperParameterTuningJob` request.
- Scope Amazon CloudWatch Logs permissions to log group of SageMaker training jobs.

The cloudwatch actions are applicable for "*" resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch-resource-summary.html) in the Amazon CloudWatch User Guide.

If you specify a private VPC for your hyperparameter tuning job, add the following permissions:

```json
{
   "Effect": "Allow",
   "Action": [
       "ec2:CreateNetworkInterface",
       "ec2:CreateNetworkInterfacePermission",
       "ec2:DeleteNetworkInterface",
       "ec2:DeleteNetworkInterfacePermission",
       "ec2:DescribeNetworkInterfaces",
       "ec2:DescribeVpcs",
       "ec2:DescribeDhcpOptions",
       "ec2:DescribeSubnets",
       "ec2:DescribeSecurityGroups"
   ]
}
```
If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ]
}
```

If you specify a KMS key in the output configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt"
    ]
}
```

If you specify a volume KMS key in the resource configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant"
    ]
}
```

---

**CreateProcessingJob API: Execution Role Permissions**

For an execution role that you can pass in a `CreateProcessingJob` API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [  
```
Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket"
      ]
    }
  ]
}
```
If `CreateProcessingJob.AppSpecification.ImageUri` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- **Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `ProcessingInputs` in a `CreateProcessingJob` request.**

- **Scope the `s3:GetObject` and `s3:PutObject` permissions to the objects that will be downloaded or uploaded in the `ProcessingInputs` and `ProcessingOutputConfig` in a `CreateProcessingJob` request.**

- **Scope Amazon ECR permissions to the registry path (`AppSpecification.ImageUri`) that you specify in a `CreateProcessingJob` request.**

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch-console.html) in the Amazon CloudWatch User Guide.
If you specify a private VPC for your processing job, add the following permissions. Don’t scope in the policy with any conditions or resource filters. Otherwise, the validation checks that occur during the creation of the processing job fail.

```json
{
   "Effect": "Allow",
   "Action": [
      "ec2:CreateNetworkInterface",
      "ec2:CreateNetworkInterfacePermission",
      "ec2:DeleteNetworkInterface",
      "ec2:DeleteNetworkInterfacePermission",
      "ec2:DescribeNetworkInterfaces",
      "ec2:DescribeVpcs",
      "ec2:DescribeDhcpOptions",
      "ec2:DescribeSubnets",
      "ec2:DescribeSecurityGroups"
   ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
   "Effect": "Allow",
   "Action": [
      "kms:Decrypt"
   ]
}
```

If you specify a KMS key in the output configuration of your processing job, add the following permissions:

```json
{
   "Effect": "Allow",
   "Action": [
      "kms:Encrypt"
   ]
}
```

If you specify a volume KMS key in the resource configuration of your processing job, add the following permissions:
CreateTrainingJob API: Execution Role Permissions

For an execution role that you can pass in a `CreateTrainingJob` API request, you can attach the following permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListBucket",
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage"
         ],
         "Resource": "*"
      }
   ]
}
```

Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListBucket",
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage"
         ],
         "Resource": "*"
      }
   ]
}
```

```json
{
    "Effect": "Allow",
    "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "s3:ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::inputbucket"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3:::inputbucket/object",
        "arn:aws:s3:::outputbucket/path"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
    ],
    "Resource": "arn:aws:ecr:region::repository/my-repo"
}
}````
If `CreateTrainingJob.AlgorithmSpecifications.TrainingImage` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateTrainingJob` request:
  - `InputDataConfig.DataSource.S3DataSource.S3Uri`
  - `OutputDataConfig.S3OutputPath`
- Scope Amazon ECR permissions to the registry path `(AlgorithmSpecification.TrainingImage)` that you specify in a `CreateTrainingJob` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch-resources-and-operations.html) in the Amazon CloudWatch User Guide.

If you specify a private VPC for your training job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:
If you specify a KMS key in the output configuration of your training job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}
```

If you specify a volume KMS key in the resource configuration of your training job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}
```

**CreateModel API: Execution Role Permissions**

For an execution role that you can pass in a `CreateModel` API request, you can attach the following permission policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
      ]
    }
  ]
}
```
"logs:CreateLogGroup",
"logs:CreateLogStream",
"s3:GetObject",
"s3:ListBucket",
"ecr:GetAuthorizationToken",
"ecr:BatchCheckLayerAvailability",
"ecr:GetDownloadUrlForLayer",
"ecr:BatchGetImage"
],
"Resource": "*
}
]
}

Instead of specifying "Resource": "*", you can scope these permissions to specific Amazon S3 and Amazon ECR resources:

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "ecr:GetAuthorizationToken"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject"
            ],
            "Resource": ["arn:aws:s3:::inputbucket/object"
            ]
        },
        {
            "Effect": "Allow",
            "Action": ["cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "ecr:GetAuthorizationToken"
            ],
            "Resource": "*"
        }
    ]
}
If `CreateModel.PrimaryContainer.Image` need to access other data sources, such as Amazon DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope S3 permissions to objects that you specify in the `PrimaryContainer.ModelDataUrl` in a `CreateModel` request.
- Scope Amazon ECR permissions to a specific registry path that you specify as the `PrimaryContainer.Image` and `SecondaryContainer.Image` in a `CreateModel` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

**Note**

If you plan to use the SageMaker deployment guardrails feature for model deployment in production, ensure that your execution role has permission to perform the `cloudwatch:DescribeAlarms` action on your auto-rollback alarms.

If you specify a private VPC for your model, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:CreateNetworkInterfacePermission",
  ],
  "Resource": [
    "arn:aws:ecr:region::repository/my-repo",
    "arn:aws:ecr:region::repository/my-repo"
  ]
}
```
SageMaker geospatial capabilities roles

As a managed service, Amazon SageMaker geospatial capabilities performs operations on your behalf on the AWS hardware that is managed by SageMaker. Use AWS Identity and Access Management to grant users, groups, and roles access to SageMaker geospatial.

An IAM Administrator can grant these permissions to user, group, or role using the AWS Management Console, AWS CLI, or one of the AWS SDKs.

**To use SageMaker geospatial you need the following IAM permissions.**

1. **An SageMaker execution role.**

   To use the SageMaker geospatial specific API operations your SageMaker execution role must include the SageMaker geospatial service principal, sagemaker-geospatial.amazonaws.com in the execution role's trust policy. This allows the SageMaker execution role to perform actions in your AWS account on your behalf.

2. **A user, group, or role that has access Amazon SageMaker Studio Classic and SageMaker geospatial**

   To get started with SageMaker geospatial you can use the AWS managed policy: AmazonSageMakerGeospatialFullAccess. This grants will grant a user, group, or role full access to SageMaker geospatial. To see the policy and learn more about which actions, resources, and conditions are available, see [AWS managed policy: AmazonSageMakerFullAccess](https://aws.amazon.com/documentation/sagemaker/iam-policy-starter/).

   To get started with Studio Classic and creating a Amazon SageMaker Domain, see [Amazon SageMaker Domain overview](https://docs.aws.amazon.com/sagemaker/latest/dg/index.html).
Use the following topics to create a new SageMaker execution role, update an existing SageMaker execution role, and learn how to manage permissions using SageMaker geospatial specific IAM actions, resources, and conditions.

Topics

- Creating a new SageMaker execution role
- Adding the SageMaker geospatial service principal to an existing SageMaker execution role
- StartEarthObservationJob API: Execution role permissions
- StartVectorEnrichmentJob API: Execution role permissions
- ExportEarthObservationJob API: Execution role permissions
- ExportVectorEnrichmentJob API: Execution Role Permissions

Creating a new SageMaker execution role

To work with SageMaker geospatial capabilities, you must set up a user, group, or role, and an execution role. A user role is an AWS identity with permissions policies that determine what the user can and cannot do within AWS. An execution role is an IAM role that grants the service permission to access your AWS resources. An execution role consists of permissions and trust policy. The trust policy specifies which principals have the permission to assume the role.

SageMaker geospatial also requires a different service principal, sagemaker-geospatial.amazonaws.com. If you are an existing SageMaker customer, you must add this additional service principal to your trust policy.

Use the following procedure to create an new execution role with the IAM managed policy, AmazonSageMakerGeospatialFullAccess, attached. If your use case requires more granular permissions, use other sections of this guide to create an execution role that meets your business needs.

⚠️ Important

The IAM managed policy, AmazonSageMakerGeospatialFullAccess, used in the following procedure, only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to update the execution role’s policy to grant it access to
To create a new role

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Select Roles and then select Create role.
4. Select Next: Permissions.
5. The IAM managed policy, AmazonSageMakerGeospatialFullAccess is automatically attached to this role. To see the permissions included in this policy, select the sideways arrow next to the policy name. Select Next: Tags.
6. (Optional) Add tags and select Next: Review.
7. Give the role a name in the text field under Role name and select Create role.
8. In the Roles section of the IAM console, select the role you just created in step 7. If needed, use the text box to search for the role using the role name you entered in step 7.
9. On the role summary page, make note of the ARN.

Adding the SageMaker geospatial service principal to an existing SageMaker execution role

To use the SageMaker geospatial specific API operations your SageMaker execution role must include the SageMaker geospatial service principal, sagemaker-geospatial.amazonaws.com in the execution role's trust policy. This allows the SageMaker execution role to perform actions in your AWS account on your behalf.

Actions like passing a role between services are common within SageMaker. For more details,

To add the SageMaker geospatial service principal to an existing SageMaker execution role update the existing policy to include the SageMaker geospatial service principal as shown in the following trust policy. By attaching the service principal to the trust policy a SageMaker execution role can now run the SageMaker geospatial specific APIs on your behalf.

To learn more about SageMaker geospatial specific IAM actions, resources, and conditions, see Actions, Resources, and Condition Keys for SageMaker in the IAM User Guide.
StartEarthObservationJob API: Execution role permissions

For an execution role that you can pass in a StartEarthObservationJob API request, you can attach the following minimum permissions policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:AbortMultipartUpload",
            "s3:PutObject",
            "s3:GetObject",
            "s3:ListBucketMultipartUploads"
         ],
         "Resource": [
            "arn:aws:s3:::*SageMaker*",
            "arn:aws:s3:::*Sagemaker*",
            "arn:aws:s3:::*sagemaker*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": "sagemaker-geospatial:GetEarthObservationJob",
         "Resource": "arn:aws:sagemaker-geospatial:*:*:earth-observation-job/*"
      }
   ]
}
```
If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.

**StartVectorEnrichmentJob API: Execution role permissions**

For an execution role that you can pass in a StartVectorEnrichmentJob API request, you can attach the following minimum permissions policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [

        {
            "Effect": "Allow",
        },

        {
            "Effect": "Allow",
            "Action": "sagemaker-geospatial:GetVectorEnrichmentJob",
            "Resource": "arn:aws:sagemaker-geospatial:*:*:vector-enrichment-job/*"
        }
    ]
}
```

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.
ExportEarthObservationJob API: Execution role permissions

For an execution role that you can pass in a ExportEarthObservationJob API request, you can attach the following minimum permissions policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:AbortMultipartUpload",
            "s3:PutObject",
            "s3:GetObject",
            "s3:ListBucketMultipartUploads"
         ],
         "Resource": [
            "arn:aws:s3:::*SageMaker*",
            "arn:aws:s3:::*Sagemaker*",
            "arn:aws:s3:::*sagemaker*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": "sagemaker-geospatial:GetEarthObservationJob",
         "Resource": "arn:aws:sagemaker-geospatial:::earth-observation-job/*"
      }
   ]
}
```

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.

ExportVectorEnrichmentJob API: Execution Role Permissions

For an execution role that you can pass in a ExportVectorEnrichmentJob API request, you can attach the following minimum permissions policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "sagemaker-geospatial:GetVectorEnrichmentJob",
         "Resource": "arn:aws:sagemaker-geospatial:::vector-enrichment-job/*"
      }
   ]
}
```
"Action": [
    "s3:AbortMultipartUpload",
    "s3:PutObject",
    "s3:GetObject",
    "s3:ListBucketMultipartUploads"
  ],
  "Resource": [
    "arn:aws:s3:::*SageMaker*",
    "arn:aws:s3:::*Sagemaker*",
    "arn:aws:s3:::*sagemaker*
  ]
},
{
  "Effect": "Allow",
  "Action": "sagemaker-geospatial:GetVectorEnrichmentJob",
  "Resource":  "arn:aws:sagemaker-geospatial:*:*:vector-enrichment-job/*"
}]
}

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys.

Amazon SageMaker Role Manager

Machine learning (ML) administrators striving for least-privilege permissions with Amazon SageMaker must account for a diversity of industry perspectives, including the unique least-privilege access needs required for personas such as data scientists, machine learning operation (MLOps) engineers, and more. Use Amazon SageMaker Role Manager to build and manage persona-based IAM roles for common machine learning needs directly through the Amazon SageMaker console.

Amazon SageMaker Role Manager provides 3 preconfigured role personas and predefined permissions for 12 common ML activities. Explore the provided personas and their suggested policies, or create and maintain roles for personas unique to your business needs. If you require additional customization, specify networking and encryption permissions for Amazon Virtual Private Cloud resources and AWS Key Management Service encryption keys in Step 1. Enter role information of the Amazon SageMaker Role Manager.

Topics

- Using the role manager (console)
Using the role manager (console)

You can use the Amazon SageMaker Role Manager from the following locations on the left-hand navigation of the Amazon SageMaker console:

- **Getting started** – Quickly add permissions policies for your users.
- **Domains** – Add permissions policies for users within an Amazon SageMaker Domain.
- **Notebooks** – Add least permissions for users who create and run notebooks.
- **Training** – Add least permissions for users who create and manage training jobs.
- **Inference** – Add least permissions for users who deploy and manage models for inference.

You can use the following procedures to start the process of creating a role from different locations in the SageMaker console.

**Getting started**

If you're using SageMaker for the first time, we recommend creating a role from the Getting started section.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Role manager.
4. Choose Create a role.

**Domains**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a Amazon SageMaker Domain.
To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. Choose **Create domain**.
5. Choose **Create role using the role creation wizard**.

**Notebook**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a notebook.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, select **Notebook**.
3. Choose **Notebook instances**.
4. Choose **Create notebook instance**.
5. Choose **Create role using the role creation wizard**.

**Training**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a training job.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, choose **Training**.
3. Select **Training jobs**.
4. Choose **Create training job**.
5. Choose **Create role using the role creation wizard**.
Inference

You can create a role using Amazon SageMaker Role Manager when you start the process of deploying a model for inference.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, choose Inference.
4. Choose Create model.
5. Choose Create role using the role creation wizard.

After you've completed one of the preceding procedures, use the information in the following sections to help you create the role.

Prerequisites

To use Amazon SageMaker Role Manager, you must have permission to create an IAM role. This permission is usually available to ML administrators and roles with least-privilege permissions for ML practitioners.

You can temporarily assume an IAM role in the AWS Management Console by switching roles. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

Step 1. Enter role information

Provide a name to use as the unique suffix of your new SageMaker role. By default, the prefix "sagemaker-" is added to every role name for easier search in the IAM console. For example, if you name your role test-123 during role creation, your role shows up as sagemaker-test-123 in the IAM console. You can optionally add a description of your role to provide additional details.

Then, choose from one of the available personas to get suggested permissions for personas such as data scientists, data engineers, or machine learning operations (MLOps) engineers. For information on available personas and their suggested permissions, see Persona reference. To create a role without any suggested permissions to guide you, choose Custom Role Settings.
### Note

We recommend that you first use the role manager to create a SageMaker Compute Role so that SageMaker compute resources have the ability to perform tasks such as training and inference. Use the SageMaker Compute Role persona to create this role with the role manager. After creating a SageMaker Compute Role, take note of its ARN for future use.

### Network and encryption conditions

We recommend that you activate VPC customization to use VPC configurations, subnets, and security groups with IAM policies associated with your new role. When VPC customization is activated, IAM policies for ML activities that interact with VPC resources are scoped down for least-privilege access. VPC customization is not activated by default. For more details on recommended networking architecture, see [Networking architecture](#) in the *AWS Technical Guide*.

You can also use a KMS key to encrypt, decrypt, and re-encrypt data for regulated workloads with highly sensitive data. When AWS KMS customization is activated, IAM policies for ML activities that support custom encryption keys are scoped down for least-privilege access. For more information, see [Encryption with AWS KMS](#) in the *AWS Technical Guide*.

### Step 2. Configure ML activities

Each Amazon SageMaker Role Manager ML activity includes suggested IAM permissions to provide access to relevant AWS resources. Some ML activities require that you add service role ARNs to complete setup. For information on predefined ML activities and their permissions, see [ML activity reference](#). For information on adding service roles, see [Service roles](#).

Based on the chosen persona, certain ML activities are already selected. You can deselect any suggested ML activities or select additional activities to create your own role. If you selected the Custom Role Settings persona, then no ML activities are preselected in this step.

You can add any additional AWS or customer-managed IAM policies to your role in [Step 3: Add additional policies and tags](#).

### Service roles

Some AWS services require a service role to perform actions on your behalf. If the ML activity that you selected requires you to pass a service role, then you must provide the ARN for that service role.
You can either create a new service role or use an existing one, such as a service role created with the SageMaker Compute Role persona. You can find the ARN of an existing role by selecting the role name in the Roles section of the IAM console. To learn more about service roles, see Creating a role for an AWS service.

**Step 3: Add additional policies and tags**

You can add any existing AWS or customer-managed IAM policies to your new role. For information on existing SageMaker policies, see AWS Managed Policies for Amazon SageMaker. You can also check your existing policies in the Roles section of the IAM console.

Optionally, use tag-based policy conditions to assign metadata information to categorize and manage AWS resources. Each tag is represented by a key-value pair. For more information, see Controlling access to AWS resources using tags.

**Review role**

Take the time to review all of the information associated with your new role. Choose Previous to go back and edit any of the information. When you are ready to create your role, choose Create role. This generates a role with permissions for your selected ML activities. You can view your new role in the Roles section of the IAM console.

**Using the role manager (AWS CDK)**

Use the AWS Cloud Development Kit (AWS CDK) with Amazon SageMaker Role Manager to programmatically create roles and set permissions. You can use the AWS CDK to accomplish any task that you could perform using the AWS Management Console. The programmatic access of the CDK makes it easier to provide permissions that give your users access to specific resources. For more information about the AWS CDK, see What is AWS CDK?

⚠️ **Important**

You must use the SageMaker Compute Role persona to create a SageMaker Compute Role. For more information about the compute persona, see SageMaker compute persona. For code that you can use to create the compute role within the AWS CDK, see Grant permissions to a Compute persona.

The following are examples of tasks that you can perform in the AWS CDK:
• Create IAM roles with granular permissions for machine learning (ML) personas, such as Data Scientists and MLOps Engineers.
• Grant permissions to CDK constructs from ML personas or ML activities.
• Set ML activity condition parameters.
• Enable global Amazon VPC and AWS Key Management Service conditions and set values for them.
• Choose from all versions of the ML activities for your users without causing disruptions in their access.

There are common AWS tasks related to machine learning (ML) with SageMaker that require specific IAM permissions. The permissions to perform the tasks are defined as ML activities in Amazon SageMaker Role Manager. ML activities specify a set of permissions that are linked to the IAM role. For example, the ML activity for Amazon SageMaker Studio Classic has all of the permissions that a user needs to access Studio Classic. For more information about ML activities, see [ML activity reference](#).

When you're creating roles, you first define the constructs for the ML persona or the ML activity. A construct is a resource within the AWS CDK stack. For example, a construct could be an Amazon S3 bucket, an Amazon VPC subnet, or an IAM role.

As you're creating the persona or activity, you can limit the permissions associated with that persona or activity to specific resources. For example, you can customize the activity to only provide permissions for a specific subnet within an Amazon VPC.

After you've defined permissions, you can create roles and then pass those roles to create other resources, such as SageMaker notebook instances.

The following are code examples in Typescript for tasks that you can accomplish using the CDK. When you create an activity, you specify an ID and the options for the activity's construct. The options are dictionaries that specify the required parameters for the activities, such as an Amazon S3. You pass an empty dictionary for activities that don't have required parameters.

**Grant permissions to a Compute persona**

The following code creates a Data Scientist ML persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the Amazon VPC and AWS KMS configurations specified in the persona construct. The following code creates a class for a Data
Grant permissions to a Data Scientist persona

The following code creates a Data Scientist ML persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the VPC and KMS configurations specified in the persona construct. The following code creates a class for a Data Scientist persona. The ML activities are defined in the activities list. The Amazon VPC permissions and the AWS KMS permissions are defined as optional parameters outside of the activities list.

After you’ve defined the class, you can create a role as a construct within the AWS CDK stack. You can also create a notebook instance. The person who is using the IAM role that you’ve created in the following code can access the notebook instance when they log in to their AWS account.
const persona = new Persona(this, 'example-persona-id', {
  activities: [
    Activity.runStudioAppsV2(this, 'example-id1', {}),
    Activity.manageJobs(this, 'example-id2', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]})],
    Activity.manageModels(this, 'example-id3', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]})],
    Activity.manageExperiments(this, 'example-id4', {}),
    Activity.visualizeExperiments(this, 'example-id5', {}),
    Activity.accessS3Buckets(this, 'example-id6', [s3.S3Bucket.fromBucketName('DOC-EXAMPLE-BUCKET')]])
],
  // optional: to configure VPC permissions
  subnets: [ec2.Subnet.fromSubnetId('example-VPC-subnet-id')],
  securityGroups: [ec2.SecurityGroup.fromSecurityGroupId('example-VPC-security-group-id')],
  // optional: to configure KMS permissions
  dataKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
  volumeKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
});

const role = persona.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');

const notebookInstance = new CfnNotebookInstance(this, 'example-notebook-instance-name', { RoleArn: role.RoleArn, ...});
}
}

Grant permissions to an ML Ops persona

The following code creates an ML Ops persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the Amazon VPC and AWS KMS configurations specified in the persona construct. The following code creates a class for an ML Ops persona. The ML activities are defined in the activities list. The VPC permissions and the KMS permissions are defined as optional parameters outside of the activities list.

After you’ve defined the class, you can create a role as a construct within the AWS CDK stack. You can also create an Amazon SageMaker Studio Classic user profile. The person who is using the IAM role that you’ve created in the following code can open SageMaker Studio Classic when they log in to their AWS account.
export class myCDKStack extends cdk.Stack {
    constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
        super(scope, id, props);

        const persona = new Persona(this, 'example-persona-id', {
            activities: [
                Activity.runStudioAppsV2(this, 'example-id1', {}),
                Activity.manageModels(this, 'example-id2', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]})
            ],
            subnets: [ec2.Subnet.fromSubnetId('example-VPC-subnet-id')],
            securityGroups: [ec2.SecurityGroup.fromSecurityGroupId('example-VPC-security-group-id')],
            dataKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
            volumeKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
        });

        const role = persona.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');

        let userProfile = new CfnNUserProfile(this, 'example-Studio Classic-profile-name', {
            RoleName: role.RoleName, ...
        });
    }
}

Grant permissions to a construct

The following code creates an ML Ops persona with a set of ML activities specific to the persona. The following code creates a class for a ML Ops persona. The ML activities are defined in the activities list.

After you’ve defined the class, you can create a role as a construct within the AWS CDK stack. You can also create a notebook instance. The code grants permissions from the ML activities to the IAM role of the Lambda function.
Grant permissions for a single ML activity

The following code creates an ML activity and creates a role from the activity. The permissions from the activity only apply to the VPC and KMS configuration that you specify for the user.
Create a role and give it permissions for a single activity

The following code creates an IAM role for a single ML activity.

```plaintext
const role = activity.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');
}

Persona reference

Amazon SageMaker Role Manager provides suggested permissions for a number of ML personas. These include user execution roles for common ML practitioner responsibilities as well as service execution roles for common AWS service interactions needed to work with SageMaker.

Each persona has suggested permissions in the form of selected ML activities. For information on predefined ML activities and their permissions, see ML activity reference.

Data scientist persona

Use this persona to configure permissions to perform general machine learning development and experimentation in a SageMaker environment. This persona includes the following preselected ML activities:

- Run Studio Classic Applications
• Manage ML Jobs
• Manage Models
• Manage Experiments
• Search and Visualize Experiments
• Amazon S3 Bucket Access

MLOps persona

Choose this persona to configure permissions for operational activities. This persona includes the following preselected ML activities:

• Run Studio Classic Applications
• Manage Models
• Manage Endpoints
• Manage Pipelines
• Search and Visualize Experiments

SageMaker compute persona

Note

We recommend that you first use the role manager to create a SageMaker Compute Role so that SageMaker compute resources can perform tasks such as training and inference. Use the SageMaker Compute Role persona to create this role with the role manager. After creating a SageMaker Compute Role, take note of its ARN for future use.

This persona includes the following preselected ML activity:

• Access Required AWS Services

ML activity reference

ML activities are common AWS tasks related to machine learning with SageMaker that require specific IAM permissions. Each persona suggests related ML activities when creating a role with
Amazon SageMaker Role Manager. You can select any additional ML activities or deselect any suggested ML activities to create a role that meets your unique business needs.

Amazon SageMaker Role Manager provides predefined permissions for the following ML activities:

<table>
<thead>
<tr>
<th>ML activity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Required AWS Services</td>
<td>Permissions to access Amazon S3, Amazon ECR, Amazon CloudWatch, and Amazon EC2. Required for execution roles for jobs and endpoints.</td>
</tr>
<tr>
<td>Run Studio Classic Applications</td>
<td>Permissions to operate within a Studio Classic environment. Required for domain and user profile execution roles.</td>
</tr>
<tr>
<td>Manage ML Jobs</td>
<td>Permissions to audit, query lineage, and visualize experiments.</td>
</tr>
<tr>
<td>Manage Models</td>
<td>Permissions to manage SageMaker jobs across their lifecycles.</td>
</tr>
<tr>
<td>Manage Endpoints</td>
<td>Permissions to manage SageMaker endpoint deployments and updates.</td>
</tr>
<tr>
<td>Manage Pipelines</td>
<td>Permissions to manage SageMaker pipelines and pipeline executions.</td>
</tr>
<tr>
<td>Manage Experiments</td>
<td>Permissions to manage SageMaker experiments and trials.</td>
</tr>
<tr>
<td>Search and Visualize Experiments</td>
<td>Permissions to audit, query lineage, and visualize experiments.</td>
</tr>
<tr>
<td>Manage Model Monitoring</td>
<td>Permissions to manage monitoring schedules for SageMaker Model Monitor.</td>
</tr>
<tr>
<td>S3 Full Access</td>
<td>Permissions to perform all Amazon S3 operations.</td>
</tr>
<tr>
<td>ML activity</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>S3 Bucket Access</td>
<td>Permissions to perform operations on specified S3 buckets.</td>
</tr>
<tr>
<td>Query Athena Workgroups</td>
<td>Permissions to run and manage Amazon Athena queries.</td>
</tr>
</tbody>
</table>

**Launch Studio Classic**

Use your persona-focused roles to launch Studio Classic. If you are an administrator, you can give your users access to Studio Classic and have them assume their persona role either directly through the AWS Management Console or through the AWS IAM Identity Center.

**Launch Studio Classic with AWS Management Console**

For data scientists or other users to assume their given persona through the AWS Management Console, they require a console role to get to the Studio Classic environment.

You cannot use Amazon SageMaker Role Manager to create a role that grants permissions to the AWS Management Console. However, after creating a service role in the role manager, you can go to the IAM console to edit the role and add a user access role. The following is an example of a role that provides user access to the AWS Management Console:

```json
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Sid": "DescribeCurrentDomain",
            "Effect": "Allow",
            "Action": "sagemaker:DescribeDomain",
        },
        {
            "Sid": "RemoveErrorMessagesFromConsole",
            "Effect": "Allow",
            "Action":
```
In the Studio Classic control panel, choose Add User to create a new user. In the General Settings section, give your user a name and set the Default execution role for the user to be the role that you created using Amazon SageMaker Role Manager.

On the next screen, choose the appropriate Jupyter Lab version, and whether to turn on SageMaker Jumpstart and SageMaker Project templates. Then choose Next. On the SageMaker Canvas settings page, choose whether to turn on SageMaker Canvas support, and additionally whether to allow for timeseries forecasting in SageMaker Canvas. Then choose Submit.

Your new user should now be visible in the Studio Classic control panel. To test this user, choose Studio from the Launch app dropdown list in the same row as the user’s name.
Launch Studio Classic with IAM Identity Center

To assign IAM Identity Center users to execution roles, the user must first exist in the IAM Identity Center directory. For more information, see Manage identities in IAM Identity Center in the AWS IAM Identity Center.

Note

Your IAM Identity Center Authentication directory and Studio Classic Domain must be in the same AWS Region.

1. To assign IAM Identity Center users to your Studio Classic Domain, choose Assign users and Groups in the Studio Classic control panel. On the Assign users and groups screen select your data scientist user, and then choose Assign Users and Groups.

2. After the user is added to the Studio Classic control panel, choose the user to open the user details screen.

3. On the User details screen, choose Edit.

4. On the Edit user profile screen, under General settings, modify the Default execution role to match the user execution role you’ve created for your data scientists.

5. Choose Next through the rest of the settings pages, and choose Submit to save your changes.

When your data scientist or other user logs into the IAM Identity Center portal, they see a tile for this Studio Classic Domain. Choosing that tile logs them into Studio Classic with their assigned user execution role.

Role Manager FAQs

Refer to the following FAQ items for answers to commonly asked questions about Amazon SageMaker Role Manager.

Q. How can I access Amazon SageMaker Role Manager?

A: You can access Amazon SageMaker Role Manager through multiple location in the Amazon SageMaker console. For information about accessing role manager and using it to create a role, see Using the role manager (console).
Q. What are personas?

A: Personas are preconfigured groups of permissions based on common machine learning (ML) responsibilities. For example, the data science persona suggests permissions for general machine learning development and experimentation in a SageMaker environment, while the MLOps persona suggests permissions for ML activities related to operations.

Q. What are ML activities?

A: ML activities are common AWS tasks related to machine learning with SageMaker that require specific IAM permissions. Each persona suggests related ML activities when creating a role with Amazon SageMaker Role Manager. ML activities include tasks such as Amazon S3 full access or searching and visualizing experiments. For more information, see ML activity reference.

Q. Are the roles that I create with the role manager AWS Identity and Access Management (IAM) roles?

A: Yes. Roles created using the Amazon SageMaker Role Manager are IAM roles with customized access policies. You can view created roles in the Roles section of the IAM console.

Q. How can I view the roles that I created using Amazon SageMaker Role Manager?

A: You can view created roles in the Roles section of the IAM console. By default, the prefix "sagemaker-" is added to every role name for easier search in the IAM console. For example, if you named your role test-123 during role creation, your role shows up as sagemaker-test-123 in the IAM console.

Q. Can I modify a role made with Amazon SageMaker Role Manager once it is created?

A: Yes. You can modify the roles and policies created by Amazon SageMaker Role Manager through the IAM console. For more information, see Modifying a role in the AWS Identity and Access Management User Guide.

Q. Can I attach my own policies to roles created using Amazon SageMaker Role Manager?

A: Yes. You can attach any AWS or customer-managed IAM policies from your account to the role that you create using Amazon SageMaker Role Manager.

Q. How many policies can I add to a role that I create with Amazon SageMaker Role Manager?

A: The maximum limit for attaching managed policies to an IAM role or user is 20. The maximum character size limit for managed policies is 6,144. For more information, see IAM object quotas and IAM and AWS Security Token Service quotas name requirements, and character limits.
Q. Can I add conditions to ML activities?

A: Any conditions that you provide in Step 1. Enter role information of the Amazon SageMaker Role Manager, such as subnets, security groups, or KMS keys, are automatically passed to any ML activities selected in Step 2. Configure ML activities. You can also add additional conditions to ML activities if necessary. For example, you might also add InstanceTypes or IntercontainerTrafficEncryption conditions to the Manage Training Jobs activity.

Q. Can I use tagging to manage access to any AWS resource?

A: You can add tags to your role in Step 3: Add additional policies and tags of the Amazon SageMaker Role Manager. To successfully manage AWS resources using tags, you must add the same tag to both the role and any associated policies. For example, you can add a tag to a role and to an Amazon S3 bucket. Then, because the role passes the tag to the SageMaker session, only a user with that role can access that S3 bucket. You can add tags to a policy through the IAM console. For more information, see Tagging IAM roles in the AWS Identity and Access Management User Guide.

Q. Can I use Amazon SageMaker Role Manager to create a role to access the AWS Management Console?

A: No. However, after creating a service role in the role manager, you can go to the IAM console to edit the role and add a human access role in IAM console.

Q. What is difference between a user federation role and a SageMaker execution role?

A: A user federation role is directly assumed by a user to access AWS resources such as access to the AWS Management Console. A SageMaker execution role is assumed by the SageMaker service to perform a function on behalf of a user or an automation tool. For example, when a user opens a Studio Classic instance, Studio Classic assumes the execution role associated with the user profile in order to access AWS resources on the behalf of the user. If the user profile does not specify an execution role, then the execution role is specified at the Amazon SageMaker Domain level.

Q. If I am using a custom web application that accesses Studio Classic through a presigned url, what role is used?

A: If you use a custom web application to access Studio Classic, then you have a hybrid user federation role and SageMaker execution role. Be sure that this role has least privilege permissions for both what the user can do and what Studio Classic can do on the associated user's behalf.
Q: Can I use Amazon SageMaker Role Manager with AWS IAM Identity Center authentication for my Studio Classic domain?

A: AWS IAM Identity Center Studio Classic Cloud Applications use a Studio Classic execution role to grant permissions to federated users. This execution role can be specified at the Studio Classic IAM Identity Center user profile level or the default domain level. User identities and groups must be synchronized into IAM Identity Center and the Studio Classic user profile must be created with IAM Identity Center user assignment using CreateUserProfile. For more information, see Launch Studio Classic with IAM Identity Center.

Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference

When you are setting up access control and writing a permissions policy that you can attach to an IAM identity (an identity-based policy), use the following as a reference. The each Amazon SageMaker API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

Note

Except for the ListTags API, resource-level restrictions are not available on List- calls. Any user calling a List- API will see all resources of that type in the account.

Warning

Some SageMaker API actions may still be accessible through the Search API. For example, if a user has an IAM policy that denies permissions to a Describe call for a particular SageMaker resource, that user can still access the description information through the Search API. To fully restrict user access to Describe calls, you must also restrict access to the Search API. For a list of SageMaker resources that are accessible through the Search API, see the SageMaker Search AWS CLI Command Reference.

AWS Managed Policies for Amazon SageMaker

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) to which the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

⚠️ Important

We recommend that you use the most restricted policy that allows you to perform your use case.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon SageMaker:

- **AmazonSageMakerFullAccess** – Grants full access to Amazon SageMaker and SageMaker geospatial resources and the supported operations. This does not provide unrestricted
Amazon S3 access, but supports buckets and objects with specific sagemaker tags. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services.

• **AmazonSageMakerReadOnly** – Grants read-only access to Amazon SageMaker resources.

The following AWS managed policies can be attached to users in your account but are not recommended:

• **AdministratorAccess** – Grants all actions for all AWS services and for all resources in the account.

• **DataScientist** – Grants a wide range of permissions to cover most of the use cases (primarily for analytics and business intelligence) encountered by data scientists.

You can review these permissions policies by signing in to the IAM console and searching for them.

You can also create your own custom IAM policies to allow permissions for Amazon SageMaker actions and resources as you need them. You can attach these custom policies to the users or groups that require them.

AWS managed policy: AmazonSageMakerFullAccess

This policy grants administrative permissions that allow a principal full access to all Amazon SageMaker and SageMaker geospatial resources and operations. The policy also provides select access to related services. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services. This policy does not include permissions to create an Amazon SageMaker domain. For information on the policy needed to create a domain, see Create an Administrative User and Group.

Permissions details

This policy includes the following permissions.

• application-autoscaling – Allows principals to automatically scale a SageMaker real-time inference endpoint.

• athena – Allows principals to query a list of data catalogs, databases, and table metadata from Amazon Athena.

• aws-marketplace – Allows principals to view AWS AI Marketplace subscriptions. You need this if you want to access SageMaker software subscribed in AWS Marketplace.

• cloudformation – Allows principals to get AWS CloudFormation templates for using SageMaker JumpStart solutions and Pipelines. SageMaker JumpStart creates resources necessary to run end-to-end machine learning solutions that tie SageMaker to other AWS services. SageMaker Pipelines creates new projects that are backed by Service Catalog.

• cloudwatch – Allows principals to post CloudWatch metrics, interact with alarms, and upload logs to CloudWatch Logs in your account.

• codebuild – Allows principals to store AWS CodeBuild artifacts for SageMaker Pipeline and Projects.

• codecommit – Needed for AWS CodeCommit integration with SageMaker notebook instances.

• cognito-idp – Needed for Amazon SageMaker Ground Truth to define private workforce and work teams.

• ec2 – Needed for SageMaker to manage Amazon EC2 resources and network interfaces when you specify an Amazon VPC for your SageMaker jobs, models, endpoints, and notebook instances.
• ecr – Needed to pull and store Docker artifacts for Amazon SageMaker Studio Classic (custom images), training, processing, batch inference, and inference endpoints. This is also required to use your own container in SageMaker. Additional permissions for SageMaker JumpStart solutions are required to create and remove custom images on behalf of users.

• elastic-inference – Allows principals to connect to Amazon Elastic Inference for using SageMaker notebook instances and endpoints.

• elasticfilesystem – Allows principals to access Amazon Elastic File System. This is needed for SageMaker to use data sources in Amazon Elastic File System for training machine learning models.

• fsx – Allows principals to access Amazon FSx. This is needed for SageMaker to use data sources in Amazon FSx for training machine learning models.

• glue – Needed for inference pipeline pre-processing from within SageMaker notebook instances.

• groundtruthlabeling – Needed for Ground Truth labeling jobs. The groundtruthlabeling endpoint is accessed by the Ground Truth console.

• iam – Needed to give the SageMaker console access to available IAM roles and create service-linked roles.

• kms – Needed to give the SageMaker console access to available AWS KMS keys and retrieve them for any specified AWS KMS aliases in jobs and endpoints.

• lambda – Allows principals to invoke and get a list of AWS Lambda functions.

• logs – Needed to allow SageMaker jobs and endpoints to publish log streams.

• redshift – Allows principals to access Amazon Redshift cluster credentials.

• redshift-data – Allows principals to use data from Amazon Redshift to run, describe, and cancel statements; get statement results; and list schemas and tables.

• robomaker – Allows principals to have full access to create, get descriptions, and delete AWS RoboMaker simulation applications and jobs. This is also needed to run reinforcement learning examples on notebook instances.

• s3, s3express – Allows principals to have full access to Amazon S3 and Amazon S3 Express resources pertaining to SageMaker, but not all of Amazon S3 or Amazon S3 Express.

• sagemaker – Allows principals to list tags on SageMaker user profiles and add tags to SageMaker apps. Allows access only to SageMaker flow-definitions of sagemaker:WorkteamType "private-crowd" or "vendor-crowd".

• sagemaker and sagemaker-geospatial – Allows principals read-only access to SageMaker domains and user profiles.
• secretsmanager – Allows principals to have full access to AWS Secrets Manager. The principals can securely encrypt, store, and retrieve credentials for databases and other services. This is also needed for SageMaker notebook instances with SageMaker code repositories that use GitHub.

• servicecatalog – Allows principals to use Service Catalog. The principals can create, get a list of, update, or terminate provisioned products, such as servers, databases, websites, or applications deployed using AWS resources. This is needed for SageMaker JumpStart and Projects to find and read service catalog products and launch AWS resources in users.

• sns – Allows principals to get a list of Amazon SNS topics. This is needed for endpoints with Async Inference enabled for notifying users that their inference has completed.

• states – Needed for SageMaker JumpStart and Pipelines to use a service catalog to create step function resources.

• tag – Needed for SageMaker Pipelines to render in Studio Classic. Studio Classic needs resources tagged with particular sagemaker:project-id tag-key. This requires the tag:GetResources permission.

AWS managed policy: AmazonSageMakerReadOnly

This policy grants read-only access to Amazon SageMaker through the AWS Management Console and SDK.

Permissions details

This policy includes the following permissions.

- **application-autoscaling** – Allows users to browse descriptions of scalable SageMaker real-time inference endpoints.
- **aws-marketplace** – Allows users to view AWS AI Marketplace subscriptions.
- **cloudwatch** – Allows users to receive CloudWatch alarms.
- **cognito-idp** – Needed for Amazon SageMaker Ground Truth to browse descriptions and lists of private workforce and work teams.
- **ecr** – Needed to read Docker artifacts for training and inference.

**AWS managed policies for Amazon SageMaker Canvas**

These AWS managed policies add permissions required to use Amazon SageMaker Canvas. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

**Topics**

- [AWS managed policy: AmazonSageMakerCanvasFullAccess](#)
- [AWS managed policy: AmazonSageMakerCanvasDataPrepFullAccess](#)
- [AWS managed policy: AmazonSageMakerCanvasDirectDeployAccess](#)
- [AWS managed policy: AmazonSageMakerCanvasAIServicesAccess](#)
- [AWS managed policy: AmazonSageMakerCanvasForecastAccess](#)
- [Amazon SageMaker updates to Amazon SageMaker Canvas managed policies](#)
AWS managed policy: AmazonSageMakerCanvasFullAccess

This policy grants permissions that allow full access to Amazon SageMaker Canvas through the AWS Management Console and SDK. The policy also provides select access to related services [for example, Amazon Simple Storage Service (Amazon S3), AWS Identity and Access Management (IAM), Amazon Virtual Private Cloud (Amazon VPC), Amazon Elastic Container Registry (Amazon ECR), Amazon CloudWatch Logs, Amazon Redshift, AWS Secrets Manager, Amazon SageMaker Autopilot, SageMaker Model Registry, and Amazon Forecast].

This policy is intended to help customers experiment and get started with all the capabilities of SageMaker Canvas. For more fine-grained control, we suggest customers build their own scoped down versions as they move to production workloads. For more information, see IAM policy types: How and when to use them.

Permissions details

This AWS managed policy includes the following permissions.

- **sagemaker** – Allows principals to create and host SageMaker models on resources whose ARN contains "Canvas", "canvas", or "model-compilation-". Additionally, users can register their SageMaker Canvas model to SageMaker Model Registry in the same AWS account.
- **ec2** – Allows principals to create Amazon VPC endpoints.
- **ecr** – Allows principals to get information about a container image.
- **glue** – Allows principals to retrieve the tables in the catalog.
- **iam** – Allows principals to pass an IAM role to Amazon SageMaker and Amazon Forecast. Also allows principals to create a service-linked role.
- **logs** – Allows principals to publish logs from training jobs and endpoints.
- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name includes "SageMaker", "Sagemaker", or "sagemaker". Also allows principals to retrieve objects from Amazon S3 buckets whose ARN starts with "jumpstart-cache-prod-" in specific regions.
- **secretsmanager** – Allows principals to store customer credentials to connect to a Snowflake database using Secrets Manager.
- **redshift** – Allows principals to get credentials for a "sagemaker_access***" dbuser on any Amazon Redshift cluster if that user exists.
- **redshift-data** – Allows principals to run queries on Amazon Redshift using the Amazon Redshift Data API. This only provides access to the Redshift Data APIs themselves and does not
directly provide access to your Amazon Redshift clusters. For more information, see Using the Amazon Redshift Data API.

- forecast – Allows principals to use Amazon Forecast.
- application-autoscaling – Allows principals to automatically scale a SageMaker inference endpoint.
- rds – Allows principals to return information about provisioned Amazon RDS instances.
- cloudwatch – Allows principals to create and manage Amazon CloudWatch alarms.
- athena – Allows principals to create, read, and manage Amazon Athena queries, catalogs, and executions.

AWS managed policy: AmazonSageMakerCanvasDataPrepFullAccess

This policy grants permissions that allow full access to the data preparation functionality of Amazon SageMaker Canvas. The policy also provides least privilege permissions for the services that integrate with the data preparation functionality [for example, Amazon Simple Storage Service (Amazon S3), AWS Identity and Access Management (IAM), Amazon EMR, Amazon EventBridge, Amazon Redshift, AWS Key Management Service (AWS KMS) and AWS Secrets Manager].

Permissions details

This AWS managed policy includes the following permissions.

- sagemaker – Allows principals to access processing jobs, training jobs, inference pipelines, AutoML jobs, and feature groups.
- athena – Allows principals to query a list of data catalogs, databases, and table metadata from Amazon Athena.
- elasticmapreduce – Allows principals to read and list Amazon EMR clusters.
- events – Allows principals to create, read, update, and add targets to Amazon EventBridge rules for scheduled jobs.
- glue – Allows principals to get and search tables from databases in the AWS Glue catalog.
- iam – Allows principals to pass an IAM role to Amazon SageMaker and EventBridge.
- kms – Allows principals to retrieve AWS KMS aliases stored in jobs and endpoints, and access the associated KMS key.
- logs – Allows principals to publish logs from training jobs and endpoints.
- redshift – Allows principals to get credentials to access an Amazon Redshift database.
- redshift-data – Allows principals to run, cancel, describe, list, and get the results of Amazon Redshift queries. Also allows principals to list Amazon Redshift schemas and tables.
- s3 – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name includes "SageMaker", "Sagemaker", or "sagemaker"; or is tagged with "SageMaker", case-insensitive.
- secretsmanager – Allows principals to store and retrieve customer database credentials using Secrets Manager.

AWS managed policy: AmazonSageMakerCanvasDirectDeployAccess

This policy grants permissions needed for Amazon SageMaker Canvas to create and manage Amazon SageMaker endpoints.

Permissions details

This AWS managed policy includes the following permissions.

- **sagemaker** – Allows principals to create and manage SageMaker endpoints with an ARN resource name that starts with "Canvas" or "canvas".
- **cloudwatch** – Allows principals to retrieve Amazon CloudWatch metric data.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SageMakerEndpointPerms",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateEndpoint",
            "sagemaker:CreateEndpointConfig",
            "sagemaker:DeleteEndpoint",
            "sagemaker:DescribeEndpoint",
            "sagemaker:DescribeEndpointConfig",
            "sagemaker:InvokeEndpoint",
            "sagemaker:UpdateEndpoint"
         ],
         "Resource": [
            "arn:aws:sagemaker::*::*:Canvas*",
            "arn:aws:sagemaker::*::*:canvas*"
         ]
      },
      {
         "Sid": "ReadCWInvocationMetrics",
         "Effect": "Allow",
         "Action": "cloudwatch:GetMetricData",
         "Resource": "*"
      }
   ]
}
```
AWS managed policy: AmazonSageMakerCanvasAIServicesAccess

This policy grants permissions for Amazon SageMaker Canvas to use Amazon Textract, Amazon Rekognition, and Amazon Comprehend.

Permissions details

This AWS managed policy includes the following permissions.

- **textract** – Allows principals to use Amazon Textract to detect documents, expenses, and identities within an image.
- **rekognition** – Allows principals to use Amazon Rekognition to detect labels and text within an image.
- **comprehend** – Allows principals to use Amazon Comprehend to detect sentiment and dominant language, and named and personally identifiable information (PII) entities within a text document.
- **bedrock** – Allows principals to use Amazon Bedrock to list and invoke foundation models.
- **iam** – Allows principals to pass an IAM role to Amazon Bedrock.

```json
{
   "Version": "2012-10-17",

AWS managed policy: AmazonSageMakerCanvasForecastAccess

This policy grants permissions commonly needed to use Amazon SageMaker Canvas with Amazon Forecast.

Permissions details

This AWS managed policy includes the following permissions.

- s3 – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name starts with "sagemaker-".

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::sagemaker-*/Canvas",
        "arn:aws:s3:::sagemaker-*/Canvas"
      ]
    }
  ]
}
```

AWS managed policies for Amazon SageMaker Cluster

These AWS managed policies add permissions required to use SageMaker Cluster. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics
- AWS managed policy: AmazonSageMakerClusterInstanceRolePolicy
- Amazon SageMaker updates to Amazon SageMaker Cluster managed policies

AWS managed policy: AmazonSageMakerClusterInstanceRolePolicy

This policy grants permissions commonly needed to use Amazon SageMaker Cluster.

Permissions details

This AWS managed policy includes the following permissions.

- cloudwatch – Allows principals to post Amazon CloudWatch metrics.
- logs – Allows principals to publish CloudWatch log streams.
- s3 – Allows principals to list and retrieve lifecycle script files from an Amazon S3 bucket in your account. These buckets are limited to those whose name starts with "sagemaker-".
- ssmmessages – Allows principals to open a connection to AWS Systems Manager.

AWS managed policies for Amazon SageMaker Feature Store

These AWS managed policies add permissions required to use Feature Store. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.
Topics

- AWS managed policy: AmazonSageMakerFeatureStoreAccess
- Amazon SageMaker updates to Amazon SageMaker Feature Store managed policies

AWS managed policy: AmazonSageMakerFeatureStoreAccess

This policy grants permissions required to enable the offline store for an Amazon SageMaker Feature Store feature group.

Permissions details

This AWS managed policy includes the following permissions.

- s3 – Allows principals to write data into an offline store Amazon S3 bucket. These buckets are limited to those whose name includes "SageMaker", "Sagemaker", or "sagemaker".
- s3 – Allows principals to read existing manifest files maintained in the metadata folder of an offline store S3 bucket.
- glue – Allows principals to read and update AWS Glue tables. These permissions are limited to tables in the sagemaker_featurestore folder.

```json
{
    "Version": "2012-10-17",

AWS managed policies for Amazon SageMaker geospatial

These AWS managed policies add permissions required to use SageMaker geospatial. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerGeospatialFullAccess
- AWS managed policy: AmazonSageMakerGeospatialExecutionRole
- Amazon SageMaker updates to Amazon SageMaker geospatial managed policies

AWS managed policy: AmazonSageMakerGeospatialFullAccess

This policy grants permissions that allow full access to Amazon SageMaker geospatial through the AWS Management Console and SDK.

Permissions details

This AWS managed policy includes the following permissions.

- sagemaker-geospatial – Allows principals full access to all SageMaker geospatial resources.
- iam – Allows principals to pass an IAM role to SageMaker geospatial.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker-geospatial:*",
            "Resource": "*"
        },
        {
```
AWS managed policy: AmazonSageMakerGeospatialExecutionRole

This policy grants permissions commonly needed to use SageMaker geospatial.

Permissions details

This AWS managed policy includes the following permissions.

- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name contains "SageMaker", "Sagemaker", or "sagemaker".
- **sagemaker-geospatial** – Allows principals to access Earth observation jobs through the GetEarthObservationJob API.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:AbortMultipartUpload",
            "s3:PutObject",
            "s3:GetObject",
            "s3:ListBucketMultipartUploads"
         ],
         "Resource": [
            "arn:aws:s3:::*SageMaker*",
            "arn:aws:s3:::*Sagemaker*",
            "arn:aws:s3:::*sagemaker*"
         ]
      }
   ]
}
```

AWS Managed Policies for Amazon SageMaker Ground Truth

These AWS managed policies add permissions required to use SageMaker Ground Truth. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.
AWS managed policy: AmazonSageMakerGroundTruthExecution

This AWS managed policy grants permissions commonly needed to use SageMaker Ground Truth.

Permissions details

This policy includes the following permissions.

- **lambda** – Allows principals to invoke Lambda functions whose name includes "sagemaker" (case-insensitive), "GtRecipe", or "LabelingFunction".
- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose case-insensitive name contains "groundtruth" or "sagemaker", or are tagged with "SageMaker".
- **cloudwatch** – Allows principals to post CloudWatch metrics.
- **logs** – Allows principals to create and access log streams, and post log events.
- **sqs** – Allows principals to create Amazon SQS queues, and send and receive Amazon SQS messages. These permissions are limited to queues whose name includes "GroundTruth".
- **sns** – Allows principals to subscribe to and publish messages to Amazon SNS topics whose case-insensitive name contains "groundtruth" or "sagemaker".
- **ec2** – Allows principals to create, describe, and delete Amazon VPC endpoints whose VPC endpoint service name contains "sagemaker-task-resources" or "labeling".

```json

AWS managed policy: GroundTruthSyntheticConsoleFullAccess

This AWS managed policy grants permissions needed to use most features of the SageMaker Ground Truth synthetic data console. The policy is available in your AWS account. In order to use all features of the console, users must add "s3:GetObject" permissions to allow SageMaker Ground Truth synthetic data console to display data from their S3 buckets. This can be done by attaching the AmazonS3ReadOnlyAccess managed policy to their role or by adding "s3:GetObject" for specific S3 resources to their role.

Permissions details

This policy includes the following permissions.

- s3 – Allows the retrieval of objects from Amazon S3 buckets to display data in the console.
- sagemaker-groundtruth-synthetic – Allows the console to call SageMaker Ground Truth synthetic data APIs.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker-groundtruth-synthetic:*",
                "s3:ListBucket"
            ],
            "Resource": "*"
        }
    ]
}
```
AWS managed policy: GroundTruthSyntheticConsoleReadOnlyAccess

This AWS managed policy grants read-only access to SageMaker Ground Truth synthetic data via the AWS Management Console. In order to use all features of the console, users must add “s3:GetObject” permissions to allow SageMaker Ground Truth synthetic data console to display data from their S3 buckets. This can be done by attaching the AmazonS3ReadOnlyAccess managed policy to their role or by adding “s3:GetObject” for specific S3 resources to their role.

Permissions details

This policy includes the following permissions.

- s3 – Allows the retrieval of objects from Amazon S3 buckets to display data in the console.
- sagemaker-groundtruth-synthetic – Allows the console to call SageMaker Ground Truth synthetic data ReadOnly APIs.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker-groundtruth-synthetic:List*",
            "sagemaker-groundtruth-synthetic:Get*",
            "s3:ListBucket"
         ],
         "Resource": "*"
      }
   ]
}
```

AWS managed policy: AmazonSageMakerModelGovernanceUseAccess

This AWS managed policy grants permissions needed to use all Amazon SageMaker Governance features. The policy is available in your AWS account.

This policy includes the following permissions.

- **s3** – Retrieve objects from Amazon S3 buckets. Retrievable objects are limited to those whose case-insensitive name contains the string "sagemaker".
- **kms** – List the AWS KMS keys to use for content encryption.

```json

AWS Managed Policies for Model Registry

These AWS managed policies adds permissions required to use Model Registry. The policies are available in your AWS account and are used by execution roles created from the Amazon SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerModelRegistryFullAccess
- Amazon SageMaker updates to Model Registry managed policies

AWS managed policy: AmazonSageMakerModelRegistryFullAccess

This AWS managed policy grants permissions needed to use all Model Registry features inside an Amazon SageMaker domain. This policy is attached to an execution role when configuring Model Registry settings to enable Model Registry permissions.

This policy includes the following permissions.

- ecr – Allows principals to retrieve information, including metadata, about Amazon Elastic Container Registry (Amazon ECR) images.
• `iam` – Allows principals to pass the execution role to the Amazon SageMaker service.

• `resource-groups` – Allows principals to create, list, tag, and delete AWS Resource Groups.

• `s3` – Allows principals to retrieve objects from the Amazon Simple Storage Service (Amazon S3) buckets where model versions are stored. Retrievable objects are limited to those whose case-insensitive name contains the string "sagemaker".

• `sagemaker` – Allows principals to catalog, manage, and deploy models using the SageMaker model registry.

```json

AWS Managed Policies for SageMaker Notebooks

These AWS managed policies add permissions required to use SageMaker Notebooks. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics
- AWS managed policy: AmazonSageMakerNotebooksServiceRolePolicy
- Amazon SageMaker updates to SageMaker Notebooks managed policies

AWS managed policy: AmazonSageMakerNotebooksServiceRolePolicy

This AWS managed policy grants permissions commonly needed to use Amazon SageMaker Notebooks. The policy is added to the AmazonSageMaker-ExecutionRole that is created when you onboard to Amazon SageMaker Studio Classic. For more information on service-linked roles, see Service-Linked Roles.

Permissions details

This policy includes the following permissions.

- elasticfilesystem – Allows principals to create and delete Amazon Elastic File System (EFS) file systems, access points, and mount targets. These are limited to those tagged with the key
**ManagedByAmazonSageMakerResource.** Allows principals to describe all EFS file systems, access points, and mount targets. Allows principals to create or overwrite tags for EFS access points and mount targets.

- **ec2** – Allows principals to create network interfaces and security groups for Amazon Elastic Compute Cloud (EC2) instances. Also allows principals to create and overwrite tags for these resources.

- **sso** – Allows principals to add and delete managed application instances to AWS IAM Identity Center.

- **sagemaker** – Allows principals to create and read SageMaker user profiles.

### AWS Managed Policies for SageMaker Pipelines

These AWS managed policies add permissions required to use SageMaker Pipelines. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

**Topics**

- [AWS managed policy: AmazonSageMakerPipelinesIntegrations](#)
- [Amazon SageMaker updates to SageMaker Pipelines managed policies](#)

### AWS managed policy: AmazonSageMakerPipelinesIntegrations

This AWS managed policy grants permissions commonly needed to use Callback steps and Lambda steps in SageMaker Pipelines. The policy is added to the AmazonSageMaker-ExecutionRole that is created when you onboard to Amazon SageMaker Studio Classic. The policy can be attached to any role used for authoring or executing a pipeline.

This policy grants appropriate AWS Lambda, Amazon Simple Queue Service (Amazon SQS), Amazon EventBridge, and IAM permissions needed when building pipelines that invoke Lambda functions or include callback steps, which can be used for manual approval steps or running custom workloads.

The Amazon SQS permissions allow you to create the Amazon SQS queue needed for receiving callback messages, and also to send messages to that queue.

The Lambda permissions allow you to create, read, update, and delete the Lambda functions used in the pipeline steps, and also to invoke those Lambda functions.

This policy grants the Amazon EMR permissions needed to run a pipelines Amazon EMR step.

**Permissions details**

This policy includes the following permissions.
- elasticmapreduce – Read, add, and cancel steps in a running Amazon EMR cluster. Read, create, and terminate a new Amazon EMR cluster.
- events – Read, create, update, and add targets to an EventBridge rule named SageMakerPipelineExecutionEMRStepStatusUpdateRule and SageMakerPipelineExecutionEMRClusterStatusUpdateRule.
- iam – Pass an IAM role to the AWS Lambda service, Amazon EMR and Amazon EC2.
- lambda – Create, read, update, delete, and invoke Lambda functions. These permissions are limited to functions whose name includes "sagemaker".
- sqs – Create an Amazon SQS queue; send an Amazon SQS message. These permissions are limited to queues whose name includes "sagemaker".

AWS Managed Policies for SageMaker projects and JumpStart

These AWS managed policies add permissions to use built-in Amazon SageMaker project templates and JumpStart solutions. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

SageMaker projects and JumpStart use AWS Service Catalog to provision AWS resources in customers' accounts. Some created resources need to assume an execution role. For example, if AWS Service Catalog creates a CodePipeline pipeline on behalf of a customer for a SageMaker machine learning CI/CD project, then that pipeline requires an IAM role.

The `AmazonSageMakerServiceCatalogProductsLaunchRole` role has the permissions required to launch the SageMaker portfolio of products from AWS Service Catalog. The `AmazonSageMakerServiceCatalogProductsUseRole` role has the permissions required to use the SageMaker portfolio of products from AWS Service Catalog. The `AmazonSageMakerServiceCatalogProductsLaunchRole` role passes an `AmazonSageMakerServiceCatalogProductsUseRole` role to the provisioned AWS Service Catalog product resources.

Topics

- AWS managed policy: `AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy`

- AWS managed policy: `AmazonSageMakerServiceCatalogProductsLambdaServiceRolePolicy`
Amazon SageMaker updates to AWS Service Catalog AWS managed policies

AWS managed policy: AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy

This service role policy is used by the AWS Service Catalog service to provision products from the Amazon SageMaker portfolio. The policy grants permissions to a set of related AWS services including AWS CodePipeline, AWS CodeBuild, AWS CodeCommit, AWS Glue, AWS CloudFormation, and others.

The AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy policy is intended to be used by the AmazonSageMakerServiceCatalogProductsLaunchRole role created from the SageMaker console. The policy adds permissions to provision AWS resources for SageMaker projects and JumpStart using Service Catalog to a customer's account.

Permissions details

This policy includes the following permissions.

- **apigateway** – Allows the role to call API Gateway endpoints that are tagged with `sagemaker:launch-source`.
- **cloudformation** – Allows AWS Service Catalog to create, update and delete CloudFormation stacks.
- **codebuild** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeBuild projects.
- **codecommit** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeCommit repositories.
- **codepipeline** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodePipelines.
- **codestar-connections** – Allows the role to pass AWS CodeStar connections.
- **cognito-idp** – Allows the role to create, update, and delete groups and user pools. Also allows tagging resources.
- **ecr** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete Amazon ECR repositories. Also allows tagging resources.
- **events** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete EventBridge rules. Used for tying together the various components of the CICD pipeline.
• firehose – Allows the role to interact with Kinesis Data Firehose streams.
• glue – Allows the role to interact with AWS Glue.
• iam – Allows the role to pass roles prepended with AmazonSageMakerServiceCatalog. This is needed when Projects provisions a AWS Service Catalog product, as a role needs to be passed to AWS Service Catalog.
• lambda – Allows the role to interact with AWS Lambda. Also allows tagging resources.
• logs – Allows the role to create, delete and access log streams.
• s3 – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to access Amazon S3 buckets where the Project template code is stored.
• sagemaker – Allows the role to interact with various SageMaker services. This is done both in CloudFormation during template provisioning, as well as in CodeBuild during CICD pipeline execution. Also allows tagging the following resources: endpoints, endpoint configurations, models, pipelines, projects, and model packages.
• states – Allows the role to create, delete, and update Step Functions prepended with sagemaker.

AWS managed policy:
AmazonSageMakerPartnerServiceCatalogProductsApiGatewayServiceRolePolicy

This policy is used by Amazon API Gateway within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by API Gateway that require a role.

Permissions details

This policy includes the following permissions.

- **lambda** – Invoke a function created by a partner template.
- **sagemaker** – Invoke an endpoint created by a partner template.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:*:*:function:sagemaker-*",
      "Condition": {
        "Null": {
          "aws:ResourceTag/sagemaker:project-name": "false",
          "aws:ResourceTag/sagemaker:partner": "false"
        }
      }
    }
  ]
}
```
"StringEquals": {
    "aws:ResourceAccount": "${aws:PrincipalAccount}"
  }
},
{
  "Effect": "Allow",
  "Action": "sagemaker:InvokeEndpoint",
  "Resource": "arn:aws:sagemaker:*:*:endpoint/*",
  "Condition": {
    "Null": {
      "aws:ResourceTag/sagemaker:project-name": "false",
      "aws:ResourceTag/sagemaker:partner": "false"
    },
    "StringEquals": {
      "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
  }
}

AWS managed policy:
AmazonSageMakerPartnerServiceCatalogProductsCloudFormationServiceRolePolicy

This policy is used by AWS CloudFormation within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by AWS CloudFormation that require a role.

Permissions details

This policy includes the following permissions.

- **iam** – Pass the AmazonSageMakerServiceCatalogProductsLambdaRole and AmazonSageMakerServiceCatalogProductsApiGatewayRole roles.
- **lambda** – Create, update, delete, and invoke AWS Lambda functions; retrieve, publish, and delete versions of a Lambda layer.
- **apigateway** – Create, update, and delete Amazon API Gateway resources.
- **s3** – Retrieve the lambda-auth-code/layer.zip file from an Amazon Simple Storage Service (Amazon S3) bucket.

AWS managed policy:
AmazonSageMakerPartnerServiceCatalogProductsLambdaServiceRolePolicy

This policy is used by AWS Lambda within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Lambda that require a role.

Permissions details

This policy includes the following permissions.

- secretsmanager – Retrieve data from partner provided secrets for a partner template.
AWS managed policy: AmazonSageMakerServiceCatalogProductsApiGatewayServiceRolePolicy

This policy is used by Amazon API Gateway within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by API Gateway that require a role.

Permissions details

This policy includes the following permissions.

- logs – Create and read CloudWatch Logs groups, streams, and events; update events; describe various resources.

These permissions are limited to resources whose log group prefix starts with "aws/apigateway/".

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogDelivery",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DeleteLogDelivery",
                "logs:DescribeLogGroups",
                "logs:DescribeLogStreams",
                "logs:DescribeResourcePolicies",
                "logs:DescribeDestinations",
                "logs:DescribeExportTasks",

                "logs:DescribeQueries",
                "logs:DescribeQueryDefinitions",
                "logs:DescribeSubscriptionFilters",
                "logs:GetLogDelivery",
```
AWS managed policy:
AmazonSageMakerServiceCatalogProductsCloudformationServiceRolePolicy

This policy is used by AWS CloudFormation within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by AWS CloudFormation that require a role.

Permissions details

This policy includes the following permissions.

- **sagemaker** – Allow access to various SageMaker resources excluding domains, user-profiles, apps, and flow definitions.
- **iam** – Pass the AmazonSageMakerServiceCatalogProductsCodeBuildRole and AmazonSageMakerServiceCatalogProductsExecutionRole roles.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",

This policy is used by AWS CodeBuild within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by CodeBuild that require a role.

Permission details

This policy includes the following permissions.

- **sagemaker** – Allow access to various SageMaker resources.
- **codecommit** – Upload CodeCommit archives to CodeBuild pipelines, get upload status, and cancel uploads; get branch and commit information. These permissions are limited to resources whose name starts with "sagemaker-".
- **ecr** – Create Amazon ECR repositories and container images; upload image layers. These permissions are limited to repositories whose name starts with "sagemaker-".
- **ecr** – Read all resources.
- **iam** – Pass the following roles:
  - AmazonSageMakerServiceCatalogProductsCloudformationRole to AWS CloudFormation.
  - AmazonSageMakerServiceCatalogProductsCodeBuildRole to AWS CodeBuild.
  - AmazonSageMakerServiceCatalogProductsCodePipelineRole to AWS CodePipeline.
• AmazonSageMakerServiceCatalogProductsEventsRole to Amazon EventBridge.
• AmazonSageMakerServiceCatalogProductsExecutionRole to Amazon SageMaker.
• logs – Create and read CloudWatch Logs groups, streams, and events; update events; describe various resources.

These permissions are limited to resources whose name prefix starts with "aws/codebuild/".
• s3 – Create, read, and list Amazon S3 buckets. These permissions are limited to buckets whose name starts with "sagemaker-".

AWS managed policy:
AmazonSageMakerServiceCatalogProductsCodePipelineServiceRolePolicy

This policy is used by AWS CodePipeline within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by CodePipeline that require a role.

Permissions details

This policy includes the following permissions.

- cloudformation – Create, read, delete, and update CloudFormation stacks; create, read, delete, and execute change sets; set stack policy. These permissions are limited to resources whose name starts with "sagemaker-".
- s3 – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL); and read the AWS Region the bucket resides in.

  These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-.
- iam – Pass the AmazonSageMakerServiceCatalogProductsCloudformationRole role.
- codebuild – Get CodeBuild build information and start builds. These permissions are limited to project and build resources whose name starts with "sagemaker-".
- **codecommit** – Upload CodeCommit archives to CodeBuild pipelines, get upload status, and cancel uploads; get branch and commit information.

```
AWS managed policy: AmazonSageMakerServiceCatalogProductsEventsServiceRolePolicy

This policy is used by Amazon EventBridge within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by EventBridge that require a role.

Permissions details

This policy includes the following permissions.

- codepipeline – Start a CodeBuild execution. These permissions are limited to pipelines whose name starts with "sagemaker-".

{
]}
}
AWS managed policy: AmazonSageMakerServiceCatalogProductsFirehoseServiceRolePolicy

This policy is used by Amazon Kinesis Data Firehose within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Kinesis Data Firehose that require a role.

Permissions details

This policy includes the following permissions.

- firehose – Send Kinesis Data Firehose records. These permissions are limited to resources whose delivery stream name starts with "sagemaker-".

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": ["firehose:PutRecord", "firehose:PutRecordBatch"],
         "Resource": "arn:aws:firehose:*:*:deliverystream/sagemaker-*"
      }
   ]
}
```
AWS managed policy: AmazonSageMakerServiceCatalogProductsGlueServiceRolePolicy

This policy is used by AWS Glue within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Glue that require a role.

Permissions details

This policy includes the following permissions.

- **glue** – Create, read, and delete AWS Glue partitions, tables, and table versions. These permissions are limited to those resources whose name starts with "sagemaker-". Create and read AWS Glue databases. These permissions are limited to databases whose name is "default", "global_temp", or starts with "sagemaker-". Get user defined functions.

- **s3** – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL), and read the AWS Region the bucket resides in.

  These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-".

- **logs** – Create, read, and delete CloudWatch Logs log group, streams, and deliveries; and create a resource policy.

  These permissions are limited to resources whose name prefix starts with "aws/glue/".

AWS managed policy: AmazonSageMakerServiceCatalogProductsLambdaServiceRolePolicy

This policy is used by AWS Lambda within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Lambda that require a role.

Permissions details

This policy includes the following permissions.

- `sagemaker` – Allow access to various SageMaker resources.
• **ecr** – Create and delete Amazon ECR repositories; create, read, and delete container images; upload image layers. These permissions are limited to repositories whose name starts with "sagemaker-".

• **events** – Create, read, and delete Amazon EventBridge rules; and create and remove targets. These permissions are limited to rules whose name starts with "sagemaker-".

• **s3** – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL), and read the AWS Region the bucket resides in.

  These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-".

• **iam** – Pass the AmazonSageMakerServiceCatalogProductsExecutionRole role.

• **logs** – Create, read, and delete CloudWatch Logs log group, streams, and deliveries; and create a resource policy.

  These permissions are limited to resources whose name prefix starts with "aws/lambda/".

**Troubleshooting Amazon SageMaker Identity and Access**

Use the following information to help you diagnose and fix common issues that you might encounter when working with SageMaker and IAM.
Topics

- I Am Not Authorized to Perform an Action in SageMaker
- I Am Not Authorized to Perform iam:PassRole
- I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources

I Am Not Authorized to Perform an Action in SageMaker

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a training job but does not have sagemaker:sagemaker:DescribeTrainingJob permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: sagemaker:DescribeTrainingJob on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the TrainingJob resource using the sagemaker:DescribeTrainingJob action.

I Am Not Authorized to Perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to SageMaker.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in SageMaker. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```
In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether SageMaker supports these features, see [How Amazon SageMaker Works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the IAM User Guide.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users (identity federation)](#) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the IAM User Guide.

Logging and Monitoring

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. You can also set alarms that watch for certain thresholds and send notifications or take actions when those thresholds are met. For more information, see [Monitor Amazon SageMaker with Amazon CloudWatch](#).

Amazon CloudWatch Logs enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. You can collect and track metrics, create
customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch.

AWS CloudTrail provides a record of actions taken by a user, role, or an AWS service in SageMaker. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, Log Amazon SageMaker API Calls with AWS CloudTrail.

Note
CloudTrail does not monitor calls to runtime_InvokeEndpoint.

You can create rules in Amazon CloudWatch Events to react to status changes in status in a SageMaker training, hyperparameter tuning, or batch transform job. For more information, see Automating Amazon SageMaker with Amazon EventBridge.

Compliance validation for Amazon SageMaker

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.

- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.
Resilience in Amazon SageMaker

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon SageMaker offers several features to help support your data resiliency and backup needs.
Infrastructure Security in Amazon SageMaker

As a managed service, Amazon SageMaker is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon SageMaker through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

SageMaker Scans AWS Marketplace Training and Inference Containers for Security Vulnerabilities

To meet our security requirements, all the pre-built SageMaker images, including AWS Deep Learning Containers, the SageMaker machine learning framework containers, and the SageMaker built-in algorithm containers, and algorithms and model packages listed in AWS Marketplace are scanned for Common Vulnerabilities and Exposures (CVE). CVE is a list of publicly known information about security vulnerability and exposure. The National Vulnerability Database (NVD) provides CVE details such as severity, impact rating, and fix information. Both CVE and NVD...
are available for public consumption and free for security tools and services to use. For more information, see CVE Frequently Asked Questions (FAQs).

**Connect to Resources From Within a VPC**

Amazon SageMaker Studio Classic and SageMaker notebook instances allow direct internet access by default. This allows you to download popular packages and notebooks, customize your development environment, and work efficiently. However, this could provide an additional avenue for unauthorized access to your data. For example, if you install malicious code on your computer in the form of a publicly available notebook or a publicly available source code library, it could access your data. You can choose to restrict which traffic can access the internet by launching your Amazon SageMaker Studio Classic and SageMaker notebook instances in an Amazon Virtual Private Cloud (Amazon VPC) of your choosing.

An Amazon Virtual Private Cloud is a virtual network dedicated to your AWS account. With an Amazon VPC, you can control the network access and internet connectivity of your Amazon SageMaker Studio Classic and notebook instances. You can disable direct internet access to add an additional layer of security.

The following topics describe how to connect your SageMaker Studio Classic instances and notebook instances to resources in a VPC.

**Topics**

**Connect Amazon SageMaker Studio in a VPC to External Resources**

⚠️ **Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.
The following topic gives information on how to connect Amazon SageMaker Studio in a VPC to external resources.

**Topics**

- Default communication with the internet
- VPC only communication with the internet

**Default communication with the internet**

By default, Amazon SageMaker Studio provides a network interface that allows communication with the internet through a VPC managed by SageMaker. Traffic to AWS services like Amazon S3 and CloudWatch goes through an internet gateway, as does traffic that accesses the SageMaker API and SageMaker runtime. Traffic between the domain and your Amazon EFS volume goes through the VPC that you specified when you onboarded to the domain or called the [CreateDomain](https://docs.aws.amazon.com/sagemaker/latest/dg/create-domain.html) API.

**VPC only communication with the internet**

To prevent SageMaker from providing internet access to Studio, you can disable internet access by specifying the VPC only network access type when you onboard to Studio Classic or call the [CreateDomain](https://docs.aws.amazon.com/sagemaker/latest/dg/create-domain.html) API. As a result, you won’t be able to run Studio unless your VPC has an interface endpoint to the SageMaker API and runtime, or a NAT gateway with internet access, and your security groups allow outbound connections.

⚠️ **Note**

The network access type can’t be changed after domain creation.

**Requirements to use VPC only mode**

When you choose Vpc0nly, follow these steps:

1. You must use private subnets only. You cannot use public subnets in Vpc0nly mode.
2. Ensure your subnets have the required number of IP addresses needed. The expected number of IP addresses needed per user can vary based on use case. We recommend between 2 and 4 IP addresses per user. The total IP address capacity for a domain is the sum of available IP addresses for each subnet provided when the domain is created. Ensure that your estimated IP address usage does not exceed the capacity supported by the number of subnets you provide.
Additionally, using subnets distributed across many availability zones can aid in IP address availability. For more information, see [VPC and subnet sizing for IPv4](#).

**Note**
You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see [Dedicated Instances](#).

3. **Warning**
When using Vpc0nly mode, you partly own the networking configuration for the domain. We recommend the security best practice of applying least-privilege permissions to the inbound and outbound access that security group rules provide. Overly permissive inbound rule configurations could allow users with access to the VPC to interact with the applications of other user profiles without authentication.

Set up one or more security groups with inbound and outbound rules that allow the following traffic:

- **NFS traffic over TCP on port 2049** between the domain and the Amazon EFS volume.
- **TCP traffic within the security group**. This is required for connectivity between the Jupyter Server application and the Kernel Gateway applications. You must allow access to at least ports in the range 8192–65535.

Create a distinct security group for each user profile and add inbound access from that same security group. We do not recommend reusing a domain-level security group for user profiles. If the domain-level security group allows inbound access to itself, then all applications in the domain would have access to all other applications in the domain.

4. If you want to allow internet access, you must use a [NAT gateway](#) with access to the internet, for example through an internet gateway.

5. If you don't want to allow internet access, create interface VPC endpoints (AWS PrivateLink) to allow Studio to access the following services with the corresponding service names. You must also associate the security groups for your VPC with these endpoints.

   - SageMaker API: `com.amazonaws.region.sagemaker.api`
- SageMaker runtime: `com.amazonaws.region.sagemaker.runtime`. This is required to run Studio Classic notebooks and to train and host models.
- Amazon S3: `com.amazonaws.region.s3`.
- To use SageMaker Projects: `com.amazonaws.region.servicecatalog`.
- Any other AWS services you require.

If you use the SageMaker Python SDK to run remote training jobs, you must also create the following Amazon VPC endpoints.

- AWS Security Token Service: `com.amazonaws.region.sts`
- Amazon CloudWatch: `com.amazonaws.region.logs`. This is required to allow SageMaker Python SDK to get the remote training job status from Amazon CloudWatch.

6. If using the domain in VpcOnly mode from an on-premises network, establish private connectivity from the network of the host running Studio in the browser and the target Amazon VPC. This is required because the Studio UI invokes AWS endpoints using API calls with temporary AWS credentials. These temporary credentials are associated with the execution role of the logged user profile. If the domain is configured in VpcOnly mode in an on-premises network, the execution role might define IAM policy conditions that enforce the execution of AWS service API calls only through the configured Amazon VPC endpoints. This causes API calls executed from the Studio UI to fail. We recommend resolving this using an AWS Site-to-Site VPN or AWS Direct Connect connection.

**Note**

For a customer working within VPC mode, company firewalls can cause connection issues with Studio or applications. Make the following checks if you encounter one of these issues when using Studio from behind a firewall.

- Verify that the Studio URL and URLs for all of your applications are in your network's allowlist. For example:
  
  ```
  *.studio.region.sagemaker.aws
  *.console.aws.a2z.com
  ```

- Verify that the websocket connections are not blocked. Jupyter uses websockets.

- Connect to SageMaker Within your VPC
- VPC with public and private subnets (NAT)

Connect SageMaker Studio Classic Notebooks in a VPC to External Resources

The following topic gives information on how to connect Studio Classic Notebooks in a VPC to external resources.

Default communication with the internet

By default, SageMaker Studio Classic provides a network interface that allows communication with the internet through a VPC managed by SageMaker. Traffic to AWS services like Amazon S3 and CloudWatch goes through an internet gateway, as does traffic that accesses the SageMaker API and SageMaker runtime. Traffic between the domain and your Amazon EFS volume goes through the VPC that you specified when you onboarded to Studio Classic or called the `CreateDomain` API. The following diagram shows the default configuration.

VPC only communication with the internet

To prevent SageMaker from providing internet access to your Studio Classic notebooks, you can disable internet access by specifying the `VPC only` network access type when you onboard to Connect to Resources From Within a VPC.
**Studio Classic** or call the CreateDomain API. As a result, you won't be able to run a Studio Classic notebook unless your VPC has an interface endpoint to the SageMaker API and runtime, or a NAT gateway with internet access, and your security groups allow outbound connections. The following diagram shows a configuration for using VPC-only mode.

![Diagram showing a configuration for using VPC-only mode](image)

**Requirements to use VPC only mode**

When you choose VpcOnly, follow these steps:

1. You must use private subnets only. You cannot use public subnets in VpcOnly mode.
2. Ensure your subnets have the required number of IP addresses needed. The expected number of IP addresses needed per user can vary based on use case. We recommend between 2 and 4 IP addresses per user. The total IP address capacity for a Studio Classic domain is the sum of available IP addresses for each subnet provided when the domain is created. Ensure that your estimated IP address usage does not exceed the capacity supported by the number of subnets you provide. Additionally, using subnets distributed across many availability zones can aid in IP address availability. For more information, see [VPC and subnet sizing for IPv4](#).

---

**Note**

You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see [Dedicated Instances](#).
3. **Warning**

When using `VpcOnly` mode, you partly own the networking configuration for the domain. We recommend the security best practice of applying least-privilege permissions to the inbound and outbound access that security group rules provide. Overly permissive inbound rule configurations could allow users with access to the VPC to interact with the applications of other user profiles without authentication.

Set up one or more security groups with inbound and outbound rules that allow the following traffic:

- **NFS traffic over TCP on port 2049** between the domain and the Amazon EFS volume.
- **TCP traffic within the security group.** This is required for connectivity between the Jupyter Server application and the Kernel Gateway applications. You must allow access to at least ports in the range 8192–65535.

Create a distinct security group for each user profile and add inbound access from that same security group. We do not recommend reusing a domain-level security group for user profiles. If the domain-level security group allows inbound access to itself, then all applications in the domain would have access to all other applications in the domain.

4. If you want to allow internet access, you must use a [NAT gateway](https://docs.aws.amazon.com/vpc/latest/userguide/using-nat-gateways.html) with access to the internet, for example through an [internet gateway](https://docs.aws.amazon.com/vpc/latest/userguide/using-internet-gateway.html).

5. If you don't want to allow internet access, [create interface VPC endpoints](https://docs.aws.amazon.com/vpc/latest/userguide/using-private-link.html) (AWS PrivateLink) to allow Studio Classic to access the following services with the corresponding service names. You must also associate the security groups for your VPC with these endpoints.

- SageMaker API: `com.amazonaws.region.sagemaker.api`
- SageMaker runtime: `com.amazonaws.region.sagemaker.runtime`. This is required to run Studio Classic notebooks and to train and host models.
- Amazon S3: `com.amazonaws.region.s3`
- To use SageMaker Projects: `com.amazonaws.region.servicecatalog`
- Any other AWS services you require.
If you use the SageMaker Python SDK to run remote training jobs, you must also create the following Amazon VPC endpoints.

- AWS Security Token Service: com.amazonaws.region.sts
- Amazon CloudWatch: com.amazonaws.region.logs. This is required to allow SageMaker Python SDK to get the remote training job status from Amazon CloudWatch.

**Note**

For a customer working within VPC mode, company firewalls can cause connection issues with SageMaker Studio or between JupyterServer and the KernelGateway. Make the following checks if you encounter one of these issues when using SageMaker Studio from behind a firewall.

- Check that the Studio URL is in your networks allowlist.
- Check that the websocket connections are not blocked. Jupyter uses websocket under the hood. If the KernelGateway application is InService, JupyterServer may not be able to connect to the KernelGateway. You should see this problem when opening System Terminal as well.

- [Securing Amazon SageMaker Studio connectivity using a private VPC](#)
- [Security groups for your VPC](#)
- [Connect to SageMaker Within your VPC](#)
- [VPC with public and private subnets (NAT)](#)

**Connect a Notebook Instance in a VPC to External Resources**

The following topic gives information on how to connect your notebook instance in a VPC to external resources.
Default communication with the internet

When your notebook allows *direct internet access*, SageMaker provides a network interface that allows the notebook to communicate with the internet through a VPC managed by SageMaker. Traffic within your VPC's CIDR goes through elastic network interface created in your VPC. All the other traffic goes through the network interface created by SageMaker, which is essentially through the public internet. Traffic to gateway VPC endpoints like Amazon S3 and DynamoDB goes through the public internet, while traffic to interface VPC interface endpoints still goes through your VPC. If you want to use gateway VPC endpoints, you might want to disable direct internet access.

VPC communication with the internet

To disable direct internet access, you can specify a VPC for your notebook instance. By doing so, you prevent SageMaker from providing internet access to your notebook instance. As a result, the notebook instance can't train or host models unless your VPC has an interface endpoint (AWS PrivateLink) or a NAT gateway and your security groups allow outbound connections.

For information about creating a VPC interface endpoint to use AWS PrivateLink for your notebook instance, see [Connect to a Notebook Instance Through a VPC Interface Endpoint](#). For information about setting up a NAT gateway for your VPC, see [VPC with Public and Private Subnets (NAT)](#) in the *Amazon Virtual Private Cloud User Guide*. For information about security groups, see [Security Groups for Your VPC](#). For more information about networking configurations in each networking mode and configuring network on premise, see [Understanding Amazon SageMaker notebook instance networking configurations and advanced routing options](#).

Security and Shared Notebook Instances

A SageMaker notebook instance is designed to work best for an individual user. It is designed to give data scientists and other users the most power for managing their development environment.

A notebook instance user has root access for installing packages and other pertinent software. We recommend that you exercise judgement when granting individuals access to notebook instances that are attached to a VPC that contains sensitive information. For example, you might grant a user access to a notebook instance with an IAM policy, as shown in the following example:

```
{
    "Version": "2012-10-17",
    "Statement": [
      {
```
"Effect": "Allow",
"Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
}
]}
}

Run Training and Inference Containers in Internet-Free Mode

SageMaker training and deployed inference containers are internet-enabled by default. This allows containers to access external services and resources on the public internet as part of your training and inference workloads. However, this could provide an avenue for unauthorized access to your data. For example, a malicious user or code that you accidentally install on the container (in the form of a publicly available source code library) could access your data and transfer it to a remote host.

If you use an Amazon VPC by specifying a value for the VpcConfig parameter when you call CreateTrainingJob, CreateHyperParameterTuningJob, or CreateModel, you can protect your data and resources by managing security groups and restricting internet access from your VPC. However, this comes at the cost of additional network configuration, and has the risk of configuring your network incorrectly. If you do not want SageMaker to provide external network access to your training or inference containers, you can enable network isolation.

Network Isolation

You can enable network isolation when you create your training job or model by setting the value of the EnableNetworkIsolation parameter to True when you call CreateTrainingJob, CreateHyperParameterTuningJob, or CreateModel.

Note

Network isolation is required to run training jobs and models using resources from AWS Marketplace.

If you enable network isolation, the containers can't make any outbound network calls, even to other AWS services such as Amazon S3. Additionally, no AWS credentials are made available to
the container runtime environment. In the case of a training job with multiple instances, network inbound and outbound traffic is limited to the peers of each training container. SageMaker still performs download and upload operations against Amazon S3 using your SageMaker execution role in isolation from the training or inference container.

The following managed SageMaker containers do not support network isolation because they require access to Amazon S3:

- Chainer
- SageMaker Reinforcement Learning

**Network isolation with a VPC**

Network isolation can be used in conjunction with a VPC. In this scenario, the download and upload of customer data and model artifacts are routed through your VPC subnet. However, the training and inference containers themselves continue to be isolated from the network, and do not have access to any resource within your VPC or on the internet.

**Connect to SageMaker Within your VPC**

You can connect directly to the SageMaker API or to Amazon SageMaker Runtime through an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. When you use a VPC interface endpoint, communication between your VPC and the SageMaker API or Runtime is conducted entirely and securely within an AWS network.

**Connect to SageMaker through a VPC interface endpoint**

The SageMaker API and SageMaker Runtime support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets. For example, an application inside your VPC uses AWS PrivateLink to communicate with SageMaker Runtime. SageMaker Runtime in turn communicates with the SageMaker endpoint. Using AWS PrivateLink allows you to invoke your SageMaker endpoint from within your VPC, as shown in the following diagram.
The VPC interface endpoint connects your VPC directly to the SageMaker API or SageMaker Runtime using AWS PrivateLink without using an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. The instances in your VPC do not need to connect to the public internet in order to communicate with the SageMaker API or SageMaker Runtime.

You can create an AWS PrivateLink interface endpoint to connect to SageMaker or to SageMaker Runtime using either the AWS Management Console or AWS Command Line Interface (AWS CLI). For instructions, see [Creating an Interface Endpoint](#).

If you haven't enabled a private Domain Name System (DNS) hostname for your VPC endpoint, after you have created a VPC endpoint, specify the internet endpoint URL to the SageMaker API or SageMaker Runtime. Example code using AWS CLI commands to specify the endpoint-url parameter follows.

```bash
aws sagemaker list-notebook-instances --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com

aws sagemaker list-training-jobs --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com

aws sagemaker-runtime invoke-endpoint --endpoint-url VPC_Endpoint_ID.runtime.sagemaker.Region.vpce.amazonaws.com --endpoint-name Endpoint_Name --body "Endpoint_Body"
```
If you enable private DNS hostnames for your VPC endpoint, you don’t need to specify the endpoint URL because the default hostname (https://api.sagemaker.Region.amazon.com) resolves to your VPC endpoint. Similarly, the default SageMaker Runtime DNS hostname (https://runtime.sagemaker.Region.amazonaws.com) also resolves to your VPC endpoint.

The SageMaker API and SageMaker Runtime support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available. SageMaker supports making calls to all of its Operations inside your VPC. The result AuthorizedUrl from the CreatePresignedNotebookInstanceUrl command is not supported by AWS PrivateLink. For information about how to enable AWS PrivateLink for the authorized URL that users use to connect to a notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint.

Note

When setting up a VPC interface endpoint for the SageMaker Runtime service (https://runtime.sagemaker.Region.amazonaws.com), you must ensure that the VPC interface endpoint is activated in the Availability Zone of your client in order for private DNS resolution to work. Otherwise, you may see DNS failures when attempting to resolve the URL.

To learn more about AWS PrivateLink, see the AWS PrivateLink documentation. Refer to AWS PrivateLink Pricing for the price of VPC endpoints. To learn more about VPC and endpoints, see Amazon VPC. For information about how to use identity-based AWS Identity and Access Management policies to restrict access to the SageMaker API and SageMaker Runtime, see Control Access to the SageMaker API by Using Identity-based Policies.

Using SageMaker training and hosting with resources inside your VPC

SageMaker uses your execution role to download and upload information from an Amazon S3 bucket and Amazon Elastic Container Registry (Amazon ECR), in isolation from your training or inference container. If you have resources that are located inside your VPC, you can still grant SageMaker access to those resources. The following sections explain how to make your resources available to SageMaker with or without network isolation.
Without network isolation enabled

If you haven't set network isolation on your training job or model, SageMaker can access resources using either of the following methods.

- SageMaker training and deployed inference containers can access the internet by default. SageMaker containers are able to access external services and resources on the public internet as part of your training and inference workloads. SageMaker containers are not able to access resources inside your VPC without a VPC configuration, as shown in the following illustration.

- Use a VPC configuration to communicate with resources inside your VPC through an elastic network interface (ENI). The communication between the container and the resources in your VPC takes place securely within your VPC network, as shown in the following illustration. In this case, you manage networking access to your VPC resources and internet.
If you employ network isolation, the SageMaker container can't communicate with resources inside your VPC or make any network calls, as shown in the following illustration. If you provide a VPC configuration, the download and upload operations will be run through your VPC. For more information about hosting and training with network isolation while using a VPC, see Network Isolation.
Create a VPC Endpoint Policy for SageMaker

You can create a policy for Amazon VPC endpoints for SageMaker to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling Access to Services with VPC Endpoints](https://docs.aws.amazon.com/vpc/latest/userguide/vpc-endpoints.html) in the *Amazon VPC User Guide*. 
Note

VPC endpoint policies aren't supported for Federal Information Processing Standard (FIPS) SageMaker runtime endpoints for `runtime_InvokeEndpoint`.

The following example VPC endpoint policy specifies that all users who have access to the VPC interface endpoint are allowed to invoke the SageMaker hosted endpoint named `myEndpoint`.

```json
{
  "Statement": [
    {
      "Action": "sagemaker:InvokeEndpoint",
      "Effect": "Allow",
      "Principal": "*",
    }
  ]
}
```

In this example, the following are denied:

- Other SageMaker API actions, such as `sagemaker:CreateEndpoint` and `sagemaker:CreateTrainingJob`.
- Invoking SageMaker hosted endpoints other than `myEndpoint`.

Note

In this example, users can still take other SageMaker API actions from outside the VPC. For information about how to restrict API calls to those from within the VPC, see [Control Access to the SageMaker API by Using Identity-based Policies](#).

Create a VPC Endpoint Policy for Amazon SageMaker Feature Store

To create a VPC Endpoint for Amazon SageMaker Feature Store, use the following endpoint template, substituting your `VPC_Endpoint_ID.api` and `Region`:
Connect to SageMaker Studio Classic Through an Interface VPC Endpoint

You can connect to Amazon SageMaker Studio Classic from your Amazon Virtual Private Cloud (Amazon VPC) through an interface endpoint in your VPC instead of connecting over the internet. When you use an interface VPC endpoint (interface endpoint), communication between your VPC and Studio Classic is conducted entirely and securely within the AWS network.

SageMaker Studio Classic supports interface endpoints that are powered by AWS PrivateLink. Each interface endpoint is represented by one or more Elastic network interfaces with private IP addresses in your VPC subnets.

Studio Classic supports interface endpoints in all AWS Regions where both Amazon SageMaker and Amazon VPC are available.

Topics

- Create a VPC Endpoint
- Create a VPC Endpoint Policy for SageMaker Studio Classic
- Allow Access Only from Within Your VPC

Create a VPC Endpoint

You can create an interface endpoint to connect to Studio Classic with either the AWS console or the AWS Command Line Interface (AWS CLI). For instructions, see Creating an interface endpoint. Make sure that you create interface endpoints for all of the subnets in your VPC from which you want to connect to Studio Classic.

When you create an interface endpoint, ensure that the security groups on your endpoint allow inbound access for HTTPS traffic from the security groups associated with SageMaker Studio Classic. For more information, see Control access to services with VPC endpoints.

Note

In addition to creating an interface endpoint to connect to SageMaker Studio Classic, create an interface endpoint to connect to the Amazon SageMaker API. When users call
CreatePresignedDomainUrl to get the URL to connect to Studio Classic, that call goes through the interface endpoint used to connect to the SageMaker API.

When you create the interface endpoint, specify aws.sagemaker.Region.studio as the service name. After you create the interface endpoint, enable private DNS for your endpoint. When you connect to SageMaker Studio Classic from within the VPC using the SageMaker API, the AWS CLI, or the console, you connect through the interface endpoint instead of the public internet. You also need to set up a custom DNS with private hosted zones for the Amazon VPC endpoint so SageMaker Studio Classic can access the SageMaker API using the api.sagemaker.$region.amazonaws.com endpoint rather than using the VPC endpoint URL. For instructions on setting up a private hosted zone, see Working with private hosted zones.

Create a VPC Endpoint Policy for SageMaker Studio Classic

You can attach an Amazon VPC endpoint policy to the interface VPC endpoints that you use to connect to SageMaker Studio Classic. The endpoint policy controls access to Studio Classic. You can specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

To use a VPC endpoint with SageMaker Studio Classic, your endpoint policy must allow the CreateApp operation on the KernelGateway app type. This allows traffic that is routed to through the VPC endpoint to call the CreateApp API. The following example VPC endpoint policy shows how to allow the CreateApp operation.

```json
{
    "Statement": [
        {
            "Action": "sagemaker:CreateApp",
            "Effect": "Allow",
            "Principal": "*"
        }
    ]
}
```
For more information, see Controlling access to services with VPC endpoints.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the user profiles in the SageMaker domain with the specified domain ID. Access to other domains is denied.

```
{
    "Statement": [
        {
            "Action": "sagemaker:CreatePresignedDomainUrl",
            "Effect": "Allow",
            "Principal": "*
        }
    ]
}
```

Allow Access Only from Within Your VPC

Users outside your VPC can connect to SageMaker Studio Classic over the internet even if you set up an interface endpoint in your VPC.

To allow access to only connections made from within your VPC, create an AWS Identity and Access Management (IAM) policy to that effect. Add that policy to every user, group, or role used to access Studio Classic. This feature is only supported in IAM mode, and is not supported in IAM Identity Center mode. The following examples demonstrate how to create such policies.

⚠️ Important

If you apply an IAM policy similar to one of the following examples, users can't access SageMaker Studio Classic or the specified SageMaker APIs through the SageMaker console. To access Studio Classic, users must use a presigned URL or call the SageMaker APIs directly.

Example 1: Allow connections only within the subnet of an interface endpoint

The following policy allows connections only to callers within the subnet where you created the interface endpoint.

```
Example 2: Allow connections only through interface endpoints using `aws:sourceVpce`  

The following policy allows connections only to those made through the interface endpoints specified by the `aws:sourceVpce` condition key. For example, the first interface endpoint could allow access through the SageMaker console. The second interface endpoint could allow access through the SageMaker API.

```json
{
    "Id": "sagemaker-studio-example-2",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceVpc": "vpc-111bbaaa"
                }
            }
        }
    ]
}
```
This policy includes the `DescribeUserProfile` action. Typically you call `DescribeUserProfile` to make sure that the status of the user profile is `InService` before you try to connect to the domain. For example:

```bash
aws sagemaker describe-user-profile \
   --domain-id domain-id \
   --user-profile-name profile-name
```

Response:

```
{
    "DomainId": "domain-id",
    "UserProfileName": "profile-name",
    "HomeEfsFileSystemUid": "200001",
    "Status": "InService",
    "LastModifiedTime": 1605418785.555,
    "CreationTime": 1605418477.297
}
```

```bash
aws sagemaker create-presigned-domain-url \
   --domain-id domain-id \
   --user-profile-name profile-name
```

Response:

```
{
    "AuthorizedUrl": "https://domain-id.studio.us-west-2.sagemaker.aws/auth?token=AuthToken"
}
```
For both of these calls, if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the following example shows a call to `create-presigned-domain-url`:

```bash
aws sagemaker create-presigned-domain-url
   --domain-id domain-id \
   --user-profile-name profile-name \
   --endpoint-url vpc-endpoint-id.api.sagemaker.Region.vpce.amazonaws.com
```

**Example 3: Allow connections from IP addresses using `aws:SourceIp`**

The following policy allows connections only from the specified range of IP addresses using the `aws:SourceIp` condition key.

```json
{
   "Id": "sagemaker-studio-example-3",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Enable SageMaker Studio Access",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreatePresignedDomainUrl",
            "sagemaker:DescribeUserProfile"
         ],
         "Resource": "*",
         "Condition": {
            "IpAddress": {
               "aws:SourceIp": [
                  "192.0.2.0/24",
                  "203.0.113.0/24"
               ]
            }"'
      }
   ]
}
```

**Example 4: Allow connections from IP addresses through an interface endpoint using `aws:VpcSourceIp`**

Connect to SageMaker Within your VPC
If you are accessing SageMaker Studio Classic through an interface endpoint, you can use the `aws:VpcSourceIp` condition key to allow connections only from the specified range of IP addresses within the subnet where you created the interface endpoint as shown in the following policy:

```json
{
  "Id": "sagemaker-studio-example-4",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable SageMaker Studio Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:DescribeUserProfile"
      ],
      "Resource": "*",
      "Condition": {
        "IpAddress": {
          "aws:VpcSourceIp": [
            "192.0.2.0/24",
            "203.0.113.0/24"
          ],
        },
        "StringEquals": {
          "aws:SourceVpc": "vpc-111bbaaa"
        }
      }
    }
  ]
}
```

**Connect to a Notebook Instance Through a VPC Interface Endpoint**

You can connect to your notebook instance from your VPC through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the public internet. When you use a VPC interface endpoint, communication between your VPC and the notebook instance is conducted entirely and securely within the AWS network.

SageMaker notebook instances support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.
Before you create an interface VPC endpoint to connect to a notebook instance, create an interface VPC endpoint to connect to the SageMaker API. That way, when users call `CreatePresignedNotebookInstanceUrl` to get the URL to connect to the notebook instance, that call also goes through the interface VPC endpoint. For information, see Connect to SageMaker Within your VPC.

You can create an interface endpoint to connect to your notebook instance with either the AWS Management Console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint. Make sure that you create an interface endpoint for all of the subnets in your VPC from which you want to connect to the notebook instance.

When you create the interface endpoint, specify `aws.sagemaker.Region.notebook` as the service name. After you create a VPC endpoint, enable private DNS for your VPC endpoint. Anyone using the SageMaker API, the AWS CLI, or the console to connect to the notebook instance from within the VPC connects to the notebook instance through the VPC endpoint instead of the public internet.

SageMaker notebook instances support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available.

Topics

- Connect Your Private Network to Your VPC
- Create a VPC Endpoint Policy for SageMaker Notebook Instances
- Restrict Access to Connections from Within Your VPC

Connect Your Private Network to Your VPC

To connect to your notebook instance through your VPC, you either have to connect from an instance that is inside the VPC, or connect your private network to your VPC by using an AWS Virtual Private Network (AWS VPN) or AWS Direct Connect. For information about AWS VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.
Create a VPC Endpoint Policy for SageMaker Notebook Instances

You can create a policy for Amazon VPC endpoints for SageMaker notebook instances to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling Access to Services with VPC Endpoints](#) in the *Amazon VPC User Guide*.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the notebook instance named `myNotebookInstance`.

```
{
  "Statement": [
    {
      "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
      "Effect": "Allow",
      "Principal": "*
    }
  ]
}
```

Access to other notebook instances is denied.

**Restrict Access to Connections from Within Your VPC**

Even if you set up an interface endpoint in your VPC, individuals outside the VPC can connect to the notebook instance over the internet.

⚠️ **Important**

If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs or the notebook instance through the console.
To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the notebook instance.

⚠️ **Note**

This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
   "Id": "notebook-example-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Enable Notebook Access",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreatePresignedNotebookInstanceUrl",
            "sagemaker:DescribeNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "aws:SourceVpc": "vpc-111bbaaa"
            }
         }
      }
   ]
}
```

If you want to restrict access to the notebook instance to only connections made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
   "Id": "notebook-example-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Enable Notebook Access",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreatePresignedNotebookInstanceUrl",
            "sagemaker:DescribeNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "aws:SourceVpce": "vpc-111bbaaa"
            }
         }
      }
   ]
}
```
Both of these policy examples assume that you have also created an interface endpoint for the SageMaker API. For more information, see Connect to SageMaker Within your VPC. In the second example, one of the values for `aws:SourceVpce` is the ID of the interface endpoint for the notebook instance. The other is the ID of the interface endpoint for the SageMaker API.

The policy examples here include `DescribeNotebookInstance`, because typically you would call `DescribeNotebookInstance` to make sure that the `NotebookInstanceStatus` is `InService` before you try to connect to it. For example:

```
aws sagemaker describe-notebook-instance \
   --notebook-instance-name myNotebookInstance
```

```json
{
   "NotebookInstanceArn":
   "NotebookInstanceName": "myNotebookInstance",
   "NotebookInstanceStatus": "InService",
   "Url": "mynotebookinstance.notebook.us-west-2.sagemaker.aws",
   "InstanceType": "ml.m4.xlarge",
   "RoleArn":
   "arn:aws:iam::1234567890ab:role/service-role/AmazonSageMaker-ExecutionRole-12345678T123456",
}
```
Note

The presigned-notebook-instance-url, AuthorizedUrl, generated can be used from anywhere on the internet.

For both of these calls, if you did not enable private DNS hostnames for your VPC endpoint, or if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the call to create-presigned-notebook-instance-url is:

```bash
aws sagemaker create-presigned-notebook-instance-url --notebook-instance-name myNotebookInstance --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
```

Connect Your Private Network to Your VPC

To call the SageMaker API and SageMaker Runtime through your VPC, you have to connect from an instance that is inside the VPC or connect your private network to your VPC by using an AWS Virtual Private Network (AWS VPN) or AWS Direct Connect. For information about AWS VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.

Give SageMaker Access to Resources in your Amazon VPC

SageMaker runs the following job types in an Amazon Virtual Private Cloud by default.
However, containers for these jobs access AWS resources—such as the Amazon Simple Storage Service (Amazon S3) buckets where you store training data and model artifacts—over the internet.

To control access to your data and job containers, we recommend that you create a private VPC and configure it so that they aren't accessible over the internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your job containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your job containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create jobs by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your job containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC

To control access to your data and processing jobs, create a Amazon VPC with private subnets. For information about creating and configuring a VPC, see Get Started With Amazon VPC in the Amazon VPC User Guide.

You can monitor all network traffic in and out of your processing containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for processing jobs.

Configure a Processing Job for Amazon VPC Access

You configure the processing job by specifying the subnets and security group IDs within the VPC. You don’t need to specify the subnet for the processing container. Amazon SageMaker automatically pulls the processing container from Amazon ECR. For more information about processing containers, see Process data.

When creating a processing job, you can specify subnets and security groups in your VPC using either the SageMaker console or the API.

To use the API, you specify the subnets and security group IDs in the NetworkConfig.VpcConfig parameter of the CreateProcessingJob operation. SageMaker uses the subnet and security group details to create the network interfaces and attaches them to the processing containers. The network interfaces provide the processing containers with a network connection within your VPC. This allows the processing job to connect to resources that exist in your VPC.

The following is an example of the VpcConfig parameter that you include in your call to the CreateProcessingJob operation:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```
## Configure Your Private VPC for SageMaker Processing

When configuring the private VPC for your SageMaker processing jobs, use the following guidelines. For information about setting up a VPC, see [Working with VPCs and Subnets](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/) in the *Amazon VPC User Guide*.

### Topics

- Ensure That Subnets Have Enough IP Addresses
- Create an Amazon S3 VPC Endpoint
- Use a Custom Endpoint Policy to Restrict Access to S3
- Configure Route Tables
- Configure the VPC Security Group
- Connect to Resources Outside Your VPC
- Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

### Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a processing job. For more information, see [VPC and Subnet Sizing for IPv4](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/) in the *Amazon VPC User Guide*.

### Create an Amazon S3 VPC Endpoint

If you configure your VPC so that processing containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your processing containers to access the buckets where you store your data. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see [Endpoints for Amazon S3](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-vpc-creating-endpoint.html).

**To create an S3 VPC endpoint:**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**.
3. For **Service Name**, choose `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. For **VPC**, choose the VPC you want to use for this endpoint.
5. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.

6. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see **Use a Custom Endpoint Policy to Restrict Access to S3**.

**Use a Custom Endpoint Policy to Restrict Access to S3**

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see **Using Endpoint Policies for Amazon S3**. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see **Using Amazon S3 Bucket Policies**.

**Restrict Package Installation on the Processing Container**

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the processing container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRpositoryAccess",
      "Principal": "*",
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::packages.*.amazonaws.com/*",
        "arn:aws:s3:::repo.*.amazonaws.com/*"
      ]
    }
  ]
}
```
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, `http://s3-aws-region.amazonaws.com/MyBucket`) resolve. If you don’t use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your processing jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed processing, you must allow communication between the different containers in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For more information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you're connecting your models to resources outside the VPC that they're running in, do one of the following:

- **Connect to other AWS services** – If your model needs access to an AWS service that supports interface Amazon VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see AWS services that integrate with AWS PrivateLink in the AWS PrivateLink User Guide. For information about creating an interface VPC endpoint, see Access an AWS service using an interface VPC endpoint in the AWS PrivateLink User Guide.
• **Connect to resources over the internet** – If your models are running on instances in an Amazon VPC that does not have a subnet with access to the internet, the models won't have access to resources on the internet. If your model needs access to an AWS service that doesn't support interface VPC endpoints, or to a resource outside of AWS, ensure that you are running your models in a private subnet that has access to the internet using a public NAT gateway in a public subnet. After you have your models running in the private subnet, configure your security groups and network access control lists (NACLs) to allow outbound connections from the private subnet to the public NAT gateway in the public subnet. For information, see [NAT gateways](#) in the Amazon VPC User Guide.

**Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics**

Amazon SageMaker provides Amazon CloudWatch logs and metrics to monitor training jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information about monitoring Amazon SageMaker processing jobs, see [Monitor Amazon SageMaker with Amazon CloudWatch](#) and [SageMaker Jobs and Endpoint Metrics](#).

**Give SageMaker Training Jobs Access to Resources in Your Amazon VPC**

ℹ️ **Note**

For training jobs, you can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see [Dedicated Instances](#).

**Configure a Training Job for Amazon VPC Access**

To control access to your training jobs, run them in an Amazon VPC with private subnets that don’t have internet access.

You configure the training job to run in the VPC by specifying its subnets and security group IDs. You don't need to specify the subnet for the container of the training job. Amazon SageMaker automatically pulls the training container image from Amazon ECR.

When you create a training job, you can specify the subnets and security groups in your VPC using the Amazon SageMaker console or the API.
To use the API, you specify the subnets and security group IDs in the VpcConfig parameter of the CreateTrainingJob operation. SageMaker uses the subnet and security group details to create the network interfaces and attaches them to the training containers. The network interfaces provide the training containers with a network connection within your VPC. This allows the training job to connect to resources that exist in your VPC.

The following is an example of the VpcConfig parameter that you include in your call to the CreateTrainingJob operation:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Training

When configuring the private VPC for your SageMaker training jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics

- Ensure That Subnets Have Enough IP Addresses
- Create an Amazon S3 VPC Endpoint
- Use a Custom Endpoint Policy to Restrict Access to S3
- Configure Route Tables
- Configure the VPC Security Group
- Connect to Resources Outside Your VPC
- Monitor Amazon SageMaker Training Jobs with CloudWatch Logs and Metrics
Ensure That Subnets Have Enough IP Addresses

Training instances that *don't use* an Elastic Fabric Adapter (EFA) should have at least 2 private IP addresses. Training instances that use an EFA should have at least 5 private IP addresses. For more information, see [Multiple IP addresses](https://docs.aws.amazon.com/AmazonS3/latest/userguide/multiple-ip-addresses.html) in the Amazon EC2 User Guide.

Your VPC subnets should have at least two private IP addresses for each instance in a training job. For more information, see [VPC and Subnet Sizing for IPv4](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/VPC-Subnet-Sizing.html) in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that training containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your training data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your training containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see [Endpoints for Amazon S3](https://docs.aws.amazon.com/AmazonS3/latest/userguide/creating-s3-vpc-endpoint.html).

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**
3. For **Service Name**, search for `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. Choose the **Gateway** type.
5. For **VPC**, choose the VPC you want to use for this endpoint.
6. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see [Use a Custom Endpoint Policy to Restrict Access to S3](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-endpoint-policies-for-amazon-s3.html).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see [Using Endpoint Policies for Amazon S3](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-endpoint-policies-for-amazon-s3.html).
only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Training Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "*",
            "Action": ["s3:GetObject"],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::packages.*.amazonaws.com/*",
                "arn:aws:s3:::repo.*.amazonaws.com/*"
            ]
        }
    ]
}
{
    "Statement": [
        {
            "Sid": "AmazonLinux2AMIRepositoryAccess",
            "Principal": "*",
            "Action": ["s3:GetObject"],
            "Effect": "Deny",
            "Resource": ["arn:aws:s3:::amazonlinux.*.amazonaws.com/*"]
        }
    ]
}
```
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your training jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed training, you must allow communication between the different containers in the same training job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For EFA-enabled instances, ensure that both inbound and outbound connections allow all traffic from the same security group. For information, see Security Group Rules in the Amazon Virtual Private Cloud User Guide.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, training jobs that use that VPC do not have access to resources outside your VPC. If your training job needs access to resources outside your VPC, provide access with one of the following options:

- If your training job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon Virtual Private Cloud User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon Virtual Private Cloud User Guide.

- If your training job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Monitor Amazon SageMaker Training Jobs with CloudWatch Logs and Metrics

Amazon SageMaker provides Amazon CloudWatch logs and metrics to monitor training jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information about monitoring Amazon SageMaker training jobs, see Monitor Amazon SageMaker with Amazon CloudWatch and SageMaker Jobs and Endpoint Metrics.
Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC

Configure a Model for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the [CreateModel](#) API, or provide this information when you create a model in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

### Note

You must create at least two subnets in different availability zones in your private VPC, even if you have only one hosting instance.

The following is an example of the VpcConfig parameter that you include in your call to [CreateModel](#):

```json
VpcConfig: {
  "Subnets": [
    "subnet-0123456789abcdef0",
    "subnet-0123456789abcdef1",
    "subnet-0123456789abcdef2"
  ],
  "SecurityGroupIds": ["sg-0123456789abcdef0"]
}
```

Configure Your Private VPC for SageMaker Hosting

When configuring the private VPC for your SageMaker models, use the following guidelines. For information about setting up a VPC, see [Working with VPCs and Subnets](#) in the Amazon VPC User Guide.

**Topics**

- [Ensure That Subnets Have Enough IP Addresses](#)
• Create an Amazon S3 VPC Endpoint
• Use a Custom Endpoint Policy to Restrict Access to Amazon S3
• Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies
• Configure Route Tables
• Connect to Resources Outside Your VPC

Ensure That Subnets Have Enough IP Addresses

Training instances that don't use an Elastic Fabric Adapter (EFA) should have at least 2 private IP addresses. Training instances that use an EFA should have at least 5 private IP addresses. For more information, see Multiple IP addresses in the Amazon EC2 User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an Amazon S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the AWS Region where your VPC resides.
4. For VPC, choose the VPC that you want to use for this endpoint.
5. For Configure route tables, choose the route tables for the endpoint to use. The VPC service automatically adds a route to each route table that you choose that points Amazon S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the Amazon S3 service by any user or service within the VPC. To restrict access further, choose Custom. For more information, see Use a Custom Endpoint Policy to Restrict Access to Amazon S3.
Use a Custom Endpoint Policy to Restrict Access to Amazon S3

The default endpoint policy allows full access to Amazon Simple Storage Service (Amazon S3) for any user or service in your VPC. To further restrict access to Amazon S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3.

You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Model Container with a Custom Endpoint Policy

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the model container. If you don't want users to install packages from those repositories, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
   "Statement": [
      {
         "Sid": "AmazonLinuxAMIRepositoryAccess",
         "Principal": "*",
         "Action": ["s3:GetObject"],
         "Effect": "Deny",
         "Resource": [
            "arn:aws:s3:::packages.*.amazonaws.com/*",
            "arn:aws:s3:::repo.*.amazonaws.com/*"
         ]
      }
   ]
}
{
   "Statement": [
      {
         "Sid": "AmazonLinux2AMIRepositoryAccess",
         "Principal": "*",
         "Action": ["s3:GetObject"],
         "Effect": "Deny",
         "Resource": [
            "arn:aws:s3:::packages2.*.amazonaws.com/*",
            "arn:aws:s3:::repo2.*.amazonaws.com/*"
         ]
      }
   ]
}
```
Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker to create an elastic network interface and attach it to model containers running in a VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for VPC access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeVpcs",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:CreateNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about the SageMakerFullAccess managed policy, see AWS managed policy: AmazonSageMakerFullAccess.
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your models resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, models that use that VPC do not have access to resources outside your VPC. If your model needs access to resources outside your VPC, provide access with one of the following options:

- If your model needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

- If your model needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give Batch Transform Jobs Access to Resources in Your Amazon VPC

To control access to your data and batch transform jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. You specify your private VPC configuration when you create a model by specifying subnets and security groups. You then specify the same model when you create a batch transform job. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your model containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for batch transform jobs.
Configure a Batch Transform Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. Then specify the same model in the ModelName request parameter of the CreateTransformJob API, or in the Model name field when you create a transform job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your transform job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

If you are creating a model using the CreateModel API operation, the IAM execution role that you use to create your model must include the permissions described in CreateModel API: Execution Role Permissions, including the following permissions required for a private VPC.

When creating a model in the console, if you select Create a new role in the Model Settings section, the AmazonSageMakerFullAccess policy used to create the role already contains these permissions. If you select Enter a custom IAM role ARN or Use existing role, the role ARN that you specify must have an execution policy attached with the following permissions.

```json
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
    ]
}
```
Configure Your Private VPC for SageMaker Batch Transform

When configuring the private VPC for your SageMaker batch transform jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics

- Ensure That Subnets Have Enough IP Addresses
- Create an Amazon S3 VPC Endpoint
- Use a Custom Endpoint Policy to Restrict Access to S3
- Configure Route Tables
- Configure the VPC Security Group
- Connect to Resources Outside Your VPC

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a transform job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**

3. For **Service Name**, choose `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.

4. For **VPC**, choose the VPC you want to use for this endpoint.

5. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.

6. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see [Use a Custom Endpoint Policy to Restrict Access to S3](#).

---

**Use a Custom Endpoint Policy to Restrict Access to S3**

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see [Using Endpoint Policies for Amazon S3](#). You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see [Using Amazon S3 Bucket Policies](#).

---

**Restrict Package Installation on the Model Container**

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::packages.*.amazonaws.com/*",
                ...
            ]
        }
    ]
}
```

---

Give SageMaker Access to Resources in your Amazon VPC 5912
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don’t use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your batch transform jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed batch transform, you must allow communication between the different containers in the same batch transform job. To do that, configure a rule for your security group that allows inbound and outbound connections between members of the same security group. Members of the same security group should be able to communicate with each other across all ports. For more information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn’t have internet access, batch transform jobs that use that VPC do not have access to resources outside your VPC. If your batch transform job needs access to resources outside your VPC, provide access with one of the following options:
• If your batch transform job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

• If your batch transform job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC

To control access to your data and SageMaker Clarify jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. For information about creating and configuring an Amazon VPC for processing jobs, see Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC.

This document explains how to add additional Amazon VPC configurations that meet the requirements for SageMaker Clarify jobs.

Topics

• Configure a SageMaker Clarify Job for Amazon VPC Access
• Configure Your Private Amazon VPC for SageMaker Clarify jobs

Configure a SageMaker Clarify Job for Amazon VPC Access

You need to specify subnets and security groups when configuring your private Amazon VPC for SageMaker Clarify jobs and to enable the job to get inferences from the SageMaker model when computing post-training bias metrics and feature contributions that help explain model predictions.

Topics

• SageMaker Clarify Job Amazon VPC Subnets and Security Groups
• Configure a Model Amazon VPC for Inference
SageMaker Clarify Job Amazon VPC Subnets and Security Groups

Subnets and security groups in your private Amazon VPC can be assigned to a SageMaker Clarify job in various ways, depending on how you create the job.

- **SageMaker console**: Provide this information when you create the job in the SageMaker Dashboard. From the Processing menu, choose Processing jobs, then choose Create processing job. Select the VPC option in the Network panel and provide the subnets and security groups using the drop-down lists. Make sure network isolation option provided in this panel is turned off.

- **SageMaker API**: Use the NetworkConfig.VpcConfig request parameter of the CreateProcessingJob API, as shown in the following example:

  ```json
  "NetworkConfig": {
    "VpcConfig": {
      "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
      ],
      "SecurityGroupIds": [
        "sg-0123456789abcdef0"
      ]
    }
  }
  ```

- **SageMaker Python SDK**: Use the NetworkConfig parameter of the SageMakerClarifyProcessor API or Processor API, as shown in the following example:

  ```python
  from sagemaker.network import NetworkConfig
  network_config = NetworkConfig(
    subnets=[
      "subnet-0123456789abcdef0",
      "subnet-0123456789abcdef1",
      "subnet-0123456789abcdef2",
    ],
    security_group_ids=[
      "sg-0123456789abcdef0",
    ],
  )
  ```
SageMaker uses the information to create network interfaces and attach them to the SageMaker Clarify job. The network interfaces provide a SageMaker Clarify job with a network connection within your Amazon VPC that is not connected to the public internet. They also enable the SageMaker Clarify job to connect to resources in your private Amazon VPC.

**Note**

The network isolation option of the SageMaker Clarify job must be turned off (by default the option is turned off) so that the SageMaker Clarify job can communicate with the shadow endpoint.

### Configure a Model Amazon VPC for Inference

In order to compute post-training bias metrics and explainability, the SageMaker Clarify job needs to get inferences from the SageMaker model that is specified by the `model_name` parameter of the [analysis configuration](#) for the SageMaker Clarify processing job. Alternatively, if you use the SageMakerClarifyProcessor API in the SageMaker Python SDK, the job needs to get the `model_name` specified by the [ModelConfig](#) class. To accomplish this, the SageMaker Clarify job creates an ephemeral endpoint with the model, known as a *shadow endpoint*, and then applies the Amazon VPC configuration of the model to the shadow endpoint.

To specify subnets and security groups in your private Amazon VPC to the SageMaker model, use the `VpcConfig` request parameter of the [CreateModel](#) API or provide this information when you create the model using the SageMaker dashboard in the console. The following is an example of the `VpcConfig` parameter that you include in your call to CreateModel:

```json
"VpcConfig": {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

You can specify the number of instances of the shadow endpoint to launch with the `initial_instance_count` parameter of the [analysis configuration](#) for the SageMaker Clarify job.
processing job. Alternatively, if you use the SageMakerClarifyProcessor API in the SageMaker Python SDK, the job needs to get the instance_count specified by the `ModelConfig` class.

**Note**
Even if you only request one instance when creating the shadow endpoint, you need at least two subnets in the model's `ModelConfig` in distinct availability zones. Otherwise the shadow endpoint creation fails with the following error:
`ClientError: Error hosting endpoint sagemaker-clarify-endpoint-XXX: Failed. Reason: Unable to locate at least 2 availability zone(s) with the requested instance type YYY that overlap with SageMaker subnets.`

If your model requires model files in Amazon S3, then the model Amazon VPC needs to have an Amazon S3 VPC endpoint. For more information about creating and configuring an Amazon VPC for SageMaker models, see [Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC](#).

**Configure Your Private Amazon VPC for SageMaker Clarify jobs**

In general, you can follow the steps in [Configure Your Private VPC for SageMaker Processing](#) to configure your private Amazon VPC for SageMaker Clarify jobs. Here are some highlights and special requirements for SageMaker Clarify jobs.

**Topics**
- [Connect to Resources Outside Your Amazon VPC](#)
- [Configure the Amazon VPC Security Group](#)

**Connect to Resources Outside Your Amazon VPC**

If you configure your Amazon VPC so that it does not have public internet access, then some additional setup is required to grant SageMaker Clarify jobs access to resources and services outside of your Amazon VPC. For example, an Amazon S3 VPC endpoint is required because a SageMaker Clarify job needs to load a dataset from an S3 bucket as well as save the analysis results to an S3 bucket. For more information, see [Create an Amazon S3 VPC Endpoint](#) for the creation guide. In addition, if a SageMaker Clarify job needs to get inferences from the shadow endpoint, then it needs to call several more AWS services.
• **Create an Amazon SageMaker API service VPC endpoint:** The SageMaker Clarify job needs to call the Amazon SageMaker API service to manipulate the shadow endpoint, or to describe a SageMaker model for Amazon VPC validation. You can follow the guidance provided in the [Securing all Amazon SageMaker API calls with AWS PrivateLink](https://aws.amazon.com/blogs/aws/securing-all-amazon-sagemaker-api-calls-with-aws-privatelink/) blog to create an Amazon SageMaker API VPC endpoint that allows the SageMaker Clarify job to make the service calls. Note that the service name of Amazon SageMaker API service is `com.amazonaws.region.sagemaker.api`, where `region` is the name of the Region where your Amazon VPC resides.

• **Create an Amazon SageMaker Runtime VPC Endpoint:** The SageMaker Clarify job needs to call the Amazon SageMaker runtime service, which routes the invocations to the shadow endpoint. The setup steps are similar to those for the Amazon SageMaker API service. Note that the service name of Amazon SageMaker Runtime service is `com.amazonaws.region.sagemaker.runtime`, where `region` is the name of the Region where your Amazon VPC resides.

**Configure the Amazon VPC Security Group**

SageMaker Clarify jobs support distributed processing when two or more processing instances are specified in one of the following ways:

• **SageMaker console:** The **Instance count** is specified in the **Resource configuration** part of the **Job settings** panel on the **Create processing job** page.

• **SageMaker API:** The **InstanceCount** is specified when you create the job with the **CreateProcessingJob** API.

• **SageMaker Python SDK:** The **instance_count** is specified when using the **SageMakerClarifyProcessor** API or the **Processor** API.

In distributed processing, you must allow communication between the different instances in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see [Security group rules](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-s3-security-groups.html).
Give SageMaker Compilation Jobs Access to Resources in Your Amazon VPC

Note
For compilation jobs, you can configure only subnets with a default tenancy VPC in which your job runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

Configure a Compilation Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateCompilationJob API, or provide this information when you create a compilation job in the SageMaker console. SageMaker Neo uses this information to create network interfaces and attach them to your compilation jobs. The network interfaces provide compilation jobs with a network connection within your VPC that is not connected to the internet. They also enable your compilation job to connect to resources in your private VPC. The following is an example of the VpcConfig parameter that you include in your call to CreateCompilationJob:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Compilation

When configuring the private VPC for your SageMaker compilation jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses
- Create an Amazon S3 VPC Endpoint
- Use a Custom Endpoint Policy to Restrict Access to S3
• Configure Route Tables

• Configure the VPC Security Group

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a compilation job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC to block access to the internet, SageMaker Neo can't connect to the Amazon S3 buckets that contain your models unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your SageMaker Neo compilation jobs to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, search for com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3.

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint
Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies. The following is a sample customized policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Principal": {
                "AWS": "*"
            },
            "Action": "s3:GetObject",
            "Resource": [
                "arn:aws:s3:::your-sample-bucket",
                "arn:aws:s3:::your-sample-bucket/*"
            ],
            "Condition": {
                "StringNotEquals": {
                    "aws:SourceVpce": [
                        "vpce-01234567890123456"
                    ]
                }
            }
        }
    ]
}
```

Add Permissions for Compilation Job Running in a Amazon VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker Neo to create an elastic network interface and attach it to compilation job running in a Amazon VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for Amazon VPC access.

```
{"Version": "2012-10-17",
 "Statement": [
     {
         "Effect": "Allow",
         "Action": [
             "ec2:DescribeVpcEndpoints",
             "ec2:DescribeDhcpOptions",
         ]
     }
 ]
}
```
"ec2:DescribeVpcs",
"ec2:DescribeSubnets",
"ec2:DescribeSecurityGroups",
"ec2:DescribeNetworkInterfaces",
"ec2:DeleteNetworkInterfacePermission",
"ec2:DeleteNetworkInterface",
"ec2:CreateNetworkInterfacePermission",
"ec2:CreateNetworkInterface",
"ec2:ModifyNetworkInterfaceAttribute"
],
"Resource": "*
"
}]

For more information about the SageMakerFullAccess managed policy, see AWS managed policy: AmazonSageMakerFullAccess.

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don’t use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your compilation jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In your security group for the compilation job, you must allow outbound communication to your Amazon S3 Amazon VPC endpoints and the subnet CIDR ranges used for the compilation job. For information, see Security Group Rules and Control access to services with Amazon VPC endpoints.

Give Inference Recommender Jobs Access to Resources in Your Amazon VPC

Note

Inference Recommender requires you to register your model with Model Registry. Note that Model Registry doesn’t allow your model artifacts or Amazon ECR image to be VPC restricted.

Inference Recommender also has a requirement that your sample payload Amazon S3 object is not VPC restricted. For inference recommendation jobs, you can’t create a custom
policy that allows only requests from your private VPC to access to your Amazon S3 buckets.

To specify subnets and security groups in your private VPC, use the RecommendationJobVpcConfig request parameter of the CreateInferenceRecommendationsJob API, or specify your subnets and security groups when you create a recommendation job in the SageMaker console.

Inference Recommender uses this information to create endpoints. When provisioning endpoints, SageMaker creates network interfaces and attaches them to your endpoints. The network interfaces provide your endpoints with a network connection to your VPC. The following is an example of the VpcConfig parameter that you include in a call to CreateInferenceRecommendationsJob:

```
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Refer to the following topics for more information on configuring your Amazon VPC for use with Inference Recommender jobs.

**Topics**

- [Ensure that subnets have enough IP addresses](#)
- [Create an Amazon S3 VPC endpoint](#)
- [Add permissions for Inference Recommender jobs running in an Amazon VPC to custom IAM policies](#)
- [Configure route tables](#)
- [Configure the VPC security group](#)
Ensure that subnets have enough IP addresses

Your VPC subnets should have at least two private IP addresses for each instance in an inference recommendation job. For more information about subnets and private IP addresses, see How Amazon VPC works in the Amazon VPC User Guide.

Create an Amazon S3 VPC endpoint

If you configure your VPC to block access to the internet, Inference Recommender can't connect to the Amazon S3 buckets that contain your models unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your SageMaker inference recommendation jobs to access the buckets where you store your data and model artifacts.

To create an Amazon S3 VPC endpoint, use the following procedure:

1. Open the Amazon VPC console.
2. In the navigation pane, choose Endpoints, and then choose Create Endpoint.
3. For Service Name, search for com.amazonaws.region.s3, where region is the name of the Region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any Amazon S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the Amazon S3 service by any user or service within the VPC.

Add permissions for Inference Recommender jobs running in an Amazon VPC to custom IAM policies

The AmazonSageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow Inference Recommender to create an elastic network interface and attach it to the inference recommendation job running in an Amazon VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for Amazon VPC access.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "ec2:CreateNetworkInterface",
            "Resource": "*",
            "Effect": "Allow",
            "Condition": {
                "StringEquals": {
                    "aws:SourceIpRanges": "0.0.0.0/0"
                }
            }
        },
        {
            "Action": "ec2:AttachNetworkInterface",
            "Resource": "*",
            "Effect": "Allow",
            "Condition": {
                "StringEquals": {
                    "aws:SourceIpRanges": "0.0.0.0/0"
                }
            }
        },
        {
            "Action": "ec2:CreateNetworkInterface",
            "Resource": "*",
            "Effect": "Allow",
            "Condition": {
                "StringEquals": {
                    "aws:SourceIpRanges": "0.0.0.0/0"
                }
            }
        },
        {
            "Action": "ec2:AttachNetworkInterface",
            "Resource": "*",
            "Effect": "Allow",
            "Condition": {
                "StringEquals": {
                    "aws:SourceIpRanges": "0.0.0.0/0"
                }
            }
        }
    ]
}
```
"Statement": [
   {"Effect": "Allow",
    "Action": [
      "ec2:DescribeVpcEndpoints",
      "ec2:DescribeDhcpOptions",
      "ec2:DescribeVpcs",
      "ec2:DescribeSubnets",
      "ec2:DescribeSecurityGroups",
      "ec2:DescribeNetworkInterfaces",
      "ec2:DeleteNetworkInterfacePermission",
      "ec2:DeleteNetworkInterface",
      "ec2:CreateNetworkInterfacePermission",
      "ec2:CreateNetworkInterface",
      "ec2:ModifyNetworkInterfaceAttribute"
    ],
    "Resource": "*"
   }
]

Configure route tables

Use the default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example: http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use the default DNS settings, ensure that the URLs that you use to specify the locations of the data in your inference recommendation jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing gateway endpoints in the Amazon VPC User Guide.

Configure the VPC security group

In your security group for the inference recommendation job, you must allow outbound communication to your Amazon S3 VPC endpoints and the subnet CIDR ranges used for the inference recommendation job. For information, see Security Group Rules and Control access to services with Amazon VPC endpoints in the Amazon VPC User Guide.
Sell algorithms and packages in the AWS Marketplace

Amazon SageMaker integrates with AWS Marketplace, enabling developers to charge other SageMaker users for the use of their algorithms and model packages. AWS Marketplace is a curated digital catalog that makes it easy for customers to find, buy, deploy, and manage third-party software and services that customers need to build solutions and run their businesses. AWS Marketplace includes thousands of software listings in popular categories, such as security, networking, storage, machine learning, business intelligence, database, and DevOps. It simplifies software licensing and procurement with flexible pricing options and multiple deployment methods.

For information, see AWS Marketplace Documentation.

Topics

- SageMaker Algorithms
- SageMaker Model Packages
- Sell Amazon SageMaker Algorithms and Model Packages
- Find and Subscribe to Algorithms and Model Packages on AWS Marketplace
- Use Algorithm and Model Package Resources

SageMaker Algorithms

An algorithm enables you to perform end-to-end machine learning. It has two logical components: training and inference. Buyers can use the training component to create training jobs in SageMaker and build a machine learning model. SageMaker saves the model artifacts generated by the algorithm during training to an Amazon S3 bucket. For more information, see Train a Model with Amazon SageMaker.

Buyers use the inference component with the model artifacts generated during a training job to create a deployable model in their SageMaker account. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker.
SageMaker Model Packages

Buyers use a model package to build a deployable model in SageMaker. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker. As a seller, you can build your model artifacts by training in SageMaker, or you can use your own model artifacts from a model that you trained outside of SageMaker. You can charge buyers for inference.

Use your own algorithms and models with the AWS Marketplace

The following sections show how to create algorithm and model package resources that you can use locally and publish to the AWS Marketplace.

Topics
- Create Algorithm and Model Package Resources
- Use Algorithm and Model Package Resources

Create Algorithm and Model Package Resources

After your training and/or inference code is packaged in Docker containers, create algorithm and model package resources that you can use in your Amazon SageMaker account and, optionally, publish on AWS Marketplace.

Topics
- Create an Algorithm Resource
- Create a Model Package Resource

Create an Algorithm Resource

To create an algorithm resource that you can use to run training jobs in Amazon SageMaker and publish on AWS Marketplace specify the following information:

- The Docker containers that contains the training and, optionally, inference code.
- The configuration of the input data that your algorithm expects for training.
- The hyperparameters that your algorithm supports.
- Metrics that your algorithm sends to Amazon CloudWatch during training jobs.
- The instance types that your algorithm supports for training and inference, and whether it supports distributed training across multiple instances.
- Validation profiles, which are training jobs that SageMaker uses to test your algorithm's training code and batch transform jobs that SageMaker runs to test your algorithm's inference code.

To ensure that buyers and sellers can be confident that products work in SageMaker, we require that you validate your algorithms before listing them on AWS Marketplace. You can list products in the AWS Marketplace only if validation succeeds. To validate your algorithms, SageMaker uses your validation profile and sample data to run the following validations tasks:

1. Create a training job in your account to verify that your training image works with SageMaker.
2. If you included inference code in your algorithm, create a model in your account using the algorithm's inference image and the model artifacts produced by the training job.
3. If you included inference code in your algorithm, create a transform job in your account using the model to verify that your inference image works with SageMaker.

When you list your product on AWS Marketplace, the inputs and outputs of this validation process persist as part of your product and are made available to your buyers. This helps buyers understand and evaluate the product before they buy it. For example, buyers can inspect the input data that you used, the outputs generated, and the logs and metrics emitted by your code. The more comprehensive your validation specification, the easier it is for customers to evaluate your product.

⚠️ **Note**

In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the **Training jobs** and **Transform jobs** pages. If validation fails, you can access the scan and validation reports from the SageMaker console. If any issues are found, you will have to create the algorithm again.
Note

To publish your algorithm on AWS Marketplace, at least one validation profile is required.

You can create an algorithm by using either the SageMaker console or the SageMaker API.

Topics

• Create an Algorithm Resource (Console)
• Create an Algorithm Resource (API)

Create an Algorithm Resource (Console)

To create an algorithm resource (console)

2. From the left menu, choose Training.
3. From the dropdown menu, choose Algorithms, then choose Create algorithm.
4. On the Training specifications page, provide the following information:
   a. For Algorithm name, type a name for your algorithm. The algorithm name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
   b. Type a description for your algorithm. This description appears in the SageMaker console and in the AWS Marketplace.
   c. For Training image, type the path in Amazon ECR where your training container is stored.
   d. For Support distributed training, Choose Yes if your algorithm supports training on multiple instances. Otherwise, choose No.
   e. For Support instance types for training, choose the instance types that your algorithm supports.
   f. For Channel specification, specify up to 8 channels of input data for your algorithm. For example, you might specify 3 input channels named train, validation, and test. For each channel, specify the following information:
i. For **Channel name**, type a name for the channel. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).

ii. To require the channel for your algorithm, choose **Channel required**.

iii. Type a description for the channel.

iv. For **Supported input modes**, choose **Pipe mode** if your algorithm supports streaming the input data, and **File mode** if your algorithm supports downloading the input data as a file. You can choose both.

v. For **Supported content types**, type the MIME type that your algorithm expects for input data.

vi. For **Supported compression type**, choose **Gzip** if your algorithm supports Gzip compression. Otherwise, choose **None**.

vii. Choose **Add channel** to add another data input channel, or choose **Next** if you are done adding channels.

5. On the **Tuning specifications** page, provide the following information:

a. For **Hyperparameter specification**, specify the hyperparameters that your algorithm supports by editing the JSON object. For each hyperparameter that your algorithm supports, construct a JSON block similar to the following:

```json
{
  "DefaultValue": "5",
  "Description": "The first hyperparameter",
  "IsRequired": true,
  "IsTunable": false,
  "Name": "intRange",
  "Range": {
    "IntegerParameterRangeSpecification": {
      "MaxValue": "10",
      "MinValue": "1"
    },
    "Type": "Integer"
  }
}
```

In the JSON, supply the following:

i. For **DefaultValue**, specify a default value for the hyperparameter, if there is one.

ii. For **Description**, specify a description for the hyperparameter.
iii. For **IsRequired**, specify whether the hyperparameter is required.

iv. For **IsTunable**, specify `true` if this hyperparameter can be tuned when a user runs a hyperparameter tuning job that uses this algorithm. For information, see [Perform Automatic Model Tuning with SageMaker](#).

v. For **Name**, specify a name for the hyperparameter.

vi. For **Range**, specify one of the following:

   - **IntegerParameterRangeSpecification** - the values of the hyperparameter are integers. Specify minimum and maximum values for the hyperparameter.

   - **ContinuousParameterRangeSpecification** - the values of the hyperparameter are floating-point values. Specify minimum and maximum values for the hyperparameter.

   - **CategoricalParameterRangeSpecification** - the values of the hyperparameter are categorical values. Specify a list of all of the possible values.

vii. For **Type**, specify **Integer**, **Continuous**, or **Categorical**. The value must correspond to the type of **Range** that you specified.

b. For **Metric definitions**, specify any training metrics that you want your algorithm to emit. SageMaker uses the regular expression that you specify to find the metrics by parsing the logs from your training container during training. Users can view these metrics when they run training jobs with your algorithm, and they can monitor and plot the metrics in Amazon CloudWatch. For information, see [Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics](#). For each metric, provide the following information:

   i. For **Metric name**, type a name for the metric.

   ii. For **Regex**, type the regular expression that SageMaker uses to parse training logs so that it can find the metric value.

   iii. For **Objective metric support** choose **Yes** if this metric can be used as the objective metric for a hyperparameter tuning job. For information, see [Perform Automatic Model Tuning with SageMaker](#).

   iv. Choose **Add metric** to add another metric, or choose **Next** if you are done adding metrics.

6. On the **Inference specifications** page, provide the following information if your algorithm supports inference:
a. For **Location of inference image**, type the path in Amazon ECR where your inference container is stored.

b. For **Container DNS host name**, type the name of a DNS host for your image.

c. For **Supported instance types for real-time inference**, choose the instance types that your algorithm supports for models deployed as hosted endpoints in SageMaker. For information, see [Deploy models for inference](#).

d. For **Supported instance types for batch transform jobs**, choose the instance types that your algorithm supports for batch transform jobs. For information, see [Use Batch Transform](#).

e. For **Supported content types**, type the type of input data that your algorithm expects for inference requests.

f. For **Supported response MIME types**, type the MIME types that your algorithm supports for inference responses.

g. Choose Next.

7. On the **Validation specifications** page, provide the following information:

   a. For **Publish this algorithm on AWS Marketplace**, choose Yes to publish the algorithm on AWS Marketplace.

   b. For **Validate this resource**, choose Yes if you want SageMaker to run training jobs and/or batch transform jobs that you specify to test the training and/or inference code of your algorithm.

   ![Note](https://example.com) **Note**
   
   To publish your algorithm on AWS Marketplace, your algorithm must be validated.

   c. For **IAM role**, choose an IAM role that has the required permissions to run training jobs and batch transform jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see [SageMaker Roles](#).

   d. For **Validation profile**, specify the following:

      - A name for the validation profile.
• A **Training job definition**. This is a JSON block that describes a training job. This is in the same format as the `TrainingJobDefinition` input parameter of the `CreateAlgorithm` API.

• A **Transform job definition**. This is a JSON block that describes a batch transform job. This is in the same format as the `TransformJobDefinition` input parameter of the `CreateAlgorithm` API.

e. Choose **Create algorithm**.

**Create an Algorithm Resource (API)**

To create an algorithm resource by using the SageMaker API, call the `CreateAlgorithm` API.

**Create a Model Package Resource**

To create a model package resource that you can use to create deployable models in Amazon SageMaker and publish on AWS Marketplace specify the following information:

• The Docker container that contains the inference code, or the algorithm resource that was used to train the model.

• The location of the model artifacts. Model artifacts can either be packaged in the same Docker container as the inference code or stored in Amazon S3.

• The instance types that your model package supports for both real-time inference and batch transform jobs.

• Validation profiles, which are batch transform jobs that SageMaker runs to test your model package's inference code.

Before listing model packages on AWS Marketplace, you must validate them. This ensures that buyers and sellers can be confident that products work in Amazon SageMaker. You can list products on AWS Marketplace only if validation succeeds.

The validation procedure uses your validation profile and sample data to run the following validations tasks:

1. Create a model in your account using the model package's inference image and the optional model artifacts that are stored in Amazon S3.
Note

A model package is specific to the region in which you create it. The S3 bucket where the model artifacts are stored must be in the same region where your created the model package.

2. Create a transform job in your account using the model to verify that your inference image works with SageMaker.

3. Create a validation profile.

Note

In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. After fixing issues, recreate the algorithm. When the status of the algorithm is COMPLETED, find it in the SageMaker console and start the listing process.

Note

To publish your model package on AWS Marketplace, at least one validation profile is required.

You can create a model package either by using the SageMaker console or by using the SageMaker API.

Topics

- Create a Model Package Resource (Console)
- Create a Model Package Resource (API)
Create a Model Package Resource (Console)

To create a model package in the SageMaker console:

2. From the left menu, choose Inference.
3. Choose Marketplace model packages, then choose Create marketplace model package.
4. On the Inference specifications page, provide the following information:
   a. For Model package name, type a name for your model package. The model package name
      must be unique in your account and in the AWS region. The name must have 1 to 64
      characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
   b. Type a description for your model package. This description appears in the SageMaker
      console and in the AWS Marketplace.
   c. For Inference specification options, choose Provide the location of the inference image
      and model artifacts to create a model package by using an inference container and model
      artifacts. Choose Provide the algorithm used for training and its model artifacts to
      create a model package from an algorithm resource that you created or subscribe to from
      AWS Marketplace.
   d. If you chose Provide the location of the inference image and model artifacts for
      Inference specification options, provide the following information for Container
      definition and Supported resources:
      i. For Location of inference image, type the path to the image that contains your
         inference code. The image must be stored as a Docker container in Amazon ECR.
      ii. For Location of model data artifacts, type the location in S3 where your model
          artifacts are stored.
      iii. For Container DNS host name, type the name of the DNS host to use for your
           container.
      iv. For Supported instance types for real-time inference, choose the instance types
          that your model package supports for real-time inference from SageMaker hosted
          endpoints.
      v. For Supported instance types for batch transform jobs, choose the instance types
         that your model package supports for batch transform jobs.
      vi. Supported content types, type the content types that your model package expects
          for inference requests.
vii. For **Supported response MIME types**, type the MIME types that your model package uses to provide inferences.

e. If you chose **Provide the algorithm used for training and its model artifacts** for **Inference specification options**, provide the following information:

i. For **Algorithm ARN**, type the Amazon Resource Name (ARN) of the algorithm resource to use to create the model package.

ii. For **Location of model data artifacts**, type the location in S3 where your model artifacts are stored.

f. Choose **Next**.

5. On the **Validation and scanning** page, provide the following information:

a. For **Publish this model package on AWS Marketplace**, choose **Yes** to publish the model package on AWS Marketplace.

b. For **Validate this resource**, choose **Yes** if you want SageMaker to run batch transform jobs that you specify to test the inference code of your model package.

   **Note**

   To publish your model package on AWS Marketplace, your model package must be validated.

   c. For **IAM role**, choose an IAM role that has the required permissions to run batch transform jobs in SageMaker, or choose **Create a new role** to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see [SageMaker Roles](#).

   d. For **Validation profile**, specify the following:

      - A name for the validation profile.

      - A **Transform job definition**. This is a JSON block that describes a batch transform job. This is in the same format as the `TransformJobDefinition` input parameter of the `CreateAlgorithm` API.

6. Choose **Create marketplace model package**.
Create a Model Package Resource (API)

To create a model package by using the SageMaker API, call the `CreateModelPackage` API.

Use Algorithm and Model Package Resources

You can create algorithms and model packages as resources in your Amazon SageMaker account, and you can find and subscribe to algorithms and model packages on AWS Marketplace.

Use algorithms to:

- Run training jobs. For information, see [Use an Algorithm to Run a Training Job](#).
- Run hyperparameter tuning jobs. For information, see [Use an Algorithm to Run a Hyperparameter Tuning Job](#).
- Create model packages. After you use an algorithm resource to run a training job or a hyperparameter tuning job, you can use the model artifacts that these jobs output along with the algorithm to create a model package. For information, see [Create a Model Package Resource](#).

**Note**

If you subscribe to an algorithm on AWS Marketplace, you must create a model package before you can use it to get inferences by creating hosted endpoint or running a batch transform job.
Use model packages to:

- Create models that you can use to get real-time inference or run batch transform jobs. For information, see [Use a Model Package to Create a Model](#).

- Create hosted endpoints to get real-time inference. For information, see [Deploy the Model to SageMaker Hosting Services](#).

- Create batch transform jobs. For information, see [Optional] Make Prediction with Batch Transform.

**Topics**

Use an Algorithm to Run a Training Job

You can create use an algorithm resource to create a training job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics
- Use an Algorithm to Run a Training Job (Console)
- Use an Algorithm to Run a Training Job (API)
- Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK)

Use an Algorithm to Run a Training Job (Console)

To use an algorithm to run a training job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create training job.

   The algorithm you chose will automatically be selected.
5. On the Create training job page, provide the following information:
   a. For Job name, type a name for the training job.
   b. For IAM role, choose an IAM role that has the required permissions to run training jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles.
   c. For Resource configuration, provide the following information:
      i. For Instance type, choose the instance type to use for training.
      ii. For Instance count, type the number of ML instances to use for the training job.
      iii. For Additional volume per instance (GB), type the size of the ML storage volume that you want to provision. ML storage volumes store model artifacts and incremental states.
iv. For **Encryption key**, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instance, specify the key.

v. For **Stopping condition**, specify the maximum amount of time in seconds, minutes, hours, or days, that you want the training job to run.

d. For **VPC**, choose a Amazon VPC that you want to allow your training container to access. For more information, see [Give SageMaker Training Jobs Access to Resources in Your Amazon VPC](#).

e. For **Hyperparameters**, specify the values of the hyperparameters to use for the training job.

f. For **Input data configuration**, specify the following values for each channel of input data to use for the training job. You can see what channels the algorithm you're using for training support, and the content type, supported compression type, and supported input modes for each channel, under **Channel specification** section of the **Algorithm summary** page for the algorithm.

   i. For **Channel name**, type the name of the input channel.

   ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.

   iii. For **Compression type**, choose the data compression type to use, if any.

   iv. For **Record wrapper**, choose **RecordIO** if the algorithm expects data in the **RecordIO** format.

   v. For **S3 data type**, **S3 data distribution type**, and **S3 location**, specify the appropriate values. For information about what these values mean, see [S3DataSource](#).

   vi. For **Input mode**, choose **File** to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose **Pipe** To stream data directly from Amazon S3 to the container.

   vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

g. For **Output** location, specify the following values:

   i. For **S3 output path**, choose the S3 location where the training job stores output, such as model artifacts.
ii. For **Encryption key**, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

h. For **Tags**, specify one or more tags to manage the training job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

i. Choose **Create training job** to run the training job.

### Use an Algorithm to Run a Training Job (API)

To use an algorithm to run a training job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) as the `AlgorithmName` field of the `AlgorithmSpecification` object that you pass to `CreateTrainingJob`. For information about training models in SageMaker, see Train a Model with Amazon SageMaker.

### Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a training job, create an `AlgorithmEstimator` object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the `algorithm_arn` argument. Then call the `fit` method of the estimator. For example:

```python
from sagemaker import AlgorithmEstimator
data_path = os.path.join(DATA_DIR, 'marketplace', 'training')

algo = AlgorithmEstimator(
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=sagemaker_session,
    base_job_name='test-marketplace')

train_input = algo.sagemaker_session.upload_data(
    path=data_path, key_prefix='integ-test-data/marketplace/train')
```
Use an Algorithm to Run a Hyperparameter Tuning Job

A hyperparameter tuning job finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose. For more information, see Perform Automatic Model Tuning with SageMaker.

You can create use an algorithm resource to create a hyperparameter tuning job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics

- Use an Algorithm to Run a Hyperparameter Tuning Job (Console)
- Use an Algorithm to Run a Hyperparameter Tuning Job (API)
- Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK)

Use an Algorithm to Run a Hyperparameter Tuning Job (Console)

To use an algorithm to run a hyperparameter tuning job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create hyperparameter tuning job.
   
   The algorithm you chose will automatically be selected.
5. On the Create hyperparameter tuning job page, provide the following information:

   a. For Warm start, choose Enable warm start to use the information from previous hyperparameter tuning jobs as a starting point for this hyperparameter tuning job. For more information, see Run a Warm Start Hyperparameter Tuning Job.

   i. Choose Identical data and algorithm if your input data is the same as the input data for the parent jobs of this hyperparameter tuning job, or choose Transfer learning to use additional or different input data for this hyperparameter tuning job.
For **Parent hyperparameter tuning job(s)**, choose up to 5 hyperparameter tuning jobs to use as parents to this hyperparameter tuning job.

b. For **Hyperparameter tuning job name**, type a name for the tuning job.

c. For **IAM role**, choose an IAM role that has the required permissions to run hyperparameter tuning jobs in SageMaker, or choose **Create a new role** to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see [SageMaker Roles](#).

d. For **VPC**, choose a Amazon VPC that you want to allow the training jobs that the tuning job launches to access. For more information, see [Give SageMaker Training Jobs Access to Resources in Your Amazon VPC](#).

e. Choose **Next**.

f. For **Objective metric**, choose the metric that the hyperparameter tuning job uses to determine the best combination of hyperparameters, and choose whether to minimize or maximize this metric. For more information, see [View the Best Training Job](#).

g. For **Hyperparameter configuration**, choose ranges for the tunable hyperparameters that you want the tuning job to search, and set static values for hyperparameters that you want to remain constant in all training jobs that the hyperparameter tuning job launches. For more information, see [Define Hyperparameter Ranges](#).

h. Choose **Next**.

i. For **Input data configuration**, specify the following values for each channel of input data to use for the hyperparameter tuning job. You can see what channels the algorithm you're using for hyperparameter tuning supports, and the content type, supported compression type, and supported input modes for each channel, under **Channel specification** section of the **Algorithm summary** page for the algorithm.

   i. For **Channel name**, type the name of the input channel.

   ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.

   iii. For **Compression type**, choose the data compression type to use, if any.

   iv. For **Record wrapper**, choose RecordIO if the algorithm expects data in the RecordIO format.

   v. For **S3 data type**, **S3 data distribution type**, and **S3 location**, specify the appropriate values. For information about what these values mean, see [S3DataSource](#).
vi. For **Input mode**, choose **File** to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose **Pipe** to stream data directly from Amazon S3 to the container.

vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

j. For **Output** location, specify the following values:

i. For **S3 output path**, choose the S3 location where the training jobs that this hyperparameter tuning job launches store output, such as model artifacts.

   **Note**
   You use the model artifacts stored at this location to create a model or model package from this hyperparameter tuning job.

ii. For **Encryption key**, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

k. For **Resource configuration**, provide the following information:

i. For **Instance type**, choose the instance type to use for each training job that the hyperparameter tuning job launches.

ii. For **Instance count**, type the number of ML instances to use for each training job that the hyperparameter tuning job launches.

iii. For **Additional volume per instance (GB)**, type the size of the ML storage volume that you want to provision each training job that the hyperparameter tuning job launches. ML storage volumes store model artifacts and incremental states.

iv. For **Encryption key**, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instances, specify the key.

l. For **Resource limits**, provide the following information:

i. For **Maximum training jobs**, specify the maximum number of training jobs that you want the hyperparameter tuning job to launch. A hyperparameter tuning job can launch a maximum of 500 training jobs.
For **Maximum parallel training jobs**, specify the maximum number of concurrent training jobs that the hyperparameter tuning job can launch. A hyperparameter tuning job can launch a maximum of 10 concurrent training jobs.

For **Stopping condition**, specify the maximum amount of time in seconds, minutes, hours, or days, that you want each training job that the hyperparameter tuning job launches to run.

For **Tags**, specify one or more tags to manage the hyperparameter tuning job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

Choose **Create jobs** to run the hyperparameter tuning job.

**Use an Algorithm to Run a Hyperparameter Tuning Job (API)**

To use an algorithm to run a hyperparameter tuning job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) of the algorithm as the **AlgorithmName** field of the **AlgorithmSpecification** object that you pass to **CreateHyperParameterTuningJob**. For information about hyperparameter tuning in SageMaker, see [Perform Automatic Model Tuning with SageMaker](#).

**Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK)**

Use an algorithm that you created or subscribed to on AWS Marketplace to create a hyperparameter tuning job, create an **AlgorithmEstimator** object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the **algorithm_arn** argument. Then initialize a **HyperparameterTuner** object with the **AlgorithmEstimator** you created as the value of the **estimator** argument. Finally, call the **fit** method of the **AlgorithmEstimator** object.

```python
from sagemaker import AlgorithmEstimator
from sagemaker.tuner import HyperparameterTuner

data_path = os.path.join(DATA_DIR, 'marketplace', 'training')

algo = AlgorithmEstimator(
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=sagemaker_session,
)"
Use a Model Package to Create a Model

Use a model package to create a deployable model that you can use to get real-time inferences by creating a hosted endpoint or to run batch transform jobs. You can create a deployable model from a model package by using the Amazon SageMaker console, the low-level SageMaker API, or the Amazon SageMaker Python SDK.

Topics

- Use a Model Package to Create a Model (Console)
- Use a Model Package to Create a Model (API)
- Use a Model Package to Create a Model (Amazon SageMaker Python SDK)

Use a Model Package to Create a Model (Console)

To create a deployable model from a model package (console)

2. Choose Model packages.
3. Choose a model package that you created from the list on the My model packages tab or choose a model package that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create model.
5. For Model name, type a name for the model.
6. For **IAM role**, choose an IAM role that has the required permissions to call other services on your behalf, or choose **Create a new role** to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see [SageMaker Roles](#).

7. For **VPC**, choose a Amazon VPC that you want to allow the model to access. For more information, see [Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC](#).

8. Leave the default values for **Container input options** and **Choose model package**.

9. For environment variables, provide the names and values of environment variables you want to pass to the model container.

10. For **Tags**, specify one or more tags to manage the model. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

11. Choose **Create model**.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see [Deploy Models for Inference](#).

**Use a Model Package to Create a Model (API)**

To use a model package to create a deployable model by using the SageMaker API, specify the name or the Amazon Resource Name (ARN) of the model package as the `ModelPackageName` field of the `ContainerDefinition` object that you pass to the `CreateModel` API.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosted endpoints in SageMaker, see [Deploy Models for Inference](#).

**Use a Model Package to Create a Model ([Amazon SageMaker Python SDK](#))**

To use a model package to create a deployable model by using the SageMaker Python SDK, initialize a `ModelPackage` object, and pass the Amazon Resource Name (ARN) of the model package as the `model_package_arn` argument. For example:

```python
from sagemaker import ModelPackage
model = ModelPackage(role='SageMakerRole',
                      model_package_arn='training-job-scikit-decision-trees-1542660466-6f92',
                      sagemaker_session=sagemaker_session)
```
After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

**Sell Amazon SageMaker Algorithms and Model Packages**

Selling Amazon SageMaker algorithms and model packages is a three-step process:

1. Develop your algorithm or model, and package it in a Docker container. For information, see Develop Algorithms and Models in Amazon SageMaker.

2. Create an algorithm or model package resource in SageMaker. For information, see Create Algorithm and Model Package Resources.

3. Register as a seller on AWS Marketplace and list your algorithm or model package on AWS Marketplace. For information about registering as a seller, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. For information about listing and monetizing your algorithms and model packages, see Listing Algorithms and Model Packages in AWS Marketplace for Machine Learning in the User Guide for AWS Marketplace Providers.

**Topics**

- Develop Algorithms and Models in Amazon SageMaker
- Create Algorithm and Model Package Resources
- List Your Algorithm or Model Package on AWS Marketplace
Develop Algorithms and Models in Amazon SageMaker

Before you can create algorithm and model package resources to use in Amazon SageMaker or list on AWS Marketplace, you have to develop them and package them in Docker containers.

Note

When algorithms and model packages are created for listing on AWS Marketplace, SageMaker scans the containers for security vulnerabilities on supported operating systems.

Only the following operating system versions are supported:

- Debian: 6.0, 7, 8, 9, 10
- CentOS: 5, 6, 7
- Oracle Linux: 5, 6, 7
- Alpine: 3.3, 3.4, 3.5
- Amazon Linux

Topics

- Develop Algorithms in SageMaker
- Develop Models in SageMaker

Develop Algorithms in SageMaker

An algorithm should be packaged as a docker container and stored in Amazon ECR to use it in SageMaker. The Docker container contains the training code used to run training jobs and, optionally, the inference code used to get inferences from models trained by using the algorithm.

For information about developing algorithms in SageMaker and packaging them as containers, see Use Docker containers to build models. For a complete example of how to create an algorithm container, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/scikitBringYourOwn/scikitBringYourOwn.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced
Functionality section, and is named scikit_bring_your_own.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks.

Always thoroughly test your algorithms before you create algorithm resources to publish on AWS Marketplace.

Note
When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.

Develop Models in SageMaker

A deployable model in SageMaker consists of inference code, model artifacts, an IAM role that is used to access resources, and other information required to deploy the model in SageMaker. Model artifacts are the results of training a model by using a machine learning algorithm. The inference code must be packaged in a Docker container and stored in Amazon ECR. You can either package the model artifacts in the same container as the inference code, or store them in Amazon S3.

You create a model by running a training job in SageMaker, or by training a machine learning algorithm outside of SageMaker. If you run a training job in SageMaker, the resulting model artifacts are available in the ModelArtifacts field in the response to a call to the DescribeTrainingJob operation. For information about how to develop a SageMaker model container, see Use your own inference code. For a complete example of how to create a model container from a model trained outside of SageMaker, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/xgboost_bring_your_own_model/xgboost_bring_your_own_model.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named xgboost_bring_your_own_model.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks.

Always thoroughly test your models before you create model packages to publish on AWS Marketplace.
**Note**

When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.

---

**List Your Algorithm or Model Package on AWS Marketplace**

After creating and validating your algorithm or model in Amazon SageMaker, list your product on AWS Marketplace. The listing process makes your products available in the AWS Marketplace and the SageMaker console.

To list products on AWS Marketplace, you must be a registered seller. To register, use the self-registration process from the AWS Marketplace Management Portal (AMMP). For information, see [Getting Started as a Seller](#) in the *User Guide for AWS Marketplace Providers*. When you start the product listing process from the Amazon SageMaker console, we check your seller registration status. If you have not registered, we direct you to do so.

To start the listing process, do one of the following:

- From the SageMaker console, choose the product, choose **Actions**, and choose **Publish new ML Marketplace listing**. This carries over your product reference, the Amazon Resource Name (ARN), and directs you to the AMMP to create the listing.

- Go to [ML listing process](#), manually enter the Amazon Resource Name (ARN), and start your product listing. This process carries over the product metadata that you entered when creating the product in SageMaker. For an algorithm listing, the information includes the supported instance types and hyperparameters. In addition, you can enter a product description, promotional information, and support information as you would with other AWS Marketplace products.

---

**Find and Subscribe to Algorithms and Model Packages on AWS Marketplace**

With AWS Marketplace, you can browse and search for hundreds of machine learning algorithms and models in a broad range of categories, such as computer vision, natural language processing,
speech recognition, text, data, voice, image, video analysis, fraud detection, predictive analysis, and more.

To find algorithms on AWS Marketplace

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Algorithms, then choose Find algorithms.

This takes you to the AWS Marketplace algorithms page. For information about finding and subscribing to algorithms on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

To find model packages on AWS Marketplace

2. Choose Model packages, then choose Find model packages.

This takes you to the AWS Marketplace model packages page. For information about finding and subscribing to model packages on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

Use Algorithms and Model Packages

For information about using algorithms and model packages that you subscribe to in SageMaker, see Use Algorithm and Model Package Resources.
Note

When you create a training job, inference endpoint, and batch transform job from an algorithm or model package that you subscribe to on AWS Marketplace, the training and inference containers do not have access to the internet. Because the containers do not have access to the internet, the seller of the algorithm or model package does not have access to your data.
Monitor AWS resources provisioned while using Amazon SageMaker

Monitoring is an important part of maintaining the reliability, availability, and performance of SageMaker and your other AWS solutions. AWS provides the following monitoring tools to watch SageMaker, report when something is wrong, and take automatic actions when appropriate:

- **Amazon CloudWatch** monitors your AWS resources and the applications that you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For example, you can have CloudWatch track CPU usage or other metrics of your Amazon EC2 instances and automatically launch new instances when needed. For more information, see the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/).

- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/).

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/).

- **CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. Create CloudWatch Events rules react to a status change in a SageMaker training, hyperparameter tuning, or batch transform job.

**Topics**

- [Monitor Amazon SageMaker with Amazon CloudWatch](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/monitoring-amazon-cloudwatch.html)
- [Log Amazon SageMaker Events with Amazon CloudWatch](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/monitoring-cloudwatch-events.html)
- [Log Amazon SageMaker API Calls with AWS CloudTrail](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/monitoring-cloudtrail.html)
- [Monitoring user resource access from Amazon SageMaker Studio Classic](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/monitoring-user-resource-access.html)
- [Automating Amazon SageMaker with Amazon EventBridge](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/monitoring-eventbridge.html)
Monitor Amazon SageMaker with Amazon CloudWatch

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. However, the Amazon CloudWatch console limits the search to metrics that were updated in the last 2 weeks. This limitation ensures that the most current jobs are shown in your namespace. To graph metrics without using a search, specify its exact name in the source view. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met. For more information, see the Amazon CloudWatch User Guide.

SageMaker Metrics and Dimensions

- **SageMaker Endpoint Invocation Metrics**
- **SageMaker Inference Component Metrics**
- **SageMaker Multi-Model Endpoint Metrics**
- **SageMaker Jobs and Endpoint Metrics**
- **SageMaker Inference Recommender Jobs Metrics**
- **SageMaker Ground Truth Metrics**
- **Amazon SageMaker Feature Store Metrics**
- **SageMaker Pipelines Metrics**

**SageMaker Endpoint Invocation Metrics**

The AWS/SageMaker namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

The following illustration shows how a SageMaker endpoint interacts with the Amazon SageMaker Runtime API. The overall time between sending a request to an endpoint and receiving a response depends on the following three components.

- Network latency – the time that it takes between making a request to the SageMaker Runtime Runtime API and receiving a response back from the SageMaker Runtime Runtime API.
• Overhead latency – the time that it takes to transport a request to the model container from the SageMaker Runtime Runtime API and transport the response back to the SageMaker Runtime Runtime API.

• Model latency – the time that it takes the model container to process the request and return a response.

Total time (end-to-end) from request to response = network latency + overhead latency + model latency

For more information about total latency, see [Best practices for load testing Amazon SageMaker real-time inference endpoints](#). For information about how long CloudWatch metrics are retained for, see [GetMetricStatistics](#) in the [Amazon CloudWatch API Reference](#).

<tr>
<td><strong>Invocations</strong></td>
<td>The number of <em>InvokeEndpoint</em> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the <strong>Sum</strong> statistic.</td>
</tr>
<tr>
<td><strong>InvocationsPerCopy</strong></td>
<td>The number of invocations normalized by each copy of an inference component.</td>
</tr>
<tr>
<td><strong>Invocation5XXErrors</strong></td>
<td>The number of <em>InvokeEndpoint</em> requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent. Units: None</td>
</tr>
<tr>
<td><strong>InvocationModelErrors</strong></td>
<td>The number of model invocation requests which did not result in 2XX HTTP response. This includes 4XX/5XX status codes, low-level socket errors, malformed HTTP responses, and request timeouts. For each error response, 1 is sent; otherwise, 0 is sent. Units: None</td>
</tr>
<tr>
<td>Valid statistics: Average, Sum</td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of invocations sent to a model, normalized by InstanceCount in each ProductionVariant. ( \frac{1}{\text{numberOfInstances}} ) is sent as the value on each request, where numberOfInstances is the number of active instances for the ProductionVariant behind the endpoint at the time of the request.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The interval of time taken by a model to respond to a SageMaker Runtime API request. This interval includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelSetupTime</td>
<td>The time it takes to launch new compute resources for a serverless endpoint. The time can vary depending on the model size, how long it takes to download the model, and the start-up time of the container.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Min, Max, Sample Count, Percentiles</td>
</tr>
</tbody>
</table>
### Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OverheadLatency</td>
<td>The interval of time added to the time taken to respond to a client request by SageMaker overheads. This interval is measured from the time SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on multiple factors, including request and response payload sizes, request frequency, and authentication/authorization of the request. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

### Dimensions for Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
<tr>
<td>Inference ComponentName</td>
<td>Filters inference component invocation metrics.</td>
</tr>
</tbody>
</table>

### SageMaker Inference Component Metrics

The `/aws/sagemaker/InferenceComponents` namespace includes the following metrics from calls to `InvokeEndpoint` for endpoints that host inference components.

Metrics are available at a 1-minute frequency.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilizationNormalized</td>
<td>The value of the CPUUtilizationNormalized metric reported by each copy of the inference component. The value ranges between 0%–100%. If you set the NumberOfCpuCoresRequired parameter in the settings for the inference component copy, the metric presents</td>
</tr>
</tbody>
</table>
### Metric

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>the utilization over the reservation. Otherwise, the metric presents the utilization over the limit.</td>
<td></td>
</tr>
<tr>
<td>GPUMemory UtilizationNormalized</td>
<td>The value of the GPUMemoryUtilizationNormalized metric reported by each copy of the inference component.</td>
</tr>
<tr>
<td>GPUUtilizationNormalized</td>
<td>The value of the GPUUtilizationNormalized metric reported by each copy of the inference component. If you set the NumberOfAcceleratorDevicesRequired parameter in the settings for the inference component copy, the metric presents the utilization over the reservation. Otherwise, the metric presents the utilization over the limit.</td>
</tr>
<tr>
<td>MemoryUtilizationNormalized</td>
<td>The value of MemoryUtilizationNormalized reported by each copy of the inference component. If you set the MinMemory RequiredInMb parameter in the settings for the inference component copy, the metrics present the utilization over the reservation. Otherwise, the metrics present the utilization over the limit.</td>
</tr>
</tbody>
</table>

### Dimensions for Inference Component Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inference ComponentName</td>
<td>Filters inference component metrics.</td>
</tr>
</tbody>
</table>

### SageMaker Multi-Model Endpoint Metrics

The AWS/SageMaker namespace includes the following model loading metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.
For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the *Amazon CloudWatch API Reference*.

## Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelLoadingWaitTime</td>
<td>The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelUnloadingTime</td>
<td>The interval of time that it took to unload the model through the container's <code>UnloadModel</code> API call.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelDownloadingTime</td>
<td>The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3).</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelLoadingTime</td>
<td>The interval of time that it took to load the model through the container's <code>LoadModel</code> API call.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelCacheHit</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to the multi-model endpoint for which the model was already loaded.</td>
</tr>
<tr>
<td></td>
<td>The Average statistic shows the ratio of requests for which the model was already loaded.</td>
</tr>
</tbody>
</table>
## Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Units: None</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Sample Count</td>
</tr>
</tbody>
</table>

### Dimensions for Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

The /aws/sagemaker/Endpoints namespaces include the following instance metrics from calls to [InvokeEndpoint](#).  

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see [GetMetricStatistics](#) in the Amazon CloudWatch API Reference.

### Multi-Model Endpoint Model Instance Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoadedModelCount</td>
<td>The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance.</td>
</tr>
</tbody>
</table>

The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.

The Sum statistic tells you the total number of models loaded across all instances in the endpoint.

The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint.

Units: None
### Dimension for Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

### SageMaker Jobs and Endpoint Metrics

The /aws/sagemaker/ProcessingJobs, /aws/sagemaker/TrainingJobs, /aws/sagemaker/TransformJobs, and /aws/sagemaker/Endpoints namespaces include the following metrics for the training jobs and endpoint instances.

Metrics are available at a 1-minute frequency.

**Note**

Amazon CloudWatch supports high-resolution custom metrics and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see [GetMetricStatistics](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_GetMetricStatistics.html) in the Amazon CloudWatch API Reference.

**Tip**

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using [Amazon SageMaker Debugger](https://docs.aws.amazon.com/sagemaker/latest/dg/deep-dive-debugger.html). SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker
Debugger also provides visualizations through Studio Classic and its profiling report. To explore the Debugger visualizations, see [SageMaker Debugger Insights Dashboard Walkthrough](#), [Debugger Profiling Report Walkthrough](#), and [Analyze Data Using the SMDebug Client Library](#).

### Processing Job, Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUReservation</td>
<td>The sum of CPUs reserved by containers on an instance. The value ranges between 0%–100%. In the settings for an inference component, you set the CPU reservation with the <code>NumberOfCpuCoresRequired</code> parameter. For example, if there are 4 CPUs, and 2 are reserved, the CPUReservation metric is 50%.</td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>The sum of each individual CPU core's utilization. The CPU utilization of each core range is 0–100. For example, if there are four CPUs, the CPUUtilization range is 0%–400%. For processing jobs, the value is the CPU utilization of the processing container on the instance. For training jobs, the value is the CPU utilization of the algorithm container on the instance. For batch transform jobs, the value is the CPU utilization of the transform container on the instance. For endpoint variants, the value is the sum of the CPU utilization of the primary and supplementary containers on the instance.</td>
</tr>
</tbody>
</table>

**Note**

For multi-instance jobs, each instance reports CPU utilization metrics. However, the default view in CloudWatch shows the average CPU utilization across all instances.

Units: Percent
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilizationNormalized</td>
<td>The normalized sum of the utilization of each individual CPU core. The value ranges between 0%–100%. For example, if there are four CPUs, and the CPUUtilization metric is 200%, then the CPUUtilizationNormalized metric is 50%.</td>
</tr>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers on an instance uses. This value range is 0%–100%. This metric is not supported for batch transform jobs. For processing jobs, the value is the disk space utilization of the processing container on the instance. For training jobs, the value is the disk space utilization of the algorithm container on the instance. For endpoint variants, the value is the sum of the disk space utilization of the primary and supplementary containers on the instance. Units: Percent</td>
</tr>
</tbody>
</table>

**Note**

For multi-instance jobs, each instance reports disk utilization metrics. However, the default view in CloudWatch shows the average disk utilization across all instances.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPUMemory Utilization</td>
<td>The percentage of GPU memory used by the containers on an instance. The value range is 0–100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the GPUMemoryUtilization range is 0%–400%. For processing jobs, the value is the GPU memory utilization of the processing container on the instance. For training jobs, the value is the GPU memory utilization of the algorithm container on the instance. For batch transform jobs, the value is the GPU memory utilization of the transform container on the instance. For endpoint variants, the value is the sum of the GPU memory utilization of the primary and supplementary containers on the instance.</td>
</tr>
<tr>
<td>Note</td>
<td>For multi-instance jobs, each instance reports GPU memory utilization metrics. However, the default view in CloudWatch shows the average GPU memory utilization across all instances.</td>
</tr>
<tr>
<td>Units: Percent</td>
<td></td>
</tr>
<tr>
<td>GPUMemory UtilizationNormalized</td>
<td>The normalized percentage of GPU memory used by the containers on an instance. The value ranges between 0%–100%. For example, if there are four GPUs, and the GPUMemoryUtilization metric is 200%, then the GPUMemoryUtilizationNormalized metric is 50%.</td>
</tr>
<tr>
<td>GPUReservation</td>
<td>The sum of GPUs reserved by containers on an instance. The value ranges between 0%–100%. In the settings for an inference component, you set the GPU reservation by NumberOfAcceleratorDevicesRequired. For example, if there are 4 GPUs and 2 are reserved, the GPUReservation metric is 50%.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>GPUUtilization</strong></td>
<td>The percentage of GPU units that are used by the containers on an instance. The value can range between 0–100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the GPUUtilization range is 0%–400%. &lt;br&gt;For processing jobs, the value is the GPU utilization of the processing container on the instance. &lt;br&gt;For training jobs, the value is the GPU utilization of the algorithm container on the instance. &lt;br&gt;For batch transform jobs, the value is the GPU utilization of the transform container on the instance. &lt;br&gt;For endpoint variants, the value is the sum of the GPU utilization of the primary and supplementary containers on the instance.</td>
</tr>
<tr>
<td><strong>GPUUtilizationNormalized</strong></td>
<td>The normalized percentage of GPU units that are used by the containers on an instance. The value ranges between 0%–100%. For example, if there are four GPUs, and the GPUUtilization metric is 200%, then the GPUUtilizationNormalized metric is 50%.</td>
</tr>
<tr>
<td><strong>MemoryReservation</strong></td>
<td>The sum of memory reserved by containers on an instance. The value ranges between 0%–100%. In the settings for an inference component, you set the memory reservation with the MinMemoryRequiredInMb parameter. For example, if a 32 GiB instance reserved 1024 MB, the MemoryReservation metric is 29.8%.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers on an instance. This value range is 0%–100%. For processing jobs, the value is the memory utilization of the processing container on the instance. For training jobs, the value is the memory utilization of the algorithm container on the instance. For batch transform jobs, the value is the memory utilization of the transform container on the instance. For endpoint variants, the value is the sum of the memory utilization of the primary and supplementary containers on the instance. Units: Percent</td>
</tr>
</tbody>
</table>

**Note**

For multi-instance jobs, each instance reports memory utilization metrics. However, the default view in CloudWatch shows the average memory utilization across all instances.

---

**Dimensions for Processing Job, Training Job and Batch Transform Job Instance Metrics**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For processing jobs, the value for this dimension has the format [processing-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified processing job and instance. This dimension format is present only in the /aws/sagemaker/ProcessingJobs namespace.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, the value for this dimension has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the</td>
</tr>
</tbody>
</table>
### Dimension Description

Specified training job and instance. This dimension format is present only in the `/aws/sagemaker/TrainingJobs` namespace.

For batch transform jobs, the value for this dimension has the format `[transform-job-name]/[instance-id]`. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the `/aws/sagemaker/TransformJobs` namespace.

---

## SageMaker Inference Recommender Jobs Metrics

The `/aws/sagemaker/InferenceRecommendationsJobs` namespace includes the following metrics for inference recommendation jobs.

### Inference Recommender Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ClientInvocations</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint, as observed by Inference Recommender. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td><strong>ClientInvocationErrors</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests that failed, as observed by Inference Recommender. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td><strong>ClientLatency</strong></td>
<td>The interval of time taken between sending an <code>InvokeEndpoint</code> call and receiving a response as observed by Inference Recommender. Note that the time is in milliseconds, whereas the ModelLatency endpoint invocation metric is in microseconds.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count, Percentiles</td>
</tr>
</tbody>
</table>

| NumberOfUsers   | The number of concurrent users sending InvokeEndpoint requests to the model endpoint. |
|                 | Units: None                                                                  |
|                 | Valid statistics: Max, Min, Average                                           |

**Dimensions for Inference Recommender Job Metrics**

<table>
<thead>

</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DatasetObjectsAutoAnnotated</td>
<td>The number of dataset objects auto-annotated in a labeling job. This metric is only emitted when automated labeling is enabled. To view the labeling job progress, use the Max metric.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Max</td>
</tr>
<tr>
<td>DatasetObjectsHumanAnnotated</td>
<td>The number of dataset objects annotated by a human in a labeling job. To view the labeling job progress, use the Max metric.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Max</td>
</tr>
<tr>
<td>DatasetObjectsLabelingFailed</td>
<td>The number of dataset objects that failed labeling in a labeling job. To view the labeling job progress, use the Max metric.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Max</td>
</tr>
<tr>
<td>JobsFailed</td>
<td>A single labeling job failed. To get the total number of labeling jobs that failed, use the Sum statistic.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum, Sample Count</td>

**SageMaker Pipelines Metrics**

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline executions.

Two categories of Pipelines execution metrics are available:

- **Execution Metrics across All Pipelines** – Account level pipeline execution metrics (for all pipelines in the current account)
- **Execution Metrics by Pipeline** – Pipeline execution metrics per pipeline

Metrics are available at a 1-minute frequency.
# Pipelines Execution Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>

### Log Amazon SageMaker Events with Amazon CloudWatch

To help you debug your compilation jobs, processing jobs, training jobs, endpoints, transform jobs, notebook instances, and notebook instance lifecycle configurations, anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr is also sent to Amazon CloudWatch Logs. In addition to debugging, you can use these for progress analysis.

**Logs**

The following table lists all of the logs provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/CompilationJobs</td>
<td>[compilation-job-name]</td>
</tr>

<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in SageMaker model] (For Inference Pipelines)</td>
</tr>
</tbody>
</table>
Note

1. The `/aws/sagemaker/NotebookInstances/[LifecycleConfigHook]` log stream is created when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script.
2. For Inference Pipelines, if you don't provide container names, the platform uses **container-1, container-2**, and so on, corresponding to the order provided in the SageMaker model.

For more information about logging events with CloudWatch logging, see What is Amazon CloudWatch Logs? in the Amazon CloudWatch User Guide.

Log Amazon SageMaker API Calls with AWS CloudTrail

Amazon SageMaker is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in SageMaker. CloudTrail captures all API calls for SageMaker, with the exception of `InvokeEndpoint` and `InvokeEndpointAsync`, as events. The calls captured include calls from the SageMaker console and code calls to the SageMaker API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for SageMaker. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

By default, log data is stored in CloudWatch Logs indefinitely. However, you can configure how long to store log data in a log group. For information, see Change Log Data Retention in CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

SageMaker Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon SageMaker, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.
For an ongoing record of events in your AWS account, including events for Amazon SageMaker, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All SageMaker actions, with the exception of InvokeEndpoint and InvokeEndpointAsync, are logged by CloudTrail and are documented in the Operations. For example, calls to the CreateTrainingJob, CreateEndpoint and CreateNotebookInstance actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Operations Performed by Automatic Model Tuning

SageMaker supports logging non-API service events to your CloudTrail log files for automatic model tuning jobs. These events are not related to your tuning jobs but, are not the direct result of a customer request to the public AWS API. For example, when you create a hyperparameter tuning job by calling CreateHyperParameterTuningJob, SageMaker creates training jobs to evaluate various combinations of hyperparameters to find the best result. Similarly, when you call StopHyperParameterTuningJob to stop a hyperparameter tuning job, SageMaker might stop any of the associated running training jobs. Non-API events for your tuning jobs are logged to
CloudTrail to help you improve governance, compliance, and operational and risk auditing of your AWS account.

Log entries that result from non-API service events have an eventType of AwsServiceEvent instead of AwsApiCall.

**Understanding SageMaker Log File Entries**

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following examples a log entry for the CreateEndpoint action, which creates an endpoint to deploy a trained model.

```json
{
    "eventVersion":"1.05",
    "userIdentity": {
        "type":"IAMUser",
        "principalId":"AIXDAYQEXAMPLEUMLYNGL",
        "arn": "arn:aws:iam::123456789012:user/intern",
        "accountId": "123456789012",
        "accessKeyId": "ASXIAGXEXAMPLEQULKNXV",
        "userName": "intern"
    },
    "eventTime": "2018-01-02T13:39:06Z",
    "eventSource": "sagemaker.amazonaws.com",
    "eventName": "CreateEndpoint",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "127.0.0.1",
    "userAgent": "USER_AGENT",
    "requestParameters": {
        "endpointName": "ExampleEndpoint",
        "endpointConfigName": "ExampleEndpointConfig"
    },
    "responseElements": {
        "endpointArn": "arn:aws:sagemaker:us-west-2:123456789012:endpoint/exampleendpoint"
    },
    "requestID": "6b1b42b9-EXAMPLE"
}
```
The following example is a log entry for the `CreateModel` action, which creates one or more containers to host a previously trained model.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AIXDAYQEXAMPLEUMLYNGL",
    "arn": "arn:aws:iam::123456789012:user/intern",
    "accountId": "123456789012",
    "accessKeyId": "ASXIAGXEXAMPLEQULKNXV",
    "userName": "intern"
  },
  "eventTime": "2018-01-02T15:23:46Z",
  "eventSource": "sagemaker.amazonaws.com",
  "eventName": "CreateModel",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "127.0.0.1",
  "userAgent": "USER_AGENT",
  "requestParameters": {
    "modelName": "ExampleModel",
    "primaryContainer": {
      "image": "174872318107.dkr.ecr.us-west-2.amazonaws.com/kmeans:latest"
    },
    "executionRoleArn": "arn:aws:iam::123456789012:role/EXAMPLEARN"
  },
  "responseElements": {
  },
  "requestID": "417b8dab-EXAMPLE",
  "eventID": "0f2b3e81-EXAMPLE",
  "eventType": "AwsApiCall",
  "recipientAccountId": "444455556666"
}
```
Monitoring user resource access from Amazon SageMaker Studio Classic

With Amazon SageMaker Studio Classic, you can monitor user resource access. To view resource access activity, you can configure AWS CloudTrail to monitor and record user activities by following the steps in Log Amazon SageMaker API Calls with AWS CloudTrail.

However, the AWS CloudTrail logs for resource access only list the Studio Classic execution IAM role as the identifier. This level of logging is enough to audit user activity when each user profile has a distinct execution role. However, when a single execution IAM role is shared between several user profiles, you can't get information about the specific user that accessed the AWS resources.

You can get information about which specific user performed an action in an AWS CloudTrail log when using a shared execution role, using the sourceIdentity configuration to propagate the Studio Classic user profile name. For more information about source identity, see Monitor and control actions taken with assumed roles.

Prerequisites

- Install and configure the AWS Command Line Interface following the steps in Installing or updating the latest version of the AWS CLI.
- Ensure that Studio Classic users in your domain don't have a policy that allows them to update or modify the domain.
- To turn on or turn off sourceIdentity propagation, all apps in the domain must be in the Stopped or Deleted state. For more information about how to stop and shut down apps, see Shut down and Update Studio Classic Apps.
- All execution roles must have the following trust policy permissions:
  - Any role that the domain's execution role assumes must have the sts:SetSourceIdentity permission in the trust policy as follows.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            }
        }
    ]
}
```
When you assume a role with another role, called role chaining, do the following:

- Permissions for `sts:SetSourceIdentity` are required in both the permissions policy of the principal that is assuming the role, and in the role trust policy of the target role. Otherwise, the assume role operation will fail.
- This role chaining can happen in Studio Classic or any other downstream service, such as Amazon EMR. For more information about role chaining, see [Roles terms and concepts](#).

### Considerations when using `sourceIdentity`

When you make AWS API calls from Studio Classic notebooks, SageMaker Canvas, or Amazon SageMaker Data Wrangler, the `sourceIdentity` is only recorded in CloudTrail if those calls are made using the Studio Classic [execution role](#) session or any [chained role](#) from that session.

When these API calls invoke other services to perform additional operations, `sourceIdentity` logging depends on the specific implementation of the invoked services.

- **Amazon SageMaker Training, Processing, and Pipeline:** When you create a job using these features, the job creation APIs are not able to ingest the `sourceIdentity` that exists in the session. As a result, any AWS API calls made from these jobs do not record `sourceIdentity` in CloudTrail logs.
- **Amazon EMR:** When connecting to Amazon EMR from Studio Classic using runtime roles, administrators must explicitly set the `PropagateSourceIdentity` field. This ensures that Amazon EMR applies the `sourceIdentity` from the calling credentials to a job or query session. The `sourceIdentity` is then recorded in CloudTrail logs.

#### Note

The following exceptions apply when using `sourceIdentity`.
• AWS API calls made from SageMaker shared spaces do not record sourceIdentity in CloudTrail logs.

• If AWS API calls are made from sessions that are created by users or other services and the sessions are not based on the Studio Classic execution role session, then the sourceIdentity is not recorded in CloudTrail logs.

**Turn on sourceIdentity**

The ability to propagate the user profile name as the sourceIdentity in Studio Classic is turned off by default.

To enable the ability to propagate the user profile name as the sourceIdentity, use the AWS CLI during domain creation and domain update. This feature is enabled at the domain level and not at the user profile level.

After you enable this configuration, administrators can view the user profile in the AWS CloudTrail log for the service accessed. The user profile is given as the sourceIdentity value in the userIdentity section. For more information about using AWS CloudTrail logs with SageMaker, see [Log Amazon SageMaker API Calls with AWS CloudTrail](#).

You can use the following code to enable the propagation of the user profile name as the sourceIdentity during domain creation using the create-domain API.

```bash
create-domain
--domain-name <value>
--auth-mode <value>
--default-user-settings <value>
--subnet-ids <value>
--vpc-id <value>
[--tags <value>]
[--app-network-access-type <value>]
[--home-efs-file-system-kms-key-id <value>]
[--kms-key-id <value>]
[--app-security-group-management <value>]
[--domain-settings "ExecutionRoleIdentityConfig=USERPROFILENAME"]
[--cli-input-json <value>]
[--generate-cli-skeleton <value>]
```
You can enable the propagation of the user profile name as the sourceIdentity during domain update using the update-domain API.

To update this configuration, all apps in the domain must be in the Stopped or Deleted state. For more information about how to stop and shut down apps, see Shut down and Update Studio Classic Apps.

Use the following code to enable the propagation of the user profile name as the sourceIdentity.

```
update-domain
  --domain-id <value>
  [--default-user-settings <value>]
  [--domain-settings-for-update "ExecutionRoleIdentityConfig=USER_PROFILE_NAME"]
  [--cli-input-json <value>]
  [--generate-cli-skeleton <value>]
```

**Turn off sourceIdentity**

You can also turn off the propagation of the user profile name as the sourceIdentity using the AWS CLI. This occurs during domain update by passing the ExecutionRoleIdentityConfig=DISABLED value for the --domain-settings-for-update parameter as part of the update-domain API call.

In the AWS CLI, use the following code to disable the propagation of the user profile name as the sourceIdentity.

```
update-domain
  --domain-id <value>
  [--default-user-settings <value>]
  [--domain-settings-for-update "ExecutionRoleIdentityConfig=DISABLED"]
  [--cli-input-json <value>]
  [--generate-cli-skeleton <value>]
```

**Automating Amazon SageMaker with Amazon EventBridge**

Amazon EventBridge monitors status change events in Amazon SageMaker. EventBridge enables you to automate SageMaker and respond automatically to events such as a training job status change or endpoint status change. Events from SageMaker are delivered to EventBridge in near
real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule. For an example of how to create a rule, see [Schedule a Pipeline with Amazon EventBridge](#).

### Note

SageMaker may send multiple events to EventBridge for each state change. This behavior is expected and does not necessarily indicate an error.

Some examples of the actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an AWS SMS queue

**SageMaker events monitored by EventBridge**

- [SageMaker model state change](#)
- [Training job state change](#)
- [Hyperparameter tuning job state change](#)
- [Transform job state change](#)
- [Endpoint state change](#)
- [Feature group state change](#)
- [Model package state change](#)
- [Pipeline execution state change](#)
- [Pipeline step state change](#)
- [Processing job state change](#)
- [SageMaker image state change](#)
- [SageMaker image version state change](#)
- [Endpoint deployment state change](#)
- [Model card state change](#)
SageMaker model state change

Indicates a change in the state of a SageMaker model. The state changes when a SageMaker model is either created or deleted.

```
{
    "source": ["aws.sagemaker"],
    "detail-type": ["SageMaker Model State Change"]
    "Resources" : ["arn:aws:sagemaker:us-east-1:123456789012:model/model-name"]
}
```

If a model is specified under `Resources`, an event will be generated and sent to EventBridge when the state of this model changes. If you do not specify a value for `Resources`, an event will generate when the status of any of the SageMaker models associated with your account changes.

Training job state change

Indicates a change in the status of a SageMaker training job.

If the value of `TrainingJobStatus` is Failed, the event contains the `FailureReason` field, which provides a description of why the training job failed.

```

         "CompressionType": "compression type",
      }
   }
}
```
Endpoint state change

Indicates a change in the status of a SageMaker hosted real-time inference endpoint.

The following shows an event with an endpoint in the IN_SERVICE state.

```json
{
  "version": "0",
  "id": "d2921b5a-b0ad-cace-a8e3-0f159d018e06",
  "detail-type": "SageMaker Endpoint State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "1583831889050",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "EndpointName": "MyEndpoint",
    "EndpointConfigName": "MyEndpointConfig",
    "ProductionVariants": [
      {
        "DesiredWeight": 1.0,
        "InstanceType": "instanceType",
        "InstanceCount": 3
      }
    ]
  }
}
```
Feature group state change

Indicates a change either in the FeatureGroupStatus or the OfflineStoreStatus of a SageMaker feature group.

```json
{
    "version": "0",
    "id": "93201303-abdb-36a4-1b9b-4c1c3e3671c0",
    "detail-type": "SageMaker Feature Group State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",

    "region": "us-east-1",
    "resources": [
        "arn:aws:sagemaker:us-east-1:123456789012:feature-group/sample-feature-group"
    ],
    "detail": {
        "FeatureGroupName": "sample-feature-group",
        "RecordIdentifierFeatureName": "RecordIdentifier",
        "EventTimeFeatureName": "EventTime",
        "FeatureDefinitions": [
            {
                "FeatureName": "RecordIdentifier",
                "FeatureType": "Integral"
            },
            {
                "FeatureName": "EventTime",
                "FeatureType": "Fractional"
            }
        ]
    }
}
```
Model package state change

Indicates a change in the status of a SageMaker model package.

```json
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",

Pipeline execution state change

Indicates a change in the status of a SageMaker pipeline execution.

currentPipelineExecutionStatus and previousPipelineExecutionStatus can be one of the following values:

- Executing
- Succeeded
- Failed
- Stopping
- Stopped

```json
{
  "version": "0",
  "id": "315c1398-40ff-a850-213b-158f73kd93ir",
  "detail-type": "SageMaker Model Building Pipeline Execution Status Change",

  }
}
```
Pipeline step state change

Indicates a change in the status of a SageMaker pipeline step.

If there is a cache hit, the event contains the cacheHitResult field. currentStepStatus and previousStepStatus can be one the following values:

- Starting
- Executing
- Succeeded
- Failed
- Stopping
- Stopped

If the value of currentStepStatus is Failed, the event contains the failureReason field, which provides a description of why the step failed.

```json
{
    "version": "0",
    "id": "ea37ccbb-5e2b-05e9-4073-1daazc940304",
    "detail-type": "SageMaker Model Building Pipeline Execution Step Status Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-03-15T16:10:10Z",

        "stepName": "myprocessingstep1",
        "stepType": "Processing",
        "previousStepStatus": "Executing"
    };
```
Processing job state change

Indicates a change in the status of a SageMaker Processing job.

The following example event is for a failed Processing job, where the ProcessingJobStatus value is Failed.

```json
{
  "version": "0",
  "id": "0a15f67d-aa23-0123-0123-01a23w89r01t",

        }
      }
    }
  }
}
```
Processing job state change

6002
SageMaker image state change

Indicates a change in the status of a SageMaker image.

```
{
    "version": "0",
    "id": "cee033a3-17d8-49f8-865f-b9ebf485d9ee",
    "detail-type": "SageMaker Image State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-04-29T01:29:59Z",
    "region": "us-east-1",
    "resources": ["arn:aws:sagemaker:us-west-2:123456789012:image/cee033a3-17d8-49f8-865f-b9ebf485d9ee"],
    "detail": {
        "ImageName": "cee033a3-17d8-49f8-865f-b9ebf485d9ee",
        "ImageArn": "arn:aws:sagemaker:us-west-2:123456789012:image/cee033a3-17d8-49f8-865f-b9ebf485d9ee",
        "ImageStatus": "Creating",
        "Version": 1.0,
        "Tags": {}
    }
}
```

SageMaker image version state change

Indicates a change in the status of a SageMaker image version.

```
{
    "version": "0",
    "id": "07fc4615-ebd7-15fc-1746-243411f09f04",
    "detail-type": "SageMaker Image Version State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-04-29T01:29:59Z",
    "region": "us-east-1",
    "resources": ["arn:aws:sagemaker:us-west-2:123456789012:image-version/07800032-2d29-48b7-8f82-5129225b2a85"],
    "detail": {
        "ImageArn": "arn:aws:sagemaker:us-west-2:123456789012:image/a70ff896-c832-4fe8-add6-eba25a0f43e6",
    }
}
```
For more information about the status values and their meanings for SageMaker jobs, endpoints, and pipelines, see the following links:

- AlgorithmStatus
- EndpointStatus
- FeatureGroupStatus
- HyperParameterTuningJobStatus
- LabelingJobStatus
- ModelPackageStatus
- NotebookInstanceStatus
- PipelineExecutionStatus
- StepStatus
- ProcessingJobStatus
- TrainingJobStatus
- TransformJobStatus

For more information, see the Amazon EventBridge User Guide.

**Endpoint deployment state change**

⚠️ Important

The following examples may not work for all endpoints. For a list of features that may exclude your endpoint, see the Exclusions page.

Indicates a state change for an endpoint deployment. The following example shows an endpoint updating with a blue/green canary deployment.

```json
{
    "ImageVersionStatus": "Creating",
    "Version": 1.0,
    "Tags": {}
}
```
"version": "0",
"id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
"detail-type": "SageMaker Endpoint Deployment State Change",
"source": "aws.sagemaker",
"account": "123456789012",
"time": "2021-10-25T01:52:12Z",
"region": "us-west-2",
"resources": [
],
"detail": {
  "EndpointName": "sample-endpoint",
  "EndpointConfigName": "sample-endpoint-config-1",
  "ProductionVariants": [
    {
      "VariantName": "AllTraffic",
      "CurrentWeight": 1,
      "DesiredWeight": 1,
      "CurrentInstanceCount": 3,
      "DesiredInstanceCount": 3
    }
  ],
  "EndpointStatus": "UPDATING",
  "CreationTime": 1635195148181,
  "LastModifiedTime": 1635195148181,
  "Tags": {},
  "PendingDeploymentSummary": {
    "EndpointConfigName": "sample-endpoint-config-2",
    "StartTime": Timestamp,
    "ProductionVariants": [
      {
        "VariantName": "AllTraffic",
        "CurrentWeight": 1,
        "DesiredWeight": 1,
        "CurrentInstanceCount": 1,
        "DesiredInstanceCount": 3,
        "VariantStatus": [
          {
            "Status": "Baking",
            "StatusMessage": "Baking for 600 seconds (TerminationWaitInSeconds) with traffic enabled on canary capacity of 1 instance(s).",
            "StartTime": 1635195269181,
          }
        ]
      }
    ]
  }
}
The following example indicates a state change for an endpoint deployment, which is being updated with new capacity on an existing endpoint configuration.

```json
{
   "version": "0",
   "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
   "detail-type": "SageMaker Endpoint Deployment State Change",
   "source": "aws.sagemaker",
   "account": "123456789012",
   "time": "2021-10-25T01:52:12Z",
   "region": "us-west-2",
   "resources": [
   ],
   "detail": {
      "EndpointName": "sample-endpoint",
      "EndpointConfigName": "sample-endpoint-config-1",
      "ProductionVariants": [
         {
            "VariantName": "AllTraffic",
            "CurrentWeight": 1,
            "DesiredWeight": 1,
            "CurrentInstanceCount": 3,
            "DesiredInstanceCount": 6,
            "VariantStatus": [
               {
                  "Status": "Updating",
                  "StatusMessage": "Scaling out desired instance count to 6.",
                  "StartTime": 1635195269181
               }
            ]
         }
      ]
   }
}
```
The following secondary deployment statuses are also available for endpoints (found in the VariantStatus object.

- **Creating**: creating instances for the production variant.
  
  Example message: "Launching X instance(s)."
- **Deleting**: terminating instances for the production variant.
  
  Example message: "Terminating X instance(s)."
- **Updating**: updating capacity for the production variant.
  
  Example messages: "Launching X instance(s).", "Scaling out desired instance count to X."
- **ActivatingTraffic**: turning on traffic for the production variant.
  
  Example message: "Activating traffic on canary capacity of X instance(s)."
- **Baking**: waiting period to monitor the CloudWatch alarms in the auto-rollback configuration.
  
  Example message: "Baking for X seconds (TerminationWaitInSeconds) with traffic enabled on full capacity of Y instance(s)."

**Model card state change**

Indicates a change in the status of an Amazon SageMaker Model Card. For more information about model cards, see Amazon SageMaker Model Cards.

```json
{
  "version": "0",
  "id": "aa7a9c4f-2caa-4d04-a6de-e67227ba4302",
  "detail-type": "SageMaker Model Card State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "2022-11-30T00:00:00Z"
}
```
Model card state change
Machine Learning Frameworks and Languages

You can use Python and R natively in Amazon SageMaker notebook kernels. There are also kernels that support specific frameworks. A very popular way to get started with SageMaker is to use the Amazon SageMaker Python SDK. It provides open source Python APIs and containers that make it easy to train and deploy models in SageMaker, as well as examples for use with several different machine learning and deep learning frameworks.

For information about using specific frameworks or how to use R in SageMaker, see the following topics.

Languages SDKs and user guides:

- Amazon SageMaker Python SDK
- R
- API Reference

Machine learning and deep learning frameworks guides:

- Apache MXNet
- Apache Spark
- Chainer
- Hugging Face
- PyTorch
Use Apache MXNet with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom MXNet code. The Amazon SageMaker Python SDK MXNet estimators and models and the SageMaker open-source MXNet container make writing a MXNet script and running it in SageMaker easier.

**What do you want to do?**

I want to train a custom MXNet model in SageMaker.

For a sample Jupyter notebook, see the [MXNet example notebooks](https://github.com/awslabs/amazon-sagemaker-examples) in the Amazon SageMaker Examples GitHub repository.

For documentation, see [Train a Model with MXNet](https://docs.aws.amazon.com/sagemaker/latest/dg/mxnet-scikit-learn-training.html).

I have an MXNet model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see [Deploy MXNet models](https://docs.aws.amazon.com/sagemaker/latest/dg/mxnet-model-deployment.html).

I have an MXNet model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see [Deploy Endpoints from Model Data](https://docs.aws.amazon.com/sagemaker/latest/dg/deploy-endpoint-from-model-data.html).

I want to see the API documentation for Amazon SageMaker Python SDK MXNet classes.

For more information, see [MXNet Classes](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client).

I want to find the SageMaker MXNet container repository.

For more information, see [SageMaker MXNet Container GitHub repository](https://github.com/awslabs/amazon-sagemaker-containers).

I want to find information about MXNet versions supported by AWS Deep Learning Containers.

For more information, see [Available Deep Learning Container Images](https://docs.aws.amazon.com/sagemaker/latest/dg/deep-learning-container-images.html).

For general information about writing MXNet script mode training scripts and using MXNet script mode estimators and models with SageMaker, see [Using MXNet with the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/mxnet-scikit-learn-training.html).
Use Apache Spark with Amazon SageMaker

Amazon SageMaker Spark is an open source Spark library that helps you construct Spark machine learning (ML) pipelines with SageMaker. This simplifies the integration of Spark ML stages with SageMaker stages, like model training and hosting. For information about SageMaker Spark, see the [SageMaker Spark GitHub repository](https://github.com/aws/sagemaker-spark).

The SageMaker Spark library is available in Python and Scala. You can use SageMaker Spark to train models in SageMaker using `org.apache.spark.sql.DataFrame` data frames in your Spark clusters. After model training, you can also host the model using SageMaker hosting services.

The SageMaker Spark library, `com.amazonaws.services.sagemaker.sparksdk`, provides the following classes, among others:

- **SageMakerEstimator**—Extends the `org.apache.spark.ml.Estimator` interface. You can use this estimator for model training in SageMaker.
- **SageMakerModel**—Extends the `org.apache.spark.ml.Model` class. You can use this `SageMakerModel` for model hosting and obtaining inferences in SageMaker.

With Amazon SageMaker Studio and Studio Classic, you can connect to an Amazon EMR cluster. For more information, see [Prepare data at Scale with Studio Classic Notebooks](https://docs.aws.amazon.com/sagemaker/latest/dg/prepare-data-at-scale-with-studio-classic.html).

**Topics**

- [Download the SageMaker Spark Library](#)
- [Integrate Your Apache Spark Application with SageMaker](#)
- [SageMaker Spark for Scala examples](#)
- [SageMaker Spark for Python (PySpark) examples](#)

**Download the SageMaker Spark Library**

You can download the source code for both Python Spark (PySpark) and Scala libraries from the [SageMaker Spark GitHub repository](https://github.com/aws/sagemaker-spark).

For specific instructions on installing the SageMaker Spark library, use any of the following options.
SageMaker Spark for Python (SageMaker PySpark):

- Install using pip:
  
  ```
  pip install sagemaker_pyspark
  ```

- Install from the source:
  
  ```
  git clone git@github.com:aws/sagemaker-spark.git
cd sagemaker-pyspark-sdk
python setup.py install
  ```

- You can also create a new notebook in a notebook instance that uses either the Sparkmagic (PySpark) or the Sparkmagic (PySpark3) kernel and connect to a remote Amazon EMR cluster.

  **Note**

  The Amazon EMR cluster must be configured with an IAM role that has the AmazonSageMakerFullAccess policy attached. For information about configuring roles for an EMR cluster, see Configure IAM Roles for Amazon EMR Permissions to AWS Services in the Amazon EMR Management Guide.

SageMaker Spark for Scala (SageMaker Spark):

- SageMaker Spark SDK for Scala is available in the Maven central repository. Add the Spark library to your project by adding the following dependency to your pom.xml file:

  ```
  <dependency>
    <groupId>com.amazonaws</groupId>
    <artifactId>sagemaker-spark_2.11</artifactId>
    <version>spark_2.2.0-1.0</version>
  </dependency>
  ```

- If your project is built with Maven, add the following to your pom.xml file:

  ```
  <dependency>
    <groupId>com.amazonaws</groupId>
  </dependency>
  ```

- If your project depends on Spark 2.1, add the following to your pom.xml file:

  ```
  <dependency>
    <groupId>com.amazonaws</groupId>
  </dependency>
  ```
Integrate Your Apache Spark Application with SageMaker

The following is high-level summary of the steps for integrating your Apache Spark application with SageMaker.

1. Continue data preprocessing using the Apache Spark library that you are familiar with. Your dataset remains a DataFrame in your Spark cluster. Load your data into a DataFrame and preprocess it so that you have a features column with \texttt{org.apache.spark.ml.linalg.Vector} of Doubles, and an optional label column with values of Double type.

2. Use the estimator in the SageMaker Spark library to train your model. For example, if you choose the k-means algorithm provided by SageMaker for model training, you call the \texttt{KMeansSageMakerEstimator.fit} method.

Provide your DataFrame as input. The estimator returns a \texttt{SageMakerModel} object.

\textbf{Note}

\texttt{SageMakerModel} extends the \texttt{org.apache.spark.ml.Model}.

The \texttt{fit} method does the following:

a. Converts the input DataFrame to the protobuf format by selecting the features and label columns from the input DataFrame and uploading the protobuf data to an Amazon S3 bucket. The protobuf format is efficient for model training in SageMaker.

b. Starts model training in SageMaker by sending a SageMaker \texttt{CreateTrainingJob} request. After model training has completed, SageMaker saves the model artifacts to an S3 bucket.

SageMaker assumes the IAM role that you specified for model training to perform tasks on your behalf. For example, it uses the role to read training data from an S3 bucket and to write model artifacts to a bucket.
c. Creates and returns a SageMakerModel object. The constructor does the following tasks, which are related to deploying your model to SageMaker.

i. Sends a CreateModel request to SageMaker.
ii. Sends a CreateEndpointConfig request to SageMaker.
iii. Sends a CreateEndpoint request to SageMaker, which then launches the specified resources, and hosts the model on them.

3. You can get inferences from your model hosted in SageMaker with the SageMakerModel.transform.

   Provide an input DataFrame with features as input. The transform method transforms it to a DataFrame containing inferences. Internally, the transform method sends a request to the InvokeEndpoint SageMaker API to get inferences. The transform method appends the inferences to the input DataFrame.

### SageMaker Spark for Scala examples

Amazon SageMaker provides an Apache Spark library (SageMaker Spark) that you can use to integrate your Apache Spark applications with SageMaker. For example, you might use Apache Spark for data preprocessing and SageMaker for model training and hosting. For information about the SageMaker Apache Spark library, including installation, see Use Apache Spark with Amazon SageMaker.

This section provides example code that uses the Apache Spark Scala library provided by SageMaker to train a model in SageMaker using DataFrames in your Spark cluster.

**Topics**

- Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark
- Use the SageMakerEstimator in a Spark Pipeline

The following example hosts the resulting model artifacts using SageMaker hosting services. Specifically, this example does the following:

- Uses the KMeansSageMakerEstimator to fit (or train) a model on data
Because the example uses the k-means algorithm provided by SageMaker to train a model, you use the `KMeansSageMakerEstimator`. You train the model using images of handwritten single-digit numbers (from the MNIST dataset). You provide the images as an input `DataFrame`. For your convenience, SageMaker provides this dataset in an Amazon S3 bucket.

In response, the estimator returns a `SageMakerModel` object.

- Obtains inferences using the trained `SageMakerModel`

To get inferences from a model hosted in SageMaker, you call the `SageMakerModel.transform` method. You pass a `DataFrame` as input. The method transforms the input `DataFrame` to another `DataFrame` containing inferences obtained from the model.

For a given input image of a handwritten single-digit number, the inference identifies a cluster that the image belongs to. For more information, see [K-Means Algorithm](#).

This is the example code:

```scala
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator

val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/"")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
```
The code does the following:

- Loads the MNIST dataset from an S3 bucket provided by SageMaker (awsai-sparksdk-dataset) into a Spark DataFrame (mnistTrainingDataFrame):

```scala
// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")
```

The show method displays the first 20 rows in the data frame:

```
+-----+--------------------+
   6016
```

</tbody>
</table>

only showing top 20 rows

In each row:

- The **label** column identifies the image's label. For example, if the image of the handwritten number is the digit 5, the label value is 5.

- The **features** column stores a vector (**org.apache.spark.ml.linalg.Vector**) of Double values. These are the 784 features of the handwritten number. (Each handwritten number is a 28 x 28-pixel image, making 784 features.)

- Creates a SageMaker estimator (**KMeansSageMakerEstimator**)

  The **fit** method of this estimator uses the k-means algorithm provided by SageMaker to train models using an input **DataFrame**. In response, it returns a **SageMakerModel** object that you can use to get inferences.
The `KMeansSageMakerEstimator` extends the SageMaker `SageMakerEstimator`, which extends the Apache Spark Estimator.

```scala
val estimator = new KMeansSageMakerEstimator(
  sagemakerRole = IAMRole(roleArn),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1)
  .setK(10).setFeatureDim(784)
```

The constructor parameters provide information that is used for training a model and deploying it on SageMaker:

- `trainingInstanceType` and `trainingInstanceCount`—Identify the type and number of ML compute instances to use for model training.

- `endpointInstanceType`—Identifies the ML compute instance type to use when hosting the model in SageMaker. By default, one ML compute instance is assumed.

- `endpointInitialInstanceCount`—Identifies the number of ML compute instances initially backing the endpoint hosting the model in SageMaker.

- `sagemakerRole`—SageMaker assumes this IAM role to perform tasks on your behalf. For example, for model training, it reads data from S3 and writes training results (model artifacts) to S3.

---

**Note**

This example implicitly creates a SageMaker client. To create this client, you must provide your credentials. The API uses these credentials to authenticate requests to
SageMaker. For example, it uses the credentials to authenticate requests to create a training job and API calls for deploying the model using SageMaker hosting services.

- After the KMeansSageMakerEstimator object has been created, you set the following parameters, are used in model training:
  - The number of clusters that the k-means algorithm should create during model training. You specify 10 clusters, one for each digit, 0 through 9.
  - Identifies that each input image has 784 features (each handwritten number is a 28 x 28-pixel image, making 784 features).

- Calls the estimator fit method

```scala
// train
val model = estimator.fit(trainingData)
```

You pass the input DataFrame as a parameter. The model does all the work of training the model and deploying it to SageMaker. For more information see, Integrate Your Apache Spark Application with SageMaker. In response, you get a SageMakerModel object, which you can use to get inferences from your model deployed in SageMaker.

You provide only the input DataFrame. You don't need to specify the registry path to the k-means algorithm used for model training because the KMeansSageMakerEstimator knows it.

- Calls the SageMakerModel.transform method to get inferences from the model deployed in SageMaker.

The transform method takes a DataFrame as input, transforms it, and returns another DataFrame containing inferences obtained from the model.

```scala
val transformedData = model.transform(testData)
transformedData.show
```

For simplicity, we use the same DataFrame as input to the transform method that we used for model training in this example. The transform method does the following:
Serializes the features column in the input DataFrame to protobuf and sends it to the SageMaker endpoint for inference.

Deserializes the protobuf response into the two additional columns (distance_to_cluster and closest_cluster) in the transformed DataFrame.

The show method gets inferences to the first 20 rows in the input DataFrame:

<table>

</tbody>
</table>

You can interpret the data, as follows:

• A handwritten number with the label 5 belongs to cluster 4 (closest_cluster).
• A handwritten number with the label 0 belongs to cluster 5.
• A handwritten number with the label 4 belongs to cluster 9.
• A handwritten number with the label 1 belongs to cluster 6.
For more information on how to run these examples, see https://github.com/aws/sagemaker-spark/blob/master/README.md on GitHub.

Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark

In SageMaker Spark for Scala examples, you use the `kMeansSageMakerEstimator` because the example uses the k-means algorithm provided by Amazon SageMaker for model training. You might choose to use your own custom algorithm for model training instead. Assuming that you have already created a Docker image, you can create your own `SageMakerEstimator` and specify the Amazon Elastic Container Registry path for your custom image.

The following example shows how to create a `KMeansSageMakerEstimator` from the `SageMakerEstimator`. In the new estimator, you explicitly specify the Docker registry path to your training and inference code images.

```scala
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.SageMakerEstimator
import com.amazonaws.services.sagemaker.sparksdk.transformation.serializers.ProtobufRequestRowSerializer
import com.amazonaws.services.sagemaker.sparksdk.transformation.deserializers.KMeansProtobufResponseRowDeserializer

val estimator = new SageMakerEstimator(
  trainingImage =
    "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
  modelImage =
    "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
  requestRowSerializer = new ProtobufRequestRowSerializer(),
  responseRowDeserializer = new KMeansProtobufResponseRowDeserializer(),
  hyperParameters = Map("k" -> "10", "feature_dim" -> "784"),
  sagemakerRole = IAMRole(roleArn),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1,
  trainingSparkDataFormat = "sagemaker"
)
```

In the code, the parameters in the `SageMakerEstimator` constructor include:

- `trainingImage` —Identifies the Docker registry path to the training image containing your custom code.
Amazon SageMaker Developer Guide

- **modelImage** — Identifies the Docker registry path to the image containing inference code.
  
- **requestRowSerializer** — Implements
  
  com.amazonaws.services.sagemaker.sparksdk.transformation.RequestRowSerializer.

  This parameter serializes rows in the input DataFrame to send them to the model hosted in SageMaker for inference.

- **responseRowDeserializer** — Implements
  
  com.amazonaws.services.sagemaker.sparksdk.transformation.ResponseRowDeserializer.

  This parameter deserializes responses from the model, hosted in SageMaker, back into a DataFrame.

- **trainingSparkDataFormat** — Specifies the data format that Spark uses when uploading training data from a DataFrame to S3. For example, "sagemaker" for protobuf format, "csv" for comma-separated values, and "libsvm" for LibSVM format.

  You can implement your own RequestRowSerializer and ResponseRowDeserializer to serialize and deserialize rows from a data format that your inference code supports, such as .libsvm or .csv.

**Use the SageMakerEstimator in a Spark Pipeline**

You can use `org.apache.spark.ml.Estimato`r estimators and `org.apache.spark.ml.Model` models, and `SageMakerEstimator` estimators and `SageMakerModel` models in `org.apache.spark.ml.Pipeline` pipelines, as shown in the following example:

```java
import org.apache.spark.ml.Pipeline
import org.apache.spark.ml.feature.PCA
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms.
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator

val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
```
The parameter `trainingSparkDataFormatOptions` configures Spark to serialize to protobuf the "projectedFeatures" column for model training. Additionally, Spark serializes to protobuf the "label" column by default.

Because we want to make inferences using the "projectedFeatures" column, we pass the column name into the `ProtobufRequestRowSerializer`.

The following example shows a transformed DataFrame:
SageMaker Spark for Python (PySpark) examples

Amazon SageMaker provides an Apache Spark Python library ([SageMaker PySpark](https://github.com/aws/sagemaker-spark)) that you can use to integrate your Apache Spark applications with SageMaker. For example, you might use Apache Spark for data preprocessing and SageMaker for model training and hosting. For information about the SageMaker Apache Spark library, including installation, see [Use Apache Spark with Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/use-apache-spark.html).

For examples on using SageMaker PySpark, see:

- [Using Amazon SageMaker with Apache Spark](https://docs.aws.amazon.com/sagemaker/latest/dg/use-apache-spark.html) in Read the Docs.
- [SageMaker Spark](https://github.com/aws/sagemaker-spark) GitHub repository.

To run the notebooks on a notebook instance, see [Example Notebooks](https://docs.aws.amazon.com/sagemaker/latest/dg/example-notebooks.html). To run the notebooks on Studio, see [Create or Open an Amazon SageMaker Studio Classic Notebook](https://docs.aws.amazon.com/sagemaker/latest/dg/studio-create-notebook.html).
Use Chainer with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom Chainer code. The SageMaker Python SDK Chainer estimators and models and the SageMaker open-source Chainer container make writing a Chainer script and running it in SageMaker easier.

What do you want to do?

I want to train a custom Chainer model in SageMaker.

For a sample Jupyter notebook, see the Chainer example notebooks in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with Chainer.

I have a Chainer model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy Chainer models.

I have a Chainer model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK Chainer classes.

For more information, see Chainer Classes.

I want to find information about SageMaker Chainer containers.

For more information, see the SageMaker Chainer Container GitHub repository.

For information about supported Chainer versions, and for general information about writing Chainer training scripts and using Chainer estimators and models with SageMaker, see Using Chainer with the SageMaker Python SDK.

Use Hugging Face with Amazon SageMaker

Amazon SageMaker enables customers to train, fine-tune, and run inference using Hugging Face models for Natural Language Processing (NLP) on SageMaker. You can use Hugging Face for both training and inference. This functionality is available through the development of Hugging Face AWS Deep Learning Containers. These containers include Hugging Face Transformers, Tokenizers and the Datasets library, which allows you to use these resources for your training and inference.
jobs. For a list of the available Deep Learning Containers images, see Available Deep Learning Containers Images. These Deep Learning Containers images are maintained and regularly updated with security patches.

To use the Hugging Face Deep Learning Containers with the SageMaker Python SDK for training, see the Hugging Face SageMaker Estimator. With the Hugging Face Estimator, you can use the Hugging Face models as you would any other SageMaker Estimator. However, using the SageMaker Python SDK is optional. You can also orchestrate your use of the Hugging Face Deep Learning Containers with the AWS CLI and AWS SDK for Python (Boto3).

For more information on Hugging Face and the models available in it, see the Hugging Face documentation.

Training

To run training, you can use any of the thousands of models available in Hugging Face and fine-tune them for your specific use case with additional training. With SageMaker, you can use standard training or take advantage of SageMaker Distributed Data and Model Parallel training. As with other SageMaker training jobs using custom code, you can capture your own metrics by passing a metrics definition to the SageMaker Python SDK as shown in Defining Training Metrics (SageMaker Python SDK). The captured metrics are then accessible via CloudWatch and as a Pandas DataFrame via the TrainingJobAnalytics method. Once your model is trained and fine-tuned, you can use it like any other model to run inference jobs.

How to run training with the Hugging Face Estimator

You can implement the Hugging Face Estimator for training jobs using the SageMaker Python SDK. The SageMaker Python SDK is an open source library for training and deploying machine learning models on SageMaker. For more information on the Hugging Face Estimator, see the SageMaker Python SDK documentation.

With the SageMaker Python SDK, you can run training jobs using the Hugging Face Estimator in the following environments:

- **SageMaker Studio**: Amazon SageMaker Studio is the first fully integrated development environment (IDE) for machine learning (ML). SageMaker Studio provides a single, web-based visual interface where you can perform all ML development steps required to prepare, build, train and tune, deploy and manage models. For information on using Jupyter Notebooks in Studio, see Use Amazon SageMaker Studio Notebooks.
• **SageMaker Notebook Instances**: An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook App. This app lets you run Jupyter Notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models without SageMaker Studio features like Debugger, Model Monitoring, and a web-based IDE.

• Locally: If you have connectivity to AWS and have appropriate SageMaker permissions, you can use the SageMaker Python SDK locally to launch remote training and inference jobs for Hugging Face in SageMaker on AWS. This works on your local machine, as well as other AWS services with a connected SageMaker Python SDK and appropriate permissions.

**Inference**

For inference, you can use your trained Hugging Face model or one of the pre-trained Hugging Face models to deploy an inference job with SageMaker. With this collaboration, you only need one line of code to deploy both your trained models and pre-trained models with SageMaker. You can also run inference jobs without having to write any custom inference code. With custom inference code, you can customize the inference logic by providing your own Python script.

**How to deploy an inference job using the Hugging Face Deep Learning Containers**

You have two options for running inference with SageMaker. You can run inference using a model that you trained, or deploy a pre-trained Hugging Face model.

• **Run inference with your trained model**: You have two options for running inference with your own trained model. You can run inference with a model that you trained using an existing Hugging Face model with the SageMaker Hugging Face Deep Learning Containers, or you can bring your own existing Hugging Face model and deploy it using SageMaker. When you run inference with a model that you trained with the SageMaker Hugging Face Estimator, you can deploy the model immediately after training completes or you can upload the trained model to an Amazon S3 bucket and ingest it when running inference later. If you bring your own existing Hugging Face model, you must upload the trained model to an Amazon S3 bucket and ingest that bucket when running inference as shown in [Deploy your Hugging Face Transformers for inference example](#).

• **Run inference with a pre-trained HuggingFace model**: You can use one of the thousands of pre-trained Hugging Face models to run your inference jobs with no additional training needed. To run inference, you select the pre-trained model from the list of [Hugging Face models](#), as outlined in [Deploy pre-trained Hugging Face Transformers for inference example](#).
What do you want to do?

The following Jupyter Notebooks in the Hugging Face notebooks repository illustrate how to use the Hugging Face Deep Learning Containers with SageMaker in various use cases.

I want to train and deploy a text classification model using Hugging Face in SageMaker with PyTorch.

   For a sample Jupyter Notebook, see the PyTorch Getting Started Demo.

I want to train and deploy a text classification model using Hugging Face in SageMaker with TensorFlow.

   For a sample Jupyter Notebook, see the TensorFlow Getting Started example.

I want to run distributed training with data parallelism using Hugging Face and SageMaker Distributed.

   For a sample Jupyter Notebook, see the Distributed Training example.

I want to run distributed training with model parallelism using Hugging Face and SageMaker Distributed.

   For a sample Jupyter Notebook, see the Model Parallelism example.

I want to use a spot instance to train and deploy a model using Hugging Face in SageMaker.

   For a sample Jupyter Notebook, see the Spot Instances example.

I want to capture custom metrics and use SageMaker Checkpointing when training a text classification model using Hugging Face in SageMaker.

   For a sample Jupyter Notebook, see the Training with Custom Metrics example.

I want to train a distributed question-answering TensorFlow model using Hugging Face in SageMaker.

   For a sample Jupyter Notebook, see the Distributed TensorFlow Training example.

I want to train a distributed summarization model using Hugging Face in SageMaker.

   For a sample Jupyter Notebook, see the Distributed Summarization Training example.

I want to train an image classification model using Hugging Face in SageMaker.

   For a sample Jupyter Notebook, see the Vision Transformer Training example.
I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy your Hugging Face Transformers for inference example.

I want to deploy a pre-trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy pre-trained Hugging Face Transformers for inference example.

**Use PyTorch with Amazon SageMaker**

You can use Amazon SageMaker to train and deploy a model using custom PyTorch code. The SageMaker Python SDK PyTorch estimators and models and the SageMaker open-source PyTorch container make writing a PyTorch script and running it in SageMaker easier.

**What do you want to do?**

I want to train a custom PyTorch model in SageMaker.

For a sample Jupyter notebook, see the PyTorch example notebook in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with PyTorch.

I have a PyTorch model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy PyTorch models.

I have a PyTorch model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploy your own PyTorch model.

I want to see the API documentation for Amazon SageMaker Python SDK PyTorch classes.

For more information, see PyTorch Classes.

I want to find the SageMaker PyTorch container repository.

For more information, see SageMaker PyTorch Container GitHub repository.

I want to find information about PyTorch versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.
For general information about writing PyTorch training scripts and using PyTorch estimators and models with SageMaker, see Using PyTorch with the SageMaker Python SDK.

R User Guide to Amazon SageMaker

This document will walk you through ways of leveraging Amazon SageMaker features using R. This guide introduces SageMaker's built-in R kernel, how to get started with R on SageMaker, and finally several example notebooks.

The examples are organized in three levels, Beginner, Intermediate, and Advanced. They start from Getting Started with R on SageMaker, continue to end-to-end machine learning with R on SageMaker, and then finish with more advanced topics such as SageMaker Processing with R script, and Bring-Your-Own (BYO) R algorithm to SageMaker.

For information on how to bring your own custom R image to Studio, see Bring your own SageMaker image. For a similar blog article, see Bringing your own R environment to Amazon SageMaker Studio.

RStudio Support in SageMaker

Amazon SageMaker supports RStudio as a fully-managed integrated development environment (IDE) integrated with Amazon SageMaker Domain. With RStudio integration, you can launch an RStudio environment in the Domain to run your RStudio workflows on SageMaker resources. For more information, see RStudio on Amazon SageMaker.

R Kernel in SageMaker

SageMaker notebook instances support R using a pre-installed R kernel. Also, the R kernel has the reticulate library, an R to Python interface, so you can use the features of SageMaker Python SDK from within an R script.

- **reticulatetlibrary**: provides an R interface to the Amazon SageMaker Python SDK. The reticulate package translates between R and Python objects.

Get Started with R in SageMaker

- **Create a Notebook Instance** using the t2.medium instance type and default storage size. You can pick a faster instance and more storage if you plan to continue using the instance for more advanced examples, or create a bigger instance later.
- Wait until the status of the notebook is In Service, and then click Open Jupyter.
• Create a new notebook with R kernel from the list of available environments.

• When the new notebook is created, you should see an R logo in the upper right corner of the notebook environment, and also R as the kernel under that logo. This indicates that SageMaker has successfully launched the R kernel for this notebook.

• Alternatively, when you are in a Jupyter notebook, you can use Kernel menu, and then select R from Change Kernel option.
Example Notebooks

Prerequisites

**Getting Started with R on SageMaker**: This sample notebook describes how you can develop R scripts using Amazon SageMaker’s R kernel. In this notebook you set up your SageMaker environment and permissions, download the abalone dataset from the UCI Machine Learning Repository, do some basic processing and visualization on the data, then save the data as .csv format to S3.

**Beginner Level**

**SageMaker Batch Transform using R Kernel**: This sample Notebook describes how to conduct a batch transform job using SageMaker's Transformer API and the XGBoost algorithm. The notebook also uses the Abalone dataset.

**Intermediate Level**

**Hyperparameter Optimization for XGBoost in R**: This sample notebook extends the previous beginner notebooks that use the abalone dataset and XGBoost. It describes how to do model tuning with hyperparameter optimization. You will also learn how to use batch transform for batching predictions, as well as how to create a model endpoint to make real-time predictions.

**Amazon SageMaker Processing with R**: SageMaker Processing lets you preprocess, post-process and run model evaluation workloads. This example shows you how to create an R script to orchestrate a Processing job.

**Advanced Level**

**Train and Deploy Your Own R Algorithm in SageMaker**: Do you already have an R algorithm, and you want to bring it into SageMaker to tune, train, or deploy it? This example walks you through
how to customize SageMaker containers with custom R packages, all the way to using a hosted endpoint for inference on your R-origin model.

**Use Scikit-learn with Amazon SageMaker**

You can use Amazon SageMaker to train and deploy a model using custom Scikit-learn code. The SageMaker Python SDK Scikit-learn estimators and models and the SageMaker open-source Scikit-learn containers make writing a Scikit-learn script and running it in SageMaker easier.

**Requirements**

Scikit-learn 1.2 has the following dependencies.

<table>
<thead>
<tr>
<th>Dependency</th>
<th>Minimum version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Python</td>
<td>3.8</td>
</tr>
<tr>
<td>NumPy</td>
<td>1.17.3</td>
</tr>
<tr>
<td>SciPy</td>
<td>1.3.2</td>
</tr>
<tr>
<td>joblib</td>
<td>1.1.1</td>
</tr>
<tr>
<td>threadpoolctl</td>
<td>2.0.0</td>
</tr>
</tbody>
</table>

The SageMaker Scikit-learn container supports the following Scikit-learn versions.

<table>
<thead>
<tr>
<th>Supported Scikit-learn version</th>
<th>Minimum Python version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.2-1</td>
<td>3.8</td>
</tr>
<tr>
<td>1.0-1</td>
<td>3.7</td>
</tr>
<tr>
<td>0.23-1</td>
<td>3.6</td>
</tr>
<tr>
<td>0.20.0</td>
<td>2.7 or 3.4</td>
</tr>
</tbody>
</table>

For general information about writing Scikit-learn training scripts and using Scikit-learn estimators and models with SageMaker, see [Using Scikit-learn with the SageMaker Python SDK](#).
What do you want to do?

Note

Matplotlib v2.2.3 or newer is required to run the SageMaker Scikit-learn example notebooks.

I want to use Scikit-learn for data processing, feature engineering, or model evaluation in SageMaker.

For a sample Jupyter notebook, see https://github.com/awslabs/amazon-sagemaker-examples/tree/master/sagemaker_processing/scikit_learn_data_processing_and_model_evaluation.

For documentation, see ReadTheDocs.

I want to train a custom Scikit-learn model in SageMaker.

For documentation, see Train a Model with Scikit-learn.

I have a Scikit-learn model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy Scikit-learn models.

I have a Scikit-learn model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK Scikit-learn classes.

For more information, see Scikit-learn Classes.

I want to see information about SageMaker Scikit-learn containers.

For more information, see SageMaker Scikit-learn Container GitHub repository.
Use SparkML Serving with Amazon SageMaker

The Amazon SageMaker Python SDK SparkML Serving model and predictor and the Amazon SageMaker open-source SparkML Serving container support deploying Apache Spark ML pipelines serialized with MLeap in SageMaker to get inferences.

For information about using the SparkML Serving container to deploy models to SageMaker, see SageMaker Spark ML Container GitHub repository. For information about the Amazon SageMaker Python SDK SparkML Serving model and predictors, see the SparkML Serving Model and Predictor API documentation.

Use TensorFlow with Amazon SageMaker

Use TensorFlow Version 1.11 and Later

For TensorFlow versions 1.11 and later, the Amazon SageMaker Python SDK supports script mode training scripts.

What do you want to do?

I want to train a custom TensorFlow model in SageMaker.

For a sample Jupyter notebook, see TensorFlow script mode training and serving.

For documentation, see Train a Model with TensorFlow.

I have a TensorFlow model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy TensorFlow Serving models.

I have a TensorFlow model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see Deploying directly from model artifacts.

I want to see the API documentation for Amazon SageMaker Python SDK TensorFlow classes.

For more information, see TensorFlow Estimator.
I want to find the SageMaker TensorFlow container repository.

For more information, see SageMaker TensorFlow Container GitHub repository.

I want to find information about TensorFlow versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing TensorFlow script mode training scripts and using TensorFlow script mode estimators and models with SageMaker, see Using TensorFlow with the SageMaker Python SDK.

**Use TensorFlow Legacy Mode for Versions 1.11 and Earlier**

The Amazon SageMaker Python SDK provides a legacy mode that supports TensorFlow versions 1.11 and earlier. Use legacy mode TensorFlow training scripts to run TensorFlow jobs in SageMaker if:

- You have existing legacy mode scripts that you do not want to convert to script mode.
- You want to use a TensorFlow version earlier than 1.11.

For information about writing legacy mode TensorFlow scripts to use with the SageMaker Python SDK, see TensorFlow SageMaker Estimators and Models.

**Use Triton Inference Server with Amazon SageMaker**

SageMaker enables customers to deploy a model using custom code with NVIDIA Triton Inference Server. This functionality is available through the development of Triton Inference Server Containers. These containers include NVIDIA Triton Inference Server, support for common ML frameworks, and useful environment variables that let you optimize performance on SageMaker. For a list of all available Deep Learning Containers images, see Available Deep Learning Containers Images. Deep Learning Containers images are maintained and regularly updated with security patches.

You can use the Triton Inference Server Container with SageMaker Python SDK as you would any other container in your SageMaker models. However, using the SageMaker Python SDK is optional. You can use Triton Inference Server Containers with the AWS CLI and AWS SDK for Python (Boto3).

For more information on NVIDIA Triton Inference Server see the Triton documentation.
Inference

Note
The Triton Python backend uses shared memory (SHMEM) to connect your code to Triton. SageMaker Inference provides up to half of the instance memory as SHMEM so you can use an instance with more memory for larger SHMEM size.

For inference, you can use your trained ML models with Triton Inference Server to deploy an inference job with SageMaker.

Some of the key features of Triton Inference Server Container are:

- **Support for multiple frameworks**: Triton can be used to deploy models from all major ML frameworks. Triton supports TensorFlow GraphDef and SavedModel, ONNX, PyTorch TorchScript, TensorRT, and custom Python/C++ model formats.

- **Model pipelines**: Triton model ensemble represents a pipeline of one model with pre/post processing logic and the connection of input and output tensors between them. A single inference request to an ensemble triggers the execution of the entire pipeline.

- **Concurrent model execution**: Multiple instances of the same model can run simultaneously on the same GPU or on multiple GPUs.

- **Dynamic batching**: For models that support batching, Triton has multiple built-in scheduling and batching algorithms that combine individual inference requests together to improve inference throughput. These scheduling and batching decisions are transparent to the client requesting inference.

- **Diverse CPU and GPU support**: The models can be executed on CPUs or GPUs for maximum flexibility and to support heterogeneous computing requirements.

What do you want to do?

I want to deploy my trained PyTorch model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch Resnet50 model with Triton Inference Server example](https://example.com).
I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch BERT model with Triton Inference Server example](https://example.com).

**API Reference**

Making API calls directly from code is cumbersome, and requires you to write code to authenticate your requests. Amazon SageMaker provides the following alternatives:

**Topics**

- [Programming Model for Amazon SageMaker](#)
- [APIs, CLI, and SDKs](#)

**Programming Model for Amazon SageMaker**

Making API calls directly from code is cumbersome, and requires you to write code to authenticate your requests. Amazon SageMaker provides the following alternatives:

- **Use the SageMaker console**—With the console, you don't write any code. You use the console UI to start model training or deploy a model. The console works well for simple jobs, where you use a built-in training algorithm and you don't need to preprocess training data.

- **Modify the example Jupyter notebooks**—SageMaker provides several Jupyter notebooks that train and deploy models using specific algorithms and datasets. Start with a notebook that has a suitable algorithm and modify it to accommodate your data source and specific needs.

- **Write model training and inference code from scratch**—SageMaker provides multiple AWS SDK languages (listed in the overview) and the Amazon SageMaker Python SDK, a high-level Python library that you can use in your code to start model training jobs and deploy the resulting models.
The SageMaker Python SDK—This Python library simplifies model training and deployment. In addition to authenticating your requests, the library abstracts platform specifics by providing simple methods and default parameters. For example:

- To deploy your model, you call only the `deploy()` method. The method creates a SageMaker model artifact, an endpoint configuration, then deploys the model on an endpoint.

- If you use a custom framework script for model training, you call the `fit()` method. The method creates a `.gzip` file of your script, uploads it to an Amazon S3 location, and then runs it for model training, and other tasks. For more information, see Machine Learning Frameworks and Languages.

- To set defaults for SageMaker API calls made by the SageMaker Python SDK, you use a default configuration dictionary. For more information, see Configuring and using defaults with the SageMaker Python SDK.

The AWS SDKs – The SDKs provide methods that correspond to the SageMaker API (see Operations). Use the SDKs to programmatically start a model training job and host the model in SageMaker. SDK clients handle authentication for you, so you don’t need to write authentication code. They are available in multiple languages and platforms. For more information, see the preceding list in the overview.

In Get started, you train and deploy a model using an algorithm provided by SageMaker. That exercise shows how to use both of these libraries. For more information, see Get started.

Integrate SageMaker into your Apache Spark workflow—SageMaker provides a library for calling its APIs from Apache Spark. With it, you can use SageMaker-based estimators in an Apache Spark pipeline. For more information, see Use Apache Spark with Amazon SageMaker.
APIs, CLI, and SDKs

Amazon SageMaker provides APIs, SDKs, and a command line interface that you can use to create and manage notebook instances and train and deploy models.

- **Amazon SageMaker Python SDK** (Recommended)
- **Amazon SageMaker API Reference**
- **Amazon Augmented AI API Reference**
- **AWS Command Line Interface**
- **AWS SDK for .NET**
- **AWS SDK for C++**
- **AWS SDK for Go**
- **AWS SDK for Java**
- **AWS SDK for JavaScript**
- **AWS SDK for PHP**
- **AWS SDK for Python (Boto)**
- **AWS SDK for Ruby**
- **Amazon SageMaker Spark**

You can also get code examples from the Amazon SageMaker example notebooks GitHub repository.

- **Example notebooks**

SageMaker Distribution Images

SageMaker Distribution is a collection of Docker images, which includes popular libraries and packages for machine learning, data science, and data analytics visualization. The Docker images include deep learning frameworks such as the following:

- PyTorch
- TensorFlow
- Keras
It also includes popular Python packages such as the following:

- numpy
- scikit-learn
- pandas

Within the container, you can use the following IDEs:

- JupyterLab
- Code Editor, based on Code-OSS (Visual Studio Code Open Source)

Each SageMaker Distribution image has a GPU variant and a CPU variant.

SageMaker Distribution is available in:

- Studio
- Studio Lab

The packages included in the container are guaranteed to be compatible with each other and the runtime is built to work anywhere. You can use the container to run Amazon SageMaker Studio notebooks or SageMaker training jobs. You can also run the container on a local laptop. Use SageMaker Distribution to quickly get started with ML development in your local environment. Seamlessly transition to tasks such as the batch execution of training jobs without needing to reconfigure your runtime environment.

For the list of all supported libraries within SageMaker distribution and their corresponding versions, see the [SageMaker Distribution GitHub](https://github.com/aws/sagemaker-distribution). You can also use the pre-built and ready-to-use SageMaker Distribution images from the [Amazon Elastic Container Registry Gallery](https://aws.amazon.com/ecr/).

### Supported packages and versions

For the list of the packages that are installed in a version of SageMaker Distribution, see the RELEASE.md file in the [build_artifacts](https://github.com/aws/sagemaker-distribution/tree/master/build_artifacts) directory of the [SageMaker Distribution GitHub](https://github.com/aws/sagemaker-distribution) repository.

### SageMaker Distribution Image Support Policy

<table>
<thead>
<tr>
<th>Major</th>
<th>A major version release of Amazon</th>
<th>Half-yearly</th>
</tr>
</thead>
</table>

**Supported packages and versions**

**For the list of the packages that are installed in a version of SageMaker Distribution, see the RELEASE.md file in the build_artifacts directory of the SageMaker Distribution GitHub repository.**
SageMaker Distribution upgrades all of its core dependencies to the latest compatible version. SageMaker Distribution can add or remove packages in a major version release. Major versions are denoted by the first number in the version string. For example, 1.0, 2.0, 3.0.

| Minor | A minor version release of Amazon SageMaker Distribution ensures that all of its core dependencies are updated to the latest compatible minor version within the same major version. SageMaker Distribution can add new packages during a minor version release. Minor versions are denoted by the second number in the version string. For example, 1.1, 1.2, or 2.1 | Monthly (additional minor versions released on an as-needed basis as well) |
### Patch

A patch version release of Amazon SageMaker Distribution ensures that all its core dependencies are updated to the latest compatible patch version within the same minor version. SageMaker Distribution does not add or remove packages during a patch version release.

7 days (overnight fixes also deployed based on the severity)

### Important

- SageMaker Distribution v0.x.y is only used in Studio Classic. SageMaker Distribution v1.x.y is only used in JupyterLab.

- We try to update the Studio images with new versions regularly. If the packages in the Distribution image are out of date, we recommend waiting for the next update.

- Some dependencies, such as Python, are treated differently. Amazon SageMaker Distribution allows for a minor upgrade of Python with a release. For example, you can upgrade Python 3.10 to Python 3.11 when you upgrade from version 4.8 to 5.0.

### Document History for Amazon SageMaker
