You can either upsample or downsample a time series. Downsampling increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The hourly
observations are aggregated into a single value using an aggregation method such as the mean or median.

Upsampling reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, you can use an interpolation method to infer hourly observations from the ones that have been taken every two hours. For information on interpolation methods, see pandas.DataFrame.interpolate.

You can resample both numeric and non-numeric data.

Use the Resample operation to resample your time series data. If you have multiple time series in your dataset, Data Wrangler standardizes the time interval for each time series.

The following table shows an example of downsampling time series data by using the mean as the aggregation method. The data is downsampled from every two hours to every hour.

**Hourly temperature readings over a day before downsampling**

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>1:00</td>
<td>32</td>
</tr>
<tr>
<td>2:00</td>
<td>35</td>
</tr>
<tr>
<td>3:00</td>
<td>32</td>
</tr>
<tr>
<td>4:00</td>
<td>30</td>
</tr>
</tbody>
</table>

**Temperature readings downsampled to every two hours**

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>2:00</td>
<td>33.5</td>
</tr>
<tr>
<td>2:00</td>
<td>35</td>
</tr>
<tr>
<td>4:00</td>
<td>32.5</td>
</tr>
</tbody>
</table>

You can use the following procedure to resample time series data.

1. Open your Data Wrangler data flow.
2. If you haven’t imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Resample.
6. For Timestamp, choose the timestamp column.
7. For Frequency unit, specify the frequency that you’re resampling.
8. (Optional) Specify a value for Frequency quantity.
9. Configure the transform by specifying the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.
Handle Missing Time Series Data

If you have missing values in your dataset, you can do one of the following:

- For datasets that have multiple time series, drop the time series that have missing values that are greater than a threshold that you specify.
- Impute the missing values in a time series by using other values in the time series.

Imputing a missing value involves replacing the data by either specifying a value or by using an inferential method. The following are the methods that you can use for imputation:

- Constant value – Replace all the missing data in your dataset with a value that you specify.
- Most common value – Replace all the missing data with the value that has the highest frequency in the dataset.
- Forward fill – Use a forward fill to replace the missing values with the non-missing value that precedes the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 7. The sequence that results from using a forward fill is [2, 4, 7, 7, 7, 7, 8].
- Backward fill – Use a backward fill to replace the missing values with the non-missing value that follows the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 8. The sequence that results from using a backward fill is [2, 4, 7, 8, 8, 8, 8].
- Interpolate – Uses an interpolation function to impute the missing values. For more information on the functions that you can use for interpolation, see pandas.DataFrame.interpolate.

Some of the imputation methods might not be able to impute of all the missing value in your dataset. For example, a Forward fill can't impute a missing value that appears at the beginning of the time series. You can impute the values by using either a forward fill or a backward fill.

You can either impute missing values within a cell or within a column.

The following example shows how values are imputed within a cell.

Electricity usage with missing values

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, NaN, NaN]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, NaN, 55]</td>
</tr>
</tbody>
</table>

Electricity usage with values imputed using a forward fill

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, 35, 35]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 45, 55]</td>
</tr>
</tbody>
</table>

The following example shows how values are imputed within a column.

Average daily household electricity usage with missing values

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>30</td>
</tr>
</tbody>
</table>
### Average daily household electricity usage with values imputed using a forward fill

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>30</td>
</tr>
<tr>
<td>household_0</td>
<td>40</td>
</tr>
<tr>
<td>household_0</td>
<td>40</td>
</tr>
<tr>
<td>household_1</td>
<td>40</td>
</tr>
<tr>
<td>household_1</td>
<td>40</td>
</tr>
</tbody>
</table>

You can use the following procedure to handle missing values.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the +, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Handle missing**.
6. For **Time series input type**, choose whether you want to handle missing values inside of a cell or along a column.
7. For **Impute missing values for this column**, specify the column that has the missing values.
8. For **Method for imputing values**, select a method.
9. Configure the transform by specifying the remaining fields.
10. Choose **Preview** to generate a preview of the transform.
11. If you have missing values, you can specify a method for imputing them under **Method for imputing values**.
12. Choose **Add** to add the transform to the Data Wrangler data flow.

### Validate the Timestamp of Your Time Series Data

You might have time stamp data that is invalid. You can use the **Validate time stamp** function to determine whether the timestamps in your dataset are valid. Your timestamp can be invalid for one or more of the following reasons:

- Your timestamp column has missing values.
- The values in your timestamp column are not formatted correctly.

If you have invalid timestamps in your dataset, you can't perform your analysis successfully. You can use Data Wrangler to identify invalid timestamps and understand where you need to clean your data.
The time series validation works in one of the two ways:

You can configure Data Wrangler to do one of the following if it encounters missing values in your dataset:

- Drop the rows that have the missing or invalid values.
- Identify the rows that have the missing or invalid values.
- Throw an error if it finds any missing or invalid values in your dataset.

You can validate the timestamps on columns that either have the timestamp type or the string type. If the column has the string type, Data Wrangler converts the type of the column to timestamp and performs the validation.

You can use the following procedure to validate the timestamps in your dataset.

1. Open your Data Wrangler data flow.
2. If you haven’t imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Validate timestamps.
6. For Timestamp Column, choose the timestamp column.
7. For Policy, choose whether you want to handle missing timestamps.
8. (Optional) For Output column, specify a name for the output column.
9. If the date time column is formatted for the string type, choose Cast to datetime.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

**Standardizing the Length of the Time Series**

If you have time series data stored as arrays, you can standardize each time series to the same length. Standardizing the length of the time series array might make it easier for you to perform your analysis on the data.

You can standardize your time series for data transformations that require the length of your data to be fixed.

Many ML algorithms require you to flatten your time series data before you use them. Flattening time series data is separating each value of the time series into its own column in a dataset. The number of columns in a dataset can't change, so the lengths of the time series need to be standardized between you flatten each array into a set of features.

Each time series is set to the length that you specify as a quantile or percentile of the time series set. For example, you can have three sequences that have the following lengths:

- 3
- 4
- 5

You can set the length of all of the sequences as the length of the sequence that has the 50th percentile length.
Time series arrays that are shorter than the length you've specified have missing values added. The following is an example format of standardizing the time series to a longer length: [2, 4, 5, NaN, NaN, NaN].

You can use different approaches to handle the missing values. For information on those approaches, see Handle Missing Time Series Data (p. 982).

The time series arrays that are longer than the length that you specify are truncated.

You can use the following procedure to standardize the length of the time series.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Standardize length.
6. For Standardize the time series length for the column, choose a column.
7. (Optional) For Output column, specify a name for the output column. If you don't specify a name, the transform is done in place.
8. If the datetime column is formatted for the string type, choose Cast to datetime.
9. Choose Cutoff quantile and specify a quantile to set the length of the sequence.
10. Choose Flatten the output to output the values of the time series into separate columns.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Extract Features from Your Time Series Data

If you're running a classification or a regression algorithm on your time series data, we recommend extracting features from the time series before running the algorithm. Extracting features might improve the performance of your algorithm.

Use the following options to choose how you want to extract features from your data:

- Use Minimal subset to specify extracting 8 features that you know are useful in downstream analyses. You can use a minimal subset when you need to perform computations quickly. You can also use it when your ML algorithm has a high risk of overfitting and you want to provide it with fewer features.
- Use Efficient subset to specify extracting the most features possible without extracting features that are computationally intensive in your analyses.
- Use All features to specify extracting all features from the tune series.
- Use Manual subset to choose a list of features that you think explain the variation in your data well.

Use the following the procedure to extract features from your time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Extract features.
6. For Extract features for this column, choose a column.
7. (Optional) Select Flatten to output the features into separate columns.
8. For **Strategy**, choose a strategy to extract the features.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

**Use Lagged Features from Your Time Series Data**

For many use cases, the best way to predict the future behavior of your time series is to use its most recent behavior.

The most common uses of lagged features are the following:

- Collecting a handful of past values. For example, for time, t + 1, you collect t, t - 1, t - 2, and t - 3.
- Collecting values that correspond to seasonal behavior in the data. For example, to predict the occupancy in a restaurant at 1:00 PM, you might want to use the features from 1:00 PM on the previous day. Using the features from 12:00 PM or 11:00 AM on the same day might not be as predictive as using the features from previous days.

1. Open your Data Wrangler data flow.
2. If you haven’t imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the +, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Lag features**.
6. For **Generate lag features for this column**, choose a column.
7. For **Timestamp Column**, choose the column containing the timestamps.
8. For **Lag**, specify the duration of the lag.
9. (Optional) Configure the output using one of the following options:
   - **Include the entire lag window**
   - **Flatten the output**
   - **Drop rows without history**
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

**Create a Datetime Range In Your Time Series**

You might have time series data that don’t have timestamps. If you know that the observations were taken at regular intervals, you can generate timestamps for the time series in a separate column.

To generate timestamps, you specify the value for the start timestamp and the frequency of the timestamps.

For example, you might have the following time series data for the number of customers at a restaurant.

**Time series data on the number of customers at a restaurant**

<table>
<thead>
<tr>
<th>Number of customers</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>24</td>
</tr>
</tbody>
</table>
If you know that the restaurant opened at 5:00 PM and that the observations are taken hourly, you can add a timestamp column that corresponds to the time series data. You can see the timestamp column in the following table.

### Time series data on the number of customers at a restaurant

<table>
<thead>
<tr>
<th>Number of customers</th>
<th>Timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1:00 PM</td>
</tr>
<tr>
<td>14</td>
<td>2:00 PM</td>
</tr>
<tr>
<td>24</td>
<td>3:00 PM</td>
</tr>
<tr>
<td>40</td>
<td>4:00 PM</td>
</tr>
<tr>
<td>30</td>
<td>5:00 PM</td>
</tr>
<tr>
<td>20</td>
<td>6:00 PM</td>
</tr>
</tbody>
</table>

Use the following procedure to add a datetime range to your data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Datetime range.
6. For Frequency type, choose the unit used to measure the frequency of the timestamps.
7. For Starting timestamp, specify the start timestamp.
8. For Output column, specify a name for the output column.
9. (Optional) Configure the output using the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

### Use a Rolling Window In Your Time Series

You can extract features over a time period. For example, for time, $t$, and a time window length of 3, and for the row that indicates the $t$th timestamp, we append the features that are extracted from the time series at times $t - 3$, $t - 2$, and $t - 1$. For information on extracting features, see Extract Features from Your Time Series Data (p. 985).

You can use the following procedure to extract features over a time period.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Rolling window features.
6. For Generate rolling window features for this column, choose a column.
7. For Timestamp Column, choose the column containing the timestamps.
8. (Optional) For Output Column, specify the name of the output column.
9. For Window size, specify the window size.
10. For Strategy, choose the extraction strategy.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Featurize Datetime

Use Featurize date/time to create a vector embedding representing a datetime field. To use this transform, your datetime data must be in one of the following formats:

- Strings describing datetime: For example, "January 1st, 2020, 12:44pm".
- A Unix timestamp: A Unix timestamp describes the number of seconds, milliseconds, microseconds, or nanoseconds from 1/1/1970.

You can choose to Infer datetime format and provide a Datetime format. If you provide a datetime format, you must use the codes described in the Python documentation. The options you select for these two configurations have implications for the speed of the operation and the final results.

- The most manual and computationally fastest option is to specify a Datetime format and select No for Infer datetime format.
- To reduce manual labor, you can choose Infer datetime format and not specify a datetime format. It is also a computationally fast operation; however, the first datetime format encountered in the input column is assumed to be the format for the entire column. If there are other formats in the column, these values are NaN in the final output. Inferring the datetime format can give you unparsed strings.
- If you don't specify a format and select No for Infer datetime format, you get the most robust results. All the valid datetime strings are parsed. However, this operation can be an order of magnitude slower than the first two options in this list.

When you use this transform, you specify an Input column which contains datetime data in one of the formats listed above. The transform creates an output column named Output column name. The format of the output column depends on your configuration using the following:

- Vector: Outputs a single column as a vector.
- Columns: Creates a new column for every feature. For example, if the output contains a year, month, and day, three separate columns are created for year, month, and day.

Additionally, you must choose an Embedding mode. For linear models and deep networks, we recommend choosing cyclic. For tree-based algorithms, we recommend choosing ordinal.

Format String

The Format string transforms contain standard string formatting operations. For example, you can use these operations to remove special characters, normalize string lengths, and update string casing.
This feature group contains the following transforms. All transforms return copies of the strings in the Input column and add the result to a new, output column.

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left pad</td>
<td>Left-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Right pad</td>
<td>Right-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Center (pad on either side)</td>
<td>Center-pad the string (add padding on both sides of the string) with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Prepend zeros</td>
<td>Left-fill a numeric string with zeros, up to a given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Strip left and right</td>
<td>Returns a copy of the string with the leading and trailing characters removed.</td>
</tr>
<tr>
<td>Strip characters from left</td>
<td>Returns a copy of the string with leading characters removed.</td>
</tr>
<tr>
<td>Strip characters from right</td>
<td>Returns a copy of the string with trailing characters removed.</td>
</tr>
<tr>
<td>Lower case</td>
<td>Convert all letters in text to lowercase.</td>
</tr>
<tr>
<td>Upper case</td>
<td>Convert all letters in text to uppercase.</td>
</tr>
<tr>
<td>Capitalize</td>
<td>Capitalize the first letter in each sentence.</td>
</tr>
<tr>
<td>Swap case</td>
<td>Converts all uppercase characters to lowercase and all lowercase characters to uppercase characters of the given string, and returns it.</td>
</tr>
<tr>
<td>Add prefix or suffix</td>
<td>Adds a prefix and a suffix the string column. You must specify at least one of Prefix and Suffix.</td>
</tr>
<tr>
<td>Remove symbols</td>
<td>Removes given symbols from a string. All listed characters are removed. Defaults to white space.</td>
</tr>
</tbody>
</table>

Handle Outliers

Machine learning models are sensitive to the distribution and range of your feature values. Outliers, or rare values, can negatively impact model accuracy and lead to longer training times. Use this feature group to detect and update outliers in your dataset.

When you define a Handle outliers transform step, the statistics used to detect outliers are generated on the data available in Data Wrangler when defining this step. These same statistics are used when running a Data Wrangler job.

Use the following sections to learn more about the transforms this group contains. You specify an Output name and each of these transforms produces an output column with the resulting data.
Robust standard deviation numeric outliers

This transform detects and fixes outliers in numeric features using statistics that are robust to outliers.

You must define an **Upper quantile** and a **Lower quantile** for the statistics used to calculate outliers. You must also specify the number of **Standard deviations** from which a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Standard Deviation Numeric Outliers

This transform detects and fixes outliers in numeric features using the mean and standard deviation.

You specify the number of **Standard deviations** a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Quantile Numeric Outliers

Use this transform to detect and fix outliers in numeric features using quantiles. You can define an **Upper quantile** and a **Lower quantile**. All values that fall above the upper quantile or below the lower quantile are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Min-Max Numeric Outliers

This transform detects and fixes outliers in numeric features using upper and lower thresholds. Use this method if you know threshold values that demark outliers.

You specify a **Upper threshold** and a **Lower threshold**, and if values fall above or below those thresholds respectively, they are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:
- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

### Replace Rare

When you use the **Replace rare** transform, you specify a threshold and Data Wrangler finds all values that meet that threshold and replaces them with a string that you specify. For example, you may want to use this transform to categorize all outliers in a column into an "Others" category.

- **Replacement string**: The string with which to replace outliers.
- **Absolute threshold**: A category is rare if the number of instances is less than or equal to this absolute threshold.
- **Fraction threshold**: A category is rare if the number of instances is less than or equal to this fraction threshold multiplied by the number of rows.
- **Max common categories**: Maximum not-rare categories that remain after the operation. If the threshold does not filter enough categories, those with the top number of appearances are classified as not rare. If set to 0 (default), there is no hard limit to the number of categories.

### Handle Missing Values

Missing values are a common occurrence in machine learning datasets. In some situations, it is appropriate to impute missing data with a calculated value, such as an average or categorically common value. You can process missing values using the **Handle missing values** transform group. This group contains the following transforms.

#### Fill Missing

Use the **Fill missing** transform to replace missing values with a **Fill value** you define.

#### Impute Missing

Use the **Impute missing** transform to create a new column that contains imputed values where missing values were found in input categorical and numerical data. The configuration depends on your data type.

For numeric data, choose an imputing strategy, the strategy used to determine the new value to impute. You can choose to impute the mean or the median over the values that are present in your dataset. Data Wrangler uses the value that it computes to impute the missing values.

For categorical data, Data Wrangler imputes missing values using the most frequent value in the column. To impute a custom string, use the **Fill missing** transform instead.

#### Add Indicator for Missing

Use the **Add indicator for missing** transform to create a new indicator column, which contains a Boolean "false" if a row contains a value, and "true" if a row contains a missing value.

#### Drop Missing

Use the **Drop missing** option to drop rows that contain missing values from the **Input column**.

### Manage Columns

You can use the following transforms to quickly update and manage columns in your dataset:
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop Column</td>
<td>Delete a column.</td>
</tr>
<tr>
<td>Duplicate Column</td>
<td>Duplicate a column.</td>
</tr>
<tr>
<td>Rename Column</td>
<td>Rename a column.</td>
</tr>
<tr>
<td>Move Column</td>
<td>Move a column's location in the dataset. Choose to move your column to the start or end of the dataset, before or after a reference column, or to a specific index.</td>
</tr>
</tbody>
</table>

### Manage Rows

Use this transform group to quickly perform sort and shuffle operations on rows. This group contains the following:

- **Sort**: Sort the entire dataframe by a given column. Select the check box next to *Ascending order* for this option; otherwise, deselect the check box and descending order is used for the sort.
- **Shuffle**: Randomly shuffle all rows in the dataset.

### Manage Vectors

Use this transform group to combine or flatten vector columns. This group contains the following transforms.

- **Assemble**: Use this transform to combine Spark vectors and numeric data into a single column. For example, you can combine three columns: two containing numeric data and one containing vectors. Add all the columns you want to combine in *Input columns* and specify a *Output column name* for the combined data.
- **Flatten**: Use this transform to flatten a single column containing vector data. The input column must contain PySpark vectors or array-like objects. You can control the number of columns created by specifying a *Method to detect number of outputs*. For example, if you select *Length of first vector*, the number of elements in the first valid vector or array found in the column determines the number of output columns that are created. All other input vectors with too many items are truncated. Inputs with too few items are filled with NaNs.

You also specify an *Output prefix*, which is used as the prefix for each output column.

### Process Numeric

Use the **Process Numeric** feature group to process numeric data. Each scalar in this group is defined using the Spark library. The following scalars are supported:

- **Standard Scaler**: Standardize the input column by subtracting the mean from each value and scaling to unit variance. To learn more, see the Spark documentation for `StandardScaler`.
- **Robust Scaler**: Scale the input column using statistics that are robust to outliers. To learn more, see the Spark documentation for `RobustScaler`.
- **Min Max Scaler**: Transform the input column by scaling each feature to a given range. To learn more, see the Spark documentation for `MinMaxScaler`.
- **Max Absolute Scaler**: Scale the input column by dividing each value by the maximum absolute value. To learn more, see the Spark documentation for `MaxAbsScaler`.
**Sampling**

After you’ve imported your data, you can use the Sampling transformer to take one or more samples of it. When you use the sampling transformer, Data Wrangler samples your original dataset.

You can choose one of the following sample methods:

- **Limit**: Samples the dataset starting from the first row up to the limit that you specify.
- **Randomized**: Takes a random sample of a size that you specify.
- **Stratified**: Takes a stratified random sample.

You can stratify a randomized sample to make sure that it represents the original distribution of the dataset.

You might be performing data preparation for multiple use cases. For each use case, you can take a different sample and apply a different set of transformations.

The following procedure describes the process of creating a random sample.

To take a random sample from your data.

1. Choose the + to the right of the dataset that you’ve imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. (Optional) Specify an integer for Random seed to create a reproducible sample.

The following procedure describes the process of creating a stratified sample.

To take a stratified sample from your data.

1. Choose the + to the right of the dataset that you’ve imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. For Stratify column, specify the name of the column that you want to stratify on.
7. (Optional) Specify an integer for Random seed to create a reproducible sample.

**Search and Edit**

Use this section to search for and edit specific patterns within strings. For example, you can find and update strings within sentences or documents, split strings by delimiters, and find occurrences of specific strings.

The following transforms are supported under Search and edit. All transforms return copies of the strings in the Input column and add the result to a new output column.
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Find substring</td>
<td>Returns the index of the first occurrence of the Substring for which you searched. You can start and end the search at Start and End respectively.</td>
</tr>
<tr>
<td>Find substring (from right)</td>
<td>Returns the index of the last occurrence of the Substring for which you searched. You can start and end the search at Start and End respectively.</td>
</tr>
<tr>
<td>Matches prefix</td>
<td>Returns a Boolean value if the string contains a given Pattern. A pattern can be a character sequence or regular expression. Optionally, you can make the pattern case sensitive.</td>
</tr>
<tr>
<td>Find all occurrences</td>
<td>Returns an array with all occurrences of a given pattern. A pattern can be a character sequence or regular expression.</td>
</tr>
<tr>
<td>Extract using regex</td>
<td>Returns a string that matches a given Regex pattern.</td>
</tr>
<tr>
<td>Extract between delimiters</td>
<td>Returns a string with all characters found between Left delimiter and Right delimiter.</td>
</tr>
<tr>
<td>Extract from position</td>
<td>Returns a string, starting from Start position in the input string, that contains all characters up to the start position plus Length.</td>
</tr>
<tr>
<td>Find and replace substring</td>
<td>Returns a string with all matches of a given Pattern (regular expression) replaced by Replacement string.</td>
</tr>
<tr>
<td>Replace between delimiters</td>
<td>Returns a string with the substring found between the first appearance of a Left delimiter and the last appearance of a Right delimiter replaced by Replacement string. If no match is found, nothing is replaced.</td>
</tr>
<tr>
<td>Replace from position</td>
<td>Returns a string with the substring between Start position and Start position plus Length replaced by Replacement string. If Start position plus Length is greater than the length of the replacement string, the output contains ....</td>
</tr>
<tr>
<td>Convert regex to missing</td>
<td>Converts a string to None if invalid and returns the result. Validity is defined with a regular expression in Pattern.</td>
</tr>
<tr>
<td>Split string by delimiter</td>
<td>Returns an array of strings from the input string, split by Delimiter, with up to Max number of splits (optional). The delimiter defaults to white space.</td>
</tr>
</tbody>
</table>

**Split data**

Use the Split data transform to split your dataset into two or three datasets. For example, you can split your dataset into a dataset used to train your model and a dataset used to test it. You can determine the
proportion of the dataset that goes into each split. For example, if you’re splitting one dataset into two datasets, the training dataset can have 80% of the data while the testing dataset has 20%.

Splitting your data into three datasets gives you the ability to create training, validation, and test datasets. You can see how well the model performs on the test dataset by dropping the target column.

Your use case determines how much of the original dataset each of your datasets get and the method you use to split the data. For example, you might want to use a stratified split to make sure that the distribution of the observations in the target column are the same across datasets. You can use the following split transforms:

- Randomized split — Each split is a random, non-overlapping sample of the original dataset. For larger datasets, using a randomized split might be computationally expensive and take longer than an ordered split.
- Ordered split – Splits the dataset based on the sequential order of the observations. For example, for an 80/20 train-test split, the first observations that make up 80% of the dataset go to the training dataset. The last 20% of the observations go to the testing dataset. Ordered splits are effective in keeping the existing order of the data between splits.
- Stratified split – Splits the dataset to make sure that the number of observations in the input column have proportional representation. For an input column that has the observations 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 3, an 80/20 split on the column would mean that approximately 80% of the 1s, 80% of the 2s, and 80% of the 3s go to the training set. About 20% of each type of observation go to the testing set.
- Split by key – Avoids data with the same key occurring in more than one split. For example, if you have a dataset with the column ‘customer_id’ and you’re using it as a key, no customer id is in more than one split.

After you split the data, you can apply additional transformations to each dataset. For most use cases, they aren’t necessary.

Data Wrangler calculates the proportions of the splits for performance. You can choose an error threshold to set the accuracy of the splits. Lower error thresholds more accurately reflect the proportions that you specify for the splits. If you set a higher error threshold, you get better performance, but lower accuracy.

For perfectly split data, set the error threshold to 0. You can specify a threshold between 0 and 1 for better performance. If you specify a value greater than 1, Data Wrangler interprets that value as 1.

If you have 10000 rows in your dataset and you specify an 80/20 split with an error of 0.001, you would get observations approximating one of the following results:

- 8010 observations in the training set and 1990 in the testing set
- 7990 observations in the training set and 2010 in the testing set

The number of observations for the testing set in the preceding example is in the interval between 8010 and 7990.

By default, Data Wrangler uses a random seed to make the splits reproducible. You can specify a different value for the seed to create a different reproducible split.

Randomized split

Use the following procedure to perform a randomized split on your dataset.

To split your dataset randomly, do the following

1. Choose the + next to the node containing the dataset that you’re splitting.
2. Choose Add transform.
3. Choose Split data.
4. (Optional) For Splits, specify the names and proportions of each split. The proportions must sum to 1.
5. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
6. (Optional) Specify a value for Error threshold other than the default value.
7. (Optional) Specify a value for Random seed.

Ordered split

Use the following procedure to perform an ordered split on your dataset.

To make an ordered split in your dataset, do the following.
1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose Add transform.
3. For Transform, choose Ordered split.
4. Choose Split data.
5. (Optional) For Splits, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
7. (Optional) Specify a value for Error threshold other than the default value.
8. (Optional) For Input column, specify a column with numeric values. Uses the values of the columns to infer which records are in each split. The smaller values are in one split with the larger values in the other splits.
9. (Optional) Select Handle duplicates to add noise to duplicate values and create a dataset of entirely unique values.
10. (Optional) Specify a value for Random seed.
12. Choose Add.

Stratified split

Use the following procedure to perform a stratified split on your dataset.

To make a stratified split in your dataset, do the following.
1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose Add transform.
3. Choose Split data.
4. For Transform, choose Stratified split.
5. (Optional) For Splits, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For Input column, specify a column with up to 100 unique values. Data Wrangler can’t stratify a column with more than 100 unique values.
8. (Optional) Specify a value for Error threshold other than the default value.
9. (Optional) Specify a value for Random seed to specify a different seed.
11. Choose Add.

Split by column keys

Use the following procedure to split by the column keys in your dataset.

To split by the column keys in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you’re splitting.
2. Choose Add transform.
3. Choose Split data.
4. For Transform, choose Split by key.
5. (Optional) For Splits, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For Key columns, specify the columns with values that you don’t want to appear in both datasets.
8. (Optional) Specify a value for Error threshold other than the default value.
10. Choose Add.

Parse Value as Type

Use this transform to cast a column to a new type. The supported Data Wrangler data types are:

• Long
• Float
• Boolean
• Date, in the format dd-MM-yyyy, representing day, month, and year respectively.
• String

Validate String

Use the Validate string transforms to create a new column that indicates that a row of text data meets a specified condition. For example, you can use a Validate string transform to verify that a string only contains lowercase characters. The following transforms are supported under Validate string.

The following transforms are included in this transform group. If a transform outputs a Boolean value, True is represented with a 1 and False is represented with a 0.
### Transform Data

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>String length</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Starts with</td>
<td>Returns True if a string starts will a specified prefix. Otherwise, returns False.</td>
</tr>
<tr>
<td>Ends with</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alphanumeric</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alpha (letters)</td>
<td>Returns True if a string only contains letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is digit</td>
<td>Returns True if a string only contains digits. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is space</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is title</td>
<td>Returns True if a string contains any white spaces. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is lowercase</td>
<td>Returns True if a string only contains lower case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is uppercase</td>
<td>Returns True if a string only contains upper case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is numeric</td>
<td>Returns True if a string only contains numbers. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is decimal</td>
<td>Returns True if a string only contains decimal numbers. Otherwise, returns False.</td>
</tr>
</tbody>
</table>

### Unnest JSON Data

If you have a .csv file, you might have values in your dataset that are JSON strings. Similarly, you might have nested data in columns of either a Parquet file or a JSON document.

Use the Flatten structured operator to separate the first level keys into separate columns. A first level key is a key that isn't nested within a value.

For example, you might have a dataset that has a person column with demographic information on each person stored as JSON strings. A JSON string might look like the following.

```
{"seq": 1,"name": {"first": "Nathaniel","last": "Ferguson"},"age": 59,"city": "Posbotno","state": "WV"}
```

The Flatten structured operator converts the following first level keys into additional columns in your dataset:

- seq
Data Wrangler puts the values of the keys as values under the columns. The following shows the column names and values of the JSON.

<table>
<thead>
<tr>
<th>seq, name,</th>
<th>age, city, state</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, {&quot;first&quot;: &quot;Nathaniel&quot;,&quot;last&quot;: &quot;Ferguson&quot;}, 59, Posbotno, WV</td>
<td></td>
</tr>
</tbody>
</table>

For each value in your dataset containing JSON, the Flatten structured operator creates columns for the first-level keys. To create columns for nested keys, call the operator again. For the preceding example, calling the operator creates the columns:

- name_first
- name_last

The following example shows the dataset that results from calling the operation again.

<table>
<thead>
<tr>
<th>seq, name,</th>
<th>age, city, state, name_first, name_last</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, {&quot;first&quot;: &quot;Nathaniel&quot;,&quot;last&quot;: &quot;Ferguson&quot;}, 59, Posbotno, WV, Nathaniel, Ferguson</td>
<td></td>
</tr>
</tbody>
</table>

Choose Keys to flatten on to specify the first-level keys that want to extract as separate columns. If you don't specify any keys, Data Wrangler extracts all the keys by default.

### Explode Array

Use Explode array to expand the values of the array into separate output rows. For example, the operation can take each value in the array, `[[1, 2, 3], [4, 5, 6], [7, 8, 9]]` and create a new column with the following rows:

- [1, 2, 3]
- [4, 5, 6]
- [7, 8, 9]

Data Wrangler names the new column, input_column_name_flatten.

You can call the Explode array operation multiple times to get the nested values of the array into separate output columns. The following example shows the result of calling the operation multiple times on a dataset with a nested array.

### Putting the values of a nested array into separate columns

<table>
<thead>
<tr>
<th>id</th>
<th>array</th>
<th>id</th>
<th>array_items</th>
<th>id</th>
<th>array_items_items</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>[[cat, dog], [bat, frog]]</td>
<td>1</td>
<td>[cat, dog]</td>
<td>1</td>
<td>cat</td>
</tr>
</tbody>
</table>
Amazon SageMaker Developer Guide

Analyze and Visualize

### Analyze and Visualize

Amazon SageMaker Data Wrangler includes built-in analyses that help you generate visualizations and data analyses in a few clicks. You can also create custom analyses using your own code.

You add an analysis to a dataframe by selecting a step in your data flow, and then choosing Add analysis. To access an analysis you’ve created, select the step that contains the analysis, and select the analysis.

All analyses are generated using 100,000 rows of your dataset.

You can add the following analysis to a dataframe:

- Data visualizations, including histograms and scatter plots.
- A quick summary of your dataset, including number of entries, minimum and maximum values (for numeric data), and most and least frequent categories (for categorical data).
- A quick model of the dataset, which can be used to generate an importance score for each feature.
- A target leakage report, which you can use to determine if one or more features are strongly correlated with your target feature.
- A custom visualization using your own code.

Use the following sections to learn more about these options.

### Histogram

Use histograms to see the counts of feature values for a specific feature. You can inspect the relationships between features using the Color by option. For example, the following histogram charts the distribution of user ratings of the best-selling books on Amazon from 2009–2019, colored by genre.
You can use the **Facet by** feature to create histograms of one column, for each value in another column. For example, the following diagram shows histograms of user reviews of best-selling books on Amazon if faceted by year.

**Scatter Plot**

Use the **Scatter Plot** feature to inspect the relationship between features. To create a scatter plot, select a feature to plot on the **X axis** and the **Y axis**. Both of these columns must be numeric typed columns.

You can color scatter plots by an additional column. For example, the following example shows a scatter plot comparing the number of reviews against user ratings of top-selling books on Amazon between 2009 and 2019. The scatter plot is colored by book genre.
Additionally, you can facet scatter plots by features. For example, the following image shows an example of the same review versus user rating scatter plot, faceted by year.

Table Summary

Use the Table Summary analysis to quickly summarize your data.

For columns with numerical data, including log and float data, a table summary reports the number of entries (count), minimum (min), maximum (max), mean, and standard deviation (stddev) for each column.

For columns with non-numerical data, including columns with string, Boolean, or date/time data, a table summary reports the number of entries (count), least frequent value (min), and most frequent value (max).
Quick Model

Use the **Quick Model** visualization to quickly evaluate your data and produce importance scores for each feature. A feature importance score indicates how useful a feature is at predicting a target label. The feature importance score is between [0, 1] and a higher number indicates that the feature is more important to the whole dataset. On the top of the quick model chart, there is a model score. A classification problem shows an F1 score. A regression problem has a mean squared error (MSE) score.

When you create a quick model chart, you select a dataset you want evaluated, and a target label against which you want feature importance to be compared. Data Wrangler does the following:

- Infers the data types for the target label and each feature in the dataset selected.
- Determines the problem type. Based on the number of distinct values in the label column, Data Wrangler determines if this is a regression or classification problem type. Data Wrangler sets a categorical threshold to 100. If there are more than 100 distinct values in the label column, Data Wrangler classifies it as a regression problem; otherwise, it is classified as a classification problem.
- Pre-processes features and label data for training. The algorithm used requires encoding features to vector type and encoding labels to double type.
- Trains a random forest algorithm with 70% of data. Spark's `RandomForestRegressor` is used to train a model for regression problems. The `RandomForestClassifier` is used to train a model for classification problems.
- Evaluates a random forest model with the remaining 30% of data. Data Wrangler evaluates classification models using an F1 score and evaluates regression models using an MSE score.
- Calculates feature importance for each feature using the Gini importance method.

The following image shows the user interface for the quick model feature.

![Quick Model Interface](image)

Target Leakage

Target leakage occurs when there is data in a machine learning training dataset that is strongly correlated with the target label, but is not available in real-world data. For example, you may have a column in your dataset that serves as a proxy for the column you want to predict with your model.

When you use the **Target Leakage** analysis, you specify the following:

- **Target**: This is the feature about which you want your ML model to be able to make predictions.
• **Problem type**: This is the ML problem type on which you are working. Problem type can either be **classification** or **regression**.

• *(Optional)* **Max features**: This is the maximum number of features to present in the visualization, which shows features ranked by their risk of being target leakage.

For classification, the target leakage analysis uses the area under the receiver operating characteristic, or AUC - ROC curve for each column, up to **Max features**. For regression, it uses a coefficient of determination, or R2 metric.

The AUC - ROC curve provides a predictive metric, computed individually for each column using cross-validation, on a sample of up to around 1000 rows. A score of 1 indicates perfect predictive abilities, which often indicates target leakage. A score of 0.5 or lower indicates that the information on the column could not provide, on its own, any useful information towards predicting the target. Although it can happen that a column is uninformative on its own but is useful in predicting the target when used in tandem with other features, a low score could indicate the feature is redundant.

For example, the following image shows a target leakage report for a diabetes classification problem, that is, predicting if a person has diabetes or not. An AUC - ROC curve is used to calculate the predictive ability of five features, and all are determined to be safe from target leakage.

![Target Leakage Report for Diabetes Classification](image)

**Multicollinearity**

Multicollinearity is a circumstance where two or more predictor variables are related to each other. The predictor variables are the features in your dataset that you're using to predict a target variable. When you have multicollinearity, the predictor variables are not only predictive of the target variable, but also predictive of each other.

You can use the **Variance Inflation Factor (VIF)**, **Principal Component Analysis (PCA)**, or **Lasso feature selection** as measures for the multicollinearity in your data. For more information, see the following.

**Variance Inflation Factor (VIF)**

The Variance Inflation Factor (VIF) is a measure of collinearity among variable pairs. Data Wrangler returns a VIF score as a measure of how closely the variables are related to each other. A VIF score is a positive number that is greater than or equal to 1.

A score of 1 means that the variable is uncorrelated with the other variables. Scores greater than 1 indicate higher correlation.
Theoretically, you can have a VIF score with a value of infinity. Data Wrangler clips high scores to 50. If you have a VIF score greater than 50, Data Wrangler sets the score to 50.

You can use the following guidelines to interpret your VIF scores:

- A VIF score less than or equal to 5 indicates that the variables are moderately correlated with the other variables.
- A VIF score greater than or equal to 5 indicates that the variables are highly correlated with the other variables.

Principle Component Analysis (PCA)

Principal Component Analysis (PCA) measures the variance of the data along different directions in the feature space. The feature space consists of all the predictor variables that you use to predict the target variable in your dataset.

For example, if you're trying to predict who survived on the *RMS Titanic* after it hit an iceberg, your feature space can include the passengers' age, gender, and the fare that they paid.

From the feature space, PCA generates an ordered list of variances. These variances are also known as singular values. The values in the list of variances are greater than or equal to 0. We can use them to determine how much multicollinearity there is in our data.

When the numbers are roughly uniform, the data has very few instances of multicollinearity. When there is a lot of variability among the values, we have many instances of multicollinearity. Before it performs PCA, Data Wrangler normalizes each feature to have a mean of 0 and a standard deviation of 1.

**Note**

PCA in this circumstance can also be referred to as Singular Value Decomposition (SVD).

Lasso feature selection

Lasso feature selection uses the L1 regularization technique to only include the most predictive features in your dataset.

For both classification and regression, the regularization technique generates a coefficient for each feature. The absolute value of the coefficient provides an importance score for the feature. A higher importance score indicates that it is more predictive of the target variable. A common feature selection method is to use all the features that have a non-zero lasso coefficient.

**Detect Anomalies In Time Series Data**

You can use the anomaly detection visualization to see outliers in your time series data. To understand what determines an anomaly, you need to understand that we decompose the time series into a predicted term and an error term. We treat the seasonality and trend of the time series as the predicted term. We treat the residuals as the error term.

For the error term, you specify a threshold as the number of standard of deviations the residual can be away from the mean for it to be considered an anomaly. For example, you can specify a threshold as being 3 standard deviations. Any residual greater than 3 standard deviations away from the mean is an anomaly.

You can use the following procedure to perform an **Anomaly detection** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the +, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Anomaly detection**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

**Seasonal Trend Decomposition In Time Series Data**

You can determine whether there's seasonality in your time series data by using the Seasonal Trend Decomposition visualization. We use the STL (Seasonal Trend decomposition using LOESS) method to perform the decomposition. We decompose the time series into its seasonal, trend, and residual components. The trend reflects the long term progression of the series. The seasonal component is a signal that recurs in a time period. After removing the trend and the seasonal components from the time series, you have the residual.

You can use the following procedure to perform a **Seasonal-Trend decomposition** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the +, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Seasonal-Trend decomposition**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

**Bias Report**

You can use the bias report in Data Wrangler to uncover potential biases in your data. To generate a bias report, you must specify the target column, or **Label**, that you want to predict and a **Facet**, or the column that you want to inspect for biases.

**Label**: The feature about which you want a model to make predictions. For example, if you are predicting customer conversion, you may select a column containing data on whether or not a customer has placed an order. You must also specify whether this feature is a label or a threshold. If you specify a label, you must specify what a **positive outcome** looks like in your data. In the customer conversion example, a positive outcome may be a 1 in the orders column, representing the positive outcome of a customer placing an order within the last three months. If you specify a threshold, you must specify a lower bound defining a positive outcome. For example, if your customer orders columns contains the number of orders placed in the last year, you may want to specify 1.

**Facet**: The column that you want to inspect for biases. For example, if you are trying to predict customer conversion, your facet may be the age of the customer. You may choose this facet because you believe that your data is biased toward a certain age group. You must identify whether the facet is measured as a value or threshold. For example, if you wanted to inspect one or more specific ages, you select **Value** and specify those ages. If you want to look at an age group, you select **Threshold** and specify the threshold of ages you want to inspect.

After you select your feature and label, you select the types of bias metrics you want to calculate.

To learn more, see **Generate reports for bias in pre-training data**.

**Create Custom Visualizations**

You can add an analysis to your Data Wrangler flow to create a custom visualization. Your dataset, with all the transformations you've applied, is available as a Pandas DataFrame. Data Wrangler uses the df variable to store the dataframe. You access the dataframe by calling the variable.
You must provide the output variable, chart, to store an Altair output chart. For example, you can use the following code block to create a custom histogram using the Titanic dataset.

```python
import altair as alt
df = df.iloc[:30]
df = df.rename(columns={"Age": "value"})
df = df.assign(count=df.groupby('value').value.transform('count'))
df = df["value", "count"]
base = alt.Chart(df)
bar = base.mark_bar().encode(x=alt.X('value', bin=True, axis=None), y=alt.Y('count'))
rule = base.mark_rule(color='red').encode(
x='mean(value):Q',
size=alt.value(5))
chart = bar + rule
```

To create a custom visualization:

1. Next to the node containing the transformation that you'd like to visualize, choose the +.
2. Choose Add analysis.
3. For Analysis type, choose Custom Visualization.
4. For Analysis name, specify a name.
5. Enter your code in the code box.
6. Choose Preview to preview your visualization.
7. Choose Save to add your visualization.

If you don’t know how to use the Altair visualization package in Python, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of visualization snippets. To use a visualization snippet, choose Search example snippets and specify a query in the search bar.
The following example uses the **Binned scatterplot** code snippet. It plots a histogram for 2 dimensions. The snippets have comments to help you understand the changes that you need to make to the code. You usually need to specify the column names of your dataset in the code.

```python
import altair as alt

# Specify the number of top rows for plotting
df = df.head(rows_number)
# You can also choose bottom rows or randomly sampled rows
# df = df.tail(rows_number)
# df = df.sample(rows_number)

chart = (alt.Chart(df)
  .mark_circle()
  .encode(
    # Specify the column names for binning and number of bins for X and Y axis
    x=alt.X("col1:Q", bin=alt.Bin(maxbins=20)),
    y=alt.Y("col2:Q", bin=alt.Bin(maxbins=20)),
    size="count()",
  )
)
```

# :Q specifies that label column has quantitative type.
# For more details on Altair typing refer to
# https://altair-viz.github.io/user_guide/encoding.html#encoding-data-types

### Reusing Data Flows for Different Datasets

For Amazon Simple Storage Service (Amazon S3) data sources, you can create and use parameters. A parameter is a variable that you've saved in your Data Wrangler flow. Its value can be any portion of the data source's Amazon S3 path. Use parameters to quickly change the data that you're importing into a Data Wrangler flow or exporting to a processing job.

After you created a Data Wrangler flow, you might have trained a model on the data that you've transformed. For datasets that have the same schema, you can use parameters to apply the same transformations on a different dataset and train a different model. You can use the new datasets to perform inference with your model or you could be using them to retrain your model.

In general, parameters have the following attributes:

- **Name** – The name you specify for the parameter
- **Type** – The type of value that the parameter represents
- **Default value** – The value of the parameter when you don't specify a new value

**Note**

Datet ime parameters have a time range attribute that they use as the default value.

Data Wrangler uses curly braces, {{}}, to indicate that a parameter is being used in the Amazon S3 path. For example, you can have a URL such as `s3://DOC-EXAMPLE-BUCKET1/{{example_parameter_name}}/example-dataset.csv`

You create a parameter when you're editing the Amazon S3 data source that you've imported. You can set any portion of the file path to a parameter value. You can set the parameter value to either a value or a pattern. The following are the available parameter value types in the Data Wrangler flow:
• Number
• String
• Pattern
• Datetime

**Note**
You can't create a pattern parameter or a datetime parameter for the name of the bucket in the Amazon S3 path.

You must set a number as the default value of a number parameter. You can change the value of the parameter to a different number when you're editing a parameter or when you're launching a processing job. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a number parameter named `number_parameter` in the place of 1. Your S3 path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-{{number_parameter}}.csv`. The path continues to point to the `example-file-1.csv` dataset until you change the value of the parameter. If you change the value of `number_parameter` to 2 the path is now `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-2.csv`. You can import `example-file-2.csv` into Data Wrangler if you've uploaded the file to that Amazon S3 location.

A string parameter stores a string as its default value. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a string parameter named `string_parameter` in the place of the filename, `example-file-1.csv`. The path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/{{string_parameter}}`. It continues to match `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv` until you change the value of the parameter.

Instead of specifying the filename as a string parameter, you can create a string parameter using the entire Amazon S3 path. You can specify a dataset from any Amazon S3 location in the string parameter.

A pattern parameter stores a regular expression (Python REGEX) string as its default value. You can use a pattern parameter to import multiple data files at the same time. To import more than one object at a time, specify a parameter value that matches the Amazon S3 objects that you're importing.

You can also create a pattern parameter for the following datasets:

• `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`
• `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-2.csv`
• `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-10.csv`
• `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-0123.csv`

For `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`, you can create a pattern parameter in the place of 1, and set the default value of the parameter to \d+. The \d+ REGEX string matches any one or more decimal digits. If you create a pattern parameter named `pattern_parameter`, your S3 path appears as `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-{{pattern_parameter}}.csv`.

You can also use pattern parameters to match all CSV objects within your bucket. To match all objects in a bucket, create a pattern parameter with the default value of .* and set the path to `s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv`. The .* character matches any string character in the path.

The `s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv` path can match the following datasets.

• `example-file-1.csv`
- other-example-file.csv
- example-file-a.csv

A datetime parameter stores the format with the following information:

- A format for parsing strings inside an Amazon S3 path.
- A relative time range to limit the datetime values that match

For example, in the Amazon S3 file path, `s3://DOC-EXAMPLE-BUCKET/2020/01/01/example-dataset.csv`, 2020/01/01 represents a datetime in the format of year/month/day. You can set the parameter's time range to an interval such as 1 year or 24 hours. An interval of 1 year matches all S3 paths with datetimes that fall between the current time and the time exactly a year before the current time. The current time is the time when you start exporting the transformations that you've made to the data. For more information about exporting data, see Export (p. 1015). If the current date is 2022/01/01 and the time range is 1 year, the S3 path matches datasets such as the following:

- `s3://DOC-EXAMPLE-BUCKET/2021/01/01/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET/2021/06/30/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET/2021/12/31/example-dataset.csv`

The datetime values within a relative time range change as time passes. The S3 paths that fall within the relative time range might also differ.

For the Amazon S3 file path, `s3://DOC-EXAMPLE-BUCKET/20220101/example-dataset.csv`, 20220101 is an example of a path that can become a datetime parameter.

To view a table of all parameters that you've created in Data Wrangler flow, choose the `{{}}` to the right of the text box containing the Amazon S3 path. If you no longer need a parameter that you've created, you can edit or delete. To edit or delete a parameter, choose icons to the right of the parameter.

**Important**
Before you delete a parameter, make sure that you haven't used it anywhere in your Data Wrangler flow. Deleted parameters that are still within the flow cause errors.

You can create parameters for any step of your Data Wrangler flow. You can edit or delete any parameter that you create. If the parameter has transformations that are no longer relevant to your use case, you can modify them.

The following sections provide additional examples and general guidance on using parameters. You can use the sections to understand the parameters that work best for you.

**Note**
The following sections contain procedures that use the Data Wrangler interface to override the parameters and create a processing job.
You can also override the parameters by using the following procedures.

To export your Data Wrangler flow and override the value of a parameter, do the following.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose the location where you're exporting the data.
4. Under parameter_overrides, specify different values for the parameters that you've created.
5. Run the Jupyter Notebook.
Applying a Data Wrangler flow to files using patterns

You can use parameters to apply transformations in your Data Wrangler flow to different files that match a pattern in the Amazon S3 URI path. This helps you specify the files in your S3 bucket that you want to transform with high specificity. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`. Different datasets named `example-dataset.csv` are stored under many different example prefixes. The prefixes might also be numbered sequentially. You can create patterns for the numbers in the Amazon S3 URI. Pattern parameters use REGEX to select any number of files that match the pattern of the expression. The following are REGEX patterns that might be useful:

- .* – Matches zero or more of any character, except newline characters
- .+ – Matches one or more of any character, excluding newline characters
- \d+ – Matches one or more of any digit
- \w+ – Matches one or more of any alphanumeric character
- [abc-\_]{2,4} – Matches a string two, three, or four characters composed of the set of characters provided within a set of brackets
- abc|def – Matches one string or another. For example, the operation matches either abc or def

You can replace each number in the following paths with a single parameter that has a value of `\d+`.

- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-3/example-prefix-4/example-prefix-5/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-8/example-prefix-12/example-prefix-13/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-4/example-prefix-9/example-prefix-137/example-dataset.csv`

The following procedure creates a pattern parameter for a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create a pattern parameter, do the following.

1. Next to the dataset that you've imported, choose **Edit dataset**.
2. Highlight the 0 in `example-prefix-0`.
3. Specify values for the following fields:
   - Name – A name for parameter
   - Type – Pattern
   - Value – `\d+` a regular expression that corresponds to one or more digits
4. Choose **Create**.
5. Replace the 1 and the 2 in S3 URI path with the parameter. The path should have the following format `s3://DOC-EXAMPLE-BUCKET1/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-dataset.csv`

The following is a general procedure for creating a pattern parameter.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the portion of the URI that you're using as the value of the pattern parameter.
4. Choose **Create custom parameter**.
5. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – **Pattern**
   - **Value** – A regular expression containing the pattern that you'd like to store.

6. Choose **Create**.

**Applying a Data Wrangler flow to files using numeric values**

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

You might have the transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix-1`. You might want to apply the same transformations to `example-dataset.csv` that falls under `example-prefix-10` or `example-prefix-20`.

You can create a parameter that stores the value 1. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create numeric parameters for `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create parameters for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the number in an example prefix of `example-prefix-number`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **Integer**.
7. For **Value**, specify the number.
8. Create parameters for the remaining numbers by repeating the procedure.

After you've created the parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see **Export** (p. 1015).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following.

1. From your Data Wrangler flow, choose **Create job**.
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.

Applying a Data Wrangler flow to files using strings

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`.

You might have transformations from your Data Wrangler flow that you’ve applied to datasets under `example-prefix`. You might want to apply the same transformations to `example-dataset.csv` under another `example-prefix` or `example-prefix-20`.

You can create a parameter that stores the value `example-prefix`. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create a string parameter for `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`.

To create a parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you’ve imported, choose Edit dataset.
3. Highlight the example prefix, example-prefix.
4. Choose Create custom parameter.
5. For Name, specify a name for the parameter.
6. For Type, choose String.
7. For Value, specify the prefix.

After you've created the parameter, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 1015).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you’ve created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose Create job
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose Configure job.
4. Choose Parameters.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.

Applying a Data Wrangler flow to different datetime ranges

Use datetime parameters to apply transformations in your Data Wrangler flow to different time ranges. Highlight the portion of the Amazon S3 URI that has a timestamp and create a parameter for it.
When you create a parameter, you specify a time range from the current time to a time in the past. For example, you might have an Amazon S3 URI that looks like the following: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv. You can save 2022/05/15 as a datetime parameter. If you specify a year as the time range, the time range includes the moment that you run the processing job containing the datetime parameter and the time exactly one year ago. If the moment you're running the processing job is September 6th, 2022 or 2022/09/06, the time ranges can include the following:

- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/03/15/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/01/08/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/07/31/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2021/09/07/example-dataset.csv

The transformations in the Data Wrangler flow apply to all of the preceding prefixes. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow. To apply the transformations to datasets within a different time range, do the following:

1. Create a destination node containing all the transformations that you'd like to use.
2. Create a Data Wrangler job.
3. Configure the job to use a different time range for the parameter. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow.

For more information about destination nodes and Data Wrangler jobs, see Export (p. 1015).

The following procedure creates a datetime parameter for the Amazon S3 path: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv. To create a datetime parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose Edit dataset.
3. Highlight the portion of the URI that you're using as the value of the datetime parameter.
4. Choose Create custom parameter.
5. For Name, specify a name for the parameter.
6. For Type, choose Datetime.

   **Note**
   By default, Data Wrangler selects Predefined, which provides a dropdown menu for you to select a date format. However, the timestamp format that you're using might not be available. Instead of using Predefined as the default option, you can choose Custom and specify the timestamp format manually.

7. For Date format, open the dropdown menu following Predefined and choose yyyy/MM/dd. The format, yyyy/MM/dd, corresponds to the year/month/day of the timestamp.
8. For Timezone, choose a time zone.

   **Note**
   The data that you're analyzing might have time stamps taken in a different time zone from your time zone. Make sure that the time zone that you select matches the time zone of the data.

9. For Time range, specify the time range for the parameter.
10. (Optional) Enter a description to describe how you're using the parameter.
11. Choose Create.
After you've created the datetime parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 1015).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a datetime parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose Create job
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose Configure job.
4. Choose Parameters.
5. Choose the name of the datetime parameter that you've created.
6. For Time range, change the time range for the datasets.
7. Choose Run.

Export

In your Data Wrangler flow, you can export some or all of the transformations that you've made to your data processing pipelines.

A Data Wrangler flow is the series of data preparation steps that you've performed on your data. In your data preparation, you perform one or more transformations to your data. Each transformation is done using a transform step. The flow has a series of nodes that represent the import of your data and the transformations that you've performed. For an example of nodes, see the following image.

The preceding image shows a Data Wrangler flow with two nodes. The Source - sampled node shows the data source from which you've imported your data. The Data types node indicates that Data Wrangler has performed a transformation to convert the dataset into a usable format.
Each transformation that you add to the Data Wrangler flow appears as an additional node. For information on the transforms that you can add, see Transform Data (p. 959). The following image shows a Data Wrangler flow that has a Rename-column node to change the name of a column in a dataset.

You can export your data transformations to the following:

- Amazon S3
- SageMaker Pipelines
- Amazon SageMaker Feature Store
- Python Code

**Important**

We recommend that you use the IAM AmazonSageMakerFullAccess managed policy to grant AWS permission to use Data Wrangler. If you don't use the managed policy, you can use an IAM policy that gives Data Wrangler access to an Amazon S3 bucket. For more information on the policy, see Security and Permissions (p. 1040).

When you export your data flow, you're charged for the AWS resources that you use. You can use cost allocation tags to organize and manage the costs of those resources. You create these tags for your user-profile and Data Wrangler automatically applies them to the resources used to export the data flow. For more information, see Using Cost Allocation Tags.

### Export to Amazon S3

Data Wrangler gives you the ability to export your data to a location within an Amazon S3 bucket. You can specify the location using one of the following methods:

- Destination node – Where Data Wrangler stores the data after it has processed it.
- Export to – Exports the data resulting from a transformation to Amazon S3.
- Export data – For small datasets, can quickly export the data that you've transformed.

Use the following sections to learn more about each of these methods.

#### Destination Node

If you want to output a series of data processing steps that you've performed to Amazon S3, you create a destination node. A destination node tells Data Wrangler where to store the data after you've processed it. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to Amazon S3.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

You can use multiple destination nodes to export different transformations or sets of transformations. The following example shows two destination nodes in a single Data Wrangler flow.
You can use the following procedure to create destination nodes and export them to an Amazon S3 bucket.

To export your data flow, you create destination nodes and a Data Wrangler job to export the data. Creating a Data Wrangler job starts a SageMaker processing job to export your flow. You can choose the destination nodes that you want to export after you've created them.

**Note**
You can choose **Create job** in the Data Wrangler flow to view the instructions to use a processing job.

Use the following procedure to create destination nodes.

1. Choose the + next to the nodes that represent the transformations that you want to export.
2. Choose **Add destination**.
3. Choose Amazon S3.

4. Specify the following fields:
   - **Dataset name** – The name that you specify for the dataset that you're exporting.
   - **File type** – The format of the file that you're exporting.
   - **Delimiter** (CSV only) – The value used to separate other values.
   - **Compression** – The compression method used to reduce the file size. You can use the following compression methods:
5. **Choose Add destination.**

Use the following procedure to create a processing job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

**Note**
You can choose **Create job** in the Data Wrangler flow to view the instructions for creating a processing job.

1. **Choose Create job.** The following image shows the pane that appears after you select **Create job.**

2. For **Job name**, specify the name of the export job.
3. Choose the destination nodes that you want to export.
4. (Optional) Specify a AWS KMS key ARN. A AWS KMS key is a cryptographic key that you can use to protect your data. For more information about AWS KMS keys, see **AWS Key Management Service.**
5. (Optional) Under **Trained parameters.** choose **Refit** if you've done the following:
   - Sampled your dataset
   - Applied a transform that uses your data to create a new column in the dataset
For more information about refitting the transformations you've made to an entire dataset, see Refit Transforms to The Entire Dataset and Export Them (p. 1031).

6. Choose Configure job. The following image shows the Configure job page.

![Configure job page](image)

7. (Optional) Configure the Data Wrangler job. You can make the following configurations:
   - Job configuration
   - Spark memory configuration
   - Network configuration
   - Tags
   - Parameters
   - Associate Schedules

Export to

As an alternative to using a destination node, you can use the Export to option to export your Data Wrangler flow to Amazon S3 using a Jupyter notebook. You can choose any data node in your Data
Wrangler flow and export it. Exporting the data node exports the transformation that the node represents and the transformations that precede it.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Amazon S3.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose Amazon S3 (via Jupyter Notebook).
4. Run the Jupyter notebook.

When you run the notebook, it exports your data flow (.flow file) in the same AWS Region as the Data Wrangler flow.

The notebook provides options that you can use to configure the processing job and the data that it outputs.

**Important**

We provide you with job configurations to configure the output of your data. For the partitioning and driver memory options, we strongly recommend that you don’t specify a configuration unless you already have knowledge about them.

Under **Job Configurations**, you can configure the following:

- **output_content_type** – The content type of the output file. Uses CSV as the default format, but you can specify Parquet.
- **delimiter** – The character used to separate values in the dataset when writing to a CSV file.
- **compression** – If set, compresses the output file. Uses gzip as the default compression format.
- **num_partitions** – The number of partitions or files that Data Wrangler writes as the output.
- **partition_by** – The names of the columns that you use to partition the output.

To change the output file format from CSV to Parquet, change the value from "CSV" to "Parquet". For the rest of the preceding fields, uncomment the lines containing the fields that you want to specify.

Under **(Optional) Configure Spark Cluster Driver Memory** you can configure Spark properties for the job, such as the Spark driver memory, in the config dictionary.
The following shows the config dictionary.

```python
config = json.dumps({
    "Classification": "spark-defaults",
    "Properties": {
        "spark.driver.memory": f"{driver_memory_in_mb}m",
    }
})
```

To apply the configuration to the processing job, uncomment the following lines:

```python
# data_sources.append(ProcessingInput(
#     source=config_s3_uri,
#     destination="/opt/ml/processing/input/conf",
#     input_name="spark-config",
#     s3_data_type="S3Prefix",
#     s3_input_mode="File",
#     s3_data_distribution_type="FullyReplicated"
# ))
```

Export data

If you have a transformation on a small dataset that you want to export quickly, you can use the **Export data** method. When you start choose **Export data**, Data Wrangler works synchronously to export the data that you've transformed to Amazon S3. You can't use Data Wrangler until either it finishes exporting your data or you cancel the operation.

For information on using the **Export data** method in your Data Wrangler flow, see the following procedure.

To use the **Export data** method:

1. Choose a node in your Data Wrangler flow by opening (double-clicking on) it.
2. Configure how you want to export the data.
3. Choose **Export data**.
When you export your data flow to an Amazon S3 bucket, Data Wrangler stores a copy of the flow file in the S3 bucket. It stores the flow file under the `data_wrangler_flows` prefix. If you use the default Amazon S3 bucket to store your flow files, it uses the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored in `sagemaker-us-east-1-111122223333`. In this example, your .flow files created in us-east-1 are stored in `s3://sagemaker-region-account number/data_wrangler_flows/`.

**Export to SageMaker Pipelines**

When you want to build and deploy large-scale machine learning (ML) workflows, you can use SageMaker Pipelines to create workflows that manage and deploy SageMaker jobs. With SageMaker Pipelines, you can build workflows that manage your SageMaker data preparation, model training, and model deployment jobs. You can use the first-party algorithms that SageMaker offers by using SageMaker Pipelines. For more information on SageMaker Pipelines, see [SageMaker Pipelines](#).

When you export one or more steps from your data flow to SageMaker Pipelines, Data Wrangler creates a Jupyter notebook that you can use to define, instantiate, run, and manage a pipeline.

**Use a Jupyter Notebook to Create a Pipeline**

Use the following procedure to create a Jupyter notebook to export your Data Wrangler flow to SageMaker Pipelines.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to SageMaker Pipelines.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.

You can use the Jupyter notebook that Data Wrangler produces to define a pipeline. The pipeline includes the data processing steps that are defined by your Data Wrangler flow.
You can add additional steps to your pipeline by adding steps to the steps list in the following code in the notebook:

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[instance_type, instance_count],
    steps=[step_process], #Add more steps to this list to run in your Pipeline
)
```

For more information on defining pipelines, see Define SageMaker Pipeline.

### Export to an Inference Endpoint

Use your Data Wrangler flow to process data at the time of inference. You can create a SageMaker serial inference pipeline from your Data Wrangler flow and a machine learning model. You can either use your own model or use the notebook we provide to train one with Amazon SageMaker Autopilot or XGBoost using the data that you've transformed in your Data Wrangler flow.

The pipeline provides the ability to perform either batch or real-time inference. You can also add the Data Wrangler flow to SageMaker Model Registry. For more information about hosting models, see Host multiple models in one container behind one endpoint (p. 1987).

When you export one or more steps from your data flow to an inference endpoint, Data Wrangler creates a Jupyter notebook that you can use to define, instantiate, run, and manage the inference pipeline.

**Use a Jupyter Notebook to create an inference endpoint**

Use the following procedure to export your Data Wrangler flow to create an inference pipeline.

To create an inference using a Jupyter notebook, do the following.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.

### Export to Python Code

To export all steps in your data flow to a Python file that you can manually integrate into any data processing workflow, use the following procedure.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Python Code.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.
You might need to configure the Python script to make it run in your pipeline. For example, if you’re running a Spark environment, make sure that you are running the script from an environment that has permission to access AWS resources.

Export to Amazon SageMaker Feature Store

You can use Data Wrangler to export features you’ve created to Amazon SageMaker Feature Store. A feature is a column in your dataset. Feature Store is a centralized store for features and their associated metadata. You can use Feature Store to create, share, and manage curated data for machine learning (ML) development. Centralized stores make your data more discoverable and reusable. For more information about Feature Store, see Amazon SageMaker Feature Store.

A core concept in Feature Store is a feature group. A feature group is a collection of features, their records (observations), and associated metadata. It's similar to a table in a database.

You can use Data Wrangler to do one of the following:

- Update an existing feature group with new records. A record is an observation in the dataset.
- Create a new feature group from a node in your Data Wrangler flow. Data Wrangler adds the observations from your datasets as records in your feature group.

If you're updating an existing feature group, your dataset's schema must match the schema of the feature group. All the records in the feature group are replaced with the observations in your dataset.

You can use either a Jupyter notebook or a destination node to update your feature group with the observations in the dataset.

If your feature groups with the Iceberg table format have a custom offline store encryption key, make sure you grant the IAM that you're using for the Amazon SageMaker Processing job permissions to use it. At a minimum, you must grant it permissions to encrypt the data that you're writing to Amazon S3. To grant the permissions, give the IAM role the ability to use the GenerateDataKey. For more information about granting IAM roles permissions to use AWS KMS keys see https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html
Destination Node

If you want to output a series of data processing steps that you've performed to a feature group, you can create a destination node. When you create and run a destination node, Data Wrangler updates a feature group with your data. You can also create a new feature group from the destination node UI. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to the feature group.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

Use the following procedure to create a destination node to update a feature group with the observations from your dataset.

To update a feature group using a destination node, do the following.

**Note**
You can choose Create job in the Data Wrangler flow to view the instructions for using a processing job to update the feature group.

1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under Add destination, choose SageMaker Feature Store.
3. Choose (double-click) the feature group. Data Wrangler checks whether the schema of the feature group matches the schema of the data that you're using to update the feature group.
4. (Optional) Select Export to offline store only for feature groups that have both an online store and an offline store. This option only updates the offline store with observations from your dataset.
5. After Data Wrangler validates the schema of your dataset, choose Add.

Use the following procedure to create a new feature group with data from your dataset.

You can store your feature group in one of the following ways:

- Online – Low-latency, high-availability cache for a feature group that provides real-time lookup of records. The online store allows quick access to the latest value for a record in a feature group.
- Offline – Stores data for your feature group in an Amazon S3 bucket. You can store your data offline when you don't need low-latency (sub-second) reads. You can use an offline store for features used in data exploration, model training, and batch inference.
- Both online and offline – Stores your data in both an online store and an offline store.
To create a feature group using a destination node, do the following.

1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under Add destination, choose SageMaker Feature Store.
3. Choose Create Feature Group.
4. In the following dialog box, if your dataset doesn't have an event time column, select Create "EventTime" column.
5. Choose Next.
6. Choose Copy JSON Schema. When you create a feature group, you paste the schema into the feature definitions.
7. Choose Create.
8. For Feature group name, specify a name for your feature group.
9. For Description (optional), specify a description to make your feature group more discoverable.
10. To create a feature group for an online store, do the following.
   a. Select Enable storage online.
   b. For Online store encryption key, specify an AWS managed encryption key or an encryption key of your own.
11. To create a feature group for an offline store, do the following.
   a. Select Enable storage offline. Specify values for the following fields:
      • S3 bucket name – The name of the Amazon S3 bucket that stores the feature group.
      • (Optional) Dataset directory name – The Amazon S3 prefix that you're using to store the feature group.
      • IAM Role ARN – The IAM role that has access to Feature Store.
      • Table Format – Table format of your offline store. You can specify Glue or Iceberg. Glue is the default format.
      • Offline store encryption key – By default, Feature Store uses an AWS Key Management Service managed key, but you can use the field to specify a key of your own.
   b. Specify values for the following fields:
      • S3 bucket name – The name of the bucket storing the feature group.
      • (Optional) Dataset directory name – The Amazon S3 prefix that you're using to store the feature group.
      • IAM Role ARN – The IAM role that has access to feature store.
      • Offline store encryption key – By default, Feature Store uses an AWS managed key, but you can use the field to specify a key of your own.
12. Choose Continue.
13. Choose JSON.
14. Remove the placeholder brackets in the window.
15. Paste the JSON text from Step 6.
16. Choose Continue.
17. For RECORD IDENTIFIER FEATURE NAME, choose the column in your dataset that has unique identifiers for each record in your dataset.
18. For EVENT TIME FEATURE NAME, choose the column with the timestamp values.
19. Choose Continue.
20. (Optional) Add tags to make your feature group more discoverable.
21. Choose Continue.
22. Choose Create feature group.
23. Navigate back to your Data Wrangler flow and choose the refresh icon next to the Feature Group search bar.

**Note**
If you've already created a destination node for a feature group within a flow, you can't create another destination node for the same feature group. If you want to create another destination node for the same feature group, you must create another flow file.

Use the following procedure to create a Data Wrangler job.

Create a job from the Data flow page and choose the destination nodes that you want to export.

1. Choose Create job. The following image shows the pane that appears after you select Create job.
2. For Job name, specify the name of the export job.
3. Choose the destination nodes that you want to export.
4. (Optional) For Output KMS Key, specify an ARN, ID, or alias of an AWS KMS key. A KMS key is a cryptographic key. You can use the key to encrypt the output data from the job. For more information about AWS KMS keys, see AWS Key Management Service.
5. The following image shows the Configure job page with the Job configuration tab open.
(Optional) Under **Trained parameters**, choose **Refit** if you've done the following:

- Sampled your dataset
- Applied a transform that uses your data to create a new column in the dataset

For more information about refitting the transformations you've made to an entire dataset, see *Refit Transforms to The Entire Dataset and Export Them* (p. 1031).

6. Choose **Configure job**.
7. (Optional) Configure the Data Wrangler job. You can make the following configurations:

- **Job configuration**
- **Spark memory configuration**
- **Network configuration**
- **Tags**
- **Parameters**
- **Associate Schedules**

8. Choose **Run**.

**Jupyter notebook**

Use the following procedure to a Jupyter notebook to export to Amazon SageMaker Feature Store.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Feature Store.

1. Choose the + next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Amazon SageMaker Feature Store (via Jupyter Notebook)**.
4. Run the Jupyter notebook.
Running a Jupyter notebook runs a Data Wrangler job. Running a Data Wrangler job starts a SageMaker processing job. The processing job ingests the flow into an online and offline feature store.

**Important**

The IAM role you use to run this notebook must have the following AWS managed policies attached: AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess.

You only need to enable one online or offline feature store when you create a feature group. You can also enable both. To disable online store creation, set `EnableOnlineStore` to `False`:

```python
# Online Store Configuration
online_store_config = {
    "EnableOnlineStore": False
}
```

The notebook uses the column names and types of the dataframe you export to create a feature group schema, which is used to create a feature group. A feature group is a group of features defined in the feature store to describe a record. The feature group defines the schema and features contained in the feature group. A feature group definition is composed of a list of features, a record identifier feature name, an event time feature name, and configurations for its online store and offline store.

Each feature in a feature group can have one of the following types: `String`, `Fractional`, or `Integral`. If a column in your exported dataframe is not one of these types, it defaults to `String`.

The following is an example of a feature group schema.

```python
column_schema = [
    {
        "name": "Height",
        "type": "long"
    },
    {
        "name": "Input",
        "type": "string"
    },
    {
        "name": "Output",
        "type": "string"
    },
    {
        "name": "Sum",
        "type": "string"
    },
    {
        "name": "Time",
        "type": "string"
    }
]
```

Additionally, you must specify a record identifier name and event time feature name:

- The **record identifier name** is the name of the feature whose value uniquely identifies a record defined in the feature store. Only the latest record per identifier value is stored in the online store. The record identifier feature name must be one of feature definitions' names.

- The **event time feature name** is the name of the feature that stores the EventTime of a record in a feature group. An EventTime is a point in time when a new event occurs that corresponds
The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see Data Sources and Ingestion.

Refit Transforms to The Entire Dataset and Export Them

When you import data, Data Wrangler uses a sample of the data to apply the encodings. By default, Data Wrangler uses the first 50,000 rows as a sample, but you can import the entire dataset or use a different sampling method. For more information, see Import (p. 890).

The following transformations use your data to create a column in the dataset:

- **Encode Categorical** (p. 973)
- **Featurize Text** (p. 976)
- **Handle Outliers** (p. 989)
- **Handle Missing Values** (p. 991)

If you used sampling to import your data, the preceding transforms only use the data from the sample to create the column. The transform might not have used all of the relevant data. For example, if you use the **Encode Categorical** transform, there might have been a category in the entire dataset that wasn’t present in the sample.

You can either use a destination node or a Jupyter notebook to refit the transformations to the entire dataset. When Data Wrangler exports the transformations in the flow, it creates a SageMaker processing job. When the processing job finishes, Data Wrangler saves the following files in either the default Amazon S3 location or an S3 location that you specify:

- The Data Wrangler flow file that specifies the transformations that are refit to the dataset
- The dataset with the refit transformations applied to it

You can open a Data Wrangler flow file within Data Wrangler and apply the transformations to a different dataset. For example, if you've applied the transformations to a training dataset, you can open and use the Data Wrangler flow file to apply the transformations to a dataset used for inference.

For a information about using destination nodes to refit transforms and export see the following pages:

- **Export to Amazon S3** (p. 1016)
- **Export to Amazon SageMaker Feature Store** (p. 1025)

Use the following procedure to run a Jupyter notebook to refit the transformations and export the data.

To run a Jupyter notebook and to refit the transformations and export your Data Wrangler flow, do the following.

1. Choose the † next to the node that you want to export.
2. Choose **Export to**.
3. Choose the location to which you're exporting the data.
4. For the refit_trained_params object, set refit to True.
5. For the output_flow field, specify the name of the output flow file with the refit transformations.
6. Run the Jupyter notebook.

**Create a Schedule to Automatically Process New Data**

If you're processing data periodically, you can create a schedule to run the processing job automatically. For example, you can create a schedule that runs a processing job automatically when you get new data. For more information about processing jobs, see Export to Amazon S3 (p. 1016) and Export to Amazon SageMaker Feature Store (p. 1025).

When you create a job you must specify an IAM role that has permissions to create the job. By default, the IAM role that you use to access Data Wrangler is the SageMakerExecutionRole.

The following permissions allow Data Wrangler to access EventBridge and allow EventBridge to run processing jobs:

- Add the following AWS Managed policy to the Amazon SageMaker Studio execution role that provides Data Wrangler with permissions to use EventBridge:

  ```
  arn:aws:iam::aws:policy/AmazonEventBridgeFullAccess
  ```

  For more information about the policy, see [AWS managed policies for EventBridge](http://example.com).

- Add the following policy to the IAM role that you specify when you create a job in Data Wrangler:

  ```
  {
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:StartPipelineExecution",
    }
  ]
  }
  ```

  If you're using the default IAM role, you add the preceding policy to the Amazon SageMaker Studio execution role.

  Add the following trust policy to the role to allow EventBridge to assume it.

  ```
  {
  "Effect": "Allow",
  "Principal": {
    "Service": "events.amazonaws.com"
  },
  "Action": "sts:AssumeRole"
  }
  ```
Important
When you create a schedule, Data Wrangler creates an eventRule in EventBridge. You incur charges for both the event rules that you create and the instances used to run the processing job.
For information about EventBridge pricing, see Amazon EventBridge pricing. For information about processing job pricing, see Amazon SageMaker Pricing.

You can set a schedule using one of the following methods:

- CRON expressions
  
  **Note**
  Data Wrangler doesn't support the following expressions:
  - LW#
  - Abbreviations for days
  - Abbreviations for months

- RATE expressions
  - Recurring – Set an hourly or daily interval to run the job.
  - Specific time – Set specific days and times to run the job.

The following sections provide procedures on creating jobs.

CRON

Use the following procedure to create a schedule with a CRON expression.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, choose CRON.
9. Specify a valid CRON expression.
10. Choose Create.
11. (Optional) Choose Add another schedule to run the job on an additional schedule.
   
   **Note**
   You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.
12. Choose one of the following:
   
   - Schedule and run now – Data Wrangler the job runs immediately and subsequently runs on the schedules.
   - Schedule only – Data Wrangler the job only runs on the schedules that you specify.

RATE

Use the following procedure to create a schedule with a RATE expression.
To specify a schedule with a RATE expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, choose Rate.
9. For Value, specify an integer.
10. For Unit, select one of the following:
    - Minutes
    - Hours
    - Days
11. Choose Create.
12. (Optional) Choose Add another schedule to run the job on an additional schedule.

   **Note**
   You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:
    - Schedule and run now – Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - Schedule only – Data Wrangler the job only runs on the schedules that you specify.
14. Choose Run

**Recurring**

Use the following procedure to create a schedule that runs a job on a recurring basis.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, make sure Recurring is selected by default.
9. For Every x hours, specify the hourly frequency that the job runs during the day. Valid values are integers in the inclusive range of 1 and 23.
10. For On days, select one of the following options:
    - Every Day
    - Weekends
    - Weekdays
• **Select Days**

• (Optional) If you've selected **Select Days**, choose the days of the week to run the job.

**Note**
The schedule resets every day. If you schedule a job to run every five hours, it runs at the following times during the day:

- 00:00
- 05:00
- 10:00
- 15:00
- 20:00

11. Choose **Create**.

12. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

**Note**
You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:

- **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
- **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

14. Choose **Run**

**Specific time**

Use the following procedure to create a schedule that runs a job at specific times.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.

2. Choose **Create job**.

3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.

4. Choose **Next, 2. Configure job**.

5. Select **Associate Schedules**.

6. Choose **Create a new schedule**.

7. For **Schedule Name**, specify the name of the schedule.

8. Choose **Create**.

9. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

**Note**
You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

10. Choose one of the following:

- **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
- **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

11. Choose **Run**
You can use Amazon SageMaker Studio view the jobs that are scheduled to run. Your processing jobs run within SageMaker Pipelines. Each processing job has its own pipeline. It runs as a processing step within the pipeline. You can view the schedules that you've created within a pipeline. For information about viewing a pipeline, see View a Pipeline (p. 3369).

Use the following procedure to view the jobs that you've scheduled.

To view the jobs you've scheduled, do the following.

1. Open Amazon SageMaker Studio.
2. Open SageMaker Pipelines
3. View the pipelines for the jobs that you've created.
   - The pipeline running the job uses the job name as a prefix. For example, if you've created a job named housing-data-feature-engineering, the name of the pipeline is data-wrangler-housing-data-feature-engineering.
4. Choose the pipeline containing your job.
5. View the status of the pipelines. Pipelines with a Status of Succeeded have run the processing job successfully.

To stop the processing job from running, do the following:

To stop a processing job from running, delete the event rule that specifies the schedule. Deleting an event rule stops all the jobs associated with the schedule from running. For information about deleting a rule, see Disabling or deleting an Amazon EventBridge rule.

You can stop and delete the pipelines associated with the schedules as well. For information about stopping a pipeline, see StopPipelineExecution. For information about deleting a pipeline, see DeletePipeline.

Use an Interactive Data Preparation Widget in an Amazon SageMaker Studio Notebook to Get Data Insights

Use the Data Wrangler data preparation widget to interact with your data, get visualizations, explore actionable insights, and fix data quality issues.

You can access the data preparation widget from an Amazon SageMaker Studio notebook. For each column, the widget creates a visualization that helps you better understand its distribution. If a column has data quality issues, a warning appears in its header.

To see the data quality issues, select the column header showing the warning. You can use the information that you get from the insights and the visualizations to apply the widget's built-in transformations to help you fix the issues.

For example, the widget might detect that you have a column that only has one unique value and show you a warning. The warning provides the option to drop the column from the dataset.

Getting started with running the widget

Use the following information to help you get started with running a notebook.

Open a notebook in Amazon SageMaker Studio. For information about opening a notebook, see Create or Open an Amazon SageMaker Studio Notebook (p. 137).

Important
To run the widget, the notebook must use one of the following images:
Use the following code to import the data preparation widget and pandas. The widget uses pandas dataframes to analyze your data.

```python
import pandas as pd
import sagemaker_datawrangler
```

The following example code loads a file into the dataframe called `df`.

```python
df = pd.read_csv("example-dataset.csv")
```

You can use a dataset in any format that you can load as a pandas dataframe object. For more information about pandas formats, see [IO tools (text, CSV, HDF5, ...)](p. 153).

The following cell runs the `df` variable to start the widget.

```python
df
```

The top of the dataframe has the following options:

- **View the Pandas table** – Switches between the interactive visualization and a pandas table.
- **Use all of the rows in your dataset to compute the insights. Using the entire dataset might increase the time it takes to generate the insights.** – If you don't select the option, Data Wrangler computes the insights for the first 10,000 rows of the dataset.

The dataframe shows the first 1000 rows of the dataset. Each column header has a stacked bar chart that shows the column's characteristics. It shows the proportion of valid values, invalid values, and missing values. You can hover over the different portions of the stacked bar chart to get the calculated percentages.

Each column has a visualization in the header. The following shows the types of visualizations the columns can have:

- Categorical – Bar chart
- Numeric – Histogram
- Datetime – Bar chart
- Text – Bar chart

For each visualization, the data preparation widget highlights outliers in orange.

When you choose a column, it opens a side panel. The side panel shows you the **Insights** tab. The pane provides a count for the following types of values:

- Invalid values – Values whose type doesn't match the column type.
- Missing values – Values that are missing, such as NaN or None.
- Valid values – Values that are neither missing nor invalid.
For numeric columns, the **Insights** tab shows the following summary statistics:

- **Minimum** – The smallest value.
- **Maximum** – The largest value.
- **Mean** – The mean of the values.
- **Mode** – The value that appears most frequently.
- **Standard deviation** – The standard deviation of the values.

For categorical columns, the **Insights** tab shows the following summary statistics:

- **Unique values** – The number of unique values in the column.
- **Top** – The value that appears most frequently.

The columns that have warning icons in their headers have data quality issues. Choosing a column opens a **Data quality** tab that you can use to find transforms to help you fix the issue. A warning has one of the following severity levels:

- **Low** – Issues that might not affect your analysis, but can be useful to fix.
- **Medium** – Issues that are likely to affect your analysis, but are likely not critical to fix.
- **High** – Severe issues that we strongly recommend fixing.

**Note**

The widget sorts the column to show the values that have data quality issues at the top of the dataframe. It also highlights the values that are causing the issues. The color of the highlighting corresponds to the severity level.

Under **SUGGESTED TRANSFORMS**, you can choose a transform to fix the data quality issue. The widget can offer multiple transforms that can fix the issue. It can offer recommendations for the transforms that are best suited to the problem. You can move your cursor over the transform to get more information about it.

To apply a transform to the dataset, choose **Apply and export code**. The transform modifies the dataset and updates the visualization with modified values. The code for the transform appears in the following cell of the notebook. If you apply additional transforms to the dataset, the widget appends the transforms to the cell. You can use the code that the widget generates to do the following:

- Customize it to better fit your needs.
- Use it in your own workflows.

You can reproduce all the transforms you've made by rerunning all of the cells in the notebook.

The widget can provide insights and warnings for the target column. The target column is the column that you're trying to predict. Use the following procedure to get target column insights.

To get target column insights, do the following.

1. Choose the column that you're using as the target column.
2. Choose **Select as target column**.
3. Choose the problem type. The widget's insights and warnings are tailored to the problem types. The following are the problem types:
   - **Classification** – The target column has categorical data.
5. (Optional) Under Target Column Insights, choose one of the suggested transforms.

Reference for the insights and transforms in the widget

For feature columns (columns that aren't the target column), you can get the following insights to warn you about issues with your dataset.

- **Missing values** – The column has missing values such as None, NaN (not a number), or NaT (not a timestamp). Many machine learning algorithms don't support missing values in the input data. Filling them in or dropping the rows with missing data is therefore a crucial data preparation step. If you see the missing values warning, you can use one of the following transforms to correct the issue.
  - **Drop missing** – Drops rows with missing values. We recommend dropping rows when the percentage of rows with missing data is small and imputing the missing values isn't appropriate.
  - **Replace with new value** – Replaces textual missing values with Other. You can change Other to a different value in the output code. Replaces numeric missing values with 0.
  - **Replace with mean** – Replaces missing values with the mean of the column.
  - **Replace with median** – Replaces missing values with the median of the column.
  - **Drop column** – Drops the column with missing values from the dataset. We recommend dropping the entire column when there's a high percentage of rows with missing data.

- **Disguised missing values** – The column has disguised missing values. A disguised missing value is a value that isn't explicitly encoded as a missing value. For example, instead of using a NaN to indicate a missing value, the value could be Placeholder. You can use one of the following transforms to handle the missing values:
  - **Drop missing** – Drops rows with missing values
  - **Replace with new value** – Replaces textual missing values with Other. You can change Other to a different value in the output code. Replaces numeric missing values with 0.
  - **Constant column** – The column only has one value. It therefore has no predictive power. We strongly recommend using the Drop column transform to drop the column from the dataset.
  - **ID column** – The column has no repeating values. All of the values in the column are unique. They might be either IDs or database keys. Without additional information, the column has no predictive power. We strongly recommend using the Drop column transform to drop the column from the dataset.
  - **High cardinality** – The column has a high percentage of unique values. High cardinality limits the predictive power of categorical columns. Examine the importance of the column in your analysis and consider using the Drop column transform to drop it.

For the target column, you can get the following insights to warn you about issues with your dataset. You can use the suggested transformation provided with the warning to correct the issue.

- **Mixed data types in target (Regression)** – There are some non-numeric values in the target column. There might be data entry errors. We recommend removing the rows that have the values that can't be converted.
- **Frequent label** – Certain values in the target column appear more frequently than what would be normal in the context of regression. There might be an error in data collection or processing. A frequently appearing category might indicate that either the value is used as a default value or that it's a placeholder for missing values. We recommend using the Replace with new value transform to replace the missing values with Other.
- **Too few instances per class** – The target column has categories that appear rarely. Some of the categories don't have enough rows for the target column to be useful. You can use one of the following transforms:
• **Drop rare target** – Drops unique values with fewer than ten observations. For example, drops the value *cat* if it appears nine times in the column.

• **Replace rare target** – Replaces categories that appear rarely in the dataset with the value *Other*.

• **Classes too imbalanced (multi-class classification)** – There are categories in the dataset that appear much more frequently than the other categories. The class imbalance might affect prediction accuracy. For the most accurate predictions possible, we recommend updating the dataset with rows that have the categories that currently appear less frequently.

• **Large amount of classes/too many classes** – There’s a large number of classes in the target column. Having many classes might result in longer training times or poor predictive quality. We recommend doing one of the following:
  
  • Grouping some of the categories into their own category. For example, if six categories are closely related, we recommend using a single category for them.
  
  • Using an ML algorithm that’s resilient to multiple categories.

### Security and Permissions

When you query data from Athena or Amazon Redshift, the queried dataset is automatically stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio. Additionally, when you export a Jupyter Notebook from Amazon SageMaker Data Wrangler and run it, your data flows, or .flow files, are saved to the same default bucket, under the prefix `data_wrangler_flows`.

For high-level security needs, you can configure a bucket policy that restricts the AWS roles that have access to this default SageMaker S3 bucket. Use the following section to add this type of policy to an S3 bucket. To follow the instructions on this page, use the AWS Command Line Interface (AWS CLI). To learn how, see Configuring the AWS CLI in the IAM User Guide.

Additionally, you need to grant each IAM role that uses Data Wrangler permissions to access required resources. If you do not require granular permissions for the IAM role you use to access Data Wrangler, you can add the IAM managed policy, `AmazonSageMakerFullAccess`, to an IAM role that you use to create your Studio user. This policy grants you full permission to use Data Wrangler. If you require more granular permissions, refer to the section, Grant an IAM Role Permission to Use Data Wrangler (p. 1041).

### Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler

You can add a policy to the S3 bucket that contains your Data Wrangler resources using an Amazon S3 bucket policy. Resources that Data Wrangler uploads to your default SageMaker S3 bucket in the AWS Region you are using Studio in include the following:

• Queried Amazon Redshift results. These are stored under the `redshift/` prefix.

• Queried Athena results. These are stored under the `athena/` prefix.

• The .flow files uploaded to Amazon S3 when you run an exported Jupyter Notebook Data Wrangler produces. These are stored under the `data_wrangler_flows/` prefix.

Use the following procedure to create an S3 bucket policy that you can add to restrict IAM role access to that bucket. To learn how to add a policy to an S3 bucket, see **How do I add an S3 Bucket policy?**.

### To set up a bucket policy on the S3 bucket that stores your Data Wrangler resources:

1. Configure one or more IAM roles that you want to be able to access Data Wrangler.

2. Open a command prompt or shell. For each role that you create, replace `role-name` with the name of the role and run the following:
3. Add the following policy to the SageMaker default bucket in the AWS Region in which you are using Data Wrangler. Replace `region` with the AWS Region in which the bucket is located, and `account-id` with your AWS account ID. Replace `userId`s starting with `AROAEXAMPLEID` with the IDs of an AWS roles to which you want to grant permission to use Data Wrangler.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::sagemaker-region-account-id/data_wrangler_flows/",
        "arn:aws:s3:::sagemaker-region-account-id/data_wrangler_flows/*",
        "arn:aws:s3:::sagemaker-region-account-id/athena",
        "arn:aws:s3:::sagemaker-region-account-id/athena/*",
        "arn:aws:s3:::sagemaker-region-account-id/redshift/",
        "arn:aws:s3:::sagemaker-region-account-id/redshift/*"
      ],
      "Condition": {
        "StringNotLike": {
          "aws:userId": [
            "AROAEXAMPLEID_1:*",
            "AROAEXAMPLEID_2:*"
          ]
        }
      }
    }
  ]
}
```

### Grant an IAM Role Permission to Use Data Wrangler

You can grant an IAM role permission to use Data Wrangler with the general IAM managed policy, **AmazonSageMakerFullAccess**. This is a general policy that includes permissions required to use all SageMaker services. This policy grants an IAM role full access to Data Wrangler. You should be aware of the following when using AmazonSageMakerFullAccess to grant access to Data Wrangler:

- If you import data from Amazon Redshift, the **Database User** name must have the prefix `sagemaker_access`.
- This managed policy only grants permission to access buckets with one of the following in the name: `SageMaker`, `SageMaker`, `sagemaker`, or `aws-glue`. If want to use Data Wrangler to import from an S3 bucket without these phrases in the name, refer to the last section on this page to learn how to grant permission to an IAM entity to access your S3 buckets.

If you have high-security needs, you can attach the policies in this section to an IAM entity to grant permissions required to use Data Wrangler.

If you have datasets in Amazon Redshift or Athena that an IAM role needs to import from Data Wrangler, you must add a policy to that entity to access these resources. The following policies are the most
restrictive policies you can use to give an IAM role permission to import data from Amazon Redshift and Athena.

To learn how to attach a custom policy to an IAM role, refer to Managing IAM policies in the IAM User Guide.

Policy example to grant access to an Athena dataset import

The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "athena:ListDataCatalogs",
                "athena:ListDatabases",
                "athena:ListTableMetadata",
                "athena:GetQueryExecution",
                "athena:GetQueryResults",
                "athena:StartQueryExecution",
                "athena:StopQueryExecution"
            ],
            "Resource": ["
        }
    ],
    "Effect": "Allow",
    "Action": ["glue:CreateTable"
        ],
    "Resource": [
        "arn:aws:glue:*:*:table/*/sagemaker_tmp_*",
        "arn:aws:glue:*:*:table/sagemaker_featurestore/**",
        "arn:aws:glue:*:*:catalog",
        "arn:aws:glue:*:*:database/**""
    }
},
{
    "Effect": "Allow",
    "Action": ["glue:DeleteTable"
        ],
    "Resource": [
        "arn:aws:glue:*:*:table/*/sagemaker_tmp_*",
        "arn:aws:glue:*:*:catalog",
        "arn:aws:glue:*:*:database/**"
    }
},
{
    "Effect": "Allow",
    "Action": ["glue:GetDatabases",
        "glue:GetTable",
        "glue:GetTables"
        ],
    "Resource": [
        "arn:aws:glue:*:*:table/**",
        "arn:aws:glue:*:*:catalog",
        "arn:aws:glue:*:*:database/**"
    }
}
```
Policy example to grant access to an Amazon Redshift dataset import

The following policy grants permission to set up an Amazon Redshift connection to Data Wrangler using database users that have the prefix `sagemaker_access` in the name. To grant permission to connect using additional database users, add additional entries under "Resources" in the following policy. The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy, if applicable.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "redshift-data:ExecuteStatement",
        "redshift-data:DescribeStatement",
        "redshift-data:CancelStatement",
        "redshift-data:GetStatementResult",
        "redshift-data:ListSchemas",
        "redshift-data:ListTables"
      ],
      "Resource": [
        "*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "redshift:GetClusterCredentials"
      ],
      "Resource": [
        "arn:aws:redshift:*:*:dbuser:*/sagemaker_access*",
        "arn:aws:redshift:*:*:dbname:*"
      ]
    }
  ]
}
```

Policy to grant access to an S3 bucket

If your dataset is stored in Amazon S3, you can grant an IAM role permission to access this bucket with a policy similar to the following. This example grants programmatic read-write access to the bucket named `test`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::test/*",
        "arn:aws:s3-*:bucket/test"
      ]
    }
  ]
}
```
"Statement": [
  {
    "Effect": "Allow",
    "Action": ["s3:ListBucket"],
    "Resource": ["arn:aws:s3:::test"]
  },
  {
    "Effect": "Allow",
    "Action": ["s3:PutObject", "s3:GetObject", "s3:DeleteObject"],
    "Resource": ["arn:aws:s3:::test/*"]
  }
]}

To import data from Athena and Amazon Redshift, you must grant an IAM role permission to access the following prefixes under the default Amazon S3 bucket in the AWS Region Data Wrangler in which is being used: athena/, redshift/. If a default Amazon S3 bucket does not already exist in the AWS Region, you must also give the IAM role permission to create a bucket in this region.

Additionally, if you want the IAM role to be able to use the Amazon SageMaker Feature Store, SageMaker Pipelines, and Data Wrangler job export options, you must grant access to the prefix data_wrangler_flows/ in this bucket.

Data Wrangler uses the athena/ and redshift/ prefixes to store preview files and imported datasets. To learn more, see Imported Data Storage (p. 933).

Data Wrangler uses the data_wrangler_flows/ prefix to store .flow files when you run a Jupyter Notebook exported from Data Wrangler. To learn more, see Export (p. 1015).

Use a policy similar to the following to grant the permissions described in the preceding paragraphs.

[ "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:CreateBucket", "s3:ListBucket"],
      "Resource": ["arn:aws:s3:::sagemaker-region-account-id"]
    }]
]
You can also access data in your Amazon S3 bucket from another AWS account by specifying the Amazon S3 bucket URI. To do this, the IAM policy that grants access to the Amazon S3 bucket in the other account should use a policy similar to the following example, where BucketFolder is the specific directory in the user's bucket UserBucket. This policy should be added to the user granting access to their bucket for another user.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": "arn:aws:s3:::UserBucket/BucketFolder/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": "arn:aws:s3:::UserBucket",
      "Condition": {
        "StringLike": {
          "s3:prefix": [
            "BucketFolder/*"
          ]
        }
      }
    }
  ]
}
```

The user that is accessing the bucket (not the bucket owner) must add a policy similar to the following example to their user. Note that AccountX and TestUser below refers to the bucket owner and their user respectively.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::AccountX:user/TestUser"
      },
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
        "arn:aws:s3:::UserBucket/BucketFolder/*"
      ]
    }
  ]
}
```
Policy example to grant access to use SageMaker Studio

Use a policy like the following to create an IAM execution role that can be used to set up a Studio instance.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeDomain",
                "sagemaker:ListDomains",
                "sagemaker:DescribeUserProfile",
                "sagemaker:ListUserProfiles",
                "sagemaker:*App",
                "sagemaker:ListApps"
            ],
            "Resource": "*"
        }
    ]
}
```

Snowflake and Data Wrangler

All permissions for AWS resources are managed via your IAM role attached to your Studio instance. The Snowflake administrator manages Snowflake-specific permissions, as they can grant granular permissions and privileges to each Snowflake user. This includes databases, schemas, tables, warehouses, and storage integration objects. You must ensure that the correct permissions are set up outside of Data Wrangler.

Note that the Snowflake COPY INTO Amazon S3 command moves data from Snowflake to Amazon S3 over the public internet by default, but data in transit is secured using SSL. Data at rest in Amazon S3 is encrypted with SSE-KMS using the default AWS KMS key.

With respect to Snowflake credentials storage, Data Wrangler does not store customer credentials. Data Wrangler uses Secrets Manager to store the credentials in a secret and rotates secrets as part of a best practice security plan. The Snowflake or Studio administrator needs to ensure that the data scientist’s Studio execution role is granted permission to perform GetSecretValue on the secret storing the credentials. If already attached to the Studio execution role, the AmazonSageMakerFullAccess policy has the necessary permissions to read secrets created by Data Wrangler and secrets created by following the naming and tagging convention in the instructions above. Secrets that do not follow the conventions must be separately granted access. We recommend using Secrets Manager to prevent sharing credentials.
over unsecured channels; however, note that a logged-in user can retrieve the plain-text password by launching a terminal or Python notebook in Studio and then invoking API calls from the Secrets Manager API.

### Data Encryption with AWS KMS

Within Data Wrangler, you can decrypt encrypted files and add them to your Data Wrangler flow. You can also encrypt the output of the transforms using either a default AWS KMS key or one that you provide.

You can import files if they have the following:

- server-side encryption
- SSE-KMS as the encryption type

To decrypt the file and import to a Data Wrangler flow, you must add the SageMaker Studio user that you're using as a key user.

The following screenshot shows a Studio user role added as a key user. See IAM Roles to access users under the left panel to make this change.

Amazon S3 customer managed key setup for Data Wrangler imported data storage

By default, Data Wrangler uses Amazon S3 buckets that have the following naming convention: `sagemaker-region-account-number`. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored with the following naming convention: `sagemaker-us-east-1-111122223333`.

The following instructions explain how to set up a customer managed key for your default Amazon S3 bucket.

1. To enable server-side encryption and setup a customer managed key for your default S3 bucket, see Using KMS Encryption.
2. After following step 1, navigate to AWS KMS in your AWS Management Console. Find the customer managed key you selected in step 1 of the previous step and add the Studio role as the key user. To do this, follow the instructions in Allows key users to use a customer managed key.

Encrypting the Data That You Export

You can encrypt the data that you export using one of the following methods:

- Specifying that your Amazon S3 bucket has object use SSE-KMS encryption.
- Specifying an AWS KMS key to encrypt the data that you export from Data Wrangler.
On the Export data page, specify a value for the AWS KMS key ID or ARN.

For more information on using AWS KMS keys, see Protecting Data Using Server-Side Encryption with AWS KMS keys Stored in AWS AWS Key Management Service (SSE-KMS).

**Amazon AppFlow Permissions**

When you're performing a transfer, you must specify an IAM role that has permissions to perform the transfer. You can use the same IAM role that has permissions to use Data Wrangler. By default, the IAM role that you use to access Data Wrangler is the SageMakerExecutionRole.

The IAM role must have the following permissions:

- Permissions to Amazon AppFlow
- Permissions to the AWS Glue Data Catalog
- Permissions for AWS Glue to discover the data sources that are available

When you run a transfer, Amazon AppFlow stores metadata from the transfer in the AWS Glue Data Catalog. Data Wrangler uses the metadata from the catalog to determine whether it's available for you to query and import.

To add permissions to Amazon AppFlow, add the AmazonAppFlowFullAccess AWS managed policy to the IAM role. For more information about adding policies, see Adding or removing IAM identity permissions.

If you're transferring data to Amazon S3, you must also attach the following policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketTagging",
        "s3:ListBucketVersions",
        "s3:CreateBucket",
        "s3:ListBucket",
        "s3:GetBucketPolicy",
        "s3:PutEncryptionConfiguration",
        "s3:GetEncryptionConfiguration",
        "s3:PutBucketTagging",
        "s3:GetObjectTagging",
        "s3:GetBucketOwnershipControls",
        "s3:PutObjectTagging",
        "s3:DeleteObject",
        "s3:DeleteBucket",
        "s3:DeleteObjectTagging",
        "s3:GetBucketPublicAccessBlock",
        "s3:GetBucketPolicyStatus",
        "s3:PutBucketPublicAccessBlock",
        "s3:PutAccountPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:GetBucketOwnershipControls",
        "s3:PutObjectVersionTagging",
        "s3:DeleteObjectVersionTagging",
        "s3:GetBucketVersioning",
        "s3:GetBucketAcl",
        "s3:GetObject"
      ]
    }
  ]
}
```
To add AWS Glue permissions, add the AWSGlueConsoleFullAccess managed policy to the IAM role. For more information about AWS Glue permissions with Amazon AppFlow, see [link-to-appflow-page].

Amazon AppFlow needs to access AWS Glue and Data Wrangler for you to import the data that you've transferred. To grant Amazon AppFlow access, add the following trust policy to the IAM role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:root",
        "Service": ["appflow.amazonaws.com"
      ],
      "Action": "sts:AssumeRole"
    }
  ]
}
```

To display the Amazon AppFlow data in Data Wrangler, add the following policy to the IAM role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "glue:SearchTables",
      "Resource": [
        "arn:aws:glue::*:table/*/*/",
        "arn:aws:glue::*:database/**",
        "arn:aws:glue::*:catalog"
      ]
    }
  ]
}
```

### Using Lifecycle Configurations in Data Wrangler

You might have an Amazon EC2 instance that is configured to run Kernel Gateway applications, but not the Data Wrangler application. Kernel Gateway applications provide access to the environment and the kernels that you use to run Studio notebooks and terminals. The Data Wrangler application is the UI application that runs Data Wrangler. Amazon EC2 instances that aren't Data Wrangler instances require a modification to their lifecycle configurations to run Data Wrangler. Lifecycle configurations are shell scripts that automate the customization of your Amazon SageMaker Studio environment.
For more information about lifecycle configurations, see Use Lifecycle Configurations with Amazon SageMaker Studio (p. 170).

The default lifecycle configuration for your instance doesn't support using Data Wrangler. You can make the following modifications to the default configuration to use Data Wrangler with your instance.

```bash
#!/bin/bash
set -eux
STATUS=$(
    python3 -c "import sagemaker_dataprep
    echo $?"
)
if [ "$STATUS" -eq 0 ]; then
    echo 'Instance is of Type Data Wrangler'
else
    echo 'Instance is not of Type Data Wrangler'
fi

# Replace this with the URL of your git repository
export REPOSITORY_URL="https://github.com/aws-samples/sagemaker-studio-lifecycle-config-examples.git"

git -C /root clone $REPOSITORY_URL

You can save the script as lifecycle_configuration.sh.

You attach the lifecycle configuration to your Studio domain or user profile. For more information about creating and attaching a lifecycle configuration, see Creating and Associating a Lifecycle Configuration (p. 171).

The following instructions show you how to attach a lifecycle configuration to a Studio domain or user profile.

You might run into errors when you're creating or attaching a lifecycle configuration. For information about debugging lifecycle configuration errors, KernelGateway App failure (p. 177).

Release Notes

Data Wrangler is regularly updated with new features and bug fixes. To upgrade the version of Data Wrangler you are using in Studio, follow the instructions in Shut down and Update Studio Apps (p. 186).

| New functionality: |
| You can now use Principal Component Analysis (PCA) as a transform. For more information, see Reduce Dimensionality within a Dataset (p. 972). |
Release Notes

10/05/2022

New functionality:

You can now refit parameters in your Data Wrangler flow. For more information, see Export (p. 1015).

10/03/2022

New functionality:

You can now deploy models from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow (p. 958).

9/20/2022

New functionality:

You can now set data retention periods in Athena. For more information, see Import data from Athena (p. 896).

6/9/2022

New functionality:

You can now use Amazon SageMaker Autopilot to train a model directly from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow (p. 958).

5/6/2022

New functionality:

You can now use additional m5 and r5 instances. For more information, see Instances (p. 934).

4/27/2022

New functionalities:

- You can now get a data quality report. For more information, see Get Insights On Data and Data Quality (p. 945)
- You can now perform random sampling and stratified sampling. For more information, see Sampling (p. 993).

4/1/2022

New functionality:

You can now use Databricks as a data source. For more information, see Import data from Databricks (JDBC) (p. 907).

2/2/2022

New functionalities:

- You can now export using destination nodes. For more information, see Export (p. 1015)
- You can import ORC and JSON files. For more information about file types, see Import (p. 890).
- Data Wrangler now supports using the SMOTE transform. For more information, see Balance Data (p. 966).
Release Notes

- Data Wrangler now supports similarity encoding for categorical data. For more information, see [Similarity encode](p. 975).
- Data Wrangler now supports unnesting JSON data. For more information, see [Unnest JSON Data](p. 998).
- Data Wrangler now supports expanding the values of an array into separate columns. For more information, see [Explode Array](p. 999).
- Data Wrangler now supports reaching out to the service team when you're having issues. For more information, see [Troubleshoot](p. 1053).
- Data Wrangler supports editing and deleting steps in your data flow. For more information, see [Delete a Step from Your Data Flow](p. 938) and [Edit a Step in Your Data Wrangler Flow](p. 943).
- You can now perform transformations on multiple columns. For more information, see [Transform Data](p. 959).
- Data Wrangler now supports cost allocation tags. For more information, see [Using Cost Allocation Tags](p. 959).

10/16/2021

New functionality:

Data Wrangler now supports Athena workgroups. For more information, see [Import data from Athena](p. 896).

10/6/2021

New functionality:

Data Wrangler now supports transforming time series data. For more information, see [Transform Time Series](p. 978).

7/15/2021

New functionalities:

- [Snowflake and Data Wrangler](p. 1046) is now supported. You can use Snowflake as a data source in Data Wrangler.
- Added support for custom field delimiter in CSV. Now comma, colon, semicolon, pipe (|) and Tab are supported.
- Now you can export results directly to Amazon S3.
- Added a few new multicollinearity analyzers: Variance Inflation Factors, Principal Component Analysis and Lasso feature selection.

Enhancements:

- The analyze charts can no longer be could be packed with overlapping labels.

Bug Fixes:

- One-hot encoder handles empty string gracefully.
- Fixed crashes that occurred when a dataframe column name contained dots.

4/26/2021
Release Notes

Enhancements:

- Added support for distributed processing Jobs. You can use multiple instances when running a processing job.
- Data Wrangler Processing job now automatically coalesces small outputs when estimated result size is less than 1 gigabytes.
- Feature Store Notebook: Improved feature store ingestion performance
- Data Wrangler Processing jobs now use 1.x as the authoritative container tag for future releases.

Bug Fixes:

- Fixed rendering issues for faceted histogram.
- Fixed Export to Processing Job to support vector type columns.
- Fixed Extract using regex operator to return the first captured group if one or more exists in the regular expression or regex.

2/8/2021

New Functionalities:

- Data Wrangler Flows supports multiple instances.
- Updated Export to Data Wrangler Job Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to add XGBoost training example as an optional step.

Enhancements:

- To improve performance, importing CSV files that contain multiple lines in a single field is no longer supported.

Bug Fixes:

- Fixed type inference issue in Quick model.
- Fixed the bias metric bug in bias reports.
- Fixed the Featurize text transform to work with columns with missing values.
- Fixed Histogram and Scatter plot built-in visualizations to work with datasets that contain array-like columns.
- Athena query now re-runs if the query execution ID has expired.

Troubleshoot

If an issue arises when using Amazon SageMaker Data Wrangler, we recommend you do the following:

- If an error message is provided, read the message and resolve the issue it reports if possible.
- Make sure the IAM role of your Studio user has the required permissions to perform the action. For more information, see Security and Permissions (p. 1040).
• If the issue occurs when you are trying to import from another AWS service, such as Amazon Redshift or Athena, make sure that you have configured the necessary permissions and resources to perform the data import. For more information, see Import (p. 890).

• If you’re still having issues, choose Get help at the top right of your screen to reach out to the Data Wrangler team. For more information, see the following images.

As a last resort, you can try restarting the kernel on which Data Wrangler is running.

1. Save and exit the .flow file for which you want to restart the kernel.
2. Select the Running Terminals and Kernels icon, as shown in the following image.
3. Select the **Stop** icon to the right of the `.flow` file for which you want to terminate the kernel, as shown in the following image.
4. Refresh the browser.
5. Reopen the .flow file on which you were working.

**Troubleshooting issues with Amazon EMR**

Use the following information to help you troubleshoot errors that might come up when you’re using Amazon EMR.

- **Connection failure** – If the connection fails with the following message *The IP address of the EMR cluster isn't private* error message, your Amazon EMR cluster might not have been launched in a private subnet. As a security best practice, Data Wrangler only supports connecting to private Amazon EMR clusters. Choose a private EC2 subnet you launch an EMR cluster.

- **Connection hanging and timing out** – The issue is most likely due to a network connectivity issue. After you start connecting to the cluster, the screen doesn’t refresh. After about 2 minutes, you might see the following error *JdbcAddConnectionError: An error occurred when trying to connect to presto: xxx: Connect to xxx failed: Connection timed out (Connection timed out)* will display on top of the screen.
The errors might have two root causes:

- The Amazon EMR and Amazon SageMaker Studio are in different VPCs. We recommend launching both Amazon EMR and Studio in the same VPC. You can also use VPC peering. For more information, see What is VPC peering?

- The Amazon EMR master security group lacks the inbound traffic rule for the security group of Amazon SageMaker Studio on the port used for Presto. To resolve the issue, allow inbound traffic on port 8889.

- Connection fails due to the connection type being misconfigured – You might see the following error message: Data Wrangler couldn’t create a connection to {connection_source} successfully. Try connecting to {connection_source} again. For more information, see Troubleshoot. If you’re still experiencing issues, contact support.

Check the authentication method. The authentication method that you’ve specified in Data Wrangler should match the authentication method that you’re using on the cluster.

- You don’t have HDFS permissions for LDAP authentication – Use the following guidance to resolve the issue Set up HDFS Permissions using Linux Credentials. You can log into the cluster using the following commands:

```
hdfs dfs -mkdir /user/USERNAME
hdfs dfs -chown USERNAME:USERNAME /user/USERNAME
```

- LDAP authentication missing connection key error – You might see the following error message: Data Wrangler couldn’t connect to EMR hive successfully. JDBC connection is missing required connection key(s): PWD.

For LDAP authentication, you must specify both a username and a password. The JDBC URL stored in Secrets Manager is missing property PWD.

- When you’re troubleshooting the LDAP configuration: We recommend making sure that the LDAP authenticator (LDAP server) is correctly configured to connect to the Amazon EMR cluster. Use the ldapwhoami command to help you resolve the configuration issue. The following are example commands that you can run:

  - For LDAPS – `ldapwhoami -x -H ldaps://ldap-server`
  - For LDAP – `ldapwhoami -x -H ldap://ldap-server`

Either command should return Anonymous if you’ve configured the authenticator successfully.

## Increase Amazon EC2 Instance Limit

You might see the following error message when you’re using Data Wrangler: The following instance type is not available: ml.m5.4xlarge. Try selecting a different instance below.

The message can indicate that you need to select a different instance type, but it can also indicate that you don’t have enough Amazon EC2 instances to successfully run Data Wrangler on your workflow. You can increase the number of instances by using the following procedure.

To increase the number of instances, do the following.

1. Open the AWS Management Console.
2. In the search bar, specify Services Quotas.
3. Choose Service Quotas.
4. Choose AWS services.
5. In the search bar, specify Amazon SageMaker.
6. Choose Amazon SageMaker.
7. Under Service quotas, specify Studio KernelGateway Apps running on \textit{ml.m5.4xlarge} instance.

\textbf{Note}
ml.m5.4xlarge is the default instance type for Data Wrangler. You can use other instance types and request quota increases for them. For more information, see Instances (p. 934).

8. Select Studio KernelGateway Apps running on \textit{ml.m5.4xlarge} instance.
9. Choose Request quota increase.
10. For Change quota value, specify a value greater than Applied quota value.
11. Choose Request.

If your request is approved, AWS sends a notification to the email address associated with your account. You can also check the status of your request by choosing Quota request history on the Service Quotas page. Processed requests have a Status of Closed.

**Update Data Wrangler**

To update Data Wrangler to the latest release, first shut down the corresponding KernelGateway app from the Amazon SageMaker Studio control panel. After the KernelGateway app is shut down, restart it by opening a new or existing Data Wrangler flow in Studio. When you open a new or existing Data Wrangler flow, the kernel that starts contains the latest version of Data Wrangler.

**Update your Studio and Data Wrangler instance**

1. Navigate to your SageMaker Console.
2. Choose SageMaker and then Studio.
3. Choose your user name.
4. Under Apps, in the row displaying the App name, choose Delete app for the app that starts with sagemaker-data-wrangler, and for the JupyterServer app.
5. Choose Yes, delete app.
6. Type delete in the confirmation box.
7. Choose Delete.
8. Reopen your Studio instance. When you begin to create a Data Wrangler flow, your instance now uses the latest version of Data Wrangler.

Alternatively, if you are using a Data Wrangler application version that is not the latest version, and you have an existing Data Wrangler flow open, you are prompted to update your Data Wrangler application version in the Studio UI. The following screenshot shows this prompt.

\textbf{Important}
This updates the Data Wrangler kernel gateway app only. You still need to shut down the JupyterServer app in your user account. To do this, follow the preceding steps.
You can also choose Remind me later, in which case an Update button appears in the top-right corner of the screen.

Shut Down Data Wrangler

When you are not using Data Wrangler, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To avoid losing work, save your data flow before shutting Data Wrangler down. To save your data flow in Studio, choose File and then choose Save Data Wrangler Flow. Data Wrangler automatically saves your data flow every 60 seconds.
To shut down the Data Wrangler instance in Studio

1. In Studio, select the Running Instances and Kernels icon.

2. Under RUNNING APPS is the sagemaker-data-wrangler-1.0 app. Select the shutdown icon next to this app.

Data Wrangler runs on an ml.m5.4xlarge instance. This instance disappears from RUNNING INSTANCES when you shut down the Data Wrangler app.

After you shut down the Data Wrangler app, it has to restart the next time you open a Data Wrangler flow file. This can take a few minutes.

Prepare Data at Scale with Studio Notebooks

Amazon SageMaker Studio gives data scientists, machine learning (ML) engineers, and general practitioners tools to perform data analytics and data preparation at scale. Analyzing, transforming, and preparing large amounts of data is a foundational step of any data science and ML workflow. SageMaker Studio comes with built-in integration of Amazon EMR and AWS Glue Interactive Sessions to handle your large-scale interactive data preparation and machine learning workflows, all within your Studio notebook.

Amazon EMR is a managed big data platform with resources to help you run petabyte-scale distributed data processing jobs using open-source analytics frameworks on AWS such as Apache Spark, Apache Hive, Presto, HBase, Flink, and Hudi among others. Data engineers and data scientists use Amazon
EMR for a wide variety of use cases, including big data analytics, what-if analyses, real time analytics, and data preparation for machine learning. Studio integration with Amazon EMR allows you to easily create, browse, discover, and connect to EMR clusters without leaving your Studio notebook. You can even monitor and debug your Spark workloads with one-click access to the Spark UI from within the notebook. You should consider EMR for your data preparation workloads if you want maximum control over hardware and software versions, containers, and big data processing applications.

AWS Glue Interactive Sessions is a serverless service that you can enlist to collect, transform, cleanse, and prepare data for storage in your data lakes and data pipelines. Glue Interactive Sessions provides an on-demand, serverless Apache Spark runtime environment that you can initialize in seconds on a dedicated Data Processing Unit (DPU) without having to worry about provisioning and managing complex compute cluster infrastructure. After initialization, you can quickly browse the Glue data catalog, run large queries, access data governed by AWS Lake Formation, and interactively analyze and prepare data using Spark, right in your Studio notebook. You can then use the prepared data to build, train, tune and deploy models using the purpose-built ML tools within SageMaker Studio. You should consider Glue Interactive Sessions for your data preparation workloads when you want a serverless Spark service with moderate control of configurability and flexibility.

Prepare Data using Amazon EMR

Data scientists and data engineers use Apache Spark, Hive, and Presto on Amazon EMR for fast data preparation. Studio comes with built-in integration of Amazon EMR, enabling you to perform petabyte-scale interactive data preparation and machine learning right in your Studio notebook. Within your notebook, you can visually browse, discover, and connect to Amazon EMR. After you connect, you can interactively explore, visualize, and prepare petabyte-scale data for machine learning (ML) using Apache Spark, Hive, and Presto. Amazon EMR can handle your ETL jobs, run large-scale model training, perform analyses, and handle reporting, among many other capabilities.

For guided instructions about how to connect to an Amazon EMR cluster from SageMaker Studio, see Create and manage Amazon EMR Clusters from SageMaker Studio to run interactive Spark and ML workloads.

Prerequisites

- You will need access to SageMaker Studio that is set up to use Amazon Virtual Private Cloud (Amazon VPC) mode.
  - To connect to Amazon EMR, Studio must be configured as Amazon VPC only mode. For more information, see Connect SageMaker Studio Notebooks to Resources in a Amazon VPC. For more information on how to onboard, see Onboard to SageMaker Domain.
  - All subnets used by SageMaker Studio must be private subnets.
  - If you use the sm-analytics utility to configure the SparkMagic kernel, follow one of these two prerequisites:
    - Make sure that the Amazon VPC interface endpoint is attached to all of the subnets used by SageMaker Studio.
    - Ensure that all of the subnets used by SageMaker Studio are routed to use a NAT gateway. For more information, see NAT gateways.
  - If either one of the following points apply to you, you must have Spark and Livy installed when using Amazon EMR.
    - Your Amazon EMR cluster is in the same Amazon VPC as Studio.
    - Your cluster is in a Amazon VPC that's connected to the Amazon VPC in Studio.
    - The security groups for both Amazon SageMaker Studio and Amazon EMR must allow access to and from each other.
    - Your Amazon EMR security group must open port 8998, so that Amazon SageMaker Studio can communicate with the Spark cluster through Livy. For more information about setting up the security group, see Build SageMaker notebooks backed by Spark in Amazon EMR.
To connect to an Amazon EMR cluster from Studio, you must first access SageMaker Studio. If you have not set up SageMaker Studio, follow the Get Started guide.

If you created a new domain during Studio setup, then discovering an Amazon EMR cluster from Studio should be available to you.

If you are reusing an existing domain, you must update both Studio and Studio applications. For detailed instructions, see Update Studio and Update Studio applications.

SageMaker Studio comes with built-in support to connect to EMR clusters in the following images and kernels:

- Images: Data Science, Data Science 2.0, SparkMagic, SparkAnalytics 1.0, PyTorch 1.8, TensorFlow 2.6
- Kernel: PySpark and Spark kernels for the SparkMagic image, Python 3 (IPython) for the Data Science, Data Science 2.0, PyTorch 1.8, TensorFlow 2.6 images.

If you want to connect to EMR clusters using another built-in image or your own image, follow instructions in Bring your own image (p. 1062).

Bring your own image

If you want to bring your own image, first install the following dependencies to your kernel. The following list shows pip commands with the library name that you will install.

```
pip install sparkmagic
pip install sagemaker-studio-sparkmagic-lib
pip install sagemaker-studio-analytics-extension
```

You can update the libraries from the previous list manually, if they are not the latest version.

If you want to connect to Amazon EMR with Kerberos authentication, you must install the kinit client. Depending on your OS, the command to install the kinit client can vary. To bring an Ubuntu (Debian based) image, use the `apt-get install -y -qq krb5-user` command.

Topics

- Discover Amazon EMR Clusters from Studio (p. 1062)
- Connect to an Amazon EMR Cluster from Studio (p. 1065)
- Troubleshoot and Monitor Workloads in Amazon EMR (p. 1076)
- Manage Amazon EMR Clusters from Studio (p. 1077)
- Required Permissions (p. 1093)

Discover Amazon EMR Clusters from Studio

From within Studio, data scientists and data engineers can easily discover, connect to, and manage Amazon EMR clusters. Your Amazon EMR clusters may be in the same AWS account as SageMaker Studio or they may be in a different AWS account. This section explains how to discover an Amazon EMR cluster that exists in the same account as SageMaker Studio. For information about discovering Amazon EMR clusters in a different AWS account, see Discover Amazon EMR Clusters Across Accounts (p. 1065).

Before you can activate discovering functionality, you must add a required policy to your Studio execution role. After you add this policy, you can connect to an Amazon EMR cluster in Studio.

To add the required policy to your Studio execution role

1. Open the IAM console.
2. Select Roles in the left-side panel.
3. Find the Studio execution role that you will be using and select it.
4. Under the Permissions tab, select Attach policies.
5. Select Create policy.
6. Select JSON.
7. Copy and paste in the following policy. For more information on required permissions, see Required Permissions (p. 1093).

```json
{
   "Statement": [
      {
         "Action": ["elasticmapreduce:DescribeCluster", "elasticmapreduce:ListInstanceGroups"],
         "Effect": "Allow",
         "Resource": ["arn:aws:elasticmapreduce:*:*:cluster/*"]
      },
      {
         "Action": ["elasticmapreduce:ListClusters"],
         "Effect": "Allow",
         "Resource": "*"
      }
   ],
   "Version": "2012-10-17"
}
```

8. Select Next: Tags.
9. Select Next: Review.
10. Enter a Name, Description, and Select Create policy.
11. Now you can log in to Studio. If this is your first time logging in, follow the instructions in Log in to Studio.
Discover Amazon EMR Clusters Across Accounts

If you want to discover Amazon EMR clusters in a different AWS account than the SageMaker Studio is in, you must specify the IAM role ARN in the remote account. This IAM role ARN must be assumed to list and describe Amazon EMR clusters. Specify this remote role in a file that's named `emr-discovery-iam-role-arns-DO_NOT_DELETE.json`, and in a directory named `.cross-account-configuration-DO_NOT_DELETE`. You will find this in your home directory, located in the Amazon EFS Storage volume used by SageMaker Studio. You can automate this process by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your Studio domain or user profile. You have the option to set your LCC script to run by default when your Jupyter server starts.

The LCC script that you use must be a JupyterServer configuration. For more information on how to create and use your LCC script and how to attach it at the Domain and UserProfile level, see Use Lifecycle Configurations with Studio. For more information on required permissions, see Required Permissions (p. 1093).

1. The following is an example LCC script that you can use. To modify the script, populate the script with the following details. Make sure that you replace ASSUMABLE-ROLE and 123456789012 with your role name and account ID, respectively. There is a limit of one role name and account ID combination.

```bash
#!/bin/bash
set -eux

FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"

mkdir -p $FILE_DIRECTORY

wget -O "$FILE" <<- "EOF"
{
  "123456789012": "arn:aws:iam::123456789012:role/ASSUMABLE-ROLE"
}
EOF
```

Connect to an Amazon EMR Cluster from Studio

This guide explains how you can connect to an Amazon EMR cluster from SageMaker Studio with the PySpark kernel selected.

To connect Amazon EMR cluster with PySpark kernel selected

1. After you connect to Studio, if you have an existing Studio notebook instance, open that. Otherwise, to create a new notebook instance, select File, and then select New.

2. After you have an open Studio notebook instance, choose a kernel and instance.

Note

Only a subset of kernels can connect to an Amazon EMR cluster. The supported images are Data Science and SparkMagic. The supported kernels are PySpark from the SparkMagic image and Python3 (IPython) from the Data Science image. Studio supports both PySpark and Scala kernels.
To switch your kernel, select in the top right of the UI the currently selected kernel where a pop-up window appears. Then select a kernel of your choice from the kernel drop-down menu. Lastly, select the **Select** button to make your changes.
3. After you have selected your kernel of choice, select **Cluster**.
4. A **Connect to cluster** UI screen will appear. Choose a cluster and select **Connect**. Not all Amazon EMR clusters can be connected to Studio. For more information, see Perform interactive data processing using Spark in Studio Notebooks.

When you connect to a cluster, it adds a code block to an active cell to establish the connection.
5. If the cluster that you're connecting to does not use Kerberos or Lightweight Directory Access Protocol (LDAP) connection, you will be prompted to select the credential type. You can choose **HTTP basic authentication** or **No credential**.
6. An active cell will populate. This will contain the connection information that you need for connecting to the Amazon EMR cluster that you selected.

   - When the authentication type is Kerberos and HTTP Basic Auth, a widget will be created in an active cell for you to provide your Username and Password.
   - If the cluster that you are connecting to does not use Kerberos or LDAP, and you selected No credentials, you will automatically connect to an Amazon EMR cluster.

7. This step is optional. If you want to change the Amazon EMR cluster that the Studio notebook is connected to, select Cluster at the top-right of your notebook. After selecting Cluster, browse the list of clusters and select a different cluster.

For more information on required permissions, see Required Permissions (p. 1093).

**Connect Amazon EMR Clusters Across Accounts**

If you have set up cross-account discoverability and connectivity, when you select Cluster, all clusters from both Studio and remote accounts will show. After you select Connect, Studio will initiate and establish a connection to the Amazon EMR cluster in the remote account. The following screenshot shows this connection.
SageMaker resources
Select the resource to view.

Clusters

Create and manage Amazon EMR Clusters from here. Use "View Clusters" to see a list of Amazon EMR clusters visible to you. Use "Create Cluster" to create an EMR cluster based on a template provided by your administrator.

Create cluster
Troubleshoot and Monitor Workloads in Amazon EMR

The following sections give instructions for accessing the Spark UI from SageMaker Studio notebooks. The Spark UI allows you to monitor and debug your Spark Jobs submitted to run on Amazon EMR from Studio notebooks. SSH tunneling and presigned URLs are two ways for accessing the Spark UI.

Set up SSH tunneling for Spark UI access

To set up SSH tunneling to access the Spark UI, follow one of the two options in this section. Note that the screenshot in Step 6b of Connect to an Amazon EMR Cluster from Studio (p. 1065) shows links under Spark UI and Driver log. These links will activate only after you complete the SSH tunneling setup.

Options for setting up SSH tunneling:

- **Option 1:** Set up an SSH tunnel to the master node using local port forwarding
- **Option 2, part 1:** Set up an SSH tunnel to the master node using dynamic port forwarding
- **Option 2, part 2:** Configure proxy settings to view websites hosted on the master node

For information about viewing web interfaces hosted on Amazon EMR clusters, see View web interfaces hosted on Amazon EMR Clusters. You can also visit your Amazon EMR console to get access to the Spark UI.

Note
You can set up an SSH tunnel even if presigned URLs are not available to you.

Presigned URLs

To create one-click URLs that can access Spark UI on Amazon EMR from SageMaker Studio notebooks, you must enable the following IAM permissions. Choose the option that applies to you:

- **For Amazon EMR clusters that are in the same account as the SageMaker Studio notebook:** Add the following permissions to the SageMaker Studio IAM execution role.
- **For Amazon EMR clusters that are in a different account (not SageMaker Studio notebook):** Add the following permissions to the cross-account role that you created for Discover Amazon EMR Clusters from Studio (p. 1062).

Note
You can access presigned URLs from the console in the following regions:

- US East (N. Virginia) Region
- US West (N. California) Region
- Canada (Central) Region
- Europe (Frankfurt) Region
- Europe (Stockholm) Region
- Europe (Ireland) Region
- Europe (London) Region
- Europe (Paris) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Sydney) Region
- Asia Pacific (Mumbai) Region
The following policy gives access to presigned URLs for your execution role.

```json
{
   "Sid": "AllowPresignedUrl",
   "Effect": "Allow",
   "Action": [
      "elasticmapreduce:DescribeCluster",
      "elasticmapreduce:ListInstanceGroups",
      "elasticmapreduce:CreatePersistentAppUI",
      "elasticmapreduce:DescribePersistentAppUI",
      "elasticmapreduce:GetPersistentAppUIPresignedURL",
      "elasticmapreduce:GetOnClusterAppUIPresignedURL"
   ],
   "Resource": [
      "arn:aws:elasticmapreduce:<region>:<account-id>:cluster/*"
   ]
}
```

For more information about required permissions, see Required Permissions (p. 1093).

**Manage Amazon EMR Clusters from Studio**

Administrators can use AWS Service Catalog to define templates. These templates allow you to create Amazon EMR clusters and make them available to selected users. Using AWS Service Catalog, administrators can fully control the organizational, security, and networking in Amazon EMR clusters. Administrators can view, select, and customize templates for their specific workloads. If they choose, admins can limit exposure to selected configuration parameters, such as only to specific data workers. Admins can create on-demand Amazon EMR clusters within SageMaker Studio. This can be done without manually setting up complex configurations. Users can also terminate Amazon EMR clusters after use, directly from SageMaker Studio.

The topics in this guide provide more details about setting up and using AWS Service Catalog templates, and creating and terminating Amazon EMR clusters.

**Topics**
- Configure AWS Service Catalog Products (p. 1077)
- Provision Amazon EMR Clusters from Studio (p. 1081)

**Configure AWS Service Catalog Products**

In this guide, you get parameters for configuring AWS Service Catalog products so you can discover CloudFormation (CFN) templates. CFN templates are used to create and manage Amazon EMR clusters. The AWS Service Catalog product can associate with an AWS Service Catalog portfolio that is shared with the Studio execution role IAM entity.

To enable Amazon EMR cluster management from Studio, you need a CloudFormation (CFN) template with Amazon EMR cluster details and configurable parameters. For information about how you can use CloudFormation, see Getting started with CloudFormation. For more information about AWS Service Catalog products, see Step 4: Create an AWS Service Catalog Product.

The AWS Service Catalog product with the Amazon EMR resource must have the following tags:

```
sagemaker:studio-visibility:emr true
```
The CFN templates in the AWS Service Catalog product must have the following mandatory stack parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMakerProjectName</td>
<td>String</td>
<td>Name of the project</td>
</tr>
<tr>
<td>SageMakerProjectId</td>
<td>String</td>
<td>Service generated Id of the project.</td>
</tr>
</tbody>
</table>

For more information about creating AWS Service Catalog portfolios and products, see Step 3: Create an AWS Service Catalog Portfolio and its subsequent sections.

Optional template parameters

When creating Amazon EMR templates from within SageMaker Studio, you can include additional options in the parameters section of your template. This section lets users input or select custom values for a cluster. The following example parameters define additional input parameters that you can use when creating an Amazon EMR template from within Studio.

```
"Parameters": {
    "EmrClusterName": { 
        "Type": "String",
        "Description": "EMR cluster Name."
    },
    "MasterInstanceType": { 
        "Type": "String",
        "Description": "Instance type of the EMR master node.",
        "Default": "m5.xlarge",
        "AllowedValues": [
            "m5.xlarge",
            "m5.2xlarge",
            "m5.4xlarge"
        ]
    },
    "CoreInstanceType": { 
        "Type": "String",
        "Description": "Instance type of the EMR core nodes.",
        "Default": "m5.xlarge",
        "AllowedValues": [
            "m5.xlarge",
            "m5.2xlarge",
            "m5.4xlarge",
            "m3.medium",
            "m3.large",
            "m3.xlarge",
            "m3.2xlarge"
        ]
    },
    "CoreInstanceCount": { 
        "Type": "String",
        "Description": "Number of core instances in the EMR cluster.",
        "Default": "2",
        "AllowedValues": [
            "2",
            "5",
            "10"
        ]
    },
    "EmrReleaseVersion": { 
        "Type": "String",
        "Description": "The release version of EMR to launch."
    }
}
```
The following image shows how the Studio UI will look when you create an Amazon EMR cluster from Studio.
Provision Amazon EMR Clusters from Studio

This section provides guided instructions with screenshots from Studio that show how to create a cluster, view a list of available clusters, and terminate a cluster.

If you configured cross-account discovery, you will see a consolidated list of clusters in Studio, and in the remote account.

To start, add the following permissions to the IAM execution role that will be accessing Studio. For more information about required permissions, see Required Permissions (p. 1093).

```json
{
   "Sid": "AllowSagemakerProjectManagement",
   "Effect": "Allow",
   "Action": [
      "sagemaker:CreateProject",
      "sagemaker:DeleteProject"
   ],
   "Resource": "arn:aws:sagemaker:<region>:<account-id>:project/*"
}
```

After you've added the previous permissions, you can connect to Studio. If you have an existing Studio notebook instance, you can open it. Otherwise, if you want to create a new notebook instance, select File, and then select New.

• To open the cluster management page, select **Clusters** from the left-side panel.
The following screenshot shows the cluster management page. From here, you can create and manage your Amazon EMR clusters.
SageMaker resource
Select the resource to
Clusters
Create and manage
"View Clusters" to see
you. Use "Create Clu

Amazon SageMaker Developer Guide
Prepare Data using Amazon EMR
A cluster can be in different statuses. To filter clusters by status, select the dropdown arrow icon. A cluster can only be in one status at a time.

Status options include Starting, Bootstrapping, Running/Walking, Terminating, Terminated, and Terminated with error. The following screenshot shows the cluster status options in the status dropdown.
The following procedure shows how to create a cluster using a template from Studio.

**To create a cluster from a template:**

1. Navigate to the cluster management page by selecting the Clusters from the left-side panel. Then, select Create cluster.
Amazon SageMaker Studio

SageMaker resources
Select the resource to view.

Clusters
Create and manage Amazon EMR Clusters. Use “View Clusters” to see a list of clusters available to you. Use “Create Cluster” to create a new cluster template provided by your administrator.

Manage Amazon EMR Clusters
Prepare data at scale with Studio.
2. Enter your SageMaker Studio subnet ID, Amazon EMR cluster name, Amazon VPC ID, and SageMaker Studio security group ID.
Create and manage Amazon EMR Clusters from "View Clusters" to see a list of Amazon EMR clusters available to you. Use "Create Cluster" to create an EMR cluster using the EMR template provided by your administrator.

Manage Amazon EMR Clusters from Studio

Prepare data at scale with Studio Notebooks
3. After entering the information from the previous step, select **Create cluster**.

The following procedure shows how to terminate a cluster.

**To terminate a cluster**

1. Navigate to the cluster management page by selecting the **Clusters** from the left-side panel.

   Select the cluster that you want to terminate, then choose **Terminate** next to **Create cluster** in the UI.

2. A window will appear advising that any pending work or data on your cluster will be lost after termination, and termination is irreversible. Select **Terminate**.
Required Permissions

This guide shows you how to apply an example IAM policy to your execution role. The examples in this guide provide you with various permissions and monitoring capabilities. At the end of this guide, you will find a comprehensive IAM policy role that includes all required permissions. These permissions provide access to Amazon EMR clusters from within Studio, and allow discoverability of clusters from within Studio (for presigned URLs). Access the IAM console to add the policy to your role.

To discover and connect to Amazon EMR clusters from within Studio, ensure that your execution role has the following permissions:

```
{
    "Sid": "AllowClusterDetailsDiscovery",
    "Effect": "Allow",
    "Action": [
        "elasticmapreduce:DescribeCluster",
        "elasticmapreduce:ListInstanceGroups"
    ],
    "Resource": [
        "arn:aws:elasticmapreduce:<region>:<account-id>:cluster/*"
    ]
},
{
    "Sid": "AllowClusterDiscovery",
    "Effect": "Allow",
    "Action": [
        "elasticmapreduce:ListClusters"
    ],
    "Resource": "*"
}
```

To enhance monitoring capabilities, attach the following permissions to your Studio execution role:

```
{
    "Sid": "AllowPresignedUrl",
    "Effect": "Allow",
    "Action": [
        "elasticmapreduce:DescribeCluster",
        "elasticmapreduce:ListInstanceGroups",
        "elasticmapreduce:CreatePersistentAppUI",
        "elasticmapreduce:DescribePersistentAppUI",
        "elasticmapreduce:GetPersistentAppUIPresignedURL",
        "elasticmapreduce:GetOnClusterAppUIPresignedURL"
    ],
    "Resource": [
        "arn:aws:elasticmapreduce:<region>:<account-id>:cluster/*"
    ]
}
```

To allow users to create Amazon EMR clusters, add the following permission to your Studio execution role:

```
{
    "Sid": "AllowSagemakerProjectManagement",
    "Effect": "Allow",
    "Action": [
        "sagemaker:CreateProject",
        "sagemaker:DeleteProject"
    ],
    "Resource": "arn:aws:sagemaker:<region>:<account-id>:project/*"
}
```
If you have provided Studio with a cross-account discovery and connectivity role, the role in the non-Studio account must allow "assume role" permissions to the Studio execution role. This can be done by attaching the following permissions to your Studio execution role:

**Note**
For all cross-account use cases, the Studio execution role must have the `sts:AssumeRole` permission added to allow Studio to assume a role in the remote account.

```json
{
   "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
   "Effect": "Allow",
   "Action": ["sts:AssumeRole"],
   "Resource": ["arn:aws:iam::<cross-account>:role/<studio-execution-role>"
}
```

To allow discoverability for Amazon EMR templates, attach the following permissions to your Studio execution role:

```json
{
   "Sid": "AllowEMRTemplateDiscovery",
   "Effect": "Allow",
   "Action": ["servicecatalog:SearchProducts"],
   "Resource": "*"
}
```

The following is a comprehensive example IAM policy that includes all of the previous permissions in this guide:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowPresignedUrl",
         "Effect": "Allow",
         "Action": ["elasticmapreduce:DescribeCluster",
                     "elasticmapreduce:ListInstanceGroups",
                     "elasticmapreduce:CreatePersistentAppUI",
                     "elasticmapreduce:DescribePersistentAppUI",
                     "elasticmapreduce:GetPersistentAppUIPresignedURL",
                     "elasticmapreduce:GetOnClusterAppUIPresignedURL"],
      },
      {
         "Sid": "AllowClusterDetailsDiscovery",
         "Effect": "Allow",
         "Action": ["elasticmapreduce:DescribeCluster",
                     "elasticmapreduce:ListInstanceGroups"],
      },
      {
         "Sid": "AllowClusterDiscovery",
         "Effect": "Allow",
         "Action": ["elasticmapreduce:DescribeCluster",
                     "elasticmapreduce:ListInstanceGroups"],
      }
   ]
}
```
Prepare Data using AWS Glue Interactive Sessions

AWS Glue Interactive Sessions is a serverless service that equips you with the tools to collect, transform, cleanse, and prepare the data that will populate your data lakes and pipelines. Glue Interactive Sessions provides an on-demand, serverless Apache Spark runtime environment that data scientists and engineers can use to rapidly build, test, and run data preparation and analytics applications.

Starting a Glue interactive session from a SageMaker Studio notebook is simple. When you create your Studio notebook, choose the built-in Glue PySpark or Glue Spark kernel and start coding in your interactive, serverless Spark session in just seconds. You don't have to worry about provisioning or managing complex compute cluster infrastructure. After initialization, you can quickly browse the Glue data catalog, run large queries, and interactively analyze and prepare data using Spark, all within your Studio notebook. You can then use the prepared data to build, train, tune, and deploy models using the purpose-built ML tools within SageMaker Studio.

Before you start your AWS Glue interactive session in SageMaker Studio, you need to set the appropriate roles and policies. You may also need access to additional resources, such as Amazon S3, which may require additional policies. For more information about required and additional IAM policies, see Permissions for Glue Interactive Sessions in SageMaker Studio (p. 1096).

SageMaker Studio provides a default configuration for your AWS Glue interactive session, but you can use Glue's full catalog of Jupyter magic commands to further customize your environment. For information about the default and additional Jupyter magics that you can use in your Glue interactive session, see Configure your Glue interactive session in SageMaker Studio (p. 1098).

The supported images and kernels for connecting to a Glue interactive session are as follows:

- Images: SparkAnalytics 1.0, SparkAnalytics 2.0
- Kernel: Glue Python [PySpark and Ray] and Glue Spark
Prerequisites:

The SparkAnalytics image that you select to launch your Glue session in Studio is a combination of two frameworks - the SparkMagic framework (used with Amazon EMR), and AWS Glue. For this reason, the prerequisites for both frameworks apply. However, you do not have to set up the EMR cluster if you only plan to use Glue Interactive Sessions. Before you start your first Glue interactive session in Studio, complete the following:

- Complete the prerequisites required to use the SparkMagic image. For a list of the prerequisites, see the Prerequisites section in Prepare Data at Scale with Studio Notebooks.
- Create an execution role with permissions for both AWS Glue and SageMaker Studio. Add the managed policy AwsGlueSessionUserRestrictedServiceRole, and create a custom policy that includes permissions sts:GetCallerIdentity, iam:GetRole, and IAM:Passrole. For instructions about how to create the necessary permissions, see Permissions for Glue Interactive Sessions in SageMaker Studio (p. 1096).
- Create a SageMaker domain with the execution role you created. For instructions about how to create a domain, see Onboard to Amazon SageMaker Domain Using IAM (p. 42).

Get Started with AWS Glue Interactive Sessions

This guide will show you how set up the necessary permissions, launch your first Glue interactive session in Studio, and manage your environment with Jupyter magics.

Permissions for Glue Interactive Sessions in SageMaker Studio

This guide will show you how to obtain the required permissions to use Glue Interactive Sessions in Studio. You will attach two managed policies, then create and attach a custom policy, and lastly, modify the trust relationship.

To add the managed policies to your execution role

1. Open the IAM console.
2. Select Roles in the left-side panel.
3. Find the Studio execution role that you will use, and choose the role name to go to the role summary page.
4. Under the Permissions tab, select Attach policies from the Add Permissions dropdown menu.
5. Select the checkbox next to the managed policy AwsGlueSessionUserRestrictedServiceRole.
6. Choose Attach policies.

   The summary page shows your newly-added managed policies.

To create the custom policy and attach it to your execution role

1. Select Create inline policy in the Add Permissions dropdown menu.
2. Select the JSON tab.
3. Copy and paste in the following policy.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "unique_statement_id",
         "Effect": "Allow",
         "Action": ["sts:GetCallerIdentity", "iam:GetRole", "IAM:Passrole"],
         "Resource": "*"
       }
     ]
   }
   ```
4. Choose **Review policy**.
5. Enter a **Name** and choose **Create policy**.

The summary page shows your newly-added custom policy.

**To modify the trust relationship**

1. Select the **Trust relationships** tab.
2. Choose **Edit trust policy**.
3. Copy and paste in the following policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "glue.amazonaws.com",
                    "sagemaker.amazonaws.com"
                ],
            "sts:GetCallerIdentity"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

4. Choose **Update policy**.

You can add additional roles and policies if you need to access other AWS resources. For a description of the additional roles and policies you can include, see **Interactive sessions with IAM** in the AWS Glue documentation.

**Launch your Glue interactive session on SageMaker Studio**

After you create the roles, policies, and SageMaker domain, you can launch your Glue interactive session in SageMaker Studio.

**To launch Glue in SageMaker Studio**

1. Create a SageMaker domain. For instructions on how to create a new domain, see **Onboard to Amazon SageMaker Domain** (p. 36).
3. Select **Control Panel** in the left-side panel.
4. In the **Launch App** dropdown menu next to the user name, select **Studio**.
5. In the Jupyter view, choose **File**, then **New**, then **Notebook**.
6. In the Image dropdown menu, select SparkAnalytics 1.0 or SparkAnalytics 2.0. In the kernel dropdown menu, select Glue Spark or Glue Python [PySpark and Ray]. Choose Select.

7. (optional) Use Jupyter magics to customize your environment. For more information about Jupyter magics, see Configure your Glue interactive session in SageMaker Studio (p. 1098).

8. Start writing your Spark data processing scripts.

**Configure your Glue interactive session in SageMaker Studio**

You can use Jupyter magics in your AWS Glue interactive session to modify your session and configuration parameters. Magics are short commands prefixed with `%` at the start of Jupyter cells that provide a quick and easy way to help you control your environment. In your Glue interactive session, the following magics are set for you by default:

<table>
<thead>
<tr>
<th>Magic</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%glue_version</code></td>
<td>3.0</td>
</tr>
<tr>
<td><code>%iam_policy</code></td>
<td>execution role attached to your SageMaker domain</td>
</tr>
<tr>
<td><code>%region</code></td>
<td>your region</td>
</tr>
</tbody>
</table>

You can use magics to further customize your environment. For example, if you want to change the number of workers allocated to your job from the default five to 10, you can specify `%number_of_workers 10`. If you want to configure your session to stop after 10 minutes of idle time instead of the default 2880, you can specify `%idle_timeout 10`.

All of the Jupyter magics currently available in AWS Glue are also available in SageMaker Studio. For the complete list of AWS Glue magics available, see Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks.

**AWS Glue Interactive Session Pricing**

When you use AWS Glue Interactive Sessions on SageMaker Studio notebooks, you are charged separately for resource usage on AWS Glue and Studio notebooks.

AWS charges for Glue Interactive Sessions based on how long the session is active and the number of Data Processing Units (DPU) used. You are charged an hourly rate for the number of DPUs used to run your workloads, billed in increments of one second. Glue Interactive Sessions assigns a default of five DPUs and requires a minimum of two DPUs. There is also a one-minute minimum billing duration for each interactive session. To see the AWS Glue rates and pricing examples, or to estimate your costs using the AWS Pricing Calculator, see AWS Glue pricing.

Your SageMaker Studio notebook runs on an Amazon EC2 instance and you are charged for the instance type you choose, based on the duration of use. Studio assigns you a default EC2 instance type of m1-t3-medium when you select the SparkAnalytics image and associated kernel. You can change the instance type for your Studio notebook to suit your workload. For information about SageMaker Studio pricing, see Amazon SageMaker Pricing.
Process Data

To analyze data and evaluate machine learning models on Amazon SageMaker, use Amazon SageMaker Processing. With Processing, you can use a simplified, managed experience on SageMaker to run your data processing workloads, such as feature engineering, data validation, model evaluation, and model interpretation. You can also use the Amazon SageMaker Processing APIs during the experimentation phase and after the code is deployed in production to evaluate performance.

The preceding diagram shows how Amazon SageMaker spins up a Processing job. Amazon SageMaker takes your script, copies your data from Amazon Simple Storage Service (Amazon S3), and then pulls a processing container. The processing container image can either be an Amazon SageMaker built-in image or a custom image that you provide. The underlying infrastructure for a Processing job is fully managed by Amazon SageMaker. Cluster resources are provisioned for the duration of your job, and cleaned up when a job completes. The output of the Processing job is stored in the Amazon S3 bucket you specified.

Note
Your input data must be stored in an Amazon S3 bucket. Alternatively, you can use Amazon Athena or Amazon Redshift as input sources.

Use Amazon SageMaker Processing Sample Notebooks

We provide two sample Jupyter notebooks that show how to perform data preprocessing, model evaluation, or both.

For a sample notebook that shows how to run scikit-learn scripts to perform data preprocessing and model training and evaluation with the SageMaker Python SDK for Processing, see scikit-learn Processing. This notebook also shows how to use your own custom container to run processing workloads with your Python libraries and other specific dependencies.

For a sample notebook that shows how to use Amazon SageMaker Processing to perform distributed data preprocessing with Spark, see Distributed Processing (Spark). This notebook also shows how to train a regression model using XGBoost on the preprocessed dataset.

For instructions on how to create and access Jupyter notebook instances that you can use to run these samples in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have
created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

Amazon SageMaker Processing provides Amazon CloudWatch logs and metrics to monitor processing jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818) and Log Amazon SageMaker Events with Amazon CloudWatch (p. 3830).

Data Processing with Apache Spark

Apache Spark is a unified analytics engine for large-scale data processing. Amazon SageMaker provides prebuilt Docker images that include Apache Spark and other dependencies needed to run distributed data processing jobs. With the Amazon SageMaker Python SDK, you can easily apply data transformations and extract features (feature engineering) using the Spark framework. For information about using the SageMaker Python SDK to run Spark processing jobs, see Data Processing with Spark in the Amazon SageMaker Python SDK.

A code repository that contains the source code and Dockerfiles for the Spark images is available on GitHub.

Running a Spark Processing Job

You can use the sagemaker.spark.PySparkProcessor or sagemaker.spark.SparkJarProcessor class to run your Spark application inside of a processing job. Note you can set MaxRuntimeInSeconds to a maximum runtime limit of 5 days. With respect to execution time, and number of instances used, simple spark workloads see a near linear relationship between the number of instances vs. time to completion.

The following code example shows how to run a processing job that invokes your PySpark script preprocess.py.

```python
from sagemaker.spark.processing import PySparkProcessor

spark_processor = PySparkProcessor(
base_job_name="spark-preprocessor",
framework_version="2.4",
role=role,
instance_count=2,
instance_type="ml.m5.xlarge",
max_runtime_in_seconds=1200,
)

spark_processor.run(
    submit_app="preprocess.py",
    arguments=['s3_input_bucket', bucket,
              's3_input_key_prefix', input_prefix,
              's3_output_bucket', bucket,
              's3_output_key_prefix', output_prefix]
)
```
For an in-depth look, see the Distributed Data Processing with Apache Spark and SageMaker Processing example notebook.

If you are not using the Amazon SageMaker Python SDK and one of its Processor classes to retrieve the pre-built images, you can retrieve these images yourself. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). For a complete list of the available pre-built Docker images, see the available images document.

To learn more about using the SageMaker Python SDK with Processing containers, see Amazon SageMaker Python SDK.

Data Processing with scikit-learn

For a sample notebook that shows how to run scikit-learn scripts using a Docker image provided and maintained by SageMaker to preprocess data and evaluate models, see scikit-learn Processing. To use this notebook, you need to install the SageMaker Python SDK for Processing.

This notebook runs a processing job using SKLearnProcessor class from the the SageMaker Python SDK to run a scikit-learn script that you provide. The script preprocesses data, trains a model using a SageMaker training job, and then runs a processing job to evaluate the trained model. The processing job estimates how the model is expected to perform in production.

To learn more about using the SageMaker Python SDK with Processing containers, see the SageMaker Python SDK. For a complete list of pre-built Docker images available for processing jobs, see Docker Registry Paths and Example Code (p. 2396) and choose your region.

The following code example shows how the notebook uses SKLearnProcessor to run your own scikit-learn script using a Docker image provided and maintained by SageMaker, instead of your own Docker image.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput

sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                     role=role,
                                     instance_type='ml.m5.xlarge',
                                     instance_count=1)

sklearn_processor.run(code='preprocessing.py',
                      inputs=[ProcessingInput(
                               source='s3://path/to/my/input-data.csv',
                               destination='/opt/ml/processing/input')],
                      outputs=[ProcessingOutput(source='/opt/ml/processing/output/train'),
                               ProcessingOutput(source='/opt/ml/processing/output/validation'),
                               ProcessingOutput(source='/opt/ml/processing/output/test')])
```

To process data in parallel using Scikit-Learn on Amazon SageMaker Processing, you can shard input objects by S3 key by setting `s3_data_distribution_type='ShardedByS3Key'` inside a `ProcessingInput` so that each instance receives about the same number of input objects.

Data Processing with Framework Processors

A FrameworkProcessor can run Processing jobs with a specified machine learning framework, providing you with an Amazon SageMaker–managed container for whichever machine learning
framework you choose. FrameworkProcessor provides premade containers for the following machine learning frameworks: Hugging Face, MXNet, PyTorch, TensorFlow, and XGBoost.

The FrameworkProcessor class also provides you with customization over the container configuration. The FrameworkProcessor class supports specifying a source directory source_dir for your processing scripts and dependencies. With this capability, you can give the processor access to multiple scripts in a directory instead of only specifying one script. FrameworkProcessor also supports including a requirements.txt file in the source_dir for customizing the Python libraries to install in the container.

For more information on the FrameworkProcessor class and its methods and parameters, see FrameworkProcessor in the Amazon SageMaker Python SDK.

To see examples of using a FrameworkProcessor for each of the supported machine learning frameworks, see the following topics.

Topics
- Hugging Face Framework Processor (p. 1102)
- MXNet Framework Processor (p. 1103)
- PyTorch Framework Processor (p. 1104)
- TensorFlow Framework Processor (p. 1105)
- XGBoost Framework Processor (p. 1106)

Hugging Face Framework Processor

Hugging Face is an open-source provider of natural language processing (NLP) models. The HuggingFaceProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with Hugging Face scripts. When you use the HuggingFaceProcessor, you can leverage an Amazon-built Docker container with a managed Hugging Face environment so that you don't need to bring your own container.

The following code example shows how you can use the HuggingFaceProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.huggingface import HuggingFaceProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the HuggingFaceProcessor
hfp = HuggingFaceProcessor(
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.g4dn.xlarge',
    transformers_version='4.4.2',
    pytorch_version='1.6.0',
    base_job_name='frameworkprocessor-hf'
)

#Run the processing job
hfp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
```
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the Hugging Face Processor class, see Hugging Face Estimator in the Amazon SageMaker Python SDK.

**MXNet Framework Processor**

Apache MXNet is an open-source deep learning framework commonly used for training and deploying neural networks. The MXNetProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with MXNet scripts. When you use the MXNetProcessor, you can leverage an Amazon-built Docker container with a managed MXNet environment so that you don't need to bring your own container.

The following code example shows how you can use the MXNetProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.mxnet import MXNetProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput

#Initialize the MXNetProcessor
mxp = MXNetProcessor(
    framework_version='1.8.0',
    py_version='py37',
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.c5.xlarge',
    base_job_name='frameworkprocessor-mxnet'
)

#Run the processing job
mxp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://(BUCKET)/(S3_INPUT_PATH)',
            destination='/opt/ml/processing/input/data/'
        ),
    ],
    outputs=[
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train/',
                        destination=f's3://(BUCKET)/(S3_OUTPUT_PATH)'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test/',
                         destination=f's3://(BUCKET)/(S3_OUTPUT_PATH)'),
        ProcessingOutput(output_name='val', source='/opt/ml/processing/output/val/',
                         destination=f's3://(BUCKET)/(S3_OUTPUT_PATH)')
    ]
)
```
PyTorch Framework Processor

PyTorch is an open-source machine learning framework. The PyTorchProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with PyTorch scripts. When you use the PyTorchProcessor, you can leverage an Amazon-built Docker container with a managed PyTorch environment so that you don’t need to bring your own container.

The following code example shows how you can use the PyTorchProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.pytorch.processing import PyTorchProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the PyTorchProcessor
pytorch_processor = PyTorchProcessor(
    framework_version='1.8',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-PT'
)

#Run the processing job
pytorch_processor.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input'
        ),
    ],
    outputs=[
        ProcessingOutput(output_name='data_structured', source='/opt/ml/processing/tmp/data_structured', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='validation', source='/opt/ml/processing/output/val', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the MXNetProcessor class, see MXNet Estimator in the Amazon SageMaker Python SDK.
TensorFlow is an open-source machine learning and artificial intelligence library. The TensorFlowProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with TensorFlow scripts. When you use the TensorFlowProcessor, you can leverage an Amazon-built Docker container with a managed TensorFlow environment so that you don't need to bring your own container.

The following code example shows how you can use the TensorFlowProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.tensorflow import TensorFlowProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the TensorFlowProcessor
tp = TensorFlowProcessor(
    framework_version='2.3',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-TF',
    py_version='py37',
)

#Run the processing job
tp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://(BUCKET)/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        ),
        ProcessingInput(
            input_name='model',
            source=f's3://(BUCKET)/{S3_PATH_TO_MODEL}',
            destination='/opt/ml/processing/input/model'
        ),
    ],
    outputs=[
        ProcessingOutput(
            output_name='predictions',
            source='/opt/ml/processing/output',
            destination=f's3://(BUCKET)/{S3_OUTPUT_PATH}')
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the PyTorchProcessor class, see PyTorch Estimator in the Amazon SageMaker Python SDK.
XGBoost Framework Processor

XGBoost is an open-source machine learning framework. The XGBoostProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with XGBoost scripts. When you use the XGBoostProcessor, you can leverage an Amazon-built Docker container with a managed XGBoost environment so that you don't need to bring your own container.

The following code example shows how you can use the XGBoostProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.xgboost import XGBoostProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the XGBoostProcessor
xgb = XGBoostProcessor(
    framework_version='1.2-2',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-XGB',
)

#Run the processing job
xgb.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://[BUCKET]/[S3_INPUT_PATH]',
            destination='/opt/ml/processing/input/data'
        ),
    ],
    outputs=[
        ProcessingOutput(
            output_name='processed_data',
            source='/opt/ml/processing/output/',
            destination=f's3://[BUCKET]/[S3_OUTPUT_PATH]'
        ),
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the TensorFlowProcessor class, see TensorFlow Estimator in the Amazon SageMaker Python SDK.
specify for source_dir. To learn more about the XGBoostProcessor class, see XGBoost Estimator in the Amazon SageMaker Python SDK.

Use Your Own Processing Code

You can install libraries to run your scripts in your own processing container or, in a more advanced scenario, you can build your own processing container that satisfies the contract to run in Amazon SageMaker. For more information about containers in SageMaker, see Using Docker containers with SageMaker (p. 2392). For a formal specification that defines the contract for an Amazon SageMaker Processing container, see Build Your Own Processing Container (Advanced Scenario) (p. 1108).

Topics
- Run Scripts with Your Own Processing Container (p. 1107)
- Build Your Own Processing Container (Advanced Scenario) (p. 1108)

Run Scripts with Your Own Processing Container

You can use scikit-learn scripts to preprocess data and evaluate your models. To see how to run scikit-learn scripts to perform these tasks, see the scikit-learn Processing sample notebook. This notebook uses the ScriptProcessor class from the Amazon SageMaker Python SDK for Processing.

The following example shows a general workflow for using a ScriptProcessor class with your own processing container. The workflow shows how to create your own image, build your container, and use a ScriptProcessor class to run a Python preprocessing script with the container. The processing job processes your input data and saves the processed data in Amazon Simple Storage Service (Amazon S3).

Before using the following examples, you need to have your own input data and a Python script prepared to process your data. For an end-to-end, guided example of this process, refer back to the scikit-learn Processing sample notebook.

1. Create a Docker directory and add the Dockerfile used to create the processing container. Install pandas and scikit-learn into it. (You could also install your own dependencies with a similar RUN command.)

   mkdir docker
   %writefile docker/Dockerfile
   FROM python:3.7-slim-buster
   RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3
   ENV PYTHONUNBUFFERED=TRUE
   ENTRYPOINT ["python3"]

2. Build the container using the docker command, create an Amazon Elastic Container Registry (Amazon ECR) repository, and push the image to Amazon ECR.

   import boto3
   account_id = boto3.client('sts').get_caller_identity().get('Account')
   region = boto3.Session().region_name
   ecr_repository = 'sagemaker-processing-container'
   tag = ':latest'
   processing_repository_uri = '{}.dkr.ecr.{}.amazonaws.com/{}'.format(account_id, region, ecr_repository + tag)
# Create ECR repository and push docker image
```bash
docker build -t $ecr_repository docker
aws ecr get-login-password --region {region} | docker login --username AWS --password-stdin {account_id}.dkr.ecr.{region}.amazonaws.com
aws ecr create-repository --repository-name $ecr_repository
docker tag {ecr_repository + tag} $processing_repository_uri
docker push $processing_repository_uri
```

3. Set up the ScriptProcessor from the SageMaker Python SDK to run the script. Replace `image_uri` with the URI for the image you created, and replace `role_arn` with the ARN for an AWS Identity and Access Management role that has access to your target Amazon S3 bucket.

```python
from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput

script_processor = ScriptProcessor(command=['python3'],
                                    image_uri='image_uri',
                                    role='role_arn',
                                    instance_count=1,
                                    instance_type='ml.m5.xlarge')
```

4. Run the script. Replace `preprocessing.py` with the name of your own Python processing script, and replace `s3://path/to/my/input-data.csv` with the Amazon S3 path to your input data.

```python
script_processor.run(code='preprocessing.py',
                     inputs=[ProcessingInput(
                     source='s3://path/to/my/input-data.csv',
                     destination='/opt/ml/processing/input')],
                     outputs=[ProcessingOutput(source='/opt/ml/processing/output/train'),
                              ProcessingOutput(source='/opt/ml/processing/output/validation'),
                              ProcessingOutput(source='/opt/ml/processing/output/test')])
```

You can use the same procedure with any other library or system dependencies. You can also use existing Docker images. This includes images that you run on other platforms such as Kubernetes.

## Build Your Own Processing Container (Advanced Scenario)

You can provide Amazon SageMaker Processing with a Docker image that has your own code and dependencies to run your data processing, feature engineering, and model evaluation workloads.

The following example of a Dockerfile builds a container with the Python libraries scikit-learn and pandas, which you can run as a processing job.

```Dockerfile
FROM python:3.7-slim-buster
# Install scikit-learn and pandas
RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3
# Add a Python script and configure Docker to run it
ADD processing_script.py /
ENTRYPOINT ["python3", "/processing_script.py"]
```

Build and push this Docker image to an Amazon Elastic Container Registry (Amazon ECR) repository and ensure that your SageMaker IAM role can pull the image from Amazon ECR. Then you can run this image on Amazon SageMaker Processing.
How Amazon SageMaker Processing Runs Your Processing Container Image

Amazon SageMaker Processing runs your processing container image in a similar way as the following command, where AppSpecification.ImageUri is the Amazon ECR image URI that you specify in a CreateProcessingJob operation.

```
docker run [AppSpecification.ImageUri]
```

This command runs the ENTRYPOINT command configured in your Docker image.

You can also override the entrypoint command in the image or give command-line arguments to your entrypoint command using the AppSpecification.ContainerEntrypoint and AppSpecification.ContainerArgument parameters in your CreateProcessingJob request. Specifying these parameters configures Amazon SageMaker Processing to run the container similar to the way that the following command does.

```
```

For example, if you specify the ContainerEntrypoint to be [python3, -v, /processing_script.py] in your CreateProcessingJob request, and ContainerArguments to be [data-format, csv], Amazon SageMaker Processing runs your container with the following command.

```
python3 -v /processing_script.py data-format csv
```

When building your processing container, consider the following details:

- Amazon SageMaker Processing decides whether the job completes or fails depending on the exit code of the command run. A processing job completes if all of the processing containers exit successfully with an exit code of 0, and fails if any of the containers exit with a non-zero exit code.
- Amazon SageMaker Processing lets you override the processing container’s entrypoint and set command-line arguments just like you can with the Docker API. Docker images can also configure the entrypoint and command-line arguments using the ENTRYPOINT and CMD instructions. The way CreateProcessingJob's ContainerEntrypoint and ContainerArgument parameters configure a Docker image's entrypoint and arguments mirrors how Docker overrides the entrypoint and arguments through the Docker API:
  - If neither ContainerEntrypoint nor ContainerArguments are provided, Processing uses the default ENTRYPOINT or CMD in the image.
  - If ContainerEntrypoint is provided, but not ContainerArguments, Processing runs the image with the given entrypoint, and ignores the ENTRYPOINT and CMD in the image.
  - If ContainerArguments is provided, but not ContainerEntrypoint, Processing runs the image with the default ENTRYPOINT in the image and with the provided arguments.
  - If both ContainerEntrypoint and ContainerArguments are provided, Processing runs the image with the given entrypoint and arguments, and ignores the ENTRYPOINT and CMD in the image.
  - You must use the exec form of the ENTRYPOINT instruction in your Dockerfile (ENTRYPOINT ["executable", "param1", "param2"]) instead of the shell form (ENTRYPOINT command param1 param2). This lets your processing container receive SIGINT and SIGKILL signals, which Processing uses to stop processing jobs with the StopProcessingJob API.
  - /opt/ml and all its subdirectories are reserved by SageMaker. When building your Processing Docker image, don't place any data required by your processing container in these directories.
• If you plan to use GPU devices, make sure that your containers are nvidia-docker compatible. Include only the CUDA toolkit in containers. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

How Amazon SageMaker Processing Configures Input and Output For Your Processing Container

When you create a processing job using the CreateProcessingJob operation, you can specify multiple ProcessingInput and ProcessingOutput values.

You use the ProcessingInput parameter to specify an Amazon Simple Storage Service (Amazon S3) URI to download data from, and a path in your processing container to download the data to. The ProcessingOutput parameter configures a path in your processing container from which to upload data, and where in Amazon S3 to upload that data to. For both ProcessingInput and ProcessingOutput, the path in the processing container must begin with /opt/ml/processing/.

For example, you might create a processing job with one ProcessingInput parameter that downloads data from s3://your-data-bucket/path/to/input/csv/data into /opt/ml/processing/csv in your processing container, and a ProcessingOutput parameter that uploads data from /opt/ml/processing/processed_csv to s3://your-data-bucket/path/to/output/csv/data. Your processing job would read the input data, and write output data to /opt/ml/processing/processed_csv. Then it uploads the data written to this path to the specified Amazon S3 output location.

Important
Symbolic links (symlinks) cannot be used to upload output data to Amazon S3. Symlinks are not followed when uploading output data.

How Amazon SageMaker Processing Provides Logs and Metrics for Your Processing Container

When your processing container writes to stdout or stderr, Amazon SageMaker Processing saves the output from each processing container and puts it in Amazon CloudWatch logs. For information about logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3830).

Amazon SageMaker Processing also provides CloudWatch metrics for each instance running your processing container. For information about metrics, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3818).

How Amazon SageMaker Processing Configures Your Processing Container

Amazon SageMaker Processing provides configuration information to your processing container through environment variables and two JSON files—/opt/ml/config/processingjobconfig.json and /opt/ml/config/resourceconfig.json—at predefined locations in the container.

When a processing job starts, it uses the environment variables that you specified with the Environment map in the CreateProcessingJob request. The /opt/ml/config/processingjobconfig.json file contains information about the hostnames of your processing containers, and is also specified in the CreateProcessingJob request.

The following example shows the format of the /opt/ml/config/processingjobconfig.json file.

```json
{
  "ProcessingJobArn": "<processing_job_arn>",
  "ProcessingJobName": "<processing_job_name>"
}
```
"AppSpecification": {  
    "ImageUri": "<image_uri>",  
    "ContainerEntrypoint": null,  
    "ContainerArguments": null  
  
  },  
"Environment": {  
    "KEY": "VALUE"  
  },  
"ProcessingInputs": [  
    {  
      "InputName": "input-1",  
      "S3Input": {  
        "LocalPath": "/opt/ml/processing/input/dataset",  
        "S3Uri": "<s3_uri>",  
        "S3DataDistributionType": "FullyReplicated",  
        "S3DataType": "S3Prefix",  
        "S3InputMode": "File",  
        "S3CompressionType": "None",  
        "S3DownloadMode": "StartOfJob"  
      }  
    }  
  ],  
"ProcessingOutputConfig": {  
    "Outputs": [  
      {  
        "OutputName": "output-1",  
        "S3Output": {  
          "LocalPath": "/opt/ml/processing/output/dataset",  
          "S3Uri": "<s3_uri>",  
          "S3UploadMode": "EndOfJob"  
        }  
      }  
    ],  
    "KmsKeyId": null  
  },  
"ProcessingResources": {  
    "ClusterConfig": {  
      "InstanceCount": 1,  
      "InstanceType": "ml.m5.xlarge",  
      "VolumeSizeInGB": 30,  
      "VolumeKmsKeyId": null  
    }  
  },  
"RoleArn": "<IAM role>",  
"StoppingCondition": {  
    "MaxRuntimeInSeconds": 86400  
  }  
}  

The /opt/ml/config/resourceconfig.json file contains information about the hostnames of your processing containers. Use the following hostnames when creating or running distributed processing code.

{  
    "current_host": "algo-1",  
    "hosts": ["algo-1","algo-2","algo-3"]  
}  

Don't use the information about hostnames contained in /etc/hostname or /etc/hosts because it might be inaccurate.

Hostname information might not be immediately available to the processing container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.
Save and Access Metadata Information About Your Processing Job

To save metadata from the processing container after exiting it, containers can write UTF-8 encoded text to the `/opt/ml/output/message` file. After the processing job enters any terminal status ("Completed", "Stopped", or "Failed"), the "ExitMessage" field in `DescribeProcessingJob` contains the first 1 KB of this file. Access that initial part of file with a call to `DescribeProcessingJob`, which returns it through the `ExitMessage` parameter. For failed processing jobs, you can use this field to communicate information about why the processing container failed.

**Important**
Don't write sensitive data to the `/opt/ml/output/message` file.

If the data in this file isn't UTF-8 encoded, the job fails and returns a `ClientError`. If multiple containers exit with an `ExitMessage`, the content of the `ExitMessage` from each processing container is concatenated, then truncated to 1 KB.

Run Your Processing Container Using the SageMaker Python SDK

You can use the SageMaker Python SDK to run your own processing image by using the `Processor` class. The following example shows how to run your own processing container with one input from Amazon Simple Storage Service (Amazon S3) and one output to Amazon S3.

```python
from sagemaker.processing import Processor, ProcessingInput, ProcessingOutput

processor = Processor(image_uri='<your_ecr_image_uri>',
                       role=role,
                       instance_count=1,
                       instance_type="ml.m5.xlarge")

processor.run(inputs=[ProcessingInput(
                      source='<s3_uri or local path>',
                      destination='/opt/ml/processing/input_data')],
                 outputs=[ProcessingOutput(
                      source='/opt/ml/processing/processed_data',
                      destination='<s3_uri>')] )

```

Instead of building your processing code into your processing image, you can provide a `ScriptProcessor` with your image and the command that you want to run, along with the code that you want to run inside that container. For an example, see Run Scripts with Your Own Processing Container (p. 1107).

You can also use the scikit-learn image that Amazon SageMaker Processing provides through `SKLearnProcessor` to run scikit-learn scripts. For an example, see Data Processing with scikit-learn (p. 1101).
Create, Store, and Share Features with Amazon SageMaker Feature Store

The machine learning (ML) development process often begins with extracting data signals also known as *features* from data to train ML models. Amazon SageMaker Feature Store makes it easy for data scientists, machine learning engineers, and general practitioners to create, share, and manage features for machine learning (ML) development. Feature Store accelerates this process by reducing repetitive data processing and curation work required to convert raw data into features for training an ML algorithm.

Further, the processing logic for your data is authored only once, and features generated are used for both training and inference, reducing the training-serving skew. Feature Store is a centralized store for features and associated metadata so features can be easily discovered and reused. You can create an online or an offline store. The online store is used for low latency real-time inference use cases, and the offline store is used for training and batch inference.

The following diagram shows how you can use Amazon SageMaker Feature Store as part of your machine learning pipeline. First, you read in your raw data and process it. You can ingest data via streaming to the online and offline store, or in batches directly to the offline store. You first create a FeatureGroup and configure it to an online or offline store, or both. Then, you can ingest data into your FeatureGroup and store it in your store. A FeatureGroup is a group of features that is defined via a schema in Feature Store to describe a record.

Online store is primarily designed for supporting real-time predictions that need low millisecond latency reads and high throughput writes. Offline store is primarily intended for batch predictions and model training. Offline store is an append only store and can be used to store and access historical feature data. The offline store can help you store and serve features for exploration and model training. The online store retains only the latest feature data. Feature group definitions are immutable after they are created.

How Feature Store Works

In Feature Store, features are stored in a collection called a *feature group*. You can visualize a feature group as a table in which each column is a feature, with a unique identifier for each row. In principle, a
feature group is composed of features and values specific to each feature. A Record is a collection of values for features that correspond to a unique RecordIdentifier. Altogether, a FeatureGroup is a group of features defined in your FeatureStore to describe a Record.

You can use Feature Store in the following modes:

- **Online** – In online mode, features are read with low latency (milliseconds) reads and used for high throughput predictions. This mode requires a feature group to be stored in an online store.
- **Offline** – In offline mode, large streams of data are fed to an offline store, which can be used for training and batch inference. This mode requires a feature group to be stored in an offline store. The offline store uses your S3 bucket for storage and can also fetch data using Athena queries.
- **Online and Offline** – This includes both online and offline modes.

You can ingest data into feature groups in Feature Store in two ways: streaming or in batches. When you ingest data through streaming, a collection of records are pushed to Feature Store by calling a synchronous PutRecord API call. This API enables you to maintain the latest feature values in Feature Store and to push new feature values as soon an update is detected.

Alternatively, Feature Store can process and ingest data in batches. You can author features using Amazon SageMaker Data Wrangler, create feature groups in Feature Store and ingest features in batches using a SageMaker Processing job with a notebook exported from Data Wrangler. This mode allows for batch ingestion into the offline store. It also supports ingestion into the online store if the feature group is configured for both online and offline use.

## Create Feature Groups

To ingest features into Feature Store, you must first define the feature group and the feature definitions (feature name and data type) for all features that belong to the feature group. After they are created, feature groups are immutable. Feature group names are unique within an AWS Region and AWS account. When creating a feature group, you can also create the metadata for the feature group, such as a short description, storage configuration, features for identifying each record, and the event time, as well as tags to store information such as the author, data source, version, and more.

**Important**
FeatureGroup names or associated metadata such as description or tags should not contain any personal identifiable information (PII) or confidential information.

## Find, Discover, and Share Features

After you create a feature group in Feature Store, other authorized users of the feature store can share and discover it. Users can browse through a list of all feature groups in Feature Store or discover existing feature groups by searching by feature group name, description, record identifier name, creation date, and tags.

## Real-Time Inference for Features Stored in the Online Store

With Feature Store, you can enrich your features stored in the online store in real time with data from a streaming source (clean stream data from another application) and serve the features with low millisecond latency for real-time inference.
You can also perform joins across different FeatureGroups for real-time inference by querying two different FeatureGroups in the client application.

Offline Store for Model Training and Batch Inference

Feature Store provides offline storage for feature values in your S3 bucket. Your data is stored in your S3 bucket using a prefixing scheme based on event time. The offline store is an append-only store, enabling Feature Store to maintain a historical record of all feature values. Data is stored in the offline store in Parquet format for optimized storage and query access.

You can query, explore, and visualize features using Data Wrangler from Amazon SageMaker Studio. Feature Store supports combining data to produce, train, validate, and test data sets, and allows you to extract data at different points in time.

Feature Data Ingestion

Feature generation pipelines can be created to process large batches (1 million rows of data or more) or small batches, and to write feature data to the offline or online store. Streaming sources such as Amazon Managed Streaming for Apache Kafka or Amazon Kinesis can also be used as data sources from which features are extracted and directly fed to the online store for training, inference, or feature creation.

You can push records to Feature Store by calling the synchronous PutRecord API call. Since this is a synchronous API call, it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon as an update is detected. These are also called streaming features.

When feature data is ingested and updated, Feature Store stores historical data for all features in the offline store. For batch ingest, you can pull feature values from your S3 bucket or use Athena to query. You can also use Data Wrangler to process and engineer new features that can then be exported to a chosen S3 bucket to be accessed by Feature Store. For batch ingestion, you can configure a processing job to batch ingest your data into Feature Store, or you can pull feature values from your S3 bucket using Athena.

To remove a Record from your online store, use the DeleteRecord API call. This will also add the deleted record to the offline store.

Get started with Amazon SageMaker Feature Store

To get started using Amazon SageMaker Feature Store, review the basic concepts, learn how to ingest data for your feature store, and then walk through a Feature Store example. The following sections explain how to create feature groups, ingest data into the groups, and how to manage security for your feature store.

Topics

- Feature Store Concepts (p. 1116)
- Create Feature Groups (p. 1116)
- Adding required policies to your IAM role (p. 1128)
Feature Store Concepts

The following list of terms are key to understanding the capabilities of Amazon SageMaker Feature Store:

- **Feature store** – Serves as the single source of truth to store, retrieve, remove, track, share, discover, and control access to features.

- **Feature** – A measurable property or characteristic that encapsulates an observed phenomenon. In the Amazon SageMaker Feature Store API, a feature is an attribute of a record. You can define a name and type for every feature stored in Feature Store. Name uniquely identifies a feature within a feature group. Type identifies the datatype for the values of the feature. Supported datatypes are: String, Integral and Fractional.

- **Feature group** – A FeatureGroup is the main Feature Store resource that contains the metadata for all the data stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features, defined in the feature store, to describe records. A feature group’s definition is composed of a list of feature definitions, a record identifier name, and configurations for its online and offline store.

- **Feature definition** – A FeatureDefinition consists of a name and one of the following data types: an Integral, String or Fractional. A FeatureGroup contains a list of feature definitions.

- **Record identifier name** – Each feature group is defined with a record identifier name. The record identifier name must refer to one of the names of a feature defined in the feature group’s feature definitions.

- **Record** – A Record is a collection of values for features for a single record identifier value. A combination of record identifier name and a timestamp uniquely identify a record within a feature group.

- **Event time** – a point in time when a new event occurs that corresponds to the creation or update of a record in a feature group. All records in the feature group must have a corresponding Eventtime. It can be used to track changes to a record over time. The online store contains the record corresponding to the last Eventtime for a record identifier name, whereas the offline store contains all historic records. Event time values can either be of a fractional or string type. Fractional values must be UNIX timestamps. Strings must follow the ISO 8601 standard. The following formats are supported yyyy-MM-dd’T’HH:mm:ssZ and yyyy-MM-dd’T’HH:mm:ss.SSSZ where yyyy, MM, and dd represent the year, month, and day respectively and HH, mm, ss, and if applicable, SSS represent the hour, minute, second and milliseconds respectively. T and Z are constants.

- **Online Store** – the low latency, high availability cache for a feature group that enables real-time lookup of records. The online store allows quick access to the latest value for a Record via the GetRecord API. A feature group contains an OnlineStoreConfig controlling where the data is stored.

- **Offline store** – the OfflineStore, stores historical data in your S3 bucket. It is used when low (sub-second) latency reads are not needed. For example, when you want to store and serve features for exploration, model training, and batch inference. A feature group contains an OfflineStoreConfig controlling where the data is stored.

- **Ingestion** – The act of populating feature groups in the feature store.

Create Feature Groups

A FeatureGroup is the main Feature Store resource that contains the metadata for all the data stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features, defined in the feature store, to describe records. A feature group’s definition is composed of a list of feature definitions, a record identifier name, and configurations for its online and offline store. The example code in this
Prior to using a feature store you typically load your dataset, run transformations, and set up your features for ingestion. This process has a lot of variation and is highly dependent on your data. The example code in the following topics refer to the Introduction to Feature Store, Fraud Detection with Amazon SageMaker Feature Store example notebooks respectively. We recommend that you run this notebook in Amazon SageMaker Studio because the code in this guide is conceptual and not fully functional if copied.

Feature Store supports the following data types: String, Fractional (IEEE 64-bit floating point value), and Integral (Int64 - 64 bit signed integral value). The default type is set to String. This means that, if a column in your dataset is not a float or long type, it defaults to String in your feature store.

You may use a schema to describe your data's columns and data types. You pass this schema into FeatureDefinitions, a required parameter for a FeatureGroup. You can use the SageMaker Python SDK, which has automatic data type detection when you use the load_feature_definitions function.

The default behavior when a new feature record is added with an already existing record ID is as follows. In the offline store, the new record will be appended. In the online store, if the event time of the new record is less than the existing event time than nothing will happen, however if the event time of the new record is greater than or equal to the existing event time, the record will be over written.

When you create a new feature group you can choose one of the following table formats:

- AWS Glue (Default)
- Apache Iceberg

Ingesting data, especially when streaming, can result in a large number of small files deposited into the offline store. This can negatively impact query performance due the higher number of file operations required. To avoid potential performance issues, use the Apache Iceberg table format when creating new feature groups. With Iceberg you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. If you choose the Iceberg option when creating new feature groups, Amazon SageMaker Feature Store will create the Iceberg tables using Parquet file format, and register the tables with the AWS Glue Data Catalog.

**Important**

Note that for feature groups in Iceberg table format, you must specify String as the value for the event time. If you specify any other type, you can't create the feature group successfully.

**Topics**

- Introduction to Feature Store (p. 1117)
- Fraud Detection with Feature Store (p. 1122)

**Introduction to Feature Store**

The example code in this topic refers to the Introduction to Amazon SageMaker Feature Store example notebook. It is recommended that you run this notebook in Amazon SageMaker Studio because the code in this guide is conceptual and not fully functional if copied.
Step 1: Set Up

To start using Feature Store, create SageMaker, boto3 and a Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**
The role that you use must have the following managed policies attached to it: AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
import sagemaker
import sys

import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```

Step 2: Inspect your data

In this notebook example we ingest synthetic data from the [Github repository](https://github.com/) that hosts the full notebook.

```python
customer_data = pd.read_csv("data/feature_store_introduction_customer.csv")
orders_data = pd.read_csv("data/feature_store_introduction_orders.csv")

print(customer_data.head())
print(orders_data.head())
```

The following diagram illustrates the steps the data goes through before it is ingested into Feature Store. In this notebook, we illustrate the use-case where you have data from multiple sources and want to store them independently in a feature store. Our example considers data from a data warehouse (customer data), and data from a real-time streaming service (order data).
Step 3: Create feature groups

We first start by creating feature group names for customer_data and orders_data. Following this, we create two Feature Groups, one for customer_data and another for orders_data.

```python
import time
from time import strftime, gmtime

customers_feature_group_name = 'customers-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
orders_feature_group_name = 'orders-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
```

Instantiate a FeatureGroup object for customers_data and orders_data.

```python
from sagemaker.feature_store.feature_group import FeatureGroup

customers_feature_group = FeatureGroup(
    name=customers_feature_group_name, sagemaker_session=sagemaker_session
)
orders_feature_group = FeatureGroup(
    name=orders_feature_group_name, sagemaker_session=sagemaker_session
)
```

```python
import time
current_time_sec = int(round(time.time()))
record_identifier_feature_name = "customer_id"
```

Append EventTime feature to your data frame. This parameter is required, and time stamps each data point.

```python
customer_data["EventTime"] = pd.Series([current_time_sec]*len(customer_data), dtype="float64")
orders_data["EventTime"] = pd.Series([current_time_sec]*len(orders_data), dtype="float64")
```

Load feature definitions to your feature group.

```python
customers_feature_group.load_feature_definitions(data_frame=customer_data)
orders_feature_group.load_feature_definitions(data_frame=orders_data)
```

Below we call create to create two feature groups, customers_feature_group and orders_feature_group respectively.

```python
customers_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)

orders_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)
```
To confirm that your FeatureGroup has been created we use DescribeFeatureGroup and ListFeatureGroups APIs to display the created feature group.

```python
customers_feature_group.describe()
orders_feature_group.describe()
sagemaker_session.boto_session.client('sagemaker', region_name=region).list_feature_groups()  # We use the boto client to list FeatureGroups
```

### Step 4: Ingest data into a feature group

After the FeatureGroups have been created, we can put data into the FeatureGroups. If you are using the SageMaker Python SDK, use the `ingest` API call. If you are using boto3 then use the PutRecord API. It will take less than 1 minute to ingest data both of these FeatureGroups. This example uses the SageMaker Python SDK, and so it uses the ingest API call.

```python
def check_feature_group_status(feature_group):
    status = feature_group.describe().get("FeatureGroupStatus")
    while status == "Creating":
        print("Waiting for Feature Group to be Created")
        time.sleep(5)
        status = feature_group.describe().get("FeatureGroupStatus")
        print(f"FeatureGroup {feature_group.name} successfully created.")

check_feature_group_status(customers_feature_group)
check_feature_group_status(orders_feature_group)

customers_feature_group.ingest(
    data_frame=customer_data, max_workers=3, wait=True
)

orders_feature_group.ingest(
    data_frame=orders_data, max_workers=3, wait=True
)
```

Using an arbitrary customer record id, 573291 we use get_record to check that the data has been ingested into the feature group.

```python
customer_id = 573291
sample_record = sagemaker_session.boto_session.client('sagemaker-featurestore-runtime',
region_name=region).get_record(FeatureGroupName=customers_feature_group_name,
RecordIdentifierValueAsString=str(customer_id))

print(sample_record)
```

Below demonstrates how to use the batch_get_record to get a batch of records.

```python
all_records = sagemaker_session.boto_session.client(
    "sagemaker-featurestore-runtime", region_name=region
).batch_get_record(
    Identifiers=[
        "FeatureGroupName": customers_feature_group_name,
        "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
    ]
)
Step 5: Clean up

Here we remove the Feature Groups we created.

```python
customers_feature_group.delete()
orders_feature_group.delete()
```

Step 6: Next steps

In this example notebook, you learned how to quickly get started with Feature Store, create feature groups, and ingest data into them.

For an advanced example on how to use Feature Store for a Fraud Detection use-case, see [Fraud Detection with Feature Store](#).

Step 7: Programmers note

In this notebook we used a variety of different API calls. Most of them are accessible through the Python SDK, however some only exist within boto3. You can invoke the Python SDK API calls directly on your Feature Store objects, whereas to invoke API calls that exist within boto3, you must first access a boto client through your boto and sagemaker sessions: e.g., `sagemaker_session.boto_session.client()`.

Below we list API calls used in this notebook that exist within the Python SDK and ones that exist in boto3 for your reference.

**Python SDK API Calls**

- `describe()`
- `ingest()`
- `delete()`
- `create()`
- `load_feature_definitions()`

**Boto3 API Calls**

- `list_feature_groups()`
- `get_record()`

### Fraud Detection with Feature Store

**Step 1: Set Up Feature Store**

To start using Feature Store, create a SageMaker session, boto3 session, and a Feature Store session. Also, set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.
Note
The role that you use must have the following managed policies attached to it:
AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess.

```python
import boto3
import sagemaker
from sagemaker.session import Session

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
boto_session = boto3.Session(region_name=region)
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
prefix = 'sagemaker-featurestore'
offline_feature_store_bucket = 's3://{}/{}'.format(default_bucket, prefix)

sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
featurestore_runtime = boto_session.client(service_name='sagemaker-featurestore-runtime',
region_name=region)

feature_store_session = Session(
boto_session=boto_session,
sagemaker_client=sagemaker_client,
sagemaker_featurestore_runtime_client=featurestore_runtime
)
```

Step 2: Load Datasets and Partition Data into Feature Groups

Load your data into data frames for each of your features. You use these data frames after you set up the feature group. In the fraud detection example, you can see these steps in the following code.

```python
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import io

fraud_detection_bucket_name = 'sagemaker-featurestore-fraud-detection'
identity_file_key = 'sampled_identity.csv'
transaction_file_key = 'sampled_transactions.csv'

identity_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
Key=identity_file_key)
transaction_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
Key=transaction_file_key)

identity_data = pd.read_csv(io.BytesIO(identity_data_object['Body'].read()))
transaction_data = pd.read_csv(io.BytesIO(transaction_data_object['Body'].read()))

identity_data = identity_data.round(5)
transaction_data = transaction_data.round(5)

identity_data = identity_data.fillna(0)
transaction_data = transaction_data.fillna(0)

# Feature transformations for this dataset are applied before ingestion into FeatureStore.
# One hot encode card4, card6
encoded_card_bank = pd.get_dummies(transaction_data['card4'], prefix = 'card_bank')
encoded_card_type = pd.get_dummies(transaction_data['card6'], prefix = 'card_type')

transformed_transaction_data = pd.concat([transaction_data, encoded_card_type,
encoded_card_bank], axis=1)
```
Step 3: Set Up Feature Groups

When you set up your feature groups, you need to customize the feature names with a unique name and set up each feature group with the `FeatureGroup` class.

```python
from sagemaker.feature_store.feature_group import FeatureGroup
feature_group_name = "some string for a name"
feature_group = FeatureGroup(name=feature_group_name,
sagemaker_session=feature_store_session)
```

For example, in the fraud detection example, the two feature groups are `identity` and `transaction`. In the following code you can see how the names are customized with a timestamp, and then each group is set up by passing in the name and the session.

```python
import time
from time import gmtime, strftime, sleep
from sagemaker.feature_store.feature_group import FeatureGroup
identity_feature_group_name = 'identity-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
transaction_feature_group_name = 'transaction-feature-group-' + strftime('%d-%H-%M-%S', gmtime())

identity_feature_group = FeatureGroup(name=identity_feature_group_name,
sagemaker_session=feature_store_session)
transaction_feature_group = FeatureGroup(name=transaction_feature_group_name,
sagemaker_session=feature_store_session)
```

Step 4: Set Up Record Identifier and Event Time Features

In this step, you specify a record identifier name and an event time feature name. This name maps to the column of the corresponding features in your data. For example, in the fraud detection example, the column of interest is `TransactionID`. `EventTime` can be appended to your data when no timestamp is available. In the following code, you can see how these variables are set, and then `EventTime` is appended to both feature's data.

```python
record_identifier_name = "TransactionID"
event_time_feature_name = "EventTime"
current_time_sec = int(round(time.time()))
identity_data[event_time_feature_name] = pd.Series([current_time_sec]*len(identity_data),
dtype="float64")
transformed_transaction_data[event_time_feature_name] = pd.Series([current_time_sec]*len(transaction_data),
dtype="float64")
```

Step 5: Load Feature Definitions

You can now load the feature definitions by passing a data frame containing the feature data. In the following code for the fraud detection example, the identity feature and transaction feature are each loaded by using `load_feature_definitions`, and this function automatically detects the data type of each column of data. For developers using a schema rather than automatic detection, see the Export Feature Groups from Data Wrangler example for code that shows how to load the schema, map it, and add it as a `FeatureDefinition` that you can use to create the `FeatureGroup`. This example also covers a boto3 implementation, which you can use instead of the SageMaker Python SDK.

```python
identity_feature_group.load_feature_definitions(data_frame=identity_data); # output is suppressed
```
Create Feature Groups

transaction_feature_group.load_feature_definitions(data_frame=transformed_transaction_data);
# output is suppressed

Step 6: Create a Feature Group

In this step, you use the `create` function to create the feature group. The following code shows all of the available parameters. The online store is not created by default, so you must set this as `True` if you want to enable it. The `s3_uri` is the S3 bucket location of your offline store.

```python
# create a FeatureGroup
feature_group.create(
    description = "Some info about the feature group",
    feature_group_name = feature_group_name,
    record_identifier_name = record_identifier_name,
    event_time_feature_name = event_time_feature_name,
    feature_definitions = feature_definitions,
    role_arn = role,
    s3_uri = offline_feature_store_bucket,
    enable_online_store = True,
    online_store_kms_key_id = None,
    offline_store_kms_key_id = None,
    disable_glue_table_creation = False,
    data_catalog_config = None,
    tags = ["tag1","tag2"])
```

The following code from the fraud detection example shows a minimal `create` call for each of the two features groups being created.

```python
identity_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)

transaction_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)
```

When you create a feature group, it takes time to load the data, and you need to wait until the feature group is created before you can use it. You can check status using the following method.

```python
status = feature_group.describe().get("FeatureGroupStatus")
```

While the feature group is being created, you receive `Creating` as a response. When this step has finished successfully, the response is `Created`. Other possible statuses are `CreateFailed`, `Deleting`, or `DeleteFailed`.

Step 7: Work with Feature Groups

Now that you've set up your feature group, you can perform any of the following tasks:

Topics
• Describe a Feature Group (p. 1126)
• List Feature Groups (p. 1126)
• Put Records in a Feature Group (p. 1126)
• Get Records from a Feature Group (p. 1126)
• Generate Hive DDL Commands (p. 1127)
• Build a Training Dataset (p. 1127)
• Write and Execute an Athena Query (p. 1127)
• Delete a Feature Group (p. 1127)

Describe a Feature Group

You can retrieve information about your feature group with the `describe` function.

```python
feature_group.describe()
```

List Feature Groups

You can list all of your feature groups with the `list_feature_groups` function.

```python
sagemaker_client.list_feature_groups()
```

Put Records in a Feature Group

You can use the `ingest` function to load your feature data. You pass in a data frame of feature data, set the number of workers, and choose to wait for it to return or not. The following example demonstrates using the `ingest` function.

```python
feature_group.ingest(
    data_frame=feature_data, max_workers=3, wait=True
)
```

For each feature group you have, run the `ingest` function on the feature data you want to load.

Get Records from a Feature Group

You can use the `get_record` function to retrieve the data for a specific feature by its record identifier. The following example uses an example identifier to retrieve the record.

```python
record_identifier_value = str(2990130)
featurestore_runtime.get_record(FeatureGroupName=transaction_feature_group_name,
    RecordIdentifierValueAsString=record_identifier_value)
```

An example response from the fraud detection example:

```json
...
'Record': [{'FeatureName': 'TransactionID', 'ValueAsString': '2990130'},
    {'FeatureName': 'isFraud', 'ValueAsString': '0'},
    {'FeatureName': 'TransactionDT', 'ValueAsString': '152647'},
    {'FeatureName': 'TransactionAmt', 'ValueAsString': '75.0'},
    {'FeatureName': 'ProductCD', 'ValueAsString': 'H'},
    {'FeatureName': 'card1', 'ValueAsString': '4577'},
    ...
```
Generate Hive DDL Commands

The SageMaker Python SDK’s `FeatureStore` class also provides the functionality to generate Hive DDL commands. The schema of the table is generated based on the feature definitions. Columns are named after feature name and data-type are inferred based on feature type.

```python
print(feature_group.as_hive_ddl())
```

Example output:

```
CREATE EXTERNAL TABLE IF NOT EXISTS sagemaker_featurestore.identity-feature-group-27-19-33-00 (
    TransactionID INT
    id_01 FLOAT
    id_02 FLOAT
    id_03 FLOAT
    id_04 FLOAT
    ...
```

Build a Training Dataset

Feature Store automatically builds an AWS Glue data catalog when you create feature groups and you can turn this off if you want. The following describes how to create a single training dataset with feature values from both identity and transaction feature groups created earlier in this topic. Also, the following describes how to run an Amazon Athena query to join data stored in the offline store from both identity and transaction feature groups.

To start, create an Athena query using `athena_query()` for both identity and transaction feature groups. The `table_name` is the AWS Glue table that is autogenerated by Feature Store.

```python
identity_query = identity_feature_group.athena_query()
transaction_query = transaction_feature_group.athena_query()
identity_table = identity_query.table_name
transaction_table = transaction_query.table_name
```

Write and Execute an Athena Query

You write your query using SQL on these feature groups, and then execute the query with the `.run()` command and specify your S3 bucket location for the data set to be saved there.

```python
# Athena query
query_string = 'SELECT * FROM "' + transaction_table + '" LEFT JOIN "' + identity_table + '" ON ' + transaction_table + '.transaction_id = ' + identity_table + '.transaction_id

# Run Athena query. The output is loaded to a Pandas dataframe.
dataset = pd.DataFrame()
identity_query.run(query_string=query_string,
output_location='s3://'+default_s3_bucket_name+'/query_results/')
identity_query.wait()
dataset = identity_query.as_dataframe()
```

From here you can train a model using this data set and then perform inference.

Delete a Feature Group

You can delete a feature group with the `delete` function.
Adding required policies to your IAM role

To get started with Amazon SageMaker Feature Store you must add the required policy to your role, AmazonSageMakerFeatureStoreAccess. Below is a walkthrough on how to add it to your role through the console.

**Step 1: Access AWS Management Console**

Sign in to the AWS Management Console and open the IAM console.

**Step 2: Choose Roles**

In the navigation pane on the left, choose Roles. The navigation pane is illustrated below with Roles outlined in red.
Identity and Access Management (IAM)

Dashboard

Access management

Groups

Users

Roles

Policies

Identity providers

Account settings

Access reports

Access analyzer

Archive rules

Analyzers

Settings

Credential report

Organization activity

Service control policies ( SCPs)
Step 3: Find your role

In the search bar, enter the role you are using for Amazon SageMaker Feature Store. Below illustrates with a red arrow where you enter your role.

Roles

What are IAM roles?

IAM roles are a secure way to grant permissions to entities that you trust. Examples of entities include:

- IAM user in another account
- Application code running on an EC2 instance that needs to perform actions on AWS resources
- An AWS service that needs to act on resources in your account to provide its features
- Users from a corporate directory who use identity federation with SAML

IAM roles issue keys that are valid for short durations, making them a more secure way to grant access.

Additional resources:

- IAM Roles FAQ
- IAM Roles Documentation
- Tutorial: Setting Up Cross Account Access
- Common Scenarios for Roles

Step 4: Attach policy

After you find your role, choose Attach policies. Below illustrates this with a red arrow.
Next you will enter in the search bar the required policy. Below illustrates the search bar you will use to enter the policy.

The policy you will need to add is `AmazonSageMakerFeatureStoreAccess`. After you enter the policy, select the check box and then choose Attach policy. Below illustrates this step.
After you have attached both policies to your role, the policy should appear under your IAM role. The following illustrates how it appears under your IAM role.
Use Amazon SageMaker Feature Store with Amazon SageMaker Studio

You can use Studio to create and view details about your feature groups.

Topics
- Create a Feature Group in Studio (p. 1133)
- View Feature Group Details in Studio (p. 1135)

Create a Feature Group in Studio

The create feature group process has four steps: enter feature group details, feature definitions, required features, and feature group tags.

Consider the following options before you start:

- If you plan to only use an online store, you just need the schema for your features. This is your columns and each column’s data type.
- If you plan to use an offline store, you need an S3 bucket URI and a Role ARN.
- If you plan to use encryption, you need a KMS key. You can use the same one for both the online store and your offline store, or have a unique key for each.
- If you plan to use AWS Glue integration, be prepared to provide a data catalog name, database name, and table name.

To create a feature group in Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Feature Store.
8. Choose Create feature group.
9. Specify the storage configuration for the feature group. You can also specify a data catalog if you are using AWS Glue.
• (Optional) For **Table format**, you can specify **Iceberg** to use the Apache Iceberg table format. For more information about the Iceberg table format, see Create Feature Groups (p. 1116).

10. Choose **Continue**.

11. Enter your feature definitions, then choose **Continue**.

You have two options for providing a schema for your features: a JSON editor, or a Table editor. The table editor accepts a column name and a data type. In a minimal example, you will need at least two for the next step: one for a record identifier and one for a time event feature. You can have up to 2,500 feature definitions.

12. Set a record identifier and a time feature to use for this feature group, then choose **Continue**.

13. (Optional) Enter tags as key value pairs, then choose **Continue**.
14. Review the feature group information and choose **Create feature group**.

When the feature group is successfully created, it appears in your feature groups list.

**View Feature Group Details in Studio**

You can view details of your feature groups, and get sample queries to run against your data sources to gather the data for features you have defined.

**To view feature group details in Studio**

1. From the **Amazon SageMaker Feature Store** landing page, in the **Feature group catalog**, choose your feature group name from the list. This will open the feature group page.
2. On the **Details** tab, you can review your feature group information and tags. Choose the **Add new tag** to add new tags or **remove button** to remove a tag.
3. On the **Features** tab, you can find a list of all features. Use the filter to refine your list. Choose a feature to view its details.

**Data Sources and Ingestion**

There are multiple ways to bring your data into Amazon SageMaker Feature Store. Feature Store offers a single API call for data ingestion called **PutRecord** that enables you to ingest data in batches or from streaming sources. You can use Amazon SageMaker Data Wrangler to engineer features and then ingest your features into your Feature Store. You can also use Amazon EMR for batch data ingestion through a Spark connector.

**Topics**

- Stream Ingestion (p. 1135)
- Data Wrangler with Feature Store (p. 1136)
- Batch Ingestion Spark Connector Setup (p. 1138)

**Stream Ingestion**

You can use streaming sources such as Kafka or Kinesis as a data source where features are extracted from there and directly fed to the online feature store for training, inference or feature creation. Records can be pushed into the feature store by calling the synchronous **PutRecord** API call. Since this is a synchronous API call it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon an update is detected. These are also called **streaming** features.
Data Wrangler with Feature Store

Data Wrangler is a feature of Studio that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. Data Wrangler enables you to engineer your features and ingest them into a feature store.

In Studio, after interacting with Data Wrangler, choose the **Export** tab, choose **Export Step**, and choose **Feature Store**, as shown in the following screenshot. This exports a Jupyter notebook that has all the source code in it to create a Feature Store feature group that adds your features from Data Wrangler to an offline or online feature store.
After the feature group has been created, you can also select and join data across multiple feature groups to create new engineered features in Data Wrangler and then export your data set to an S3 bucket.
For more information on how to export to Feature Store, see Export to SageMaker Feature Store.

**Batch Ingestion Spark Connector Setup**

**Introduction**

Amazon SageMaker Feature Store supports batch data ingestion with Spark, using your existing ETL pipeline. It can be a pipeline on Amazon EMR, GIS, a AWS Glue Job, a Amazon SageMaker Processing job, or a Amazon SageMaker Studio Notebook.

Methods for installing and implementing batch data ingestion are provided for Python and Scala. Python developers can use the `sagemaker-feature-store-pyspark` Python library for local development and installation on Amazon EMR. They can also run it from their Jupyter Notebooks. Scala developers can use the Feature Store Spark connector available in Maven.

You can use the Spark connector to ingest data in the following ways:

1. Ingest by default – Ingest your dataframe into the online store. When you use the connector to update the online store, the Spark connector uses the `PutRecord` operation to make the update. Within 15 minutes, Feature Store replicates the data from the online store to the offline store. The online store contains the latest value for the record. For more information about how the online and offline stores work, see Feature Store Concepts (p. 1116).
2. Offline store direct ingestion – Use the Spark connector to ingest your dataframe directly into the offline store. Ingesting the dataframe directly into the offline store doesn't update the online store.

For information about using the different ingestion methods, see Example Implementations (p. 1141).

**Installation**

**Scala Users**

**Requirements**

- Spark >= 3.0.0 and <= 3.3.0
- iceberg-spark-runtime >= 0.14.0
- Scala >= 2.12.x
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)

**Declare the Dependency in POM.xml**

The Feature Store Spark connector has a dependency on the `iceberg-spark-runtime` library. You must therefore add corresponding version of the `iceberg-spark-runtime` library to the dependency if you're ingesting data into a feature group that you've auto-created with the Iceberg table format. The Feature Store Spark connector is available in the Maven central repository. For example, if you're using Spark 3.1, you must declare the following in your project's `POM.xml`:

```xml
<dependency>
    <groupId>software.amazon.sagemaker.featurestore</groupId>
    <artifactId>sagemaker-feature-store-spark-sdk_2.12</artifactId>
    <version>1.0.0</version>
</dependency>

<dependency>
    <groupId>org.apache.iceberg</groupId>
    <artifactId>iceberg-spark-runtime-3.1_2.12</artifactId>
    <version>0.14.0</version>
</dependency>
```
Python Users

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)
- Kernel = conda_python3

We recommend setting the $SPARK_HOME to the directory where you have Spark installed. During installation, Feature Store uploads the required jar to SPARK_HOME, so that the dependencies load automatically. Spark starting a JVM is required to make this PySpark library work.

Local Installation

To find more info about the installation, enable verbose mode by appending --verbose to the following installation command.

```
pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

Installation on Amazon EMR

Create an Amazon EMR cluster with the release version 6.1.0 or later. Enable SSH to help you troubleshoot any issues.

You can do one of the following to install the library:

- Create a custom step within Amazon EMR.
- SSH into your cluster and install the library from there.

You can either create a custom step within EMR to start installing the library or SSH into your cluster to install the library directly in console.

**Note**
The following information uses Spark version 3.1, but you can specify any version that meets the requirements.

```
export SPARK_HOME=/usr/lib/spark
sudo -E pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all: --verbose
```

**Note**
If you want to install the dependent jars automatically to SPARK_HOME, do not use the bootstrap step.

Installation on a Amazon SageMaker Studio Notebook

Install a version of PySpark that's compatible with the Spark connector using the following commands:

```
!pip3 install pyspark==3.1
!pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

If you're performing batch ingestion to the offline store, the dependencies aren't within the notebook instance environment.
Installation on Notebooks with GIS

**Important**
You must use AWS Glue Version 2.0 or later to install the Spark connector on the AWS Glue Interactive Session.

Use the following information to help you install the PySpark Connector in an AWS Glue Interactive Session.

The Amazon SageMaker Feature Store Spark Connector requires specific Spark connector JARs during the initialization of the session. You can upload them to your Amazon S3 bucket. After you've uploaded them, you must provide the GIS sessions with the JARs using the following command.

```
%extra_jars s3://spark-connector-jars/sagemaker-feature-store-spark-sdk.jar
```

To install the Spark Connector in the AWS Glue runtime, use the `%additional_python_modules` magic command within the GIS notebook. AWS Glue runs pip to the modules that you've specified under `%additional_python_modules`.

```
%additional_python_modules sagemaker-feature-store-pyspark-3.1
```

Before you start the AWS Glue session, you must use both of the preceding magic commands.

Installation on an AWS Glue Job

**Important**
You must use AWS Glue Version 2.0 or later to install the Spark connector on the AWS Glue Interactive Session.

To install the Spark connect on an AWS Glue job, use the `--extra-jars` method to provide the necessary Jars and `--additional-python-modules` to install the Spark Connector as job parameters when you create the AWS Glue job as shown in the following example.

```python
from pyspark.sql import SparkSession
import feature_store_pyspark

extra_jars = "",.join(feature_store_pyspark.classpath_jars())

spark = SparkSession.builder 
 .config("spark.jars", extra_jars) 
 .config("spark.jars.packages", "org.apache.hadoop:hadoop-aws:3.2.1,org.apache.hadoop:hadoop-common:3.2.1") 
 .getOrCreate()
```

```python
# To install the Spark Connector in the AWS Glue runtime, use the
# %additional_python_modules magic command within the GIS notebook. AWS Glue runs pip to the modules that you've specified under
# %additional_python_modules.

# %additional_python_modules sagemaker-feature-store-pyspark-3.1
```

```python
# Before you start the AWS Glue session, you must use both of the preceding magic commands.

# Installation on an AWS Glue Job

# %additional_python_modules sagemaker-feature-store-pyspark-3.1
```

```python
# To install the Spark connect on a AWS Glue job, use the --extra-jars method to provide the necessary Jars and --additional-python-modules to install the Spark Connector as job parameters when you create the AWS Glue job as shown in the following example.

# glue_client = boto3.client('glue', region_name=region)
# response = glue_client.create_job(
#     Name=pipeline_id,
#     Description='Feature Store Compute Job',
#     Role=glue_role_arn,
#     ExecutionProperty={'MaxConcurrentRuns': max_concurrent_run},
#     Command={
#         'Name': 'glueetl',
#         'ScriptLocation': script_location_uri,
#         'PythonVersion': '3'
#     },
#     DefaultArguments={
#         '--TempDir': temp_dir_location_uri,
#         '--additional-python-modules': 'sagemaker-feature-store-pyspark-3.1',
#         '--extra-jars': "s3://spark-connector-jars/sagemaker-feature-store-spark-sdk.jar",
#         ...
#     }
# )
```

```
# glue_client = boto3.client('glue', region_name=region)
# response = glue_client.create_job(
#     Name=pipeline_id,
#     Description='Feature Store Compute Job',
#     Role=glue_role_arn,
#     ExecutionProperty={'MaxConcurrentRuns': max_concurrent_run},
#     Command={
#         'Name': 'glueetl',
#         'ScriptLocation': script_location_uri,
#         'PythonVersion': '3'
#     },
#     DefaultArguments={
#         '--TempDir': temp_dir_location_uri,
#         '--additional-python-modules': 'sagemaker-feature-store-pyspark-3.1',
#         '--extra-jars': "s3://spark-connector-jars/sagemaker-feature-store-spark-sdk.jar",
#         ...
#     }
# )
```

1140
Installation on a Amazon SageMaker Processing Job

To use the Feature Store Spark Connector with Amazon SageMaker Processing jobs, bring your own image. For more information about bringing your image, see Bring your own SageMaker image (p. 157). Add the installation step to a Dockerfile. After you've pushed the docker image to an Amazon ECR repository, you can use the PySparkProcessor to create the processing job. For more information about creating a processing job with the PySpark processor, see Data Processing with Apache Spark (p. 1100).

The following is an example of adding an installation step to the Dockerfile.

```
FROM account-id.dkr.ecr.AWS Region.amazonaws.com/sagemaker-spark-processing:3.1-cpu-py38-v1.0
RUN /usr/bin/python3 -m pip install sagemaker-feature-store-pyspark-3.1 --no-binary :all: --verbose
```

Retrieving the JAR for the Spark Connector

To retrieve the Spark connector dependency Jar, you must install the Spark connector from the Python Package Index (PyPI) repository using pip in any Python environment with network access. A SageMaker Jupyter Notebook is an example of a Python environment with network access.

The following command installs the Spark connector.

```
!pip install sagemaker-feature-store-pyspark-3.1
```

After you've installed the Amazon SageMaker Feature Store PySpark connector, you can retrieve the Jar that the installation in your notebook directory and upload it to Amazon S3.

The feature-store-pyspark-dependency-jars command provides a list of locations for all of the necessary dependency jars that the Spark connector added. You can use the command to retrieve the Jar and upload it to Amazon S3.

```
jar_location = !feature-store-pyspark-dependency-jars
jar_location = jar_location[0]
s3_client = boto3.client("s3")
s3_client.upload_file(jar_location, "feature-store-spark-connector","spark-connector-jars/sagemaker-feature-store-spark-sdk.jar")
```

Example Implementations

Scala

*FeatureStoreBatchIngestion.scala*
import software.amazon.sagemaker.featurestore.sparksdk.FeatureStoreManager
import org.apache.spark.sql.types.{StringType, StructField, StructType}
import org.apache.spark.sql.{Row, SparkSession}

object TestSparkApp {
  def main(args: Array[String]): Unit = {
    val spark = SparkSession.builder().getOrCreate()

    // Construct test DataFrame
    val data = List(
      Row("1", "2021-07-01T12:20:12Z"),
      Row("2", "2021-07-02T12:20:13Z"),
      Row("3", "2021-07-03T12:20:14Z")
    )

    val schema = StructType(
      List(StructField("RecordIdentifier", StringType), StructField("EventTime", StringType))
    )

    val df = spark.createDataFrame(spark.sparkContext.parallelize(data), schema)

    // Initialize FeatureStoreManager with a role arn if your feature group is created by another account
    val featureStoreManager = new FeatureStoreManager("arn:aws:iam::111122223333:role/role-arn")

    // Load the feature definitions from input schema. The feature definitions can be used to create a feature group
    val featureDefinitions = featureStoreManager.loadFeatureDefinitionsFromSchema(df)

    // Ingest by default. The connector will leverage PutRecord API to ingest your data in stream
    featureStoreManager.ingestData(df, featureGroupArn)

    // To select the target stores for ingestion, you can specify the target store as the parameter
    // If OnlineStore is selected, the connector will leverage PutRecord API to ingest your data in stream
    // featureStoreManager.ingestData(df, featureGroupArn, List("OfflineStore", "OnlineStore"))

    // If only OfflineStore is selected, the connector will batch write the data to offline store directly
    featureStoreManager.ingestData(df, featureGroupArn, List("OfflineStore"))

    // To retrieve the records failed to be ingested by spark connector
    val failedRecordsDf = featureStoreManager.getFailedStreamIngestionDataFrame()
  }
}

Python

FeatureStoreBatchIngestion.py

from pyspark.sql import SparkSession
from feature_store_pyspark.FeatureStoreManager import FeatureStoreManager
import feature_store_pyspark

df = spark.createDataFrame(data=data, schema=columns)

# Initialize FeatureStoreManager with a role arn if your feature group is created by another account
feature_store_manager = FeatureStoreManager(arn=arn)

# Create a feature group
feature_definitions = feature_store_manager.load_feature_definitions_from_schema(df)

# Ingest by default. The connector will leverage PutRecord API to ingest your data in stream
feature_store_manager.ingest_data(input_data_frame=df, feature_group_arn=feature_group_arn)

# To select the target stores for ingestion, you can specify the target store as the parameter
# If OnlineStore is selected, the connector will leverage PutRecord API to ingest your data in stream
feature_store_manager.ingest_data(input_data_frame=df, feature_group_arn=feature_group_arn, target_stores=['OnlineStore'])

# If only OfflineStore is selected, the connector will batch write the data to offline store directly
feature_store_manager.ingest_data(input_data_frame=df, feature_group_arn=feature_group_arn, target_stores=['OfflineStore'])

# To retrieve the records failed to be ingested by spark connector
failed_records = feature_store_manager.get_failed_stream_ingestion_dataframe()
Add Features to a Feature Group

You can use the Amazon SageMaker Feature Store API or Amazon SageMaker Studio to add features to your feature group. You can think of a feature group as a data table and a feature as a column in the table. When you add a feature to the feature group, you're effectively adding a column to the table.

The features that you've added don't have any data. You can add new records to the feature group or overwrite them. You can think of a record as a row in the data table.

The following sections provide an overview of using the API and Studio to add features to a feature group. With the API, you can also add or overwrite records after you've updated the feature group.

**Studio**

To search through your features, do the following.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Feature Store.
8. Choose Feature group catalog.
9. Under Feature group name, choose a feature group.
10. From the dropdown list that says Actions, choose Add feature definitions.
11. Specify a name for the Feature name field.
12. For Type, select the feature's data type.
13. Choose Add new feature definition.
14. (Optional) Choose Add new feature definition to add feature definitions.
15. Specify information for the additional features.
16. Choose Save changes.
17. Choose Confirm.

**API**

Use the UpdateFeatureGroup operation to add features to a feature group.

If you are running this application on Amazon EMR, it’s recommended to run the application in client mode, so that you do not need to distribute the dependent jars to other task nodes. Add one more step in Amazon EMR cluster with Spark argument like this:

```
spark-submit --deploy-mode client --master yarn s3://<path-to-script>/FeatureStoreBatchIngestion.py
```
You can use the `DescribeFeatureGroup` operation to see if you've added the features successfully.

To add or overwrite records, use the `PutRecord` operation.

To see the updates that you've made to a record, use the `GetRecord` operation. To see the updates that you've made to multiple records, use the `BatchGetRecord` operation. It can take up to five minutes for the updates that you've made to appear.

You can use the example code in the following section to walk through adding features and records using the AWS SDK for Python (Boto3).

**Example Code**

The example code walks you through the following process:

1. Adding features to the feature group
2. Verifying that you've added them successfully
3. Adding a record to the feature group
4. Verifying that you've added it successfully

**Step 1: Add Features To a Feature Group**

The following code uses the `UpdateFeatureGroup` operation to add new features to the feature group. It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see [Introduction to Feature Store](p. 1117).

```python
import boto3
sagemaker_client = boto3.client("sagemaker")
sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    FeatureAdditions=[
        {"FeatureName": "new-feature-1", "FeatureType": "Integral"},
        {"FeatureName": "new-feature-2", "FeatureType": "Fractional"},
        {"FeatureName": "new-feature-3", "FeatureType": "String"}
    ]
)
```

The following code uses the `DescribeFeatureGroup` operation to check the status of the update. If the `LastUpdateStatus` field is `Successful`, you've added the features successfully.

```python
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

**Step 2: Add a New Record To The Feature Group**

The following code uses the `PutRecord` operation to add records to the feature group that you've created.
record_identifier_value = 'new_record'
sagemaker_featurestore_runtime_client = boto3.client("sagemaker-featurestore-runtime")
sagemaker_runtime_client.put_record(
    FeatureGroupName=feature_group_name,
    Record=[
        {
            'FeatureName': "record-identifier-feature-name",
            'ValueAsString': record_identifier_value
        },
        {
            'FeatureName': "event-time-feature",
            'ValueAsString': "timestamp-that-feature-store-returns"
        },
        {
            'FeatureName': "new-feature-1",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-2",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-3",
            'ValueAsString': "value-as-string"
        }
    ]
)

Use the GetRecord operation to see which records in your feature group don't have data for the features that you've added. You can use the PutRecord operation to overwrite the records that don't have data for the features that you've added.

Find Features in Your Feature Groups

With Amazon SageMaker Feature Store, you can search for the features that you've created in your feature groups. You can search through all of your features without needing to first select a feature group. You can use the search functionality to quickly find the features that are relevant to your use case.

To search for features in your feature groups, the feature groups must be within the same AWS account and Region.

**Important**
Use the latest version of Amazon SageMaker Studio to make sure that you're using the most recent version of the search functionality. For information on updating Studio, see Shut down and Update SageMaker Studio (p. 185).

If you're on a team, you might have teammates that are looking for features to use in their models, they can search through all the features in all of the feature groups.

You can add searchable parameters and descriptions to make your features more discoverable. For more information, see Adding Searchable Metadata to Your Features (p. 1149).

The following are the types of metadata that you can use in your search.

You can search for features using either Amazon SageMaker Studio or the Search operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in Studio.
The following sections show you how to search for your features.

### Studio

Use the following procedure to search through all the features that you've created.

To search through your features, do the following.

1. Sign in to Studio. For more information, see *Onboard to Amazon SageMaker Domain (p. 36)*.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Feature Store**.
8. Choose **Feature Catalog**.
9. Specify a text query with at least three characters to search for your features.
10. (Optional) Use advanced filters after you've specified a query. You can use filters to specify parameters or date ranges in your search results. If you're searching for a parameter, specify both its key and value. To find your features more easily, you can do the following:
    - Specify time ranges.
    - Deselect columns that you don't want to query.

### SDK for Python (Boto3)

The example uses the `Search` operation in the AWS SDK for Python (Boto3) to run the search query. For information about the other languages to submit a query, see *See Also* in the *Amazon SageMaker API Reference*.

The following code shows different example search queries using the API.

```python
# Return all features in your feature groups
sagemaker_client.search()
```
Find Features in Your Feature Groups

```python
# Search for all features that belong to a feature group that contain the "ver" substring
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Contains', 'Value': 'ver'},
        ]
    }
)

# Search for all features that belong to a feature group that have the EXACT name "airport"
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Equals', 'Value': 'airport'},
        ]
    }
)

# Search for all features that belong to a feature group that contains the name "ver" AND have a name that contains "wha" AND have a parameter (key or value) that contains "hea"

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName', 'Operator': 'Contains', 'Value': 'ver'},
            {'Name': 'FeatureName', 'Operator': 'Contains', 'Value': 'wha'},
            {'Name': 'AllParameters', 'Operator': 'Contains', 'Value': 'hea'},
        ]
    }
)

# Search for all features that belong to a feature group with substring "ver" in its name OR features that have a name that contain "wha" OR features that have a parameter (key or value) that contains "hea"

sagemaker_client.search(

```
1148
Adding Searchable Metadata to Your Features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:

- Description – A searchable description of the feature.

```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Parameters.org',
                'Operator': 'Contains',
                'Value': 'Sage'
            }
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is "And"
    }
)
```
• Parameters – Searchable key-value pairs.

The description can have up to 255 characters.

For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either Amazon SageMaker Studio or the UpdateFeatureMetadata operation.

Use the following procedure to update the metadata using Amazon SageMaker Studio.

To update the feature metadata with Studio, do the following.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Feature Store.
8. Choose Feature catalog.
9. In the Feature name column, choose a feature name.
10. Choose Edit metadata.
11. In the Description field, add or update the description.
12. In the Parameters field under Parameters, specify a key-value pair for the parameter.
13. (Optional) Choose Add new parameter to add another parameter.
14. Choose Save changes.
15. Choose Confirm.

The following describes how you can use the UpdateFeatureMetadata operation for different scenarios.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

• FeatureGroupName
• Feature
• Parameters

The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterAdditions=[["Key": "example-key-0", "Value": "example-value-0"],
                         
    "Key": "example-key-1", "Value": "example-value-1"]
"
)```
Add a description to a feature

To add a description to a feature, specify values for the following fields:

- FeatureGroupName
- Feature
- Description

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify the keys for the parameters that you're removing under ParameterRemovals.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify an empty string for Description.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description=""
)
```
After you’ve updated the metadata for a feature, you can use the DescribeFeatureMetadata operation to see the updates that you’ve made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3).

**Example Code**

The example code does the following:

1. Sets up your SageMaker environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

**Step 1: Setup**

To start using Feature Store, create SageMaker, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

Note

The role that you use must have the following managed policies attached to it:
AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
!pip install 'sagemaker>=2.0.0'
import sagemaker
import sys
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session() 
region = sagemaker_session.boto_region_name 
s3_bucket_name = sagemaker_session.default_bucket()
```

**Step 2: Create a Feature Group and Add Features**

```
feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {"FeatureName": "feature-1", "FeatureType": "String"},
]```
Example Code

```python
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
        FeatureDefinitions=feature_definitions,
        OnlineStoreConfig={'EnableOnlineStore': True}
    )
except ClientError as e:
    if e.response['Error']['Code'] == 'ResourceInUse':
        pass
    else:
        raise e

Step 3: Add Metadata

Before you add metadata, use the `DescribeFeatureGroup` operation to make sure that the status of the feature group is `Created`.

```python
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

Add a description to the feature.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    Description="new description"
)
```

You can use the `DescribeFeatureMetadata` operation to see if you have successfully updated the description for the feature group.

```python
sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

You can also use it to add parameters to the feature group.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    ParameterAdditions=[
        {'Key': "team", 'Value': "featurestore"},
        {'Key': "org", 'Value': "sagemaker"},
    ]
)
You can use the `DescribeFeatureMetadata` operation again to see if you have successfully added the parameters.

```python
sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

### Create a Dataset From Your Feature Groups

After a Feature Store feature group has been created in an offline store, you can choose to use the following methods to get your data:

- Using the Amazon SageMaker Python SDK
- Running SQL queries in the Amazon Athena

**Important**

Feature Store requires data to be registered in a AWS Glue data catalog. By default, Feature Store automatically builds an AWS Glue data catalog when you create a feature group.

After you've created feature groups for your offline store and populated them with data, you can create a dataset by running queries or using the SDK to join data stored in the offline store from different feature groups. You can also join the feature groups to a single pandas dataframe. You can use Amazon Athena to write and execute SQL queries.

**Note**

To make sure that your data is up to date, you can set up a AWS Glue crawler to run on a schedule.
To set up a AWS Glue crawler, specify an IAM role that the crawler is using to access the offline store's S3 buckets. For more information, see Create an IAM role.
For more information on how to use AWS Glue and Athena to build a training dataset for model training and inference, see Create Feature Groups (p. 1116).

### Using the Amazon SageMaker Python SDK to get your data from your feature groups

You can use the Feature Store APIs to create a dataset from your feature groups. Data scientists create ML datasets for training by retrieving ML feature data from one or more feature groups in the offline store. Use the `create_dataset()` function to create the dataset. You can use the SDK to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from the feature groups and a pandas dataframe.

By default, Feature Store doesn't include records that you've deleted from the dataset. It also doesn't include duplicated records. A duplicate record has the record ID and timestamp value in the event time column.
Before you use the SDK to create a dataset, you must start a SageMaker session. Use the following code to start the session.

```python
region = boto3.Session().region_name
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto3.Session(region_name=region).client(service_name="sagemaker")
featurestore_runtime = boto3.Session(region_name=region).client(service_name="sagemaker-featurestore-runtime")
feature_store_session = Session(boto_session=boto_session, sagemaker_client=sagemaker_client, sagemaker_featurestore_runtime_client=featurestore_runtime)
feature_store = FeatureStore(feature_store_session)
```

The following code shows an example of creating a dataset from multiple feature groups.

```python
s3_bucket_name = "offline-store-sdk-test"
base_fg_name = "base_fg_name"
base_fg = FeatureGroup(name=base_fg_name, sagemaker_session=feature_store_session)
first_fg_name = "first_fg_name"
first_fg = FeatureGroup(name=first_fg_name, sagemaker_session=feature_store_session)
second_fg_name = "second_fg_name"
second_fg = FeatureGroup(name=second_fg_name, sagemaker_session=feature_store_session)
builder = feature_store.create_dataset(
    base=base_fg, 
    output_path=f"s3://[{s3_bucket_name}]", 
).with_feature_group(first_fg 
).with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The following code shows an example of creating a dataset from multiple feature groups and a pandas dataframe.

```python
base_data = [[1, 187512346.0, 123, 128],
[2, 187512347.0, 168, 258],
[3, 187512348.0, 125, 184],
[1, 187512349.0, 195, 206]]
base_data_df = pd.DataFrame( 
    base_data, 
    columns=['base_id', 'base_time', 'base_feature_1', 'base_feature_2']
)
builder = feature_store.create_dataset(
    base=base_data_df, 
    event_time_identifier_feature_name='base_time', 
    record_identifier_feature_name='base_id', 
    output_path=f"s3://[{s3_bucket_name}]"
).with_feature_group(first_fg 
).with_feature_group(second_fg, "base_id", ['base_feature_1'])
```
The Feature Store APIs provides you with helper methods for the `create_dataset` function. You can use them to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from multiple feature groups and a pandas dataframe.
- Create a dataset from a single feature group and a pandas dataframe.
- Create a dataset using a point in time accurate join where records in the joined feature group follow sequentially.
- Create a dataset with the duplicated records, instead of following the default behavior of the function.
- Create a dataset with the deleted records, instead of following the default behavior of the function.
- Create a dataset for time periods that you specify.
- Save the dataset as a CSV file.
- Save the dataset as a pandas dataframe.

The base feature group is an important concept for joins. The base feature group is the feature group that has other feature groups or the pandas dataframe joined to it. For each dataset you can add the following optional methods to the `create_dataset` function to configure how you're creating dataset:

- `with_feature_group` – Performs an inner join between the base feature group and another feature group using the record identifier and the target feature name in the base feature group. The following provides information about the parameters that you specify:
  - `feature_group` – The feature group that you're joining.
  - `target_feature_name_in_base` – The name of the feature in the base feature group that you're using as a key in the join. The record identifier in the other feature groups are the other keys that Feature Store uses in the join.
  - `included_feature_names` – A list of strings representing the feature names of the base feature group. You can use the field to specify the features that you want to include in the dataset.
  - `event_time_range` – Creates a dataset using the event time range that you specify.
  - `as_of` – Creates a dataset up to a timestamp that you specify. For example, if you specify `datetime(2021, 11, 28, 23, 55, 59, 342380)` as the value, creates a dataset up to November 28th, 2021.
  - `point_time_accurate_join` – Creates a dataset where all of the event time values of the base feature group is less than all the event time values of the feature group or pandas dataframe that you're joining.
  - `include_duplicated_records` – Keeps duplicated values in the feature groups.
  - `include_deleted_records` – Keeps deleted values in the feature groups.
  - `with_number_of_recent_records_by_record_identifier` – An integer that you specify to determine how many of the most recent records appear in the dataset.
  - `with_number_of_records_by_record_identifier` – An integer that represents how many records appear in the dataset.

After you've configured the dataset, you can specify the output using one of the following methods:

- `to_csv_file` – Saves the dataset as a CSV file.
- `to_dataframe` – Saves the dataset as a pandas dataframe.

You can retrieve data that comes after a specific period in time. The following code retrieves data after a timestamp.
fg1 = FeatureGroup("example-feature-group-1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-S3-path"
).with_number_of_records_from_query_results(5).to_csv_file()

You can also retrieve data from a specific time period. You can use the following code to get data for a specific time range:

fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="example-S3-path"
).with_event_time_range(
    datetime(2021, 11, 28, 23, 55, 59, 342380),
    datetime(2020, 11, 28, 23, 55, 59, 342380)
).to_csv_file() #example time range specified in datetime functions

You might want to join multiple feature groups to a pandas dataframe where the event time values of the feature group happen no later than the event time of the data frame. Use the following code as a template to help you perform the join.

fg1 = FeatureGroup("fg1")
fg2 = FeatureGroup("fg2")
events = [['2020-02-01T08:30:00Z', 6, 1],
          ['2020-02-02T10:15:30Z', 5, 2],
          ['2020-02-03T13:20:59Z', 1, 3],
          ['2021-01-01T00:00:00Z', 1, 4]]
df = pd.DataFrame(events, columns=['event_time', 'customer-id', 'title-id'])
feature_store.create_dataset(
    base=df,
    event_time_identifier_feature_name='event_time',
    record_identifier_feature_name='customer_id',
    output_path="s3://example-S3-path"
).with_feature_group(fg1, "customer-id")
    with_feature_group(fg2, "title-id")
    .point_in_time_accurate_join(
).to_csv_file()

You can also retrieve data that comes after a specific period in time. The following code retrieves data after the time specified by the timestamp in the as_of method.

fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-s3-file-path"
).as_of(datetime(2021, 11, 28, 23, 55, 59, 342380)
).to_csv_file() # example datetime values

The following code uses a point in time accurate join. The event time values of the base feature group come before the event time values of the target feature group.

fg1 = FeatureGroup("fg1")
fg2 = FeatureGroup("fg2")
events = [['2020-02-01T08:30:00Z', 6, 1],
          ['2020-02-02T10:15:30Z', 5, 2],
          ['2020-02-03T13:20:59Z', 1, 3],
          ['2021-01-01T00:00:00Z', 1, 4]]
df = pd.DataFrame(events, columns=['event_time', 'customer-id', 'title-id'])
Sample Amazon Athena Queries

You can write queries in Amazon Athena to create a dataset from your feature groups. You can also write queries that create a dataset from feature groups and a single pandas dataframe.

Interactive Exploration

This query selects the first 1000 records.

```
SELECT *
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
LIMIT 1000
```

Latest snapshot without duplicates

This query selects the latest non-duplicate records.

```
SELECT *
FROM (SELECT *,
    row_number()
    OVER (PARTITION BY <RecordIdentifierFeatureName>
          ORDER BY <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC) AS row_num
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1;
```

Latest snapshot without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from the offline store.

```
SELECT *
FROM (SELECT *,
    row_number()
    OVER (PARTITION BY <RecordIdentifierFeatureName>
          ORDER BY <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC) AS row_num
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1 and NOT is_deleted;
```

Time Travel without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from a particular point in time.
Cross-Account Offline Store Access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). This can be set up using the steps in the following section.

Topics
- Step 1: Set Up the Offline Store Access Role in Account A (p. 1159)
- Step 2: Set up an Offline Store S3 Bucket in Account B (p. 1160)
- Step 3: Set up an Offline Store KMS Encryption Key in Account A (p. 1161)
- Step 4: Create a Feature Group in Account A (p. 1162)

Step 1: Set Up the Offline Store Access Role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the AmazonSageMakerFeatureStoreAccess policy or to use an existing role that already has the AmazonSageMakerFeatureStoreAccess policy attached. This document refers to this policy as Account-A-Offline-Feature-Store-Role-ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        }
    ]
}
```
The preceding code snippet shows the AmazonSageMakerFeatureStoreAccess policy. The Resource section of the policy is scoped down by default to S3 buckets with names that contain SageMaker, Sagemaker, or sagemaker. This means the offline store S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your S3 bucket policy in the console, customize the Resource section to be arn:aws:s3:::your-offline-store-bucket-name, and then attach to the role.

Additionally, this role must have KMS permissions attached. At a minimum, it requires the kms:GenerateDataKey permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross-account scenario and how to set it up. The following example shows an inline policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": [
            "kms:GenerateDataKey"
         ],
      }
   ]
}
```

The Resource section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

**Step 2: Set up an Offline Store S3 Bucket in Account B**

Create an S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "S3CrossAccountBucketAccess",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:GetBucketAcl"
         ],
         "Principal": {
            "AWS": [
               "*Account-A-Offline-Feature-Store-Role-ARN*
            ],
            "*Account-A-Offline-Feature-Store-Bucket-ARN*"
         },
         "Resource": [
            "arn:aws:s3:::offline-store-bucket-name/*",
            "arn:aws:s3:::your-offline-store-bucket-name/*"
         ]
      }
   ]
}
```
Step 3: Set up an Offline Store KMS Encryption Key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for S3 objects in the offline store. For cross-account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, Account-A-Offline-Feature-Store-Role-ARN from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as Account-A-Offline-Feature-Store-KMS-Key-ARN.

```json
{
   "Version": "2012-10-17",
   "Id": "key-consolepolicy-3",
   "Statement": [
      {
         "Sid": "Enable IAM User Permissions",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::Account-A-Account-Id:root"
         },
         "Action": "kms:*",
         "Resource": "*"
      },
      {
         "Sid": "Allow access for Key Administrators",
         "Effect": "Allow",
         "Principal": {
            "AWS": [
               "arn:aws:iam::Account-A-Account-Id:role/Administrator",
            ]
         },
         "Action": [
            "kms:Create",
            "kms:Describe",
            "kms:Enable",
            "kms:List",
            "kms:Put",
            "kms:Update",
            "kms:Revoke",
            "kms:Disable",
            "kms:Get",
            "kms:Delete",
            "kms:TagResource",
            "kms:UntagResource",
            "kms:ScheduleKeyDeletion",
            "kms:CancelKeyDeletion"
         ],
         "Resource": "*"
      }
   ]
}
```

In the preceding policy, the principal is Account-A-Offline-Feature-Store-Role-ARN, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under Principal.
Step 4: Create a Feature Group in Account A

Next, create the feature group in Account A, with an offline store S3 bucket in Account B. To do this, provide the following parameters for RoleArn, OfflineStoreConfig.S3StorageConfig.KmsKeyId and OfflineStoreConfig.S3StorageConfig.S3Uri respectively:

- Provide Account-A-Offline-Feature-Store-Role-ARN as the RoleArn.
- Provide Account-A-Offline-Feature-Store-KMS-Key-ARN for OfflineStoreConfig.S3StorageConfig.KmsKeyId.
- Provide Account-B-Offline-Feature-Store-Bucket for OfflineStoreConfig.S3StorageConfig.S3Uri.

Security and Access Control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide a AWS Key Management Service customer managed key to encrypt all your data at
rest. In case you do not provide a AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide a AWS KMS key for encrypting data, then you can call various APIs for data management such as PutRecord, GetRecord, DeleteRecord.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

### Using AWS KMS Permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an **AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore**. Feature Store supports an option to encrypt your online or offline store under **customer managed key**. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only **symmetric customer managed keys**. You cannot use an **asymmetric customer managed key** to encrypt your data in your online or offline store. For help determining whether a customer managed key is symmetric or asymmetric, see **Identifying symmetric and asymmetric customer managed keys**.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the **key policies**, **IAM policies** and **grants** to control access to the customer managed key. You can **enable and disable** the customer managed key, enable and disable **automatic key rotation**, and **delete the customer managed key** when it is no longer in use.
- You can use a customer managed key with **imported key material** or a customer managed key in a **custom key store** that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in **AWS CloudTrail logs**.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will **incur a charge** for each API call and AWS Key Management Service quotas apply to each customer managed key.

### Authorizing Use of a Customer Managed Key for Your Online Store

If you use a **customer managed key** to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default **AWS owned KMS key** to protect your online or offline stores in your AWS account.
Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

- "kms:Encrypt", "kms:Decrypt", "kms:DescribeKey", "kms:CreateGrant", "kms:RetireGrant",
  "kms:ReEncryptFrom", "kms:ReEncryptTo", "kms:GenerateDataKey", "kms:ListAliases", "kms:ListGrants",
  "kms:RevokeGrant"

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for kms:ViaService should be sagemaker.*.amazonaws.com.

Note
The kms:ViaService condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to your customer managed key, and use the same AWS KMS key for both the online and offline store, then it will fail the CreateFeatureGroup API operation.

- Gives the customer managed key administrators read-only access to the customer managed key and permission to revoke grants, including the grants that Feature Store uses to protect your data.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```json
{"Id": "key-policy-feature-store",
 "Version":"2012-10-17",
 "Statement": ["Sid": "Allow access through Amazon SageMaker Feature Store for all principals in the account that are authorized to use Amazon SageMaker Feature Store",
 "Effect": "Allow",
 "Principal": {"AWS": "arn:aws:iam::111122223333:user/featurestore-user"},
 "Action": ["kms:Encrypt",
 "kms:Decrypt",
 "kms:DescribeKey",
 "kms:CreateGrant",
 "kms:RetireGrant",
 "kms:ReEncryptFrom",
 "kms:ReEncryptTo",
 "kms:GenerateDataKey",
 "kms:ListAliases",
 "kms:ListGrants"],
 "Resource": "*",
 "Condition": {"StringLike": {"kms:ViaService": "sagemaker.*.amazonaws.com"}}
],

Using Grants to Authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the ListGrants operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per FeatureGroup using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

Monitoring Feature Store interaction with AWS KMS

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.

Accessing Data in Your Online Store

The caller (either IAM user or IAM role) to ALL DataPlane operations (Put, Get, DeleteRecord) must have below permissions on the customer managed key:

"kms:Decrypt"

Authorizing Use of a Customer Managed Key for your Offline Store

The roleArn that is passed as a parameter to createFeatureGroup must have below permissions to the OfflineStore KmsKeyId:
"kms:GenerateDataKey"

Note
The key policy for the online store also works for the offline store, only when the kms:ViaService condition is not specified.

Important
You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

Quotas, Naming Rules and Data Types

Limits and Quotas

Note
Soft limits can be increased based on your needs.

• Maximum number of feature groups per AWS account: Soft limit of 100.
• Maximum number of feature definitions per feature group: 2500.
• Maximum Transactions per second (TPS) per API per AWS account: Soft limit of 10000 TPS per API excluding the BatchGetRecord API call, which has a soft limit of 500 TPS.
• Maximum size of a record: 350KB.
• Maximum size of a record identifier: 2KB.
• Maximum size of a feature value: 350KB.
• Maximum number of concurrent feature group creation workflows: 4.
• BatchGetRecord API: Can contain as many as 100 records and can query up to 10 feature groups.

Naming Rules

• Reserved Words: The following are reserved words and cannot be used as feature names in feature definitions: is_deleted, write_time, and api_invocation_time.

Data Types

• String Feature Type: Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.
• Fractional Feature Type: Fractional feature values must conform to a double precision floating point number as defined by the IEEE 754 standard.
• Integral Feature Type: Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of \(-2^{63}\) and a maximum value: \(2^{63} - 1\).
• Event Time Features: All feature groups have an event time feature. The feature can have a feature type of either String or Fractional. A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): [yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-dd'T'HH:mm:ss.SSSZ]. A fractional event time value is accepted as seconds from unix epoch, with millisecond precision. Event times must be in the range of [0000-01-01T00:00:00.000Z, 9999-12-31T23:59:59.999Z]. For feature groups in the Iceberg table format, you can only use String type for the event time.
Amazon SageMaker Feature Store Offline Store Data Format

Amazon SageMaker Feature Store supports the AWS Glue and Apache Iceberg table formats for the offline store. You can choose the table format when you're creating a new feature group. AWS Glue is the default format.

Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call PutRecord, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format. Specifically, when your data is written to your offline store, the data can only be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple Records.

For the Iceberg format, Feature Store saves the table's metadata in the same Amazon S3 bucket that you're using to store the offline store data. You can find it under the metadata prefix.

Feature Store also exposes the OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri field, which can be found from in the DescribeFeatureGroup API call. This is the S3 path under which the files for the specific feature group are written.

The following additional fields are added by Feature Store to each Record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the PutRecord or DeleteRecord call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
- **write_time** – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.
- **is_deleted** – False by default. If DeleteRecord is called, a new Record is inserted into RecordIdentifierValue and set to True in the offline store.

The following information shows the organization of a Parquet file using the AWS Glue format:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix-name/111122223333/sagemaker/AWS Region/ offline-store/example-feature-group-account-id/data/year=year/month=month/day=day/ hour=hour/timestamp_of_latest_event_time_in_file_16-random-alphanumeric-digits.parquet
```

Records in the offline store are partitioned by event time into hourly partitions. You can't configure the partitioning scheme. The following shows an example of the output location of a Parquet file:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline- store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/ hour=00/20200631T064401Z_108934320012Az11.parquet
```

The following shows the organization of the data files saved in the Iceberg table format.

```
```

Records in the offline store are partitioned by event time into daily partitions. You can't configure the partitioning scheme. The following shows an example of the output location of a Parquet file where the event time feature name is EventTime:
The following shows the example location of a metadata file for data files saved in the Iceberg table format.

```

Amazon SageMaker Feature Store Notebook Examples

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks in the table below. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: AmazonSageMakerFeatureStoreAccess.

See IAM Roles to access your role and attach this policy. For a walkthrough see Adding policies to your IAM role. The following screenshot illustrates how the policy appears under your IAM role after it has been attached.

**Feature Store sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker Feature Store.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction to Feature Store</td>
<td>An introduction to key Feature Store capabilities such as how to create, configure a feature group, and how to ingest data into an online or offline feature store.</td>
</tr>
<tr>
<td>Fraud Detection with Feature Store</td>
<td>An advanced example on how to train a fraud detection model by ingesting data into a Feature Store, querying it to form a training dataset, and how to train a simple model for inference.</td>
</tr>
<tr>
<td>Notebook Title</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Encrypt Data in your Online or Offline Feature Store using KMS key</td>
<td>An advanced example on how to encrypt and decrypt data in an Online or Offline Feature Store using KMS key and how to verify that your data is encrypted. Note that this notebook tackles encryption at rest.</td>
</tr>
<tr>
<td>Client-side Encryption with Feature Store using AWS Encryption SDK</td>
<td>An advanced example how to do client-side encryption with Feature Store using the AWS Encryption SDK library which encrypts your data prior to ingesting it into your Online or Offline Feature Store.</td>
</tr>
<tr>
<td>How to securely store an image dataset in Feature Store with KMS key?</td>
<td>An advanced example that demonstrates how to securely store a dataset of images into your Feature Store using KMS key for server-side encryption.</td>
</tr>
<tr>
<td>Create a machine learning workflow from a Ground Truth classification labelling job to Feature Store</td>
<td>A machine learning (ML) workflow that demonstrates how to feed the output of an image or text classification labelling job from AWS Ground Truth to Feature Store.</td>
</tr>

Train Models

For an overview on training models with Amazon SageMaker, see Train a Model with Amazon SageMaker (p. 10).

SageMaker provides features to monitor and manage the training and validation of machine learning models. For guidance on metrics available, incremental training, automatic model tuning, and the use of augmented manifest files to label training data, see the following topics.

- For guidance on choosing a machine learning algorithm and its implementation for your task or problem, see Choose an Algorithm (p. 1171).
- For guidance on debugging and profiling the training of machine learning models, see Debug and Profile Training Jobs Using Amazon SageMaker Debugger (p. 1479).
- For guidance on distributed training of deep learning models, see Distributed Training in Amazon SageMaker (p. 1685).
- For guidance on compiling and training deep learning models, see Amazon SageMaker Training Compiler (p. 1799).
- For guidance on metrics used to monitor and train models, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 1936).
- For guidance on metrics used to detect model post-processing bias, see Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 1863).
- For guidance on model explainability, see Amazon SageMaker Clarify Model Explainability (p. 1884).
- For guidance on incremental training in SageMaker, see Incremental Training in Amazon SageMaker (p. 1909).
- For guidance on using managed spot training in SageMaker, see Managed Spot Training in Amazon SageMaker (p. 1927).
- For guidance on using training checkpoints in SageMaker, see Use Checkpoints in Amazon SageMaker (p. 1928).
- For guidance on automatic model tuning, also known as hyperparameter tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).
- For guidance on using an augmented manifest file to label training data, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1932).

Choose an Algorithm

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning (p. 1174)
- Unsupervised learning (p. 1174)
- Reinforcement learning (p. 1175)

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics
- Choose an algorithm implementation (p. 1171)
- Problem types for the basic machine learning paradigms (p. 1173)
- Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175)
- Use Reinforcement Learning with Amazon SageMaker (p. 1449)

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker supports three implementation options that require increasing levels of effort.

- Pre-trained models require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
• **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.

• If there is no built-in solution that works, try to develop one that uses **pre-made images for machine and deep learning frameworks** for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.

• If you need to run custom packages or use any code which isn’t a part of a supported framework or available via PyPi, then you need to build your own custom Docker image that is configured to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

**Topics**

- Use a built-in algorithm (p. 1172)
- Use script mode in a supported framework (p. 1173)
- Use a custom Docker image (p. 1173)

**Use a built-in algorithm**

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker’s built-in algorithms. These built-in algorithms come with two major benefits.

- The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.

- The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.
For more information on the built-in algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175).

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1181).

Use script mode in a supported framework

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a .py extension. As the table above indicates, SageMaker supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework’s image.

For more information on the frameworks supported by SageMaker, see Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 14).

Use a custom Docker image

Amazon SageMaker's built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker, see Using Docker containers with SageMaker (p. 2392).

Problem types for the basic machine learning paradigms

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker provides to address these problem types, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1175).

Topics
- Supervised learning (p. 1174)
- Unsupervised learning (p. 1174)
- Reinforcement learning (p. 1175)
Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a classification problem. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a regression problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker, see Supervised Learning (p. 1179).

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.

- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.

- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.

- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density
estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker, see Unsupervised Learning (p. 1180).

**Reinforcement learning**

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker’s frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker (p. 1449).

**Use Amazon SageMaker Built-in Algorithms or Pre-trained Models**

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker, choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

Use Built-in Algorithms

Example problems and use cases | Learning paradigm or domain | Problem types | Data input format | Built-in algorithms |
--- | --- | --- | --- | --- |
Tag every pixel of an image individually with a category: self-driving cars prepare to identify objects in their way | Computer vision | Image | Semantic Segmentation Algorithm (p. 1439) |

For important information about Docker registry paths, data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1181).

The following sections provide additional guidance for the Amazon SageMaker built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Choose an Algorithm (p. 1171). Sections are also provided for the SageMaker built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained Models and Solution Templates (p. 1179)
- Supervised Learning (p. 1179)
- Unsupervised Learning (p. 1180)
- Textual Analysis (p. 1180)
- Image Processing (p. 1181)

### Pre-trained Models and Solution Templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types that use the SageMaker SDK as well as Studio. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart (p. 46).

### Supervised Learning

Amazon SageMaker provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1195)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1202)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1211)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1221)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- **LightGBM (p. 1229)**—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
- **Linear Learner Algorithm (p. 1238)**—learns a linear function for regression or a linear threshold function for classification.
- **TabTransformer (p. 1255)**—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- **XGBoost Algorithm (p. 1262)**—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker also provides several built-in supervised learning algorithms that are used for more specialized tasks during feature engineering and forecasting from time series data.

- **Object2Vec Algorithm (p. 1311)**—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, as it requires labeled data for training, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data, without any explicit human annotation.
- **DeepAR Forecasting Algorithm (p. 1350)**—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

### Unsupervised Learning

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- **Principal Component Analysis (PCA) Algorithm (p. 1383)**—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- **K-Means Algorithm (p. 1375)**—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- **IP Insights (p. 1366)**—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- **Random Cut Forest (RCF) Algorithm (p. 1387)**—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

### Textual Analysis

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- **BlazingText algorithm (p. 1290)**—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- **Sequence-to-Sequence Algorithm (p. 1327)**—a supervised algorithm commonly used for neural machine translation.
- **Latent Dirichlet Allocation (LDA) Algorithm (p. 1300)**—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
- **Neural Topic Model (NTM) Algorithm (p. 1305)**—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- **Text Classification - TensorFlow (p. 1340)**—a supervised algorithm that supports transfer learning with available pretrained models for text classification.
Image Processing

SageMaker also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 1396)**—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 1407)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Semantic Segmentation Algorithm (p. 1439)**—provides a fine-grained, pixel-level approach to developing computer vision applications.
- **Object Detection - MXNet (p. 1420)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- **Object Detection - TensorFlow (p. 1431)**—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

Algorithms that are parallelizable can be deployed on multiple compute instances for distributed training.

The following topics provide information about data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by Amazon SageMaker.

**Tip**
To look up the Docker image URIs of the built-in algorithms managed by SageMaker, see Docker Registry Paths and Example Code (p. 2396).

**Topics**
- Common Data Formats for Built-in Algorithms (p. 1184)
- Instance Types for Built-in Algorithms (p. 1193)
- Logs for Built-in Algorithms (p. 1193)

**Common Data Formats for Built-in Algorithms**
The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

**Topics**
- Common Data Formats for Training (p. 1184)
- Common Data Formats for Inference (p. 1188)

**Common Data Formats for Training**
To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

**Topics**
- Content Types Supported by Built-In Algorithms (p. 1185)
- Using Pipe Mode (p. 1185)
- Using CSV Format (p. 1185)
- Using RecordIO Format (p. 1185)
- Trained Model Deserialization (p. 1188)

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported ContentType values and the algorithms that use them:

**ContentTypes for Built-in Algorithms**

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>

<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>image/png</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>text/libsvm</td>
<td>XGBoost</td>
</tr>
</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this [table](#).

**Using Pipe Mode**

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the [AlgorithmSpecification](#) for additional details on the training input mode.

**Using CSV Format**

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify `text/csv` as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case `content_type=text/csv;label_size=0`. For a notebook example that uses CSV format, see [Breast Cancer Prediction](#). For more information, see [Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms](#).

**Using RecordIO Format**

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However,
if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**
For an example that shows how to convert the commonly used numpy array into the protobuf recordIO format, see *An Introduction to Factorization Machines with MNIST*.

```proto
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 20) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated double values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated int32 values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```
repeated uint64 shape = 3 [packed = true];
}
// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
    repeated bytes value = 1;
    // If the content type of the data is known, stores it.
    // This allows for the possibility of using decoders for common formats
    // in the future.
    optional string content_type = 2;
}
message Value {
    oneof value {
        // The numbering assumes the possible use of:
        // - float16, float128
        // - int8, int16, int32
        Float32Tensor float32_tensor = 2;
        Float64Tensor float64_tensor = 3;
        Int32Tensor int32_tensor = 7;
        Bytes bytes = 9;
    }
}
message Record {
    // Map from the name of the feature to the value.
    // For vectors and libsvm-like datasets,
    // a single feature with the name 'values'
    // should be specified.
    map<string, Value> features = 1;
    // An optional set of labels for this record.
    // Similar to the features field above, the key used for
    // generic scalar / vector labels should be 'values'.
    map<string, Value> label = 2;
    // A unique identifier for this record in the dataset.
    // Whilst not necessary, this allows better
    // debugging where there are data issues.
    optional string uid = 3;
    // Textual metadata describing the record.
    // This may include JSON-serialized information
    // about the source of the record.
    // This is not used by the algorithm directly.
    optional string metadata = 4;
    // An optional serialized JSON object that allows per-record
    // hyper-parameters/configuration/other information to be set.
    // The meaning/interpretation of this field is defined by
    // the algorithm author and may not be supported.
    // This is used to pass additional inference configuration
    // when batch inference is used (e.g. types of scores to return).
    optional string configuration = 5;
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

**Note**
For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

**Trained Model Deserialization**

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is untarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

**Common Data Formats for Inference**

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

**Topics**
- Convert Data for Inference Request Serialization (p. 1188)
- Convert Data for Inference Response Deserialization (p. 1189)
- Common Request Formats for All Algorithms (p. 1190)
- Use Batch Transform with Built-in Algorithms (p. 1192)

**Convert Data for Inference Request Serialization**

Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5,16.0,14,23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

For application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
  // Instances might contain multiple rows that predictions are sought for.
};
```
“instances”: [
  {
    // Request and algorithm specific inference parameters.
    "configuration": {},
    // Data in the specific format required by the algorithm.
    "data": {
      "<field name>": dataElement
    }
  }
]

You have the following options for specifying the `dataElement`:

**Protocol buffers equivalent**

// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}

**Simple numeric vector**

// An array containing numeric values is treated as an instance containing a single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": {
    "values": dataElement
  }
}

**For multiple records**

let request = {
  "instances": [
    // First instance.
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    },
    // Second instance.
    {
      "features": [-2.0, 100.2, 15.2, 9.2]
    }
  ]
}

**Convert Data for Inference Response Deserialization**

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

let response = {
  "predictions": [
    // Fields in the response object are defined on a per algorithm-basis.
  ]
}
The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

**Single-record inference**

```plaintext
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

**Multi-record inference**

```plaintext
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

**Multi-record inference with protobuf input**

```plaintext
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```plaintext
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the jsonlines response type by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

**Common Request Formats for All Algorithms**

Most algorithms use several of the following inference request formats.
**JSON Request Format**

**Content type:** application/JSON

**Dense format**

```json
let request = {
  "instances": [
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    }
  ]
}
```

```json
let request = {
  "instances": [
    {
      "data": {
        "features": {
          "values": [1.5, 16.0, 14.0, 23.0]
        }
      }
    }
  ]
}
```

**Sparse format**

```json
[
  {
    "instances": [
      {
        "data": {
          "features": {
            "keys": [26, 182, 232, 243, 431],
            "shape": [2000],
            "values": [1, 1, 1, 4, 1]
          }
        }
      },
      {
        "data": {
          "features": {
            "keys": [0, 182, 232, 243, 431],
            "shape": [2000],
            "values": [13, 1, 1, 4, 1]
          }
        }
      }
    ]
  }
]
```

**JSONLINES Request Format**

**Content type:** application/JSONLINES

**Dense format**

A single record in dense format can be represented as either:

```json
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```json
{ "data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } }
```
Sparse Format

A single record in sparse format is represented as:

```json
{"data": {"features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```json
{"data": {"features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{"data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } } }
```

CSV Request Format

- **Content type:** text/CSV; label_size=0

  **Note**
  CSV support is not available for factorization machines.

RECORDIO Request Format

Content type: application/x-recordio-protobuf

Use Batch Transform with Built-in Algorithms

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

When you create a transform job, the SplitType must be set according to the ContentType of the input data. Similarly, depending on the Accept field in the CreateTransformJobRequest, AssembleWith must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Recommended SplitType</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
</tr>
<tr>
<td>text/csv</td>
<td>Line</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/x-image</td>
<td>None</td>
</tr>
<tr>
<td>image/*</td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Accept</th>
<th>Recommended AssembleWith</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>None</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
</tbody>
</table>

For more information on response formats for specific algorithms, see the following:
• DeepAR Inference Formats (p. 1362)
• Factorization Machines Response Formats (p. 1219)
• IP Insights Inference Data Formats (p. 1373)
• K-Means Response Formats (p. 1382)
• k-NN Request and Response Formats (p. 1226)
• Linear learner response formats (p. 1253)
• NTM Response Formats (p. 1310)
• Data Formats for Object2Vec Inference (p. 1325)
• Encoder Embeddings for Object2Vec (p. 1326)
• PCA Response Formats (p. 1386)
• RCF Response Formats (p. 1393)

Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.12xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. For most algorithm training, we support P2, P3, G4dn, and G5 GPU instances. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution. To get an automatic instance recommendation or conduct custom load tests, use Amazon SageMaker Inference Recommender.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

Note
If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

• Confirmation of arguments provided at the beginning of the log
• Errors that occurred during training
• Measurement of an algorithm's accuracy or numerical performance
• Timings for the algorithm and any major stages within the algorithm
Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```plaintext
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```plaintext
   AlgorithmError: u'abc' is not valid under any of the given schemas
   Failed validating u'oneOf' in
   schema[u'properties'][u'feature_dim']: u'
   [u'oneOf':
    [{u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},
     {u'minimum': 1, u'type': u'integer'}]]
   ```

3. Inaccurate protobuf file format.

   **From the CloudWatch log**

   ```plaintext
   [10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
   copy sequence with size 785 to array axis with dimension 784
   ```

Built-in SageMaker Algorithms for Tabular Data

Amazon SageMaker provides built-in algorithms that are tailored to the analysis of tabular data. The built-in SageMaker algorithms for tabular data can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1195)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1202)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1211)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1221)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
• **LightGBM (p. 1229)**—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).

• **Linear Learner Algorithm (p. 1238)**—learns a linear function for regression or a linear threshold function for classification.

• **TabTransformer (p. 1255)**—a novel deep tabular data modeling architecture built on self-attention-based Transformers.

• **XGBoost Algorithm (p. 1262)**—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

**AutoGluon-Tabular**

*AutoGluon-Tabular* is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily
focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers.

**How to use SageMaker AutoGluon-Tabular**

You can use AutoGluon-Tabular as an Amazon SageMaker built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio UI, see [SageMaker JumpStart](p. 46).

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-regression-ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)
```

1196
# [Optional] Override default hyperparameters with custom values

```python
hyperparameters[
    "auto_stack"
] = "True"
print(hyperparameters)
```

```python
from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {"training": training_dataset_s3_path}, logs=True, job_name=training_job_name
)
```

For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm
- Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm

## Input and Output interface for the AutoGluon-Tabular algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be **text/csv**.
- For **Inference ContentType**, valid inputs must be **text/csv**.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.
• **Validation data input format**: You can optionally include another directory called validation/ that also has a data.csv file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then a fraction of your training data is randomly sampled to serve as the validation data. This fraction is selected based on the number of rows in your training data. For more information see Tabular Prediction in the AutoGluon documentation.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the InstanceType) must be able to hold the training dataset.

SageMaker AutoGluon-Tabular uses the autogluon.tabular.TabularPredictor module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker AutoGluon-Tabular with the AutoGluon framework**

• Use the following trained Python code:

```python
import tarfile
from autogluon.tabular import TabularPredictor

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = TabularPredictor.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

**Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm**

SageMaker AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AutoGluon-Tabular currently does not support multi-GPU training.

**AutoGluon-Tabular sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AutoGluon-Tabular algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.
How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are ensembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.

![Multi-layer stacking strategy diagram](image)

*Figure 2. AutoGluon’s multi-layer stacking strategy, shown here using two stacking layers and n types of base learners.*

For more information, see [AutoGluon-Tabular: Robust and Accurate AutoML for Structured Data](#).

AutoGluon-Tabular hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AutoGluon-Tabular algorithm is an implementation of the open-source AutoGluon-Tabular package.

**Note**

The default hyperparameters are based on example datasets in the AutoGluon-Tabular sample notebooks (p. 1198).

By default, the SageMaker AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root
mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the eval_metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| eval_metric    | The evaluation metric for validation data. If eval_metric is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - "root_mean_squared_error" for regression  
  - "roc_auc" for binary classification  
  - "accuracy" for multi-class classification  
  
  Valid values: string, refer to the AutoGluon documentation for valid values.  
  Default value: "auto". |
| presets        | List of preset configurations for various arguments in fit().  
  - "best_quality": high predictive accuracy, slower inference times and higher disk usage  
  - "high_quality": high predictive accuracy and fast inference  
  - "good_quality": good predictive accuracy and very fast inference  
  - "medium_quality": medium predictive accuracy, very fast inference and training time  
  - "optimize_for_deployment": delete unused models and remove training artifacts  
  - "interpretable": fits only interpretable rule-based models from the imodels package  
  
  For more details, see AutoGluon Predictors.  
  Valid values: string, any of the following: ("best_quality", "high_quality", "good_quality", "medium_quality", "optimize_for_deployment", or "interpretable").  
  Default value: "medium_quality". |
| auto_stack     | Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set auto_stack to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the num_bag_folds and num_stack_levels arguments based on dataset properties.  
  Valid values: string, "True" or "False".  
  Default value: "False". |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_bag_folds</td>
<td>Number of folds used for bagging of models. When <code>num_bag_folds</code> is equal to <code>k</code>, training time is roughly increased by a factor of <code>k</code>. Set <code>num_bag_folds</code> to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing <code>num_bag_folds</code> results in models with lower bias, but that are more prone to overfitting. One is an invalid value for this parameter, and will raise a <code>ValueError</code>. Values greater than 10 may produce diminishing returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing <code>num_bag_folds</code> and instead increase <code>num_bag_sets</code>. Valid values: string, any integer between (and including) &quot;0&quot; and &quot;10&quot;. Default value: &quot;0&quot;.</td>
</tr>
<tr>
<td>num_bag_sets</td>
<td>Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to <code>num_bag_folds * num_bag_sets</code>. This parameter defaults to one if <code>time_limit</code> is not specified. This parameter is disabled if <code>num_bag_folds</code> is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [1, 20]. Default value: 1.</td>
</tr>
<tr>
<td>num_stack_levels</td>
<td>Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of <code>num_stack_levels + 1</code>. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a <code>ValueError</code>, <code>num_bag_folds</code> must be greater than or equal to 2. Valid values: float, range: [0, 3]. Default value: 0.</td>
</tr>
<tr>
<td>refit_full</td>
<td>Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>set_best_to_refit_full</td>
<td>Whether or not to change the default model that the predictor uses for prediction. If set_best_to_refit_full is set to &quot;True&quot;, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by refit_full). Only valid if refit_full is set. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>save_space</td>
<td>Whether or note to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting save_space to &quot;True&quot; if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if save_space is set to &quot;True&quot;. Refer to the predictor.save_space() documentation for more details. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>verbosity</td>
<td>The verbosity of print messages. verbosity levels range from 0 to 4, with higher levels corresponding to more detailed print statements. A verbosity of 0 suppresses warnings. Valid values: integer, any of the following: (0, 1, 2, 3, or 4). Default value: 2.</td>
</tr>
</tbody>
</table>

**Tuning an AutoGluon-Tabular model**

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see [AutoGluon-Tabular hyperparameters (p. 1199)]().

**CatBoost**

CatBoost is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.
How to use SageMaker CatBoost

You can use CatBoost as an Amazon SageMaker built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

• Use CatBoost as a built-in algorithm

Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "catboost-classification-model", "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
```

1203
hyperparameters[
    "iterations"
] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
    tabular_estimator.fit(
        {"training": training_dataset_s3_path}, logs=True, job_name=training_job_name
    )

For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples.
- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of CatBoost supports CSV for training and inference:
- For Training ContentType, valid inputs must be text/csv.
- For Inference ContentType, valid inputs must be text/csv.

Note
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- Training data input format: Your training data should be in a subdirectory named train/ that contains a data.csv file. The target variables should be in the first column of data.csv. The predictor variables (features) should be in the remaining columns.
- Validation data input format: You can optionally include another directory called validation/ that also has a data.csv file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the
validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker CatBoost uses the `catboost.CatBoostClassifier` and `catboost.CatBoostRegressor` modules to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker CatBoost with catboost**

- Use the following trained Python code:

```python
import tarfile
from catboost import CatBoostClassifier
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

**Amazon EC2 instance recommendation for the CatBoost algorithm**

SageMaker CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

**CatBoost sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker CatBoost algorithm.

<table>
<thead>

</thead>
<tbody>
<tr>
<td><strong>Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm</strong></td>
<td>This notebook demonstrates the use of the Amazon SageMaker CatBoost algorithm to train and host a tabular classification model.</td>
</tr>
</tbody>
</table>
For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works (p. 1267). For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see CatBoost: unbiased boosting with categorical features.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker CatBoost algorithm is an implementation of the open-source CatBoost package.

Note

The default hyperparameters are based on example datasets in the CatBoost sample notebooks (p. 1205).

By default, the SageMaker CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy. You can use the eval_metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>

</table>
| max_leaves       | The maximum number of leaves in the resulting tree. Can only be used with the "Lossguide" growing policy.  
                                | Valid values: integer, range: [2, 64].  
                                | Default value: 31.                                                                 |
| rsm              | Random subspace method. The percentage of features to use at each split selection, when features are selected over again at random.  
                                | Valid values: float, range: (0.0, 1.0].  
                                | Default value: 1.0.                                                                |
| sampling_frequency | Frequency to sample weights and objects when building trees.  
                                | Valid values: string, either: "PerTreeLevel" or "PerTree".  
                                | Default value: "PerTreeLevel".                                                     |
| min_data_in_leaf | The minimum number of training samples in a leaf. CatBoost does not search for new splits in leaves with a sample count less than the specified value. Can only be used with the "Lossguide" and "Depthwise" growing policies.  
                                | Valid values: integer, range: (1 or ∞).  
                                | Default value: 1.                                                                  |
| bagging_temperature | Defines the settings of the Bayesian bootstrap. Use the Bayesian bootstrap to assign random weights to objects. If bagging_temperature is set to 1.0, then the weights are sampled from an exponential distribution. If bagging_temperature is set to 0.0, then all weights are 1.0.  
                                | Valid values: float, range: Non-negative float.  
                                | Default value: 1.0.                                                                |
| boosting_type    | The boosting scheme. "Auto" means that the boosting_type is selected based on processing unit type, the number of objects in the training dataset, and the selected learning mode.  
                                | Valid values: string, any of the following: ("Auto", "Ordered", "Plain").  
                                | Default value: "Auto".                                                             |
| scale_pos_weight | The weight for positive class in binary classification. The value is used as a multiplier for the weights of objects from positive class.  
                                | Valid values: float, range: Positive float.  
                                | Default value: 1.0.                                                                |
### Parameter Name | Description
--- | ---
**max_bin** | The number of splits for numerical features. "Auto" means that max_bin is selected based on the processing unit type and other parameters. For details, see the CatBoost documentation.
Valid values: string, either: ("Auto" or string of integer from "1" to "65535" inclusively).
Default value: "Auto".
**grow_policy** | The tree growing policy. Defines how to perform greedy tree construction.
Valid values: string, any of the following: ("SymmetricTree", "Depthwise", or "Lossguide").
Default value: "SymmetricTree".
**random_seed** | The random seed used for training.
Valid values: integer, range: Non-negative integer.
Default value: 1.0.
**thread_count** | The number of threads to use during the training. If thread_count is -1, then the number of threads is equal to the number of processor cores. thread_count cannot be 0.
Valid values: integer, either: (-1 or positive integer).
Default value: -1.
**verbose** | The verbosity of print messages, with higher levels corresponding to more detailed print statements.
Valid values: integer, range: Positive integer.
Default value: 1.

### Tune a CatBoost model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**
The learning loss function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see [CatBoost hyperparameters](p. 1206).

- A learning loss function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.
Note
Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Evaluation metrics computed by the CatBoost algorithm

The SageMaker CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For a

**Factorization Machines Algorithm**

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

**Note**

The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

**Topics**

- **Input/Output Interface for the Factorization Machines Algorithm** (p. 1211)
- **EC2 Instance Recommendation for the Factorization Machines Algorithm** (p. 1212)
- **Factorization Machines Sample Notebooks** (p. 1212)
- **How Factorization Machines Work** (p. 1212)
- **Factorization Machines Hyperparameters** (p. 1213)
- **Tune a Factorization Machines Model** (p. 1218)
- **Factorization Machines Response Formats** (p. 1219)

**Input/Output Interface for the Factorization Machines Algorithm**

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For **training**, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with Float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For **inference**, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that
the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.

- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks (p. 1212) for more details on training and inference file formats.

**EC2 Instance Recommendation for the Factorization Machines Algorithm**

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

**Factorization Machines Sample Notebooks**

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How Factorization Machines Work**

The prediction task for a Factorization Machines model is to estimate a function \( \hat{y} \) from a feature set \( x_i \) to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset \((x_i, y_j)\) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[
\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j>i} < v_i, v_j > x_i x_j
\]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w_0 \) term represents the global bias.
- The \( w_i \) linear terms model the strength of the \( i^{th} \) variable.
- The \( < v_i, v_j > \) factorization terms model the pairwise interaction between the \( i^{th} \) and \( j^{th} \) variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[
L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2
\]
For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[ L = \frac{1}{N} \sum_{n} [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)] \]

where:

\[ \hat{p}_n = \frac{1}{1 + e^{-y_n}} \]

For more information about loss functions for classification, see [Loss functions for classification](#).

**Factorization Machines Hyperparameters**

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

<table>

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if bias_init_method==uniform, then bias_init_scale, linear_init_scale, and factors_init_scale are tunable. Similarly, if the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

**Factorization Machines Response Formats**

**JSON Response Format**

Binary classification

```javascript
let response = {
  "predictions": 
  [ 
    {
      "score": 0.4,
      "predicted_label": 0 
    }
  ]
}
```
Regression

let response = {
    "predictions": [
        {
            "score": 0.4
        }
    ]
}

**JSONLINES Response Format**

Binary classification

{"score": 0.4, "predicted_label": 0}

Regression

{"score": 0.4}

**RECORDIO Response Format**

Binary classification

[  
  Record = {  
    features = {},  
    label = {  
      'score': {  
        keys: [],  
        values: [0.4] # float32  
      },  
      'predicted_label': {  
        keys: [],  
        values: [0.0] # float32  
      }  
    }  
  }  ]

Regression

[  
  Record = {  
    features = {},  
    label = {  
      'score': {  
        keys: [],  
        values: [0.4] # float32  
      }  
    }  
  }  ]
K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the $k$ points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the $k$ closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d > 1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the $k$ nearest points to use for inference.

- k-NN Request and Response Formats (p. 1226)

Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

- Use a train channel for data that you want to sample and construct into the k-NN index.
- Use a test channel to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports text/csv and application/x-recordio-protobuf data formats. For input type text/csv, the first label_size columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the application/json, application/x-recordio-protobuf, and text/csv data formats. The text/csv format accepts a label_size and encoding parameter. It assumes a label_size of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the application/json and application/x-recordio-protobuf data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the application/jsonlines data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines
```
An example output is as follows:

```
accept: application/json
lines
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 1226) for training, k-NN Request and Response Formats (p. 1226) for inference, and the k-NN Sample Notebooks (p. 1222).

### k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

### How the k-NN Algorithm Works

**Step 1: Sample**

To specify the total number of data points to be sampled from the training dataset, use the sample_size parameter. For example, if the initial dataset has 1,000 data points and the sample_size is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

**Step 2: Perform Dimension Reduction**

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the dimension_reduction_type hyperparameter. The sign method specifies a random projection, which uses a linear projection using a matrix of random signs, and the fjlt method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The fjlt method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The sign method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The fjlt method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

**Step 3: Build an Index**

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the index_type parameter.

### Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- model_algo-1: Contains the serialized index for computing the nearest neighbors.
• model_algo-1.labels: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
• model_algo-1.json: Contains the JSON-formatted model metadata which stores the k and predictor_type hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change k to 10 or change predictor_type to regressor.

```json
{
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {
    "type": "sign",
    "seed": 3,
    "target_dim": 10,
    "input_dim": 20
  },
  "normalize": false,
  "version": "1.0"
}
```

**EC2 Instance Recommendation for the k-NN Algorithm**

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

### Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

### Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the predictor_type hyper-parameter.

- **classifier** specifies a classification task and computes **test:accuracy**
- **regressor** specifies a regression task and computes **test:mse**.

Choose the predictor_type value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:accuracy</td>
<td>When predictor_type is set to classifier, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:mse</td>
<td>When predictor_type is set to regressor, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.</td>
<td>Minimize</td>
</tr>

Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in [Common Data Formats - Training](#). This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

**CSV Data Format**

content-type: text/csv; label_size=1

```
4,1.2,1.3,9.6,20.3
```

The first label_size columns are interpreted as the label vector for that row.

**RECORDIO Data Format**

content-type: application/x-recordio-protobuf

```
[  
  Record = {  
    features = {  
      'values': {  
        values: [1.2, 1.3, 9.6, 20.3] # float32  
      }  
    },  
    label = {  
      'values': {  
        values: [4] # float32  
      }  
    }  
  }  
]
```

k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

**INPUT: CSV Request Format**

content-type: text/csv
This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

**INPUT: JSON Request Format**

```json
content-type: application/json

{
  "instances": [
    {
      "data": {
        "features": {
          "values": [-3, -1, -4, 2]
        }
      }
    },
    {
      "features": [3.0, 0.1, 0.04, 0.002]
    }
  ]
}
```

**INPUT: JSONLINES Request Format**

```json
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

**INPUT: RECORDIO Request Format**

```json
content-type: application/x-recordio-protobuf

[ Record = {
    features = {
        'values': {
            values: [-3, -1, -4, 2]  # float32
        }
    },
    label = {}
},
 Record = {
    features = {
        'values': {
            values: [3.0, 0.1, 0.04, 0.002]  # float32
        }
    },
    label = {}
},
]
```

**OUTPUT: JSON Response Format**

```json
accept: application/json

{
  "predictions": [
    {"predicted_label": 0.0},
    {"predicted_label": 2.0}
  ]
}
```

**OUTPUT: JSONLINES Response Format**

```json
accept: application/jsonlines

{"predicted_label": 0.0}
```
OUTPUT: VERBOSE JSON Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, $k$ is set to 3.

```
accept: application/json; verbose=true

{
  "predictions": [
    {
      "predicted_label": 0.0,
      "distances": [3.11792408, 3.89746071, 6.32548437],
      "labels": [0.0, 1.0, 0.0]
    },
    {
      "predicted_label": 2.0,
      "distances": [1.08470316, 3.04917915, 5.25393973],
      "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

OUTPUT: RECORDIO-PROTOBUF Response Format

```
content-type: application/x-recordio-protobuf

[ Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0]  # float32
      },
    },
  },
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [2.0]  # float32
      },
      'distances': {
      },
    }
  }
]
```

OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format

```
accept: application/x-recordio-protobuf; verbose=true

[
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0]  # float32
      },
      'distances': {
      },
    }
  }
]
```
Sample output for the k-NN algorithm

For regressor tasks:

```
[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse', 0.013333333333333334)
```

For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy', 0.98666666666666669)
```

LightGBM

LightGBM is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT.

How to use SageMaker LightGBM

You can use LightGBM as an Amazon SageMaker built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

  ```python
  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "lightgbm-classification-model", "+", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["num_boost_round"] = "500"
print(hyperparameters)

from sagemaker import estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = estimator.Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=500000,
)
# Use Built-in Algorithms

```python
hyperparameters=hyperparameters,
output_path=s3_output_location
)
```

# Launch a SageMaker Training job by passing the S3 path of the training data
```python
tabular_estimator.fit(
    "training": training_dataset_s3_path}, logs=True, job_name=training_job_name
)
```

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

### Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of LightGBM supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.
- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.
- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.
To use a model trained with SageMaker LightGBM with the JobLib module

- Use the following Python code:

```python
import joblib
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = joblib.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the LightGBM algorithm

SageMaker LightGBM currently only trains using CPUs. LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

LightGBM sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker LightGBM algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How LightGBM works

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.
For more information on gradient boosting, see How XGBoost Works (p. 1267). For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see LightGBM: A Highly Efficient Gradient Boosting Decision Tree.

LightGBM hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker LightGBM algorithm is an implementation of the open-source LightGBM package.

**Note**
The default hyperparameters are based on example datasets in the LightGBM sample notebooks (p. 1232).

By default, the SageMaker LightGBM algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The LightGBM algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error and the objective function is L2 loss. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric is multiclass cross entropy and the objective function is softmax. You can use the `metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
<th>Valid values</th>
<th>Default value</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>
| max_delta_step      | Used to limit the max output of tree leaves. If max_delta_step is less than or equal to 0, then there is no constraint. The final max output of leaves is learning_rate * max_delta_step.  
  Valid values: float.  
  Default value: 0.0. |
| lambda_l1           | L1 regularization.  
  Valid values: float, range: Non-negative float.  
  Default value: 0.0. |
| lambda_l2           | L2 regularization.  
  Valid values: float, range: Non-negative float.  
  Default value: 0.0. |
| boosting            | Boosting type  
  Valid values: string, any of the following: ("gbdt", "rf", "dart", or "goss").  
  Default value: "gbdt". |
| min_gain_to_split   | The minimum gain to perform a split. Can be used to speed up training.  
  Valid values: integer, float: Non-negative float.  
  Default value: 0.0. |
| scale_pos_weight    | The weight of the labels with positive class. Used only for binary classification tasks. scale_pos_weight cannot be used if is_unbalance is set to "True".  
  Valid values: float, range: Positive float.  
  Default value: 1.0. |
| tree_learner        | Tree learner type.  
  Valid values: string, any of the following: ("serial", "feature", "data", or "voting").  
  Default value: "serial". |
| feature_fraction_by_node | Selects a subset of random features on each tree node. For example, if feature_fraction_by_node is 0.8, then 80% of features are selected. Can be used to deal with overfitting.  
  Valid values: integer, range: [0.0, 1.0].  
  Default value: 1.0. |
### Parameter Name | Description
--- | ---
**is_unbalance** | Set to "True" if training data is unbalanced. Used only for binary classification tasks. `is_unbalance` cannot be used with `scale_pos_weight`.  
Valid values: string, either: ("True" or "False").  
Default value: "False".

**max_bin** | The maximum number of bins used to bucket feature values. A small number of bins may reduce training accuracy, but may increase general performance. Can be used to deal with overfitting.  
Valid values: integer, range: (1, ∞).  
Default value: 255.

**tweedie_variance_power** | Controls the variance of the Tweedie distribution. Set this closer to 2.0 to shift toward a gamma distribution. Set this closer to 1.0 to shift toward a Poisson distribution. Used only for regression tasks.  
Valid values: float, range: [1.0, 2.0).  
Default value: 1.5.

**num_threads** | Number of parallel threads used to run LightGBM. Value 0 means default number of threads in OpenMP.  
Valid values: integer, range: Non-negative integer.  
Default value: 0.

**verbosity** | The verbosity of print messages. If the verbosity is less than 0, then print messages only show fatal errors. If verbosity is set to 0, then print messages include errors and warnings. If verbosity is 1, then print messages show more information. A verbosity greater than 1 shows the most information in print messages and can be used for debugging.  
Valid values: integer.  
Default value: 1.

---

### Tune a LightGBM model

*Automated model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**  
The learning objective function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see *LightGBM hyperparameters* (p. 1233).

- A learning objective function to optimize during model training  
- An evaluation metric that is used to evaluate model performance during validation  
- A set of hyperparameters and a range of values for each to use when tuning the model automatically
Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**
Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

**Evaluation metrics computed by the LightGBM algorithm**

The SageMaker LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

<table>

Tunable LightGBM hyperparameters

Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: learning_rate, num_leaves, feature_fraction, bagging_fraction, bagging_freq, max_depth and min_data_in_leaf. For a list of all the LightGBM hyperparameters, see LightGBM hyperparameters (p. 1233).

Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(num\_classes - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see CreateTrainingJob. You can specify
additional parameters in the HyperParameters string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1253). For more information on inference formats, and the Linear learner sample notebooks (p. 1240).
EC2 instance recommendation for the linear learner algorithm

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

<table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

Note
For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the normalize_data and normalize_label hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.
Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

Note
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

</table>
| binary_classifier_model_selection_criteria | When predictor_type is set to binary_classifier, the model evaluation criteria for the validation dataset (or for the training dataset if you don't provide a validation dataset). Criteria include:  
  - accuracy—The model with the highest accuracy.  
  - f_beta—The model with the highest F1 score. The default is F1.  
  - precision_at_target_recall—The model with the highest precision at a given recall target.  
  - recall_at_target_precision—The model with the highest recall at a given precision target.  
  - loss_function—The model with the lowest value of the loss function used in training.  
  Optional  
  Valid values: accuracy, f_beta, precision_at_target_recall, recall_at_target_precision, or loss_function  
  Default value: accuracy |
| early_stopping_patience                | If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for binary_classifier_model_selection_criteria, the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter.  
  The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set early_stopping_patience to a value greater than the value specified for epochs.  
  Optional  
  Valid values: Positive integer  
  Default value: 3 |
| early_stopping_tolerance               | The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero.  
  Optional  
  Valid values: Positive floating-point integer  
  Default value: 0.001 |
| epochs                                 | The maximum number of passes over the training data.  
  Optional  
  Valid values: Positive integer  
  Default value: 15 |
<table>

</thead>
</table>
| **f_beta**     | The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for binary_classifier_model_selection_criteria is f_beta.  
Optional  
Valid values: Positive floating-point integers 
Default value: 1.0 |
| **feature_dim** | The number of features in the input data.  
Optional  
Valid values: auto or positive integer 
Default values: auto |
| **huber_delta** | The parameter for Huber loss. During training and metric evaluation, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta.  
Optional  
Valid values: Positive floating-point integer 
Default value: 1.0 |
| **init_bias**   | Initial weight for the bias term.  
Optional  
Valid values: Floating-point integer 
Default value: 0 |
| **init_method** | Sets the initial distribution function used for model weights. Functions include:  
• uniform—Uniformly distributed between (-scale, +scale)  
• normal—Normal distribution, with mean 0 and sigma  
Optional  
Valid values: uniform or normal 
Default value: uniform |
| **init_scale**  | Scales an initial uniform distribution for model weights. Applies only when the init_method hyperparameter is set to uniform.  
Optional  
Valid values: Positive floating-point integer 
Default value: 0.07 |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| init_sigma     | The initial standard deviation for the normal distribution. Applies only when the init_method hyperparameter is set to normal.  
**Optional**  
Valid values: Positive floating-point integer  
Default value: 0.01 |
| l1             | The L1 regularization parameter. If you don’t want to use L1 regularization, set the value to 0.  
**Optional**  
Valid values: auto or non-negative float  
Default value: auto |
| learning_rate  | The step size used by the optimizer for parameter updates.  
**Optional**  
Valid values: auto or positive floating-point integer  
Default value: auto, whose value depends on the optimizer chosen. |
| loss           | Specifies the loss function.  
The available loss functions and their default values depend on the value of predictor_type:  
- If the predictor_type is set to regressor, the available options are auto, squared_loss, absolute_loss, eps_insensitive_squared_loss, eps_insensitive_absolute_loss, quantile_loss, and huber_loss. The default value for auto is squared_loss.  
- If the predictor_type is set to binary_classifier, the available options are auto, logistic, and hinge_loss. The default value for auto is logistic.  
- If the predictor_type is set to multiclass_classifier, the available options are auto and softmax_loss. The default value for auto is softmax_loss.  
Valid values: auto, logistic, squared_loss, absolute_loss, hinge_loss, eps_insensitive_squared_loss, eps_insensitive_absolute_loss, quantile_loss, or huber_loss  
**Optional**  
Default value: auto |

Tune a linear learner model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:absolute_loss</td>
<td>The absolute loss of the final model on the test dataset. This objective metric is only valid for regression.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:binary_classification_accuracy</td>
<td>The accuracy of the final model on the test dataset. This objective metric is only valid for binary classification.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:binary_f_beta</td>
<td>The F-beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall. This objective metric is only valid for binary classification.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:dcg</td>
<td>The discounted cumulative gain of the final model on the test dataset. This objective metric is only valid for multiclass classification.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:macro_f_beta</td>
<td>The F-beta score of the final model on the test dataset. This objective metric is only valid for multiclass classification.</td>

<tr>
<td>l1</td>
<td>ContinuousParameterRanges</td>
<td>MinValue: 1e-7, MaxValue: 1</td>
</tr>
<tr>
<td>learning_rate</td>
<td>ContinuousParameterRanges</td>
<td>MinValue: 1e-5, MaxValue: 1</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>IntegerParameterRanges</td>
<td>MinValue: 100, MaxValue: 5000</td>
</tr>
<tr>
<td>use_bias</td>
<td>CategoricalParameterRanges</td>
<td>[True, False]</td>
</tr>
<tr>
<td>positive_example_weight</td>
<td>ContinuousParameterRanges</td>
<td>MinValue: 1e-5, MaxValue: 1e5</td>
</tr>
</tbody>
</table>

**Linear learner response formats**

**JSON response formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

**Binary Classification**

```javascript
let response = {
  "predictions": [
```
**Multiclass Classification**

```json
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

**Regression**

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES response formats**

**Binary Classification**

```json
{"score": 0.4, "predicted_label": 0}
```

**Multiclass Classification**

```json
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

**Regression**

```json
{"score": 0.4}
```

**RECORDIO response formats**

**Binary Classification**

```json
[
  Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      },
      'predicted_label': {
        keys: [],
        values: [0.0]  # float32
      }
    }
  ]
]```
Multiclass Classification

```
[  
  Record = {
    "features": [],
    "label": {
      "score": {
        "values": [0.1, 0.2, 0.3, 0.4]
      },
      "predicted_label": {
        "values": [3]
      }
    }
  },
  "uid": "abc123",
  "metadata": "{created_at: '2017-06-03'}"
]
```

Regression

```
[  
  Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      }
    }
  }
]
```

TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

How to use SageMaker TabTransformer

You can use TabTransformer as an Amazon SageMaker built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

- Use TabTransformer as a built-in algorithm

  Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

  After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["n_epochs"] = "50"
print(hyperparameters)

from sagemaker import Estimator

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=560000,"
# Launch a SageMaker Training job by passing the S3 path of the training data

```python
tabular_estimator.fit(
    {'training': training_dataset_s3_path},
    logs=True, job_name=training_job_name
)
```

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker TabTransformer algorithm
- Tabular regression with Amazon SageMaker TabTransformer algorithm

## Input and Output interface for the TabTransformer algorithm

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the TabTransformer model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.

- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.
Amazon EC2 instance recommendation for the TabTransformer algorithm

SageMaker TabTransformer supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker TabTransformer currently does not support multi-GPU training.

TabTransformer sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker TabTransformer algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker TabTransformer algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker TabTransformer algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How TabTransformer works

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.
Figure 1: The architecture of TabTransformer.

For more information, see *TabTransformer: Tabular Data Modeling Using Contextual Embeddings*. 
TabTransformer hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker TabTransformer algorithm is an implementation of the open-source TabTransformer package.

**Note**
The default hyperparameters are based on example datasets in the TabTransformer sample notebooks (p. 1258).

The SageMaker TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is r square and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

**Note**
The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n_epochs</td>
<td>Number of epochs to train the deep neural network. Valid values: integer, range: Positive integer. Default value: 5.</td>
</tr>
<tr>
<td>patience</td>
<td>The training will stop if one metric of one validation data point does not improve in the last patience round. Valid values: integer, range: (2, 60). Default value: 10.</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: Positive floating point number. Default value: 0.001.</td>
</tr>
<tr>
<td>batch_size</td>
<td>The number of examples propagated through the network. Valid values: integer, range: (1, 2048). Default value: 256.</td>
</tr>
<tr>
<td>input_dim</td>
<td>The dimension of embeddings to encode the categorical and/or continuous columns. Valid values: string, any of the following: &quot;16&quot;, &quot;32&quot;, &quot;64&quot;, &quot;128&quot;, &quot;256&quot;, or &quot;512&quot;. Default value: &quot;32&quot;.</td>

<td>frac_shared_embed</td>
<td>The fraction of embeddings shared by all the different categories for one</td>
</tr>
</tbody>
</table>

#### Parameters

- **attn_dropout**
  - Description: Dropout rate applied to the Multi-Head Attention layers.  
  - Valid values: float, range: (0, 1).  
  - Default value: 0.2.

- **mlp_dropout**
  - Description: Dropout rate applied to the FeedForward network within the encoder layers.  
  - Valid values: float, range: (0, 1).  
  - Default value: 0.1.

- **frac_shared_embed**
  - Description: The fraction of embeddings shared by all the different categories for one particular column.  
  - Valid values: float, range: (0, 1).  
  - Default value: 0.25.

---

### Tune a TabTransformer model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**

Automatic model tuning for TabTransformer is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1654).

### Evaluation metrics computed by the TabTransformer algorithm

The SageMaker TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.
### Tunable TabTransformer hyperparameters

Tune the TabTransformer model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the TabTransformer evaluation metrics are: `learning_rate`, `input_dim`, `n_blocks`, `attn_dropout`, `mlp_dropout`, and `frac_shared_embed`. For a list of all the TabTransformer hyperparameters, see [TabTransformer hyperparameters](p. 1260).

### XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as an Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, and 1.5.
Supported versions

- Framework (open source) mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1
- Algorithm mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1

Important

When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1263) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

Warning

The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. It is highly recommended to upgrade the XGBoost version to one of the newer versions.

Note

XGBoost v1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker XGBoost 1.2-2 or later.

How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK. For information on how to use XGBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

• Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:squarederror",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}{}'.format(bucket, prefix, 'abalone-xgb-framework')
```
# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.5-1',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
                          content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
                             content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

- **Use XGBoost as a built-in algorithm**

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

**Important**
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1263) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

```python
import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
```
output_path = 's3://{}/{}/{}-abalone-xgb-built-in-algo'.format(bucket, prefix, 'output')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}").format(bucket, prefix, 'train'),
                                          content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}").format(bucket, prefix, 'validation'),
                                          content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm (default) or text/csv.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.
For v1.3-1 and later, SageMaker XGBoost saves the model in the XGBoost internal binary format, using `Booster.save_model`. Previous versions use the Python pickle module to serialize/deserialize the model.

**Note**

Be mindful of versions when using an SageMaker XGBoost model in open source XGBoost. Versions 1.3-1 and later use the XGBoost internal binary format while previous versions use the Python pickle module.

**To use a model trained with SageMaker XGBoost v1.3-1 or later in open source XGBoost**

- Use the following Python code:

```python
import xgboost as xgb
xgb_model = xgb.Booster()
xgb_model.load_model(model_file_path)
xgb_model.predict(dtest)
```

**To use a model trained with previous versions of SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))
# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Algorithm**

SageMaker XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. SageMaker XGBoost version 1.2 or later supports P2 and P3 instances.

SageMaker XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.
To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker XGBoost currently does not support multi-GPU training.

SageMaker XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see Amazon SageMaker ML Instance Types.

**XGBoost Sample Notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>

</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

**How XGBoost Works**

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the
regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It’s called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.

\[
F_m(X) = F_{m-1}(X) + \alpha_m h_m(X, r_{m-1}),
\]

where \( \alpha_i \) and \( r_i \) are the regularization parameters and residuals computed with the \( i^{th} \) tree respectfully, and \( h_i \) is a function that is trained to predict residuals, \( r_i \) using \( X \) for the \( i^{th} \) tree. To compute \( \alpha_i \) we use the residuals computed, \( r_i \) and compute the following: \( \arg \min_{\alpha} \sum_{i=1}^{m} L(Y_i, F_{i-1}(X_i) + h_i(X_i, r_{i-1})) \) where \( L(Y, F(X)) \) is a differentiable loss function.

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

### XGBoost Hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_class</td>
<td>The number of classes.</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
---|---
| **num_round** | The number of rounds to run the training.  
**Required**  
Valid values: integer
| | **alpha** | L1 regularization term on weights. Increasing this value makes models more conservative.  
**Optional**  
Valid values: float  
Default value: 0
| | **base_score** | The initial prediction score of all instances, global bias.  
**Optional**  
Valid values: float  
Default value: 0.5
| | **booster** | Which booster to use. The `gbtree` and `dart` values use a tree-based model, while `gblinear` uses a linear function.  
**Optional**  
Valid values: String. One of `gbtree`, `gblinear`, or `dart`.  
Default value: `gbtree`
| | **colsample_bylevel** | Subsample ratio of columns for each split, in each level.  
**Optional**  
Valid values: Float. Range: [0,1].  
Default value: 1
| | **colsample_bynode** | Subsample ratio of columns from each node.  
**Optional**  
Valid values: Float. Range: (0,1].  
Default value: 1
| | **colsample_bytree** | Subsample ratio of columns when constructing each tree.  
**Optional**  
Valid values: Float. Range: [0,1].  
Default value: 1

| refresh_leaf               | This is a parameter of the 'refresh' updater plug-in. When set to true (1), tree leaves and tree node stats are updated. When set to false (0), only tree node stats are updated.  
Optional  
Valid values: 0/1  
Default value: 1 |
| sample_type                | Type of sampling algorithm.                                                                                                                  |
Optional  
Valid values: Either uniform or weighted.  
Default value: uniform |
| scale_pos_weight           | Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: sum(negative cases) / sum(positive cases).  
Optional  
Valid values: float  
Default value: 1 |
| seed                       | Random number seed.                                                                                                                          |
Optional  
Valid values: integer  
Default value: 0 |
| single_precision_histogram | When this flag is enabled, XGBoost uses single precision to build histograms instead of double precision. Used only if tree_method is set to hist or gpu_hist.  
For a full list of valid inputs, please refer to XGBoost Parameters.  
Optional  
Valid values: String. Range: true or false  
Default value: false |
| sketch_eps                 | Used only for approximate greedy algorithm. This translates into $O(1 / \text{sketch\_eps})$ number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy.  
Optional  
Valid values: Float, Range: [0, 1].  
Default value: 0.03 |

</table>
Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

Note
Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Classification rate, calculated as #(right)/#(all cases).</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:auc</td>
<td>Area under the curve.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:error</td>
<td>Binary classification error rate, calculated as #(wrong cases)/#(all cases).</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:f1</td>
<td>Indicator of classification accuracy, calculated as the harmonic mean of precision and recall.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:logloss</td>
<td>Negative log-likelihood.</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mae</td>

<td>Root mean square error.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>
Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: alpha, min_child_weight, subsample, eta, and num_round.

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics
- Upgrade XGBoost Version 0.90 to Version 1.5 (p. 1277)
- XGBoost Version 0.72 (p. 1279)

Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost version and framework_version parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.
Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must upgrade to version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```bash
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost built-in algorithm, change the version parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```python
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.5-1',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```python
content_type = "libsvm"
train_input = TrainingInput("s3://{}//{}//train".format(bucket, prefix, 'train'),
                         content_type=content_type)
validation_input = TrainingInput("s3://{}//{}//validation".format(bucket, prefix, 'validation'),
                             content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.
{  
  "AlgorithmSpecification": {  
    "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.5-1"
  }  
}  

If you using the SageMaker Python SDK to retrieve registry path, change the version parameter in image_uris.retrieve.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

**Update Hyperparameters and Learning Objectives**

The silent parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use verbosity instead. If you were using the reg:linear learning objective, it has been deprecated as well in favor of reg:squarederror. Use reg:squarederror instead.

```python
hyperparameters = {  
  "verbosity": "2",  
  "objective": "reg:squarederror",  
  "num_round": "50",  
  ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,  
hyperparameters=hyperparameters,  
...)
```

### XGBoost Version 0.72

**Important**

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

**SageMaker Python SDK v1**

```python
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",  
repo_version="1")
```

**SageMaker Python SDK v2**

```python
import boto3
from sagemaker import image_uris
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 1263)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. **XGBoost** (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of
the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1262). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

**Input/Output Interface for the XGBoost Release 0.72**

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.
- For Inference ContentType, valid inputs are `text/libsvm` or (the default) `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: `<label> <index0>:<value0> <index1>:<value1> ...` Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```
pred = model.predict(dtest)

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight idx_0:val_0 idx_1:val_1... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.

<table>
<thead>

</table>
| **eta**        | Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The eta parameter actually shrinks the feature weights to make the boosting process more conservative.  
   **Optional**  
   Valid values: Float. Range: [0,1].  
   Default value: 0.3 |
| **eval_metric**| Evaluation metrics for validation data. A default metric is assigned according to the objective:  
   • rmse: for regression  
   • error: for classification  
   • map: for ranking  
   For a list of valid inputs, see XGBoost Parameters.  
   **Optional**  
   Valid values: string  
   Default value: Default according to objective. |
| **gamma**      | Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is.  
   **Optional**  
   Valid values: Float. Range: [0,∞).  
   Default value: 0 |
| **grow_policy**| Controls the way that new nodes are added to the tree. Currently supported only if tree_method is set to hist.  
   **Optional**  
   Valid values: String. Either depthwise or lossguide.  
   Default value: depthwise |
| **lambda**     | L2 regularization term on weights. Increasing this value makes models more conservative.  
   **Optional**  
   Valid values: float  
   Default value: 1 |

Tune an XGBoost Release 0.72 Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>

### Built-in SageMaker Algorithms for Text Data

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- **BlazingText algorithm (p. 1290)**—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- **Latent Dirichlet Allocation (LDA) Algorithm (p. 1300)**—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
- **Neural Topic Model (NTM) Algorithm (p. 1305)**—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- **Object2Vec Algorithm (p. 1311)**—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- **Sequence-to-Sequence Algorithm (p. 1327)**—a supervised algorithm commonly used for neural machine translation.
- **Text Classification - TensorFlow (p. 1340)**—a supervised algorithm that supports transfer learning with available pretrained models for text classification.
**Algorithm**

### BlazingText algorithm

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's
implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>

</tr>
</tbody>
</table>

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

**Topics**

- Input/Output Interface for the BlazingText Algorithm (p. 1291)
- EC2 Instance Recommendation for the BlazingText Algorithm (p. 1294)
- BlazingText Sample Notebooks (p. 1294)
- BlazingText Hyperparameters (p. 1295)
- Tune a BlazingText Model (p. 1298)

**Input/Output Interface for the BlazingText Algorithm**

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.
Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the train channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string __label__. Here is an example of a training/validation file:

```plaintext
__label__4  linux ready for prime time, intel says, despite all the linux hype, the open-source movement has yet to make a huge splash in the desktop market. that may be about to change, thanks to chipmaking giant intel corp.
__label__2  bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived.
```

Note
The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the source tag and the label can be specified using the label tag. Both source and label tags should be provided under the AttributeNames parameter value as specified in the request.

```json
{"source":"linux ready for prime time, intel says, despite all the linux hype","label":1}
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly","label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```json
{"source":"linux ready for prime time, intel says, despite all the linux hype","label": [1, 3]}
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly","label": [2, 4, 5]}
```

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File](#).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores
the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesn't_match('breakfast cereal dinner lunch'.split())
```

If the evaluation parameter is set to `True`, an additional file, `eval.json`, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

**Sample JSON Request**

Mime-type: application/json

```
{
  "instances": ["word1", "word2", "word3"]
}
```

**Model Artifacts for the Text Classification Algorithm**

Training with supervised outputs creates a `model.bin` file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

**Sample JSON Request**

Mime-type: application/json

```
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top \( k \) predictions, you can set \( k \) in the configuration, as follows:

```
{
  "instances": ["the movie was excellent", "i did not like the plot ."],
  "configuration": {"k": 2}
}
```

For BlazingText, the content-type and accept parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the Accept field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}
```

if you need to pass the value of \( k \) for top-\( k \), then you can do it in the following way:

```
{"source": "source_0", "k": 2}
```
For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```bash
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks Text Classification with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the Word2Vec Algorithm.

**EC2 Instance Recommendation for the BlazingText Algorithm**

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the S3DataDistributionType field of the S3DataSource object that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.

**BlazingText Sample Notebooks**

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After creating and opening a
notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

**BlazingText Hyperparameters**

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

**Word2Vec Hyperparameters**

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Parameter Name</th>

### Tune a BlazingText Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric
from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: train:mean_rho. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the validation:accuracy. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat, sleep, play, meow,* and *bark,* LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>eat</th>
<th>sleep</th>
<th>play</th>
<th>meow</th>
<th>bark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to number of records * vocabulary size. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_mixture vector for each observation.

Please see the LDA Sample Notebooks (p. 1302) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.
LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

Note
Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data.

An LDA model is defined by two parameters:

- $\alpha$—A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- $\beta$—a collection of $k$ topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a “topic-word distribution.”

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture $\theta \sim \text{Dirichlet}(\alpha)$.

For each word in the document:

- Choose a topic $z \sim \text{Multinomial}(\theta)$
- Choose the corresponding topic-word distribution $\beta_z$.
- Draw a word $w \sim \text{Multinomial}(\beta_z)$.

When training the model, the goal is to find parameters $\alpha$ and $\beta$, which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a $V \times V \times V$ tensor, which summarizes the moments of the documents in our corpus. $V$ is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters $\alpha$ and $\beta$, which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this $V \times V \times V$ tensor is prohibitively large to store in memory.

2. Instead, it uses a $V \times V$ moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension $V \times k$. This matrix can be used to convert the $V \times V$ moment matrix into a $k \times k$ identity matrix. $k$ is the number of topics in the model.

3. This same whitening matrix can then be used to find a smaller $k \times k \times k$ tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the $V \times V \times V$ tensor.

4. **Alternating Least Squares** is used to decompose the smaller $k \times k \times k$ tensor. This provides a substantial improvement in memory consumption and speed. The parameters $\alpha$ and $\beta$ can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model’s parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

**LDA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see *How LDA Works* (p. 1302).

Use Built-in Algorithms

Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1654).

**Metrics Computed by the LDA Algorithm**

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>test:pwll</code></td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable LDA Hyperparameters**

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

**Neural Topic Model (NTM) Algorithm**

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into topics that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as “bike”, “car”, “train”, “mileage”, and “speed” are likely to share a topic on “transportation” for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on...
topic similarities. The topics from documents that NTM learns are characterized as a latent representation because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only UTF-8 encoding is supported.

For inference, text/csv, application/json, application/json-lines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.
See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats (p. 1310) for inference and the NTM Sample Notebooks (p. 1307).

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference. NTM training supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

Tune an NTM Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. Training loss measures how well the model fits the training data. Validation loss measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it’s preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

### Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:total_loss</td>
<td>Total Loss on validation set</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

### Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don’t necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters (p. 1307).

### NTM Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.
Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 1290). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

- Object2Vec Hyperparameters (p. 1315)
I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequences of discrete tokens, which is represented as a list of integer-ids. For example, [0, 12, 10, 13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the output_layer hyperparameter when you create the model training job.
EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the INFEERENCE_PREFERRED_MODE environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 1325) or the section called “GPU optimization: Encoder Embeddings” (p. 1326) inference network is loaded into GPU.

Object2Vec Sample Notebooks

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

Note

To run the notebooks on a notebook instance, see Example Notebooks (p. 373). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137).

How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics

- Step 1: Process Data (p. 1313)
- Step 2: Train a Model (p. 1313)
- Step 3: Produce Inferences (p. 1314)

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 1325). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For Python, you could use np.random.shuffle; for Unix, shuf.

Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.

- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.

- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.
During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

![Architecture of the Object2Vec Algorithm from Data Inputs to Scores](image)

**Step 3: Produce Inferences**

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.
Object2Vec Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enc0_max_seq_len</td>
<td>The maximum sequence length for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $1 \leq \text{integer} \leq 5000$</td>
</tr>
<tr>
<td>enc0_vocab_size</td>
<td>The vocabulary size of enc0 tokens.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $2 \leq \text{integer} \leq 3000000$</td>
</tr>
<tr>
<td>bucket_width</td>
<td>The allowed difference between data sequence length when bucketing is enabled.</td>
</tr>
<tr>
<td></td>
<td>To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0 \leq \text{integer} \leq 100$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (no bucketing)</td>
</tr>
<tr>
<td>comparator_list</td>
<td>A list used to customize the way in which two embeddings are compared.</td>
</tr>
<tr>
<td></td>
<td>The Object2Vec comparator operator layer takes the encodings from both</td>
</tr>
<tr>
<td></td>
<td>encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the comparator_list and the order in which they are passed determine how these subvectors are assembled. For example, if comparator_list=&quot;hadamard, concat&quot;, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, comparator_list=&quot;hadamard&quot;, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: A string that contains any combination of the names of the</td>
</tr>
<tr>
<td></td>
<td>three binary operators: hadamard, concat, or abs_diff.</td>
</tr>
<tr>
<td></td>
<td>The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</td>
</tr>
<tr>
<td></td>
<td>• hadamard: Constructs a vector as the Hadamard (element-wise) product of two encodings.</td>
</tr>
<tr>
<td></td>
<td>• concat: Constructs a vector as the concatenation of two encodings.</td>
</tr>
<tr>
<td></td>
<td>• abs_diff: Constructs a vector as the absolute difference between two encodings.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Default value: &quot;hadamard, concat, abs_diff&quot;</td>
</tr>
<tr>
<td>dropout</td>
<td>The dropout probability for network layers. Dropout is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0.0 ≤ float ≤ 1.0</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.0</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the early_stopping_tolerance hyperparameter.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 ≤ integer ≤ 5</td>
</tr>
<tr>
<td></td>
<td>Default value: 3</td>
</tr>
<tr>
<td>early_stopping_tolerance</td>
<td>The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the early_stopping_patience hyperparameter concludes.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0.000001 ≤ float ≤ 0.1</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.01</td>
</tr>
<tr>
<td>enc_dim</td>
<td>The dimension of the output of the embedding layer.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 4 ≤ integer ≤ 10000</td>
</tr>
<tr>
<td></td>
<td>Default value: 4096</td>
</tr>
<tr>
<td>enc0_network</td>
<td>The network model for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td>Valid values: hcnn, bilstm, or pooled_embedding</td>
</tr>
<tr>
<td></td>
<td>• hcnn: A hierarchical convolutional neural network.</td>
</tr>
<tr>
<td></td>
<td>• bilstm: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.</td>
</tr>
<tr>
<td></td>
<td>• pooled_embedding: Averages the embeddings of all of the tokens in the input.</td>

### Tune an Object2Vec Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1654).

### Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

#### Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

<td>test:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

#### Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

<table>

Data Formats for Object2Vec Training

**Input: JSON Lines Request Format**

Content-type: application/jsonlines

```json
[{
  "label": 0,
  "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
  "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
},
{
  "label": 1,
  "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
  "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]
},
{
  "label": 1,
  "in0": [774, 14, 21, 206],
  "in1": [21, 366, 125]
}]
```

The "in0" and "in1" are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field "label" can accept real valued inputs.

Data Formats for Object2Vec Inference

**GPU optimization: Classification or Regression**

Due to GPU memory scarcity, the INference_PREFERRED_MODE environment variable can be specified to optimize on whether the classification/regression or the section called "Output: Encoder Embeddings" (p. 1327) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify INference_PREFERRED_MODE=classification. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```python
transformer = o2v.transformer(instance_count=4,
                               instance_type="ml.p2.xlarge",
                               max_concurrent_transforms=2,
                               max_payload=1,  # 1MB
                               strategy='MultiRecord',
                               env={'INFERENCE_PREFERRED_MODE': 'classification'},  # only useful with GPU
                               output_path=output_s3_path)
```

**Input: Classification or Regression Request Format**

Content-type: application/json

```json
{
  "instances": [
    {
      "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
      "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
    },
    {
      "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
      "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]
    },
    {
      "in0": [774, 14, 21, 206],
      "in1": [21, 366, 125]
    }
  ]
}
```

Content-type: application/jsonlines

```json
[{
  "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
  "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
},
{
  "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
  "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]
},
{
  "in0": [774, 14, 21, 206],
  "in1": [21, 366, 125]
}]
```

For classification problems, the length of the scores vector corresponds to num_classes. For regression problems, the length is 1.
Output: Classification or Regression Response Format

Accept: application/json

```json
{
  "predictions": [
    {
      "scores": [
        0.6533935070037842,
        0.07582679390907288,
        0.2707797586917877
      ],
    },
    {
      "scores": [
        0.026291321963071823,
        0.6577019095420837,
        0.31600672006607056
      ]
    }]
}
```

Accept: application/jsonlines

```json
"scores": [0.195667684078216, 0.395351558923721, 0.408980727195739]
"scores": [0.251988261938095, 0.258233487606048, 0.489778339862823]
"scores": [0.280087798833847, 0.368331134319305, 0.351581096649169]
```

In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFEERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called "Inference Formats: Scoring" (p. 1325) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFEERENCE_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```python
transformer = o2v.transformer(instance_count=4,
                                instance_type="ml.p2.xlarge",
                                max_concurrent_transforms=2,
                                max_payload=1,  # 1MB
                                strategy='MultiRecord',
                                env={'INFEERENCE_PREFERRED_MODE': 'embedding'},  # only useful
                                output_path=output_s3_path)
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.
Use Built-in Algorithms

Amazon SageMaker Developer Guide

Content-type: application/jsonlines; infer_max_seqlen=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

Output: Encoder Embeddings

Content-type: application/json

```
{
  "predictions": [
    {
      "embeddings": [0.057368703186511, 0.030703511089086, 0.099890425801277, 0.063688032329082, 0.026327300816774, 0.003637571120634, 0.021305780857801, 0.004316598642617, 0.0, 0.003397724591195, 0.0, 0.000378780066967, 0.0, 0.0, 0.0, 0.007419463712722],
    {
      "embeddings": [0.150190666317939, 0.05145975202322, 0.098204270005226, 0.064249359071254, 0.056249320507049, 0.01513972133398, 0.047553978860378, 0.0, 0.0, 0.011533712036907, 0.011472506448626, 0.010696629062294, 0.0, 0.0, 0.0, 0.008508535102009]
    }
  ]
}
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

Sequence-to-Sequence Algorithm

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

Topics

- Input/Output Interface for the Sequence-to-Sequence Algorithm (p. 1328)
- EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm (p. 1329)
- Sequence-to-Sequence Sample Notebooks (p. 1329)
Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
- **validation**: It should contain the validation data (for example, the val.rec file generated by the preprocessing script).
- **vocab**: It should contain two vocabulary files (vocab.src.json and vocab.trg.json)

If the algorithm doesn't find data in any of these three channels, training results in an error.

Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the application/json format. Otherwise, use the recordio-protobuf format to work with the integer encoded data. Both modes support batching of input data. application/json format also allows you to visualize the attention matrix.

- **application/json**: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be application/json. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:
  
  configuration: `{attention_matrix: true}`: Returns the attention matrix for the particular input sequence.
  
  configuration: `{application/x-recordio-protobuf: true}`: Expects the input in recordio-protobuf format and returns the output in recordio-protobuf format. Both content and accept types should be recordio-protobuf. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be application/jsonlines. The format for input is as follows:

```
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:
For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the Sequence-to-Sequence Sample Notebooks (p. 1329).

**EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm**

The Amazon SageMaker seq2seq algorithm only supports on GPU instance types and can only train on a single machine. However, you can use instances with multiple GPUs. The seq2seq algorithm supports P2, P3, G4dn, and G5 GPU instance families.

**Sequence-to-Sequence Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train an English-German translation model, see Machine Translation English-German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How Sequence-to-Sequence Works**

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- **An embedding layer.** In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

- **An encoder layer.** After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)

- **A decoder layer.** The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.
### Sequence-to-Sequence Hyperparameters

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tbody>
</table>
### Parameter Name | Description
--- | ---
``max_seq_len_source`` | Maximum length for the source sequence length. Sequences longer than this length are truncated to this length.  
Optional  
Valid values: positive integer  
Default value: 100
``max_seq_len_target`` | Maximum length for the target sequence length. Sequences longer than this length are truncated to this length.  
Optional  
Valid values: positive integer  
Default value: 100
``min_num_epochs`` | Minimum number of epochs the training must run before it is stopped via early_stopping conditions.  
Optional  
Valid values: positive integer  
Default value: 0
``momentum`` | Momentum constant used for sgd. Don't pass this parameter if you are using adam or rmsprop.  
Optional  
Valid values: float  
Default value: none
``num_embed_source`` | Embedding size for source tokens.  
Optional  
Valid values: positive integer  
Default value: 512
``num_embed_target`` | Embedding size for target tokens.  
Optional  
Valid values: positive integer  
Default value: 512

### Tune a Sequence-to-Sequence Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](#).

### Metrics Computed by the Sequence-to-Sequence Algorithm

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Accuracy computed on the validation dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:bleu</td>
<td><strong>Bleu</strong> score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the <code>bleu_sample_size</code> parameter to specify the subsample.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:perplexity</td>
<td><strong>Perplexity</strong>, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

### Tunable Sequence-to-Sequence Hyperparameters

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective
metrics are: batch_size, optimizer_type, learning_rate, num_layers_encoder, and num_layers_decoder.

<table>

#### Text Classification - TensorFlow

The Amazon SageMaker Text Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of text data is not available. The text classification algorithm takes a text string as input and outputs a probability for each of the class labels. Training datasets must be in CSV format.

**Topics**
- How to use the SageMaker Text Classification - TensorFlow algorithm (p. 1340)
- Input and output interface for the Text Classification - TensorFlow algorithm (p. 1341)
- Amazon EC2 instance recommendation for the Text Classification - TensorFlow algorithm (p. 1342)
- Text Classification - TensorFlow sample notebooks (p. 1343)
- How Text Classification - TensorFlow Works (p. 1343)
- TensorFlow Hub Models (p. 1343)
- Text Classification - TensorFlow Hyperparameters (p. 1346)
- Tune a Text Classification - TensorFlow model (p. 1349)

#### How to use the SageMaker Text Classification - TensorFlow algorithm

You can use Text Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Text Classification - TensorFlow with the SageMaker Python SDK. For information on how to use Text Classification - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

The Text Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Hub Models (p. 1343). Every pretrained model has a unique model_id. The following example uses BERT Base Uncased (model_id: tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Text Classification - TensorFlow Hyperparameters (p. 1346). Use these values to construct a SageMaker Estimator.

**Note**

Default hyperparameter values are different for different models. For example, for larger models, the default batch size is smaller.
This example uses the SST2 dataset, which contains positive and negative movie reviews. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
    image_uris.retrieve(model_id=model_id, model_version=model_version, image_scope="training", instance_type=training_instance_type)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version, script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version, model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id, model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/SST2/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tc-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_tc_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
tf_tc_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the [Introduction to JumpStart - Text Classification](#) notebook.

**Input and output interface for the Text Classification - TensorFlow algorithm**

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset made up of text sentences with any number of classes. The pretrained model attaches a classification layer to
the Text Embedding model and initializes the layer parameters to random values. The output dimension of the classification layer is determined based on the number of classes detected in the input data.

Be mindful of how to format your training data for input to the Text Classification - TensorFlow model.

- **Training data input format:** A directory containing a data.csv file. Each row of the first column should have integer class labels between 0 and the number of classes. Each row of the second column should have the corresponding text data.

The following is an example of an input CSV file. Note that the file should not have any header. The file should be hosted in an Amazon S3 bucket with a path similar to the following:
s3://bucket_name/input_directory/. Note that the trailing / is required.

<p>| | |</p>

<td>that loves its characters and communicates something rather beautiful about human nature</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**

You can only seed a SageMaker Text Classification - TensorFlow model with another Text Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model.

For more information on using incremental training with the SageMaker Text Classification - TensorFlow algorithm, see the **Introduction to JumpStart - Text Classification** sample notebook.

**Inference with the Text Classification - TensorFlow algorithm**

You can host the fine-tuned model that results from your TensorFlow Text Classification training for inference. Any raw text formats for inference must be content type application/x-text.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Text Classification - TensorFlow model processes a single string per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json; verbose

{ "probabilities": [prob_0, prob_1, prob_2, ...],
  "labels": [label_0, label_1, label_2, ...],
  "predicted_label": predicted_label }
```

If accept is set to application/json, then the model only outputs probabilities.

**Amazon EC2 instance recommendation for the Text Classification - TensorFlow algorithm**

The Text Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:
We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Text Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How Text Classification - TensorFlow Works

The Text Classification - TensorFlow algorithm takes text as classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for text classification. There are also deep learning networks that are trained on large text datasets, such as TextNet, which has more than 11 million texts with about 11,000 categories. After a network is trained with TextNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific text classification tasks. The Amazon SageMaker Text Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a text classification layer is attached to the pretrained TensorFlow model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully connected layer with L2-norm regularization, and is initialized with random weights. You can change the hyperparameter values for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer.

You can fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Text Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

**Text Classification - TensorFlow Hyperparameters**

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Object Detection - TensorFlow algorithm. See [Tune a Text Classification - TensorFlow model](p. 1349) for information on hyperparameter tuning.

<table>

**Tune a Text Classification - TensorFlow model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 1654)](#).

## DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.
In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the cat field and a vector of dynamic (time-dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the context_length hyperparameter. To control how far in the future predictions can be made, use the prediction_length hyperparameter. For more information, see How the DeepAR Algorithm Works (p. 1355).

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named _SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz, or .parquet) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input class.

The records in your input files should contain the following fields:

- start—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time zone information.
- target—An array of floating-point values or integers that represent the time series. You can encode missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- dynamic_feat (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the
same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated target value plus prediction_length. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated dynamic_feat might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```json
{"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]
```

- cat (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the embedding_dimension hyperparameter. For more information, see DeepAR Hyperparameters (p. 1357).

If you use a JSON file, it must be in JSON Lines format. For example:

```json
["start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1], "dynamic_feat": [[1.1, 1.2, 0.5, ...]]
["start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat": [[1.1, 2.05, ...]]
["start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat": [[1.3, 0.4]]
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the datetime type. You can compress Parquet files using gzip (gzip) or the Snappy compression library (snappy).

If the algorithm is trained without cat and dynamic_feat fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the cat and dynamic_feat feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding cat features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional cat vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```json
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with cat values that are combinations of the cat values observed in the training data, for example:

```json
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
• Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.

• Make sure to set the start field correctly. The algorithm uses the start timestamp to derive the internal features.

• If you use categorical features (cat), all time series must have the same number of categorical features. If the dataset contains the cat field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the cat field, but you don't want to use it, you can disable it by setting cardinality to "". If a model was trained using a cat feature, you must include it for inference.

• If your dataset contains the dynamic_feat field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the dynamic_feat field should have the same length as the target. If the dataset contains the dynamic_feat field, but you don't want to use it, disable it by setting num_dynamic_feat to "". If the model was trained with the dynamic_feat field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the prediction_length. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

\[
RMSE = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}
\]

\(y_{i,t}\) is the true value of time series \(i\) at the time \(t\). \(\hat{y}_{i,t}\) is the mean prediction. The sum is over all \(n\) time series in the test set and over the last \(T\) time points for each time series, where \(T\) corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the prediction_length hyperparameter. For more information, see DeepAR Hyperparameters (p. 1357).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range [0, 1], the weighted quantile loss is defined as follows:

\[
w\text{QuantileLoss}[\tau] = 2 \frac{\sum_{i,t} \hat{Q}_{i,t}^{(\tau)}}{\sum_{i,t} |y_{i,t}|}, \text{ with } \hat{Q}_{i,t}^{(\tau)} = \begin{cases} (1 - \tau)|\hat{q}_{i,t}^{(\tau)} - y_{i,t}| & \text{if } \hat{q}_{i,t}^{(\tau)} > y_{i,t} \\ \tau|\hat{q}_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}
\]

\(\hat{q}_{i,t}^{(\tau)}\) is the \(\tau\)-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the test_quantiles hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 1357).

For inference, DeepAR accepts JSON format and the following fields:

• "instances", which includes one or more time series in JSON Lines format
• A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 1362).

Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

1. Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
2. Make sure to set the start field correctly. The algorithm uses the start timestamp to derive the internal features.
3. If you use categorical features (cat), all time series must have the same number of categorical features. If the dataset contains the cat field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the cat field, but you don't want to use it, you can disable it by setting cardinality to "". If a model was trained using a cat feature, you must include it for inference.
4. If your dataset contains the dynamic_feat field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the dynamic_feat field should have the same length as the target. If the dataset contains the dynamic_feat field, but you don't want to use it, disable it by setting num_dynamic_feat to "". If the model was trained with the dynamic_feat field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the prediction_length. In other words, you must provide the feature value in the future.
Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.

When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` time points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withhold the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 1361).

Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use `5min` instead of `1min`.

Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.

We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

**EC2 Instance Recommendations for the DeepAR Algorithm**

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, `ml.c4.2xlarge` or `ml.c4.4xlarge`), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for `context_length`, `prediction_length`, `num_cells`, `num_layers`, or `mini_batch_size` can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

**DeepAR Sample Notebooks**

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see Time series forecasting with DeepAR - Synthetic data as well as DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.
How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 1351).

For example, the following is an element of a training set indexed by $i$ which consists of a target time series, $Z_{i,t}$, and two associated feature time series, $X_{i,1,t}$ and $X_{i,2,t}$:

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

How Feature Time Series Work in the DeepAR Algorithm

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.
The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

<table>
<thead>
<tr>
<th>Frequency of the Time Series</th>
<th>Derived Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minute</td>
<td>minute-of-hour, hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Hour</td>
<td>hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Day</td>
<td>day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Week</td>
<td>day-of-month, week-of-year</td>
</tr>
<tr>
<td>Month</td>
<td>month-of-year</td>
</tr>
</tbody>
</table>

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The context_length hyperparameter controls how far in the past the network can see, and the prediction_length hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element $i$. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$. 

![Graph](image.png)
To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, \( t = T \), the model exposes the \( z_{i,t} \) values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next \( \text{prediction} \_\text{length} \) values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

**DeepAR Hyperparameters**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context_length</td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the ( \text{prediction} _\text{length} ). The model also receives lagged inputs from the target, so context_length can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. Required Valid values: Positive integer</td>

## Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **likelihood** | The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected:  
  - *gaussian*: Use for real-valued data.  
  - *beta*: Use for real-valued targets between 0 and 1 inclusive.  
  - *negative-binomial*: Use for count data (non-negative integers).  
  - *student-T*: An alternative for real-valued data that works well for bursty data.  
  - *deterministic-L1*: A loss function that does not estimate uncertainty and only learns a point forecast.  

Optional  
Valid values: One of *gaussian*, *beta*, *negative-binomial*, *student-T*, or *deterministic-L1*.  
Default value: student-T |
| **mini_batch_size** | The size of mini-batches used during training. Typical values range from 32 to 512.  

Optional  
Valid values: positive integer  
Default value: 128 |
| **num_cells** | The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100.  

Optional  
Valid values: positive integer  
Default value: 40 |
| **num_dynamic_feat** | The number of dynamic_features provided in the data. Set this to auto to infer the number of dynamic features from the data. The auto mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter.  

To force DeepAR to not use dynamic features, even if they are present in the data, set num_dynamic_feat to ignore.  

To perform additional data validation, it is possible to explicitly set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2.  

Optional  
Valid values: auto, ignore, positive integer, or empty string  
Default value: auto |
**Parameter Name** | **Description**  
---|---  
num_eval_samples | The number of samples that are used per time-series when calculating test accuracy metrics. This parameter does not have any influence on the training or the final model. In particular, the model can be queried with a different number of samples. This parameter only affects the reported accuracy scores on the test channel after training. Smaller values result in faster evaluation, but then the evaluation scores are typically worse and more uncertain. When evaluating with higher quantiles, for example 0.95, it may be important to increase the number of evaluation samples.  
*Optional*  
Valid values: integer  
Default value: 100  

num_layers | The number of hidden layers in the RNN. Typical values range from 1 to 4.  
*Optional*  
Valid values: positive integer  
Default value: 2  

test_quantiles | Quantiles for which to calculate quantile loss on the test channel.  
*Optional*  
Valid values: array of floats  
Default value: [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9]  

---

**Tune a DeepAR Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1654).

**Metrics Computed by the DeepAR Algorithm**

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see [Best Practices for Using the DeepAR Algorithm](p. 1353).

DeepAR Inference Formats

DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the instances field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a cat for each instance. If the model was trained without the cat field, it should be omitted.

If the model was trained with a custom feature time series (dynamic_feat), you have to provide the same number of dynamic_feat values for each instance. Each of them should have a length given by length(target) + prediction_length, where the last prediction_length values correspond to
the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```json
{
  "instances": [
    {
      "start": "2009-11-01 00:00:00",
      "target": [4.0, 10.0, "NaN", 100.0, 113.0],
      "cat": [0, 1],
      "dynamic_feat": [[[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
    },
    {
      "start": "2012-01-30",
      "target": [1.0],
      "cat": [2, 1],
      "dynamic_feat": [[[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
    },
    {
      "start": "1999-01-30",
      "target": [2.0, 1.0],
      "cat": [1, 3],
      "dynamic_feat": [[[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
    }
  ],
  "configuration": {
    "num_samples": 50,
    "output_types": ["mean", "quantiles", "samples"],
    "quantiles": ["0.5", "0.9"]
  }
}
```

The configuration field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are "mean" "quantiles" and "samples". If you specify "quantiles", each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

**DeepAR JSON Response Formats**

The following is the format of a response, where [...] are arrays of numbers:

```json
{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]}
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]}
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]}
    }
  ]
}
```
DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable MODEL_SERVER_WORKERS. For example, by setting MODEL_SERVER_WORKERS=1 when calling the SageMaker CreateModel API.

### Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see [Input/Output Interface for the DeepAR Algorithm](p. 1351). For example:

```json
[{
  "start": "2009-11-01 00:00:00",
  "target": [4.3, "NaN", 5.1, ...],
  "cat": [0, 1],
  "dynamic_feat": [[1.1, 1.2, 0.5, ...]]
},
{
  "start": "2012-01-30 00:00:00",
  "target": [1.0, -5.0, ...],
  "cat": [2, 3],
  "dynamic_feat": [[1.1, 2.05, ...]]
},
{
  "start": "1999-01-30 00:00:00",
  "target": [2.0, 1.0],
  "cat": [1, 4],
  "dynamic_feat": [[1.3, 0.4]]
}]
```

**Note**
When creating the transformation job with CreateTransformJob, set the BatchStrategy value to SingleRecord and set the SplitType value in the TransformInput configuration to Line, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the cat and the dynamic_feat fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the cat and the dynamic_feat fields.
- The corresponding cardinality and num_dynamic_feat values used in the training job are not set to "".

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using an environment variable named DEEPAR_INFERENCE_CONFIG. The value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment, the inference container uses the following default:

```json
{
  "num_samples": 100,
  "output_types": ["mean", "quantiles"],
  "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]
}
```
The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```json
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the `TransformInput` configuration of the SageMaker `CreateTransformJob` request clients must explicitly set the `AssembleWith` value to `Line`, as the default value `None` concatenates all JSON objects on the same line.

For example, here is a SageMaker `CreateTransformJob` request for a DeepAR job with a custom `DEEPAR_INFERENCE_CONFIG`:

```json
{
    "BatchStrategy": "SingleRecord",
    "Environment": {
        "DEEPAR_INFERENCE_CONFIG": "{ "num_samples": 200, "output_types": ["mean"] }",
        ...,
    },
    "TransformInput": {
        "SplitType": "Line",
        ...
    },
    "TransformOutput": {
        "AssembleWith": "Line",
        ...
    }
}
```

### Unsupervised Built-in SageMaker Algorithms

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- **IP Insights** (p. 1366)—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- **K-Means Algorithm** (p. 1375)—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- **Principal Component Analysis (PCA) Algorithm** (p. 1383)—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- **Random Cut Forest (RCF) Algorithm** (p. 1387)—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

IP Insights

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as embeddings. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column

<table>

</tr>
</tbody>
</table>
is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats (p. 1373).

**Inference**

For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference (p. 1188). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats (p. 1373).

**EC2 Instance Recommendation for the IP Insights Algorithm**

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances. IP Insights supports P2, P3, G4dn, and G5 GPU families.

**GPU Instances for the IP Insights Algorithm**

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

**CPU Instances for the IP Insights Algorithm**

The type of CPU instance that we recommend depends largely on the instance’s available memory and the model size. The model size is determined by two hyperparameters: vector_dim and num_entity_vectors. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for vector_dim in the first column range from 32 to 2048 and the values for num_entity_vectors in the first row range from 10,000 to 50,000,000.

<table>

</table>

The values for the mini_batch_size, num_ip_encoder_layers, random_negative_sampling_rate, and shuffled_negative_sampling_rate hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.
**IP Insights Sample Notebooks**

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see [An Introduction to the SageMaker IP Insights Algorithm](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](p. 358). After creating a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. To open a notebook, choose its **Use** tab and choose **Create copy**.

**How IP Insights Works**

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see [Feature Hashing for Large Scale Multitask Learning](#). For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the log loss, defined as follows:

$$L = \frac{1}{N} \sum_{n} [y_n \log p_n + (1 - y_n) \log (1 - p_n)]$$

$y_n$ is the label that indicates whether the sample is from the real distribution governing observed data ($y_n=1$) or from the distribution generating negative samples ($y_n=0$). $p_n$ is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the `random_negative_sampling_rate` and `shuffled_negative_sampling_rate` hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a score, $S_n$, that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log \left( \frac{P_{real}(n)}{P_{neg}(n)} \right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality.
than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, \( p_n \), to use in the cross entropy minimization, where:

\[
p_n = \frac{1}{1 + e^{-s_n}}
\]

### IP Insights Hyperparameters

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| num_entity_vectors          | The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers. **Required**  
Valid values: \( 1 \leq \text{positive integer} \leq 250,000,000 \)                                                                 |
| vector_dim                  | The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128. **Required**  
Valid values: \( 4 \leq \text{positive integer} \leq 4096 \)                                                                 |
| batch_metrics_publish_interval | The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). **Optional**  
Valid values: positive integer \( \geq 1 \)  
Default value: 1,000 |

Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (positive samples) from randomly generated data points (negative samples). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This validation:discriminator_auc metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a validation:discriminator_auc metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

Topics

- IP Insights Training Data Formats (p. 1373)
- IP Insights Inference Data Formats (p. 1373)

IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for Training (p. 1184). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

IP Insights Training Data Input Formats

INPUT: CSV

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1188). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

IP Insights Input Request Formats

INPUT: CSV Format

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1188).

content-type: application/json

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```
Use Built-in Algorithms

**INPUT: JSONLINES Format**

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1188). For more information on running batch transform jobs, see Use Batch Transform (p. 2191).

```json
content-type: application/jsonlines

["data": {"features": {"values": ["entity_id_1", "192.168.1.2"]},
"features": ["entity_id_2", "10.10.1.2"]}
]
```

**IP Insights Output Response Formats**

**OUTPUT: JSON Response Format**

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMakerIP Insights Algorithm.

```json
accept: application/json

[ "predictions": [ 
  { "dot_product": 0.0},
  { "dot_product": 2.0}
 ]
]
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

```json
accept: application/json;verbose=True

[ "predictions": [ 
  { "dot_product": 0.0,
    "entity_embedding": [1.0, 0.0, 0.0],
    "ip_embedding": [0.0, 1.0, 0.0]
  },
  { "dot_product": 2.0,
    "entity_embedding": [1.0, 0.0, 1.0],
    "ip_embedding": [1.0, 0.0, 1.0]
  }
 ]
]
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The \( n \) attributes in each row represent a point in \( n \)-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works (p. 1376).

Topics
- Input/Output Interface for the K-Means Algorithm (p. 1375)
- EC2 Instance Recommendation for the K-Means Algorithm (p. 1376)
- K-Means Sample Notebooks (p. 1376)
- How K-Means Clustering Works (p. 1376)
- K-Means Hyperparameters (p. 1379)
- Tune a K-Means Model (p. 1381)
- K-Means Response Formats (p. 1382)

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the train channel (recommended S3DataDistributionType=ShardedByS3Key), with an optional test channel (recommended S3DataDistributionType=FullyReplicated) to score the data on. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, text/csv, application/json, and application/x-recordio-protobuf are supported. k-means returns a closest_cluster label and the distance_to_cluster for each observation.

For more information on input and output file formats, see K-Means Response Formats (p. 1382) for inference and the K-Means Sample Notebooks (p. 1376). The k-means algorithm does not support
multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

**EC2 Instance Recommendation for the K-Means Algorithm**

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to single-GPU instances (such as ml.g4dn.xlarge) because only one GPU is used per instance. The k-means algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

**K-Means Sample Notebooks**

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see [Analyze US census data for population segmentation using Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/k-means-sage-maker.html). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](https://docs.aws.amazon.com/sagemaker/latest/dg/notebook-instances.html). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How K-Means Clustering Works**

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the $n$-dimensional space (where $n$ is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points $(t, h)$ in 2-dimensional space.

**Note**  
Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters ($k$) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space $(x, y)$. To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

**Note**  
Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create $k$ clusters, you might choose to improve model accuracy by specifying extra cluster centers ($K = k \times x$). However, the algorithm ultimately reduces these to $k$ clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see CreateTrainingJob. In the request body, you add the HyperParameters string map to specify the $k$ and extra_center_factor strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial $K$ cluster centers.
Note
In the following topics, K clusters refer to k * x, where you specify k and x when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to k (if the data scientist specified the creation of k*x clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

Topics
• Step 1: Determine the Initial Cluster Centers (p. 1377)
• Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 1378)
• Step 3: Reduce the Clusters from K to k (p. 1378)

Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

• The random approach—Randomly choose K observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.

• The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
     • For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     • Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the K cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following HyperParameters string maps:

• To specify the number of clusters to create, add the k string.
• For greater accuracy, add the optional extra_center_factor string.
• To specify the strategy that you want to use to determine the initial cluster centers, add the init_method string and set its value to random or k-means++.
For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

**Step 2: Iterate over the Training Dataset and Calculate Cluster Centers**

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the $K$ cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   **Note**
   When creating a model training job, you specify the batch size in the mini_batch_size string in the HyperParameters string map.

   a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

   b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

      For example, consider the following clusters:

      Cluster $c_1$ = 100 previously assigned points. You added 25 points from the mini-batch in this step.
      Cluster $c_2$ = 150 previously assigned points. You added 40 points from the mini-batch in this step.
      Cluster $c_3$ = 450 previously assigned points. You added 5 points from the mini-batch in this step.

      Calculate the proportion of new points assigned to each of clusters as follows:

      \[
      p_1 = \text{proportion of points assigned to } c_1 = \frac{25}{100+25} \\
      p_2 = \text{proportion of points assigned to } c_2 = \frac{40}{150+40} \\
      p_3 = \text{proportion of points assigned to } c_3 = \frac{5}{450+5}
      \]

   c. Compute the center of the new points added to each cluster:

      \[
      d_1 = \text{center of the new points added to cluster 1} \\
      d_2 = \text{center of the new points added to cluster 2} \\
      d_3 = \text{center of the new points added to cluster 3}
      \]

   d. Compute the weighted average to find the updated cluster centers as follows:

      \[
      \text{Center of cluster 1} = \left( (1 - p_1) \times \text{center of cluster 1} \right) + (p_1 \times d_1) \\
      \text{Center of cluster 2} = \left( (1 - p_2) \times \text{center of cluster 2} \right) + (p_2 \times d_2) \\
      \text{Center of cluster 3} = \left( (1 - p_3) \times \text{center of cluster 3} \right) + (p_3 \times d_3)
      \]

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.

3. For more information about mini-batch k-means, see Web-Scale k-means Clustering.

**Step 3: Reduce the Clusters from $K$ to $k$**

If the algorithm created $K$ clusters—($K = k \times x$) where $x$ is greater than 1—then it reduces the $K$ clusters to $k$ clusters. (For more information, see extra_center_factor in the preceding discussion.) It does this
by applying Lloyd's method with kmeans++ initialization to the $K$ cluster centers. For more information about Lloyd's method, see k-means clustering.

**K-Means Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see *How K-Means Clustering Works* (p. 1376).

**Tune a K-Means Model**

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

**Metrics Computed by the K-Means Algorithm**

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:msd</td>
<td>Mean squared distances between each record in the test set and the closest center of the model.</td>

**K-Means Response Formats**

All SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-means algorithm.

**JSON Response Format**

```json
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ...
  ]
}
```

**JSONLINES Response Format**

```json
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

**RECORDIO Response Format**

```json
[
  Record = {
    features = {},
    label = {
      'closest_cluster': {
        keys: [],
        values: [1.0, 2.0]  # float32
      },
      'distance_to_cluster': {
        keys: [],
        values: [3.0, 5.0]  # float32
      }
    }
  }
]```
CSV Response Format

The first value in each line corresponds to closest_cluster.

The second value in each line corresponds to distance_to_cluster.

```
1.0,3.0
2.0,5.0
```

**Principal Component Analysis (PCA) Algorithm**

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called components, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

**Topics**

- EC2 Instance Recommendation for the PCA Algorithm (p. 1384)
- PCA Sample Notebooks (p. 1384)
- How PCA Works (p. 1384)
- PCA Hyperparameters (p. 1385)
- PCA Response Formats (p. 1386)

**Input/Output Interface for the PCA Algorithm**

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, PCA supports text/csv, application/json, and application/x-recordio-protobuf. Results are returned in either application/json or application/x-recordio-protobuf format with a vector of "projections."
For more information on input and output file formats, see PCA Response Formats (p. 1386) for inference and the PCA Sample Sample (p. 1384).

EC2 Instance Recommendation for the PCA Algorithm

PCA supports CPU and GPU instances for training and inference. Which instance type is most performant depends heavily on the specifics of the input data. For GPU instances, PCA supports P2, P3, G4dn, and G5.

PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebooks (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called components, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows \( x_1, \ldots, x_n \) each of dimension \( 1 \times d \), the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm's last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

Mode 1: Regular

The workers jointly compute both \( \sum x_i^T x_i \) and \( \sum x_i \).

Note

Because \( x_i \) are \( 1 \times d \) row vectors, \( x_i^T x_i \) is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.
The covariance matrix is computed as \( \sum a_i^T x_i - (1/n)(\sum x_i)^T \sum x_i \), and its top `num_components` singular vectors form the model.

**Note**

If `subtract_mean` is `False`, we avoid computing and subtracting \( \sum x_i \).

Use this algorithm when the dimension \( d \) of the vectors is small enough so that \( d^2 \) can fit in memory.

**Mode 2: Randomized**

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch \( X_i \) of dimension \( b \times d \), we randomly initialize a \((num\_components + extra\_components) \times b\) matrix that we multiply by each mini-batch, to create a \((num\_components + extra\_components) \times d\) matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final \((num\_components + extra\_components) \times d\) matrix. The top right `num_components` singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let \( \ell = num\_components + extra\_components \). Given a mini-batch \( X_i \) of dimension \( b \times d \), the worker draws a random matrix \( H \) of dimension \( \ell \times b \). Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is \( +1 \) or a FJLT (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes \( H_i X_i \) and maintains \( B = \sum H_i X_i \). The worker also maintains \( h^T \), the sum of columns of \( H_1, \ldots, H_T \) (\( T \) being the total number of mini-batches), and \( s \), the sum of all input rows. After processing the entire shard of data, the worker sends the server \( B \), \( h \), \( s \), and \( n \) (the number of input rows).

Denote the different inputs to the server as \( B^i, h^i, s^i, n^i \). The server computes \( B, h, s, n \) the sums of the respective inputs. It then computes \( C = B - (1/n)h^T s \), and finds its singular value decomposition. The top-right singular vectors and singular values of \( C \) are used as the approximate solution to the problem.

**PCA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see How PCA Works (p. 1384).

<table>

Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Topics
- Input/Output Interface for the RCF Algorithm (p. 1387)
- Instance Recommendations for the RCF Algorithm (p. 1388)
- RCF Sample Notebooks (p. 1388)
- How RCF Works (p. 1389)
- RCF Hyperparameters (p. 1391)
- Tune an RCF Model (p. 1392)
- RCF Response Formats (p. 1393)

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and
test data content types can be either application/x-recordio-protobuf or text/csv formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

The train channel only supports S3DataDistributionType=ShardedByS3Key and the test channel only supports S3DataDistributionType=FullyReplicated. The following example specifies the S3 distribution type for the train channel using the Amazon SageMaker Python SDK.

**Note**
The sagemaker.inputs.s3_input method was renamed to sagemaker.inputs.TrainingInput in SageMaker Python SDK v2.

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.TrainingInput(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, AmazonSageMakerFullAccess and AmazonEC2ContainerRegistryFullAccess. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger then the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the S3DataSource for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports application/x-recordio-protobuf, text/csv and application/json input data content types. See the Common Data Formats for Built-in Algorithms (p. 1184) documentation for more information. RCF inference returns application/x-recordio-protobuf or application/json formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 1393) for inference and the RCF Sample Notebooks (p. 1388).

**Instance Recommendations for the RCF Algorithm**

For training, we recommend the ml.m4, ml.c4, and ml.c5 instance families. For inference we recommend using a ml.c5.x1 instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

**RCF Sample Notebooks**

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook...
instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How RCF Works**

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

**Sample Data Randomly**

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size \( K \) from \( N \) total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw \( K \) elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

**Reservoir sampling** is an algorithm for efficiently drawing random samples from a dataset \( S = \{S_1, \ldots, S_N\} \) where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when \( N \) is not known \textit{a priori}. If only one sample is requested, such as when \( K = 1 \), the algorithm is like this:

**Algorithm: Reservoir Sampling**

- Input: dataset or data stream \( S = \{S_1, \ldots, S_N\} \)
- Initialize the random sample \( X = S_1 \)
- For each observed sample \( S_n, n = 2, \ldots, N \):
  - Pick a uniform random number \( \xi \in [0,1] \)
  - If \( \xi < 1/n \)
    - Set \( X = S_n \)
  - Return \( X \)

This algorithm selects a random sample such that \( P(X = S_n) = 1/N \) for all \( n = 1, \ldots, N \). When \( K > 1 \) the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

**Train a RCF Model and Produce Inferences**

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest.
Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.
A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm described above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that 1/`num_samples_per_tree` approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies 1/256 or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

References

RCF Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker RCF algorithm. For more information, including recommendations on how to choose hyperparameters, see How RCF Works (p. 1389).

| eval_metrics   | A list of metrics used to score a labeled test data set. The following metrics can be selected for output:  
  - **accuracy** - returns fraction of correct predictions.  
  - **precision_recall_fscore** - returns the positive and negative precision, recall, and F1-scores.  
  
  **Optional**  
  Valid values: a list with possible values taken from **accuracy** or **precision_recall_fscore**.  
  Default value: Both **accuracy**, **precision_recall_fscore** are calculated. |
| num_samples_per_tree | Number of random samples given to each tree from the training data set.  
  **Optional**  
  Valid values: Positive integer (min: 1, max: 2048)  
  Default value: 256 |
| num_trees | Number of trees in the forest.  
  **Optional**  
  Valid values: Positive integer (min: 50, max: 1000)  
  Default value: 100 |

### Tune an RCF Model

**Automatic model tuning**, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test data points and then labels the data points as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

### Metrics Computed by the RCF Algorithm

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.
**Metric Name** | **Description** | **Optimization Direction**
--- | --- | ---
``test:f1`` | F1-score on the test dataset, based on the difference between calculated labels and actual labels. | Maximize

**Tunable RCF Hyperparameters**

You can tune a RCF model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>num_samples_per_tree</code></td>
<td>IntegerParameterRanges</td>
<td>MinValue: 1, MaxValue: 2048</td>
</tr>
<tr>
<td><code>num_trees</code></td>
<td>IntegerParameterRanges</td>
<td>MinValue: 50, MaxValue: 1000</td>
</tr>
</tbody>
</table>

**RCF Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

**JSON Response Format**

ACCEPT: application/json.

```json
{
    "scores": [
        {
            "score": 0.02,
        },
        {
            "score": 0.25
        }
    ]
}
```

**JSONLINES Response Format**

ACCEPT: application/jsonlines.

```
{"score": 0.02},
```
RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```json
[  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.25]  # float32  
            }  
        }  
    },  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.25]  # float32  
            }  
        }  
    },  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.25]  # float32  
            }  
        }  
    }  
]```

Built-in SageMaker Algorithms for Computer Vision

SageMaker provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 1396)**—uses example data with answers (referred to as a supervised algorithm). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 1407)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a supervised algorithm). Use this algorithm to classify images.
- **Object Detection - MXNet (p. 1420)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- **Object Detection - TensorFlow (p. 1431)**—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.
- **Semantic Segmentation Algorithm (p. 1439)**—provides a fine-grained, pixel-level approach to developing computer vision applications.

**Image Classification - MXNet**

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to [this discussion](#) for a broad overview of efficient data preparation and loading for machine learning systems.

**Note**

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

- Deep residual learning for image recognition Kaiming He, et al., 2016 IEEE Conference on Computer Vision and Pattern Recognition
- ImageNet image database
- Image classification with Gluon-CV and MXNet

- Tune an Image Classification Model (p. 1406)
Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the S3DataDistributionType of the S3DataSource to FullyReplicated. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports image/png, image/jpeg, and application/x-image for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio.

Train with Image Format

If you use the Image format for training, specify train, validation, train_lst, and validation_lst channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify the individual image data (.jpg or .png files) for the train and validation channels. Specify one .lst file in each of the train_lst and validation_lst channels. Set the content type for all four channels to application/x-image.

Note
SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

<table>
<thead>
<tr>
<th>Image Index</th>
<th>Class Label</th>
<th>Relative Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td>your_image_directory/train_img_dog1.jpg</td>
</tr>
<tr>
<td>1000</td>
<td>0</td>
<td>your_image_directory/train_img_cat1.jpg</td>
</tr>
<tr>
<td>22</td>
<td>1</td>
<td>your_image_directory/train_img_dog2.jpg</td>
</tr>
</tbody>
</table>

For example, if your training images are stored in s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on, specify the path for your train channel as s3://<your_bucket>/train, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named train_image_dog1.jpg in the class_dog class directory as class_dog/train_image_dog1.jpg. You can also store all your image files under one subdirectory inside the train directory. In that case, use that subdirectory for the relative path. For example, s3://<your_bucket>/train/your_image_directory.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding
annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ['"source-ref", "class"']. The corresponding label value is '0' for the first image and '1' for the second image:

```
{"source-ref":"s3://image/filename1.jpg", "class":"0"}
{"source-ref":"s3://image/filename2.jpg", "class":"1", "class-metadata": {"class-name": "cat", "type" : "groundtruth/image-classification"}}
```

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}
```

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data point. The previous example would instead look like this:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}
```

The multi-hot format is the default, but can be explicitly set in the content type with the label-format parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; label-format=class-id".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1932).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker image classification models can be seeded only with another built-in image classification model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the num_layers, image_shape and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.
For a sample notebook that shows how to use incremental training with the SageMaker image classification algorithm, see the End-to-End Incremental Training Image Classification Example. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1909).

Inference with the Image Classification Algorithm

The generated models can be hosted for inference and support encoded .jpg and .png image formats as image/png, image/jpeg, and application/x-image content-type. The input image is resized automatically. The output is the probability values for all classes encoded in JSON format, or in JSON Lines text format for batch transform. The image classification model processes a single image per request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a response in JSON Lines format:

```json
accept: application/jsonlines

{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances referenced in the introduction.

EC2 Instance Recommendation for the Image Classification Algorithm

For image classification, we support P2, P3, G4dn, and G5 instances. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. Both CPU (such as C4) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the caltech-256 dataset and then to deploy it to perform inferences, see the End-to-End Multiclass Image Classification Example. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet[2] is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.
Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model (p. 1406) for information on image classification hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm (p. 1397) for details on how to work with multi-label classification with augmented manifest files. Required Valid values: positive integer</td>
</tr>
<tr>
<td>num_training_samples</td>
<td>Number of training examples in the input dataset. If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter is undefined and distributed training accuracy might be affected. Required Valid values: positive integer</td>
</tr>
</tbody>
</table>
| augmentation_type    | Data augmentation type. The input images can be augmented in multiple ways as specified below.  
  • crop: Randomly crop the image and flip the image horizontally  
  • crop_color: In addition to ‘crop’, three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the corresponding Hue-Saturation-Lightness channels respectively  
  • crop_color_transform: In addition to crop_color, random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25. Optional Valid values: crop, crop_color, or crop_color_transform. Default value: no default value |
<p>| beta_1               | The beta1 for adam, that is the exponential decay rate for the first moment estimates. Optional Valid values: float. Range in [0, 1]. |</p>
<table>

<tr>
<td>----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>image_shape</td>
<td>The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3,224,224'. This is similar to the ImageNet dataset. For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken. At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped. <strong>Optional</strong> Valid values: string Default value: ‘3,224,224’</td>
</tr>
<tr>
<td>kv_store</td>
<td>Weight update synchronization mode during distributed training. The weight updates can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See distributed training in MXNet for more details. This parameter is not applicable to single machine training. <strong>Optional</strong> Valid values: dist_sync or dist_async Default value: no default value</td>
</tr>
<tr>
<td>learning_rate</td>
<td>Initial learning rate. <strong>Optional</strong> Valid values: float. Range in [0, 1]. Default value: 0.1</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>lr_scheduler_factor</td>
<td>The ratio to reduce learning rate used in conjunction with the lr_scheduler_step parameter, defined as ( \text{lr}<em>{\text{new}} = \text{lr}</em>{\text{old}} \times ) ( \text{lr}_{\text{scheduler factor}} ). Optional. Valid values: float. Range in ([0, 1]). Default value: 0.1</td>
</tr>
<tr>
<td>lr_scheduler_step</td>
<td>The epochs at which to reduce the learning rate. As explained in the lr_scheduler_factor parameter, the learning rate is reduced by ( \text{lr}<em>{\text{scheduler factor}} ) at these epochs. For example, if the value is set to &quot;10, 20&quot;, then the learning rate is reduced by ( \text{lr}</em>{\text{scheduler factor}} ) after 10th epoch and again by ( \text{lr}_{\text{scheduler factor}} ) after 20th epoch. The epochs are delimited by &quot;,&quot;. Optional. Valid values: string. Default value: no default value</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-GPU setting, each GPU handles ( \text{mini_batch_size}/\text{num_gpu} ) training samples. For the multi-machine training in dist_sync mode, the actual batch size is ( \text{mini_batch_size} \times \text{number of machines} ). See MXNet docs for more details. Optional. Valid values: positive integer. Default value: 32</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for sgd and nag, ignored for other optimizers. Optional. Valid values: float. Range in ([0, 1]). Default value: 0.9</td>
</tr>
<tr>
<td>multi_label</td>
<td>Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged. Optional. Valid values: 0 or 1. Default value: 0</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| num_layers     | Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200].  
Optional  
Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110]  
Default value: 152 |
| optimizer      | The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.  
Optional  
Valid values: One of sgd, adam, rmsprop, or nag.  
- sgd: Stochastic gradient descent  
- adam: Adaptive momentum estimation  
- rmsprop: Root mean square propagation  
- nag: Nesterov accelerated gradient  
Default value: sgd |
| precision_dtype| The precision of the weights used for training. The algorithm can use either single precision (float32) or half precision (float16) for the weights. Using half-precision for weights results in reduced memory consumption.  
Optional  
Valid values: float32 or float16  
Default value: float32 |
| resize         | The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of image_shape to prevent training failure.  
Required when using image content types  
Optional when using the RecordIO content type  
Valid values: positive integer  
Default value: no default value |

### Tune an Image Classification Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1654).

### Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.
Use Built-in Algorithms

### Tunable Image Classification Hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `mini_batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `weight_decay`, `beta_1`, `beta_2`, `eps`, and `gamma`, based on the selected optimizer. For example, use `beta_1` and `beta_2` only when `adam` is the optimizer.

For more information about which hyperparameters are used in each optimizer, see [Image Classification Hyperparameters](p. 1400).

### Image Classification - TensorFlow

The Amazon SageMaker Image Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The image classification algorithm takes an image as input and outputs a probability for each provided class label. Training datasets must consist of images in .jpg, .jpeg, or .png format.

**Topics**

- How to use the SageMaker Image Classification - TensorFlow algorithm (p. 1408)
How to use the SageMaker Image Classification - TensorFlow algorithm

You can use Image Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Image Classification - TensorFlow with the SageMaker Python SDK. For information on how to use Image Classification - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

The Image Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow Hub models. For a list of all available pretrained models, see TensorFlow Hub Models (p. 1411). Every pretrained model has a unique model_id. The following example uses MobileNet V2 1.00 224 (model_id: tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Image Classification - TensorFlow Hyperparameters (p. 1416). Use these values to construct a SageMaker Estimator.

Note
Default hyperparameter values are different for different models. For larger models, the default batch size is smaller and the train_only_on_top hyperparameter is set to "True".

This example uses the tf_flowers dataset, which contains five classes of flower images. We pre-downloaded the dataset from TensorFlow under the Apache 2.0 license and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
    image_uris.retrieve(model_id=model_id, model_version=model_version, image_scope="training", instance_type=training_instance_type)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
    script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
    model_scope="training")

# Retrieve the default hyper-parameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
    model_version=model_version)
```
# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# The sample training data is available in the following S3 bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tf_flowers/

training_dataset_s3_path = f"s3://{training_data_bucket}/(training_data_prefix)"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-ic-training"
s3_output_location = f"s3://{output_bucket}/(output_prefix)/output"

# Create SageMaker Estimator instance
tf_ic_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Use S3 path of the training data to launch SageMaker TrainingJob
tf_ic_estimator.fit({"training": training_dataset_s3_path}, logs=True)

Input and output interface for the Image Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Image Classification - TensorFlow model.

- **Training data input format**: Your training data should be a directory with as many subdirectories as the number of classes. Each subdirectory should contain images belonging to that class in .jpg, .jpeg, or .png format.

The following is an example of an input directory structure. This example dataset has two classes: roses and dandelion. The image files in each class folder can have any name. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: s3://bucket_name/input_directory/. Note that the trailing / is required.

```
input_directory
    |--roses
        |--abc.jpg
        |--def.jpg
    |--dandelion
        |--ghi.jpg
        |--jkl.jpg
```

Trained models output label mapping files that map class folder names to the indices in the list of output class probabilities. This mapping is in alphabetical order. For example, in the preceding example, the dandelion class is index 0 and the roses class is index 1.

After training, you have a fine-tuned model that you can further train using incremental training or deploy for inference. The Image Classification - TensorFlow algorithm automatically adds a pre-processing and post-processing signature to the fine-tuned model so that it can take in images as input
and return class probabilities. The file mapping class indices to class labels is saved along with the models.

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**

You can only seed a SageMaker Image Classification - TensorFlow model with another Image Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For an example of incremental training with the SageMaker Image Classification - TensorFlow algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

**Inference with the Image Classification - TensorFlow algorithm**

You can host the fine-tuned model that results from your TensorFlow Image Classification training for inference. Any input image for inference must be in .jpg, .jpeg, or .png format and be content type application/x-image. The Image Classification - TensorFlow algorithm resizes input images automatically.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Image Classification - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
 "labels": [label_0, label_1, label_2, ...],
 "predicted_label": predicted_label}
```

If accept is set to application/json, then the model only outputs probabilities. For more information on training and inference with the Image Classification - TensorFlow algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

**Amazon EC2 instance recommendation for the Image Classification - TensorFlow algorithm**

The Image Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- ml.p2.xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.16xlarge
- ml.g4dn.xlarge
- ml.g4dn.16.xlarge
- ml.g5.xlarge
- ml.g5.48xlarge

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.
**Image Classification - TensorFlow sample notebooks**

For more information about how to use the SageMaker Image Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Image Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

**How Image Classification - TensorFlow Works**

The Image Classification - TensorFlow algorithm takes an image as input and classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for image classification. There are also deep learning networks that are trained on large image datasets, such as ImageNet, which has over 11 million images and almost 11,000 classes. After a network is trained with ImageNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific classification tasks. The Amazon SageMaker Image Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a classification layer is attached to the pretrained TensorFlow Hub model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully-connected layer with 2-norm regularizer that is initialized with random weights. The model has hyperparameters for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

**TensorFlow Hub Models**

The following pretrained models are available to use for transfer learning with the Image Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Image Classification - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification - TensorFlow algorithm. See Tune an Image Classification - TensorFlow model (p. 1419) for information on hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tbody>
</table>
| beta_2          | The beta2 for the "adam" optimizer. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers.  
Valid values: float, range: [0.0, 1.0].  
Default value: 0.999. |
| binary_mode     | When binary_mode is set to "True", the model returns a single probability number for the positive class and can use additional eval_metric options. Use only for binary classification problems.  
Valid values: string, either: ("True" or "False").  
Default value: "False". |
| dropout_rate    | The dropout rate for the dropout layer in the top classification layer.  
Valid values: float, range: [0.0, 1.0].  
Default value: 0.2 |
| early_stopping  | Set to "True" to use early stopping logic during training. If "False", early stopping is not used.  
Valid values: string, either: ("True" or "False").  
Default value: "False". |
| early_stopping_min_delta | The minimum change needed to qualify as an improvement. An absolute change less than the value of early_stopping_min_delta does not qualify as improvement. Used only when early_stopping is set to "True".  
Valid values: float, range: [0.0, 1.0].  
Default value: 0.0 |
| early_stopping_patience | The number of epochs to continue training with no improvement. Used only when early_stopping is set to "True".  
Valid values: positive integer.  
Default value: 5. |
| epochs          | The number of training epochs.  
Valid values: positive integer.  
Default value: 3. |
<table>
<thead>

| optimizer     | The optimizer type. For more information, see Optimizers in the TensorFlow documentation.  

Valid values: string, any of the following: ("adam", "sgd", "nesterov", "rmsprop", "adagrad", "adadelta").  

Default value: "adam". |
| regularizers_l2 | The L2 regularization factor for the dense layer in the classification layer.  

Valid values: float, range: [0.0, 1.0].  

Default value: 0.0001. |
| reinitialize_top_layer | If set to "Auto", the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to "True".  

Valid values: string, any of the following: ("Auto", "True" or "False").  

Default value: "Auto". |
| rho | The discounting factor for the gradient of the "adadelta" and "rmsprop" optimizers. Ignored for other optimizers.  

Valid values: float, range: [0.0, 1.0].  

Default value: 0.95. |
| train_only_on_top_layer | If "True", only the top classification layer parameters are fine-tuned. If "False", all model parameters are fine-tuned.  

Valid values: string, either: ("True" or "False").  

Default value: "False". |

**Tune an Image Classification - TensorFlow model**

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

**Metrics computed by the Image Classification - TensorFlow algorithm**

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.
### Tunable Image Classification - TensorFlow hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `batch_size`, `learning_rate`, and optimizer. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected optimizer. For example, use `beta_1` and `beta_2` only when `adam` is the optimizer.

For more information about which hyperparameters are used for each optimizer, see Image Classification - TensorFlow Hyperparameters (p. 1416).

### Object Detection - MXNet

The Amazon SageMaker Object Detection - MXNet algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

**Topics**
Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 1423) for more details on data formats.

Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```
{
    "file": "your_image_directory/sample_image1.jpg",
    "image_size": [
        {
            "width": 500,
            "height": 400,
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
```
Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the
CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames are contained in the list ["source-ref", "bounding-box"]:

```json
["source-ref": "s3://your_bucket/image1.jpg", "bounding-box":{"image_size":[{ "width": 500, "height": 400, "depth":3}], "annotations":[{"class_id": 0, "left": 111, "top": 154, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width": 88, "height": 50}]), "bounding-box-metadata":{"class-map":{"0": "dog", "5": "horse"}, "type": "groundtruth/object-detection"}]
"source-ref": "s3://your_bucket/image2.jpg", "bounding-box":{"image_size":[{ "width": 400, "height": 300, "depth":3}], "annotations":[{"class_id": 1, "left": 100, "top": 120, "width": 43, "height": 78}]), "bounding-box-metadata":{"class-map":{"1": "cat"}, "type": "groundtruth/object-detection"}]
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1932).

**Incremental Training**

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1909).

**EC2 Instance Recommendation for the Object Detection Algorithm**

The object detection algorithm supports P2, P3, G4dn, and G5 GPU instance families. We recommend using GPU instances with more memory for training with large batch sizes. You can run the object detection algorithm on multi-GPU and mult-machine settings for distributed training.

You can use both CPU (such as C5 and M5) and GPU (such as P3 and G4dn) instances for inference.

**Object Detection Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the

Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see Amazon SageMaker Object Detection for Bird Species. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The object detection example notebook using
the Object Detection algorithm is located in the **Introduction to Amazon Algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object’s location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the **Single Shot multibox Detector (SSD)** algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as **VGG** and **ResNet** have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the **CreateTrainingJob** request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see **How Object Detection Works** (p. 1424).

<tr>
<td>freeze_layer_pattern</td>
<td>The regular expression (regex) for freezing layers in the base network.</td>
</tr>
</tbody>
</table>
|                    | For example, if we set freeze_layer_pattern = 
<p>|                    | &quot;^(conv1_|conv2_).<em>&quot;, then any layers with a name that contains &quot;conv1_&quot; |
|                    | or &quot;conv2_&quot; are frozen, which means that the weights for these layers are   |
|                    | not updated during training. The layer names can be found in the network   |
|                    | symbol files vgg16-symbol.json and resnet-50-symbol.json. Freezing a layer  |
|                    | means that its weights can not be modified further. This can reduce training |
|                    | time significantly in exchange for modest losses in accuracy. This         |
|                    | technique is commonly used in transfer learning where the lower layers in  |
|                    | the base network do not need to be retrained.                              |
|                    | <strong>Optional</strong>                                                                |
|                    | Valid values: string                                                        |
|                    | Default: No layers frozen.                                                  |
| kv_store           | The weight update synchronization mode used for distributed training. The  |
|                    | weights can be updated either synchronously or asynchronously across      |
|                    | machines. Synchronous updates typically provide better accuracy than      |
|                    | asynchronous updates but can be slower. See the Distributed Training MXNet|
|                    | tutorial for details.                                                       |
|                    | <strong>Note</strong>                                                                    |
|                    | This parameter is not applicable to single machine training.                |
|                    | <strong>Optional</strong>                                                                |
|                    | Valid values: 'dist_sync' or 'dist_async'                                   |
|                    | • 'dist_sync': The gradients are synchronized after every batch with all   |
|                    | the workers. With 'dist_sync', batch-size now means the batch size used on |
|                    | each machine. So if there are n machines and we use batch size b, then    |
|                    | dist_sync behaves like a single machine with batch size n</em>b.               |
|                    | • 'dist_async': Performs asynchronous updates. The weights are updated     |
|                    | whenever gradients are received from any machine and the weight updates    |
|                    | are atomic. However, the order is not guaranteed.                         |
|                    | Default: -                                                                  |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label_width</td>
<td>The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the label_width should be no smaller than ((10 \times 5 + \text{header information length})). The header information length is usually 2. We recommend using a slightly larger label_width for the training, such as 60 for this example.</td>

| mini_batch_size        | The batch size for training. In a single-machine multi-gpu setting, each GPU handles mini_batch_size/num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. A large mini_batch_size usually leads to faster training, but it may cause out of memory problem. The memory usage is related to mini_batch_size, image_shape, and base_network architecture. For example, on a single p3.2xlarge instance, the largest mini_batch_size without an out of memory error is 32 with the base_network set to "resnet-50" and an image_shape of 300. With the same instance, you can use 64 as the mini_batch_size with the base network vgg-16 and an image_shape of 300. *Optional*  
  Valid values: positive integer  
  Default: 32                                                                                   |
| momentum               | The momentum for sgd. Ignored for other optimizers. *Optional*  
  Valid values: float in (0, 1]  
  Default: 0.9                                                                                 |
| nms_threshold          | The non-maximum suppression threshold. *Optional*  
  Valid values: float in (0, 1]  
  Default: 0.45                                                                               |
| optimizer              | The optimizer types. For details on optimizer values, see MXNet's API. *Optional*  
  Valid values: ['sgd', 'adam', 'rmsprop', 'adadelta']  
  Default: 'sgd'                                                                              |
| overlap_threshold      | The evaluation overlap threshold. *Optional*  
  Valid values: float in (0, 1]  
  Default: 0.5                                                                                 |

**Tune an Object Detection Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see *Perform Automatic Model Tuning with SageMaker* (p. 1654).

**Metrics Computed by the Object Detection Algorithm**

The object detection algorithm reports on a single metric during training: `validation:mAP`. When tuning a model, choose this metric as the objective metric.

<table>

Object Detection Request and Response Formats
Request Format
Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats
with image/jpeg and image/png content-types.

Response Formats
The response is the class index with a conﬁdence score and bounding box coordinates for all objects
within the image encoded in JSON format. The following is an example of response .json ﬁle:
{"prediction":[
[4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507,
0.9345266819000244],
[0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571,
0.9712159633636475],
[4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486, 0.6318609714508057,
0.5967587828636169],
[8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051,
0.8985623121261597],
[3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702,
0.39093565940856934, 0.9574796557426453]
]}

Each row in this .json ﬁle contains an array that represents a detected object. Each of these object
arrays consists of a list of six numbers. The ﬁrst number is the predicted class label. The second
number is the associated conﬁdence score for the detection. The last four numbers represent the
bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices
are normalized by the overall image size. Note that this encoding is diﬀerent than that use by the
input .json format. For example, in the ﬁrst entry of the detection result, 0.3088374733924866 is the
left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image
width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding
box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of
lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244
is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the
overall image height.
To avoid unreliable detection results, you might want to ﬁlter out the detection results with low
conﬁdence scores. In the object detection sample notebook, we provide examples of scripts that use a
threshold to remove low conﬁdence detections and to plot bounding boxes on the original images.
For batch transform, the response is in JSON format, where the format is identical to the JSON format
described above. The detection results of each image is represented as a JSON ﬁle. For example:
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id,
confidence_score, xmin, ymin, xmax, ymax]]}

1430


For more details on training and inference, see the Object Detection Sample Notebooks (p. 1423).

**Object Detection - TensorFlow**

The Amazon SageMaker Object Detection - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Model Garden. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The object detection algorithm takes an image as input and outputs a list of bounding boxes. Training datasets must consist of images in .jpg, .jpeg, or .png format.

**Topics**

- How to use the SageMaker Object Detection - TensorFlow algorithm (p. 1432)
- Input and output interface for the Object Detection - TensorFlow algorithm (p. 1433)
- Amazon EC2 instance recommendation for the Object Detection - TensorFlow algorithm (p. 1434)
- Object Detection - TensorFlow sample notebooks (p. 1434)
- How Object Detection - TensorFlow Works (p. 1434)
- TensorFlow Models (p. 1435)
- Object Detection - TensorFlow Hyperparameters (p. 1436)
- Tune an Object Detection - TensorFlow model (p. 1438)
How to use the SageMaker Object Detection - TensorFlow algorithm

You can use Object Detection - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Object Detection - TensorFlow with the SageMaker Python SDK. For information on how to use Object Detection - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 46).

The Object Detection - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Models (p. 1435). Every pretrained model has a unique model_id. The following example uses ResNet50 (model_id: tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Object Detection - TensorFlow Hyperparameters (p. 1436). Use these values to construct a SageMaker Estimator.

Note
Default hyperparameter values are different for different models. For example, for larger models, the default number of epochs is smaller.

This example uses the PennFudanPed dataset, which contains images of pedestrians in the street. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri = image_uris.retrieve(model_id=model_id, model_version=model_version, image_scope="training", instance_type=training_instance_type)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version, script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version, model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id, model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/PennFudanPed_COCO_format/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-od-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"
```
# Create an Estimator instance

tf_od_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job

tf_od_estimator.fit({"training": training_dataset_s3_path}, logs=True)

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

**Input and output interface for the Object Detection - TensorFlow algorithm**

Each of the pretrained models listed in TensorFlow Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Object Detection - TensorFlow model.

- **Training data input format:** Your training data should be a directory with an images subdirectory and an annotations.json file.

The following is an example of an input directory structure. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: s3://bucket_name/input_directory/. Note that the trailing / is required.

```
input_directory
    |--images
    |   |--abc.png
    |   |--def.png
    |   |--annotations.json
```

The annotations.json file should contain information for bounding boxes and their class labels in the form of a dictionary "images" and "annotations" keys. The value for the "images" key should be a list of dictionaries. There should be one dictionary for each image with the following information: 
{"file_name": image_name, "height": height, "width": width, "id": image_id}. The value for the "annotations" key should also be a list of dictionaries. There should be one dictionary for each bounding box with the following information: 
{"image_id": image_id, "bbox": [xmin, ymin, xmax, ymax], "category_id": bbox_label}.

After training, a label mapping file and trained model are saved to your Amazon S3 bucket.

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**
You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For more information about how to use incremental training with the SageMaker Object Detection - TensorFlow, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Inference with the Object Detection - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Object Detection training for inference. Any input image for inference must be in .jpg, .jpeg, or .png format and be content type application/x-image. The Object Detection - TensorFlow algorithm resizes input images automatically.

Running inference results in bounding boxes, predicted classes, and the scores of each prediction encoded in JSON format. The Object Detection - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json;verbose

{"normalized_boxes": [[xmin1, xmax1, ymin1, ymax1], ...],
 "classes": [classidx1, class_idx2, ...],
 "scores": [score_1, score_2, ...],
 "labels": [label1, label2, ...],
 "tensorflow_model_output": <original output of the model>}
```

If accept is set to application/json, then the model only outputs normalized boxes, classes, and scores.

Amazon EC2 instance recommendation for the Object Detection - TensorFlow algorithm

The Object Detection - TensorFlow algorithm supports all GPU instances for training, including:

- ml.p2.xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.16xlarge

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2 or P3) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Object Detection - TensorFlow sample notebooks

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How Object Detection - TensorFlow Works

The Object Detection - TensorFlow algorithm takes an image as input and predicts bounding boxes and object labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for object detection. There are also deep learning networks that are trained on large
image datasets, such as Common Objects in Context (COCO), which has 328,000 images. After a network is trained with COCO data, you can then fine-tune the network on a dataset with a particular focus to perform more specific object detection tasks. The Amazon SageMaker Object Detection - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Model Garden.

According to the number of class labels in your training data, an object detection layer is attached to the pretrained TensorFlow model of your choice. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Models

The following pretrained models are available to use for transfer learning with the Object Detection - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

### Tune an Object Detection - TensorFlow model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1654).

### Metrics computed by the Object Detection - TensorFlow algorithm

Refer to the following chart to find which metrics are computed by the Object Detection - TensorFlow algorithm.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
<th>Regex Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:localization</td>
<td>The localization loss for box prediction.</td>
<td>Minimize</td>
<td>Val_localization=([0-9\ .]+)</td>

</tbody>
</table>
**Tunable Object Detection - TensorFlow hyperparameters**

Tune an object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on object detection objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected optimizer. For example, use `beta_1` and `beta_2` only when `adam` is the optimizer.

For more information about which hyperparameters are used for each optimizer, see Object Detection - TensorFlow Hyperparameters (p. 1436).

**Semantic Segmentation Algorithm**

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification - MXNet (p. 1396) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection - MXNet (p. 1420) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is
represented as a grayscale image, called a **segmentation mask**. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the **MXNet Gluon framework and the Gluon CV toolkit**. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the **Fully-Convolutional Network (FCN)** algorithm, **Pyramid Scene Parsing (PSP)** algorithm, or **DeepLabV3**.

Each of the three algorithms has two distinct components:

- The **backbone** *(or encoder)*—A network that produces reliable activation maps of features.
- The **decoder**—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: **ResNet50** or **ResNet101**. These backbones include pretrained artifacts that were originally trained on the **ImageNet** classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

- Semantic Segmentation Sample Notebooks (p. 1440)
- Input/Output Interface for the Semantic Segmentation Algorithm (p. 1440)
- EC2 Instance Recommendation for the Semantic Segmentation Algorithm (p. 1443)
- Semantic Segmentation Hyperparameters (p. 1443)
- Tuning a Semantic Segmentation Model (p. 1448)

**Semantic Segmentation Sample Notebooks**

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the **Semantic Segmentation Example**. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see **Use Amazon SageMaker Notebook Instances** (p. 358).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the **SageMaker Examples** tab. The example semantic segmentation notebooks are located under **Introduction to Amazon algorithms**. To open a notebook, choose its **Use** tab, and choose **Create copy**.

**Input/Output Interface for the Semantic Segmentation Algorithm**

SageMaker semantic segmentation expects the customer's training dataset to be on **Amazon Simple Storage Service (Amazon S3)**. Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for **train** and one for **validation** using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (**application/x-image**) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an **image/jpg** content type.
How Training Works

The training data is split into four directories: `train`, `train_annotation`, `validation`, and `validation_annotation`. There is a channel for each of these directories. The dataset also expected to have one `label_map.json` file per channel for `train_annotation` and `validation_annotation` respectively. If you don't provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
  |  |- train
  |  |  |  - 0000.jpg
  |  |  - coffee.jpg
  |  |- validation
  |  |  |  - 00a0.jpg
  |  |  - banana.jpg
  |  |- train_annotation
  |  |  |  - 0000.png
  |  |  - coffee.png
  |  |- validation_annotation
  |  |  |  - 00a0.png
  |  |  - banana.png
  |- label_map
  |  - train_label_map.json
  |  - validation_label_map.json
```

Every JPG image in the `train` and `validation` directories has a corresponding PNG label image with the same name in the `train_annotation` and `validation_annotation` directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The `train`, `train_annotation`, `validation`, and `validation_annotation` channels are mandatory.

The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the `label map`. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don’t provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn’t convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```
The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:

```
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the CreateTrainingJob request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a source-ref key. The source-ref key should contain the value of the Amazon S3 URI to the image. The labels are provided under the AttributeNames parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the AttributeNames are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO" and value of the ContentType parameter must be application/x-recordio.

```
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1932).

Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.
To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1909).

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2, P3, G4dn, or G5 instances in single machine configurations.

For inference, you can use either CPU instances (such as C5 and M5) and GPU instances (such as P3 and G4dn) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.

<table>
<thead>
<tr>
<th>Parameter Name</th>

Parameter Name | Description
--- | ---
weight_decay | The weight decay coefficient for the sgd optimizer. When you use other optimizers, the algorithm ignores this parameter.

**Optional**

Valid values: 0 < float < 1

Default value: 0.0001

**Tuning a Semantic Segmentation Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

**Metrics Computed by the Semantic Segmentation Algorithm**

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Topics
- Why is Reinforcement Learning Important? (p. 1449)

Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.
Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

 Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

 Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

 What the agent does. For example, the robot takes a step forward.

Reward

 A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a policy.

Observation

 Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many episodes. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.

Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see [RL Environments in Amazon SageMaker (p. 1453)](https://aws.amazon.com/sagemaker/rl/).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker reinforcement learning.

<table>

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

For complete code examples, see the sample notebooks at https://github.com/awslabs/amazon-sagemaker-examples/tree/master/reinforcement-learning.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   a. **Objective**—Scale instance capacity so that it matches the desired load profile.
   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   c. **State**—The current load, number of failed jobs, and number of active machines.
   d. **Action**—Remove, add, or keep the same number of instances.
   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the main() function.

5. **Train the RL Model**—Use the SageMaker RLEstimator in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance.
When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The RLEstimator requires the following information as parameters.

a. The source directory where the environment, presets, and training code are uploaded.

b. The path to the training script.

c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.

d. The training parameters, such as the instance count, job name, and S3 path for output.

e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. Visualize training metrics and output—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**
   If you train in local mode, you can't visualize metrics in CloudWatch.

7. Evaluate the model—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. Deploy RL models—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/rl.html).

**RL Environments in Amazon SageMaker**

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.
The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form \( \text{state}_t, \text{action}, \text{state}_{t+1}, \text{reward}_{t+1} \). Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**
- Use OpenAI Gym Interface for Environments in SageMaker RL (p. 1454)
- Use Open-Source Environments (p. 1455)
- Use Commercial Environments (p. 1455)

**Use OpenAI Gym Interface for Environments in SageMaker RL**

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see [https://gym.openai.com/docs/](https://gym.openai.com/docs/).

- \( \text{env.action_space} \) — Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- \( \text{env.observation_space} \) — Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- \( \text{env.reset()} \) — Initializes a training episode. The \( \text{reset()} \) function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to \( \text{step()} \) repeatedly until the episode reaches a terminal state. When \( \text{step()} \) returns \( \text{done} = \text{True} \), the episode ends. The RL toolkit re-initializes the environment by calling \( \text{reset()} \).
- \( \text{step()} \) — Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an \( \text{info} \) dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- \( \text{env.render()} \) — Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the \( \text{step()} \) function.
Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you create, manage, analyze, and compare your machine learning experiments.

Experimentation in machine learning

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithms, and parameters, all while observing the impact of incremental changes on model accuracy. Over time, this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It’s also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements. Use SageMaker Experiments to organize, view, analyze, and compare iterative ML experimentation to gain comparative insights and track your best performing models.

Manage ML experimentation with SageMaker Experiments
SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as runs. You can assign, group, and organize these runs into experiments. SageMaker Experiments is integrated with Amazon SageMaker Studio, providing a visual interface to browse your active and past experiments, compare runs on key performance metrics, and identify the best performing models. SageMaker Experiments tracks all of the steps and artifacts that went into creating a model, and you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

Use SageMaker Experiments to view, manage, analyze, and compare both custom experiments that you programmatically create and experiments automatically created from SageMaker jobs.

Supported AWS Regions

SageMaker Experiments is generally available in all AWS commercial Regions where Amazon SageMaker Studio is available, except the China Regions.

Topics

• Create an Amazon SageMaker Experiment (p. 1456)
• View, search, and compare experiment runs (p. 1460)
• SageMaker integrations (p. 1464)

Create an Amazon SageMaker Experiment

Create an Amazon SageMaker experiment to track your machine learning (ML) workflows with a few lines of code from your preferred development environment. You can then browse your experiments, create visualizations for analysis, and find the best performing model. You can also integrate SageMaker Experiments into your SageMaker training script using the SageMaker Python SDK.

Overview

The following components make up the building blocks of an experiment in Amazon SageMaker.

• experiment: An experiment is a collection of runs. When you initialize a run in your training loop, you include the name of the experiment that the run belongs to. Experiment names must be unique within your AWS account.
• Run: A run consists of all the inputs, parameters, configurations, and results for one iteration of model training. Initialize an experiment run for tracking a training job with Run.init().

  Note
  We recommend that you initialize a Run object in a Jupyter Notebook, and create the SageMaker job for your experiment within the context of this Run object initialization. To refer to this Run object in script mode, use the load_run() method.

  Note
  The SageMaker Python SDK automatically turns experiment names and run names to lowercase.
• load_run: To run your experiments in script mode, refer to an initialized Run object with load_run(). If an experiment for a run exists, load_run returns the experiment context. Generally, you use load_run with no arguments to track metrics, parameters, and artifacts within a SageMaker training or processing job script.
# Load run from a local script passing experiment and run names
with load_run(experiment_name=experiment_name, run_name=run_name) as run:
    run.log_parameter("param1", "value1")

# Load run within a training or processing Job (automated context sharing)
with load_run() as run:
    run.log_parameter("param1", "value1")

- **log_parameter**: Log parameters for a run, such as batch size or epochs, over time in a training loop
  with run.log_parameter(). log_parameter records a single name-value pair in a run. You can use
  run.log_parameters() to log multiple parameters. If called multiple times within a run for a
  parameter of the same name, log_parameter overwrites any previous value. The name must be a
  string and the value must be either a string, integer, or float.

  # Log a single parameter
  run.log_parameter("param1", "value1")

  # Log multiple parameters
  run.log_parameters({
      "param2": "value2",
      "param3": "value3"
  })

- **log_metric**: Log metrics for a run, such as accuracy or loss, over time in a training loop with
  run.log_metric(). log_metric records a name-value pair where the name is a string and the
  value is an integer or float. To declare the frequency of logging over the course of the run, define
  a step value. You can then visualize these metrics in the Studio Experiments UI. For more information,
  see [View, search, and compare experiment runs](p. 1460).

  # Log a metric over the course of a run
  run.log_metric(name="Final_loss", value=finalloss)

  # Log a metric over the course of a run at each epoch
  run.log_metric(name="test:loss", value=loss, step=epoch)

- **log_artifact**: Log any input or output artifacts related to a run with run.log_artifact(). Log
  artifacts such as S3 URIs, datasets, models, and more for your experiment to help you keep track of
  artifacts across multiple runs. is_output is True by default. To record the artifact as an input artifact
  instead of an output artifact, set is_output to False.

  # Track a string value as an input or output artifact
  run.log_artifact(name="training_data", value="data.csv" is_output=False)

- **log_file**: Log any input or output files related to a run, such as training or test data, and store them
  in Amazon S3 with run.log_file(). is_output is True by default. To record the file as an input artifact
  instead of an output artifact, set is_output to False.

  # Upload a local file to S3 and track it as an input or output artifact
  run.log_file("training_data.csv", name="training_data", is_output=False)

For more information on initializing a Run object, see [Experiments](#) in the SageMaker Python SDK
documentation. For information on visualizing logged experiment data and automatic logging, see [View,
search, and compare experiment runs](p. 1460).
Create an experiment with the SageMaker Python SDK

The following section demonstrates how to create an Amazon SageMaker Experiment using the SageMaker Python SDK. This example uses the Run class to track a Keras model in a notebook environment. The Keras Callback class provides a method on_epoch_end which emits metrics at the end of each epoch. First, define a Callback class.

```python
class ExperimentCallback(keras.callbacks.Callback):
    def __init__(self, run, model, x_test, y_test):
        self.run = run
        self.model = model
        self.x_test = x_test
        self.y_test = y_test

    def on_epoch_end(self, epoch, logs=None):
        keys = list(logs.keys())
        for key in keys:
            self.run.log_metric(name=key, value=logs[key], step=epoch)
            print(f"Epoch: {epoch} \n{key} -> {logs[key]}")
```

Next, train the Keras model in a notebook environment and track it as an experiment.

**Note**
This example carries out jobs sequentially. To run SageMaker jobs asynchronously, you may need to increase your resource limit.

```python
from sagemaker.experiments import Run

# The run name is an optional argument to `run.init()`
with Run(experiment_name = 'my-experiment') as run:
    # Define values for the parameters to log
    run.log_parameter("batch_size", batch_size)
    run.log_parameter("epochs", epochs)
    run.log_parameter("dropout", 0.5)

    # Define input artifacts
    run.log_file('datasets/input_train.npy', is_output = False)
    run.log_file('datasets/input_test.npy', is_output = False)
    run.log_file('datasets/input_train_labels.npy', is_output = False)
    run.log_file('datasets/input_test_labels.npy', is_output = False)

    # Train locally
    model.fit(
        x_train,
        y_train,
        batch_size=batch_size,
        epochs=epochs,
        validation_split=0.1,
        callbacks = [ExperimentCallback(run, model, x_test, y_test)]
    )

    score = model.evaluate(x_test, y_test, verbose=0)
    print("Test loss:", score[0])
    print("Test accuracy:", score[1])

    # Define metrics to log
    run.log_metric(name = "Final Test Loss", value = score[0])
```

1458
Create an experiment using SageMaker script mode

You can use SageMaker script mode to write your own code to train a model and track it as an experiment. When creating an experiment with script mode, use `load_run()`.

```python
# Make sure that you have the latest version of the SageMaker Python SDK
import os
os.system("pip install -U sagemaker")

# Import additional requirements
import boto3
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

# Define training script
if __name__ == "__main__":
    session = Session(boto3.session.Session(region_name=args.region))
    with load_run(sagemaker_session=session) as run:
        # Define values for the parameters to log
        run.log_parameters(
            {
                "batch_size": batch_size,
                "epochs": epochs,
                "dropout": 0.5
            }
        )

        # Define input artifacts
        run.log_file('datasets/input_train.npy', is_output=False)
        run.log_file('datasets/input_test.npy', is_output=False)
        run.log_file('datasets/input_train_labels.npy', is_output=False)
        run.log_file('datasets/input_test_labels.npy', is_output=False)

        # Train the model
        model.fit(
            x_train,
            y_train,
            batch_size=batch_size,
            epochs=epochs,
            validation_split=0.1,
            callbacks = [ExperimentCallback(run, model, x_test, y_test)]
        )

        score = model.evaluate(x_test, y_test, verbose=0)
        print("Test loss:", score[0])
        print("Test accuracy:", score[1])

        # Define metrics to log
        run.log_metric(name = "Final Test Loss", value = score[0])
        run.log_metric(name = "Final Test Loss", value = score[1])
```

For more information on script mode, see Use script mode in a supported framework. You can also define custom metrics in script mode by specifying a name and regular expression for each metric that a tuning job monitors. See Use a custom algorithm for training for more information.

View your experiment in Studio

To view the experiment in Studio, in the left sidebar, choose Experiments.

Select the name of the experiment to view all associated runs. It might take a moment for the list to refresh and display a new experiment or experiment run. You can click Refresh to update the page. Your experiment list should look similar to the following:
To view the runs that make up your experiment, select the experiment name. For more information, see View, search, and compare experiment runs (p. 1460).

**View unassigned runs**

All SageMaker jobs, including training jobs, processing jobs, and transform jobs, correspond to runs and create Run objects by default. If you launch these jobs without explicitly associating them with an experiment, the resulting runs are unassigned and can be viewed in the Unassigned runs section of the Studio Experiments UI.

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 1467).

**View, search, and compare experiment runs**

An Amazon SageMaker experiment consists of multiple run groups with a related objective. A run group consists of one or more runs, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 118).
Topics

- View experiments and runs (p. 1461)
- Compare and analyze runs (p. 1462)

View experiments and runs

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments and runs. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments and runs

1. To view the experiment in Studio, in the left sidebar, choose **Experiments**.

   Select the name of the experiment to view all associated runs. You can search experiments by typing directly into the **Search** bar or filtering for experiment type. You can also choose which columns to display in your experiment or run list.

   It might take a moment for the list to refresh and display a new experiment or experiment run. You can click **Refresh** to update the page. Your experiment list should look similar to the following:

2. In the experiments list, double-click an experiment to display a list of the runs in the experiment.
3. Double-click a run to display information about a specific run.

   In the Overview pane, choose any of the following headings to see available information about each run:

   - **Metrics** – Metrics that are logged during a run.
   - **Charts** – Build your own charts to compare runs.
   - **Output artifacts** – Any resulting artifacts of the experiment run and the artifact locations in Amazon S3.
   - **Bias reports** – Pe-training or post-training bias reports generated using Clarify.
   - **Explainability** – Explainability reports generated using Clarify.
   - **Debugs** – A list of debugger rules and any issues found.

**Compare and analyze runs**

To analyze experiment runs, select the experiment of your choice in the Amazon SageMaker Studio Experiments UI and then select the runs that you want to compare. You must select between 1 and 20 runs. After you have your runs selected, choose Analyze in the upper right-hand corner.

**To compare experiment runs:**

1. After navigating to the experiment of your choice, select all the runs that you want to compare. You must choose more than 1 and less than 20 runs to analyze.
2. Choose Analyze in the upper right-hand corner.
3. Visualize the comparative metrics of multiple experiment runs in a histogram, line chart, scatter plot, or bar chart. To add a chart, choose Add Chart, select values for your chart axes, and choose Create.
You can update, download, or delete existing charts.

**Automatic logging**

Automatic logging and visualization is available for classification models. You can automatically log a confusion matrix, receiver operating characteristics, or precision and recall graphs.

Log and visualize metrics with the following Python SDK methods:

- `log_confusion_matrix`: Records a confusion matrix artifact that you can view in the **Charts** section of the **Run Overview** in Studio.
• `log_roc_curve`: Records a receiver operating characteristic artifact that you can view in the **Charts** section of the **Run Overview** in Studio.

• `log_precision_recall`: Records a precision recall graph that you can view in the **Charts** section of the **Run Overview** in Studio.

An automatically logged precision recall record creates a chart similar to the following:

![Precision Recall Chart](image)

**SageMaker integrations**

Amazon SageMaker Experiments is integrated with a number of SageMaker features. Certain SageMaker jobs automatically create experiments. You can view and manage SageMaker Clarify bias reports or SageMaker Debugger output tensors for specific experiment runs directly in the Studio Experiments UI.

• **Automatic experiment creation** (p. 1464)

• **Bias and explainability reports** (p. 1465)

• **Debugging** (p. 1466)

**Automatic experiment creation**

Amazon SageMaker automatically creates experiments when running Autopilot jobs, hyperparameter optimization (HPO) jobs, or Pipeline executions. You can view these experiments in the Studio Experiments UI.

**Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for that job as well as runs for each of the different combinations of the available run components, parameters, and artifacts. You can find these runs in the SageMaker Experiments UI by filtering for the run type **Autopilot**. For more information, see Automate model development with Amazon SageMaker Autopilot.
HPO

Amazon SageMaker Experiments is integrated with HPO jobs. An HPO job automatically creates Amazon SageMaker experiments, runs, and components for each training job that it completes. You can find these runs in the SageMaker Experiments UI by filtering for the run type **HPO**. For more information, see [Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model](#).

Pipelines

Amazon SageMaker Model Building Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when SageMaker Pipelines creates and executes a pipeline, experiments, runs, and components are created if they do not already exist. You can find these runs in the SageMaker Experiments UI by filtering for the run type **Pipelines**. For more information, see [Amazon SageMaker Experiments Integration](#).

Bias and explainability reports

Manage SageMaker Clarify bias and explainability reports for experiment runs directly through Studio. To view reports, find and select the name of the experiment run of your choice in Studio. Choose **Bias reports** to see any Clarify bias reports associated with the experiment run.

Choose **Explanations** to see any Clarify explainability reports associated with the experiment run.
You can generate pre-training or post-training bias reports that analyze bias in datasets or model predictions using labels and bias metrics with SageMaker Clarify. You can also use SageMaker Clarify to generate explainability reports that document model behavior for global or local data samples. For more information, see Amazon SageMaker Clarify Bias Detection and Model Explainability.

**Debugging**

You can debug model training progress with Amazon SageMaker Debugger and view debug output tensors in the Studio Experiments UI. Choose the name of the run associated with the Debugger report and choose **Debugs**.

Then, choose the training job name to view the associated Amazon SageMaker Debugger dashboard.
Clean up experiment resources

For more information, see Debug Training Jobs Using Amazon SageMaker Debugger.

Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using the SageMaker Python SDK, Boto3, and the Experiments SDK.

Topics

- Clean Up Using the SageMaker Python SDK (p. 1467)
- Clean Up Using the Python SDK (Boto3) (p. 1467)
- Clean Up Using the Experiments SDK (p. 1468)

Clean Up Using the SageMaker Python SDK

To clean up using the SageMaker Python SDK

```python
from sagemaker.experiments.experiment import _Experiment

exp = _Experiment.load(experiment_name=experiment_name, sagemaker_session=sm_session)
exp._delete_all(action='--force')
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto3

```python
import boto3

sm = boto3.Session().client('sagemaker')

Define cleanup_boto3

def cleanup_boto3(experiment_name):
    trials = sm.list_trials(ExperimentName=experiment_name)['TrialSummaries']
    print('TrialNames:')
    for trial in trials:
```
trial_name = trial['TrialName']
print(f"\n{trial_name}\n")

components_in_trial = sm.list_trial_components(TrialName=trial_name)
print('TrialComponentNames:
')
for component in components_in_trial['TrialComponentSummaries']:
    component_name = component['TrialComponentName']
    print(f"{component_name}\n")
sm.disassociate_trial_component(TrialComponentName=component_name, TrialName=trial_name)
try:
    sm.delete_trial_component(TrialComponentName=component_name)
except:
    # component is associated with another trial
    continue
    # to prevent throttling
    time.sleep(.5)
sm.delete_trial(TrialName=trial_name)
sm.delete_experiment(ExperimentName=experiment_name)
print(f"\nExperiment {experiment_name} deleted\n")

Call cleanup_boto3

# Use experiment name not display name
experiment_name = "experiment-name"
cleanup_boto3(experiment_name)

Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

import sys
!{sys.executable} -m pip install sagemaker-experiments

import time
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent

Define cleanup_sme_sdk

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
                # to prevent throttling
                time.sleep(.5)
            trial.delete()
    experiment_name = experiment.experiment_name
experiment.delete()
print(f"\nExperiment {experiment_name} deleted")

Call cleanup_sme_sdk

experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")
cleanup_sme_sdk(experiment_to_cleanup)

Additional supported SDK

Important
As of v2.123.0, SageMaker Experiments is now fully integrated with the SageMaker Python SDK and you no longer need to use the separate SageMaker Experiments SDK. We recommend creating an experiment with sagemaker.experiments.run rather than the following smexperiments module.

The following section describes how to create a SageMaker Experiment with the SageMaker Experiments SDK.

Create an Amazon SageMaker Experiment with the SageMaker Experiments SDK

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

1. Import the sys module to install the SDKs.

   ```python
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.

   ```python
   import time
   from time import strftime
   import sagemaker
   from smexperiments.experiment import Experiment
   from smexperiments.trial import Trial
   from smexperiments.trial_component import TrialComponent
   from smexperiments.tracker import Tracker
   ```

5. Get the execution role and create the SageMaker session.
6. Create a SageMaker experiment. The experiment name must be unique in your account.

    Note
    The tags parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components.

    ```python
    create_date = strftime("%Y-%m-%d-%H-%M-%S")
    demo_experiment = Experiment.create(experiment_name = "DEMO-{}.format(create_date),
                                           description = "Demo experiment",
                                           tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
    ```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the Experiments.

   After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:

8. Create a trial for the experiment. The trial name must be unique in your account.

    ```python
    demo_trial = Trial.create(trial_name = "DEMO-{}.format(create_date),
                               experiment_name = demo_experiment.experiment_name,
                               tags = [{'Key': 'demo-trials', 'Value': 'demo1'}])
    ```

9. Create a trial component as part of the trial. The trial component is the SageMaker job.

    Add the `ExperimentConfig` parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

    | Job   | SageMaker Python SDK method | Boto3 method          |
    |-------|-----------------------------|-----------------------|
    | Training | `Estimator.fit`             | `CreateTrainingJob`   |
### Additional supported SDK

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Processing</td>
<td>Processor.run</td>
<td>CreateProcessingJob</td>
</tr>
<tr>
<td>Transform</td>
<td>Transformer.transform</td>
<td>CreateTransformJob</td>
</tr>
</tbody>
</table>

The following examples are for a training job. The Tags parameter adds a tag to the trial component. ExperimentName isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

#### Using the SageMaker Python SDK

```python
sagemaker.estimator.Estimator(
    ...,  
    sagemaker_session = sm_sess, 
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])
estimator.fit(
    ...,  
    experiment_config = {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

#### Using Boto3

```python
create_training_job(
    ...,  
    "ExperimentConfig": {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    },
    "Tags": [{'Key': 'demo-jobs', 'Value': 'demo2'}])
```

10. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment. In the Studio UI, trials are referred to as run groups and trial components are referred to as runs. Your list should look similar to the following:
11. (Studio) To view information about the experiment, trial, and job (trial component), see View, search, and compare experiment runs (p. 1460).

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 1467).

Experiments FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Experiments.

Q. What is the recommended method to create an experiment?

A: Experiments are a collection of runs aimed at finding the best model to solve a problem. To initialize a run within an experiment, use the SageMaker Python SDK Run class. For more examples, see Create an Amazon SageMaker Experiment (p. 1456).

Q. Can I create an experiment using SageMaker script mode?

Yes. You can create experiments using SageMaker script mode. In the Jupyter notebook or Python file you are using to define your estimator, initialize a run using the Run class. Within the run, launch an estimator with your custom entry point script. Within that entry point script, use the load_run method to initialize the run you defined within the entry point script and log your metrics.

Q. What SageMaker jobs automatically create experiments?

SageMaker Hyperparameter Optimization (HPO) jobs (also known as tuning jobs) automatically create experiments to track all the training jobs launched during a hyperparameter search. All other SageMaker jobs create unassigned runs unless launched from within an experiment.

Q. What kind of SageMaker jobs can I create an experiment for?

You can use SageMaker Experiments to track metrics from training jobs, processing jobs, and transform jobs.
**Q. Is the SageMaker Experiments SDK still supported?**

Yes, the SageMaker Experiments SDK is still supported. However, as of v2.123.0, SageMaker Experiments is fully integrated with the SageMaker Python SDK. We recommend using the SageMaker Python SDK to create experiments and runs. For more information, see Create an Amazon SageMaker Experiment (p. 1456).

**Q. Can I use distributed training with my experiments?**

A: Yes. However, metrics for distributed training can be logged only at the epoch level. Be sure that you only log metrics generated by the leader node, as shown in the following example:

```python
if rank == 0:
    test_loss, correct, target, pred = test(model, test_loader, device, tracker)
    logger.info(
        "Test Average loss: {:.4f}, Test Accuracy: {:.0f}%;\n".format(
            test_loss, test_accuracy)
    )
    run.log_metric(name = "train_loss", value = loss.item(), step = epoch)
    run.log_metric(name = "test_loss", value = test_loss, step = epoch)
    run.log_metric(name = "test_accuracy", value = test_accuracy, step = epoch)
```

For more information, see the Run a SageMaker Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification example notebook.

**Q. What are unassigned runs?**

A: All jobs in SageMaker (training jobs, processing jobs, transform jobs) correspond to runs. When launching these jobs, TrialComponents are created by default. TrialComponents map directly to runs. If these jobs are launched without being explicitly associated with an experiment or run, they are created as unassigned runs.

**Q. Do I need to pass the experiment run context to the training script when running a SageMaker training job?**

A: Yes. You need to load the run context into the training script, along with the SageMaker session information.

```python
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

session = Session(boto3.session.Session(region_name=args.region))

with load_run(sagemaker_session=session) as run:
    run.log_parameters(
        {
            "num_train_samples": len(train_set.data),
            "num_test_samples": len(test_set.data)
        }
    )
```

**Q. How do I add a new run to an experiment analysis?**

A: If you already created a comparison for your experiment and want to add a new run to analyze, select all the runs from your previous analysis as well as the new run and choose Analyze. If you don’t see your new run in the resulting analysis page, then refresh the Studio browser. Note that refreshing your Studio browser may impact your other open tabs.
Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API.

Topics
- Sample Notebooks for Managing ML Experiments (p. 1474)
- Organize, Find, and Evaluate Training Jobs (Console) (p. 1474)
- Find and Evaluate Training Jobs (API) (p. 1476)
- Verify the Datasets Used by Your Training Jobs (p. 1478)
- Trace Model Lineage (p. 1478)

Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see Managing ML Experimentation using Amazon SageMaker Model Tracking Capability.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 358). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the Advanced Functionality section. To open a notebook, choose its Use tab, and choose Create copy. If you have questions, post them on the Amazon Machine Learning Developer Forum.

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics
- Use Tags to Track Training Jobs (Console) (p. 1475)
- Find Training Jobs (Console) (p. 1475)
- Evaluate Models (Console) (p. 1475)
Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

**Add tags to training jobs (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.
4. To add another tag, choose Add tag, and add another key-value pair.

Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, Tags appears only if you have added a tag for a training job.

**To find training jobs (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search.
3. Add Parameters.
   a. In the search box, enter a parameter and choose a parameter type, for example TrainingJobName.
   b. Choose a conditional operation. For numeric values, use operators such as **is equals to**, **lesser than**, or **greater than**. For text-based values, use operators such as **equals to** or **contains**.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose Add row and enter the parameter values.
5. Choose Search.

Evaluate Models (Console)

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

**To evaluate a model (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search and search for training jobs by specifying relevant parameters. The results are displayed in a table.
3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing Hyperparameter or Metric.
5. Make necessary changes, then choose Update view.
6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

Find and Evaluate Training Jobs (API)

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the Search API.

Topics
- Find Training Jobs (API) (p. 1476)
- Evaluate Models (API) (p. 1476)
- Get Suggestions for a Search (API) (p. 1477)

Find Training Jobs (API)

To find training jobs, create a search parameter using the search_params parameter. Then use the search function in the smclient subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the Search API to find training jobs.

```python
import boto3

search_params={
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "Tags.Project",
            }
        ]
    }
}
```
Evaluate Models (API)

To evaluate models, run a search as described in Find Training Jobs (API) (p. 1476), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers=['Training Job Name', 'Training Job Status', 'Batch Size', 'Binary Classification Accuracy']
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
    rows.append([trainingJob['TrainingJobName'],
                 trainingJob['TrainingJobStatus'],
                 trainingJob['HyperParameters']['mini_batch_size'],
                 metrics[[x['MetricName'] for x in metrics].index('train:binary_classification_accuracy')]['Value']])

df = pandas.DataFrame(data=rows,columns=headers)
from IPython.display import display, HTML
display(HTML(df.to_html()))
```

Get Suggestions for a Search (API)

To get suggestions for a search, use the GetSearchSuggestions API.

The following example for AWS SDK for Python (Boto3) is a get_search_suggestions request for items containing linear.

```python
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a get_search_suggestions request.

```json
{
    'PropertyNameSuggestions': [{'PropertyName': 'hyperparameters.linear_init_method'},
                               {'PropertyName': 'hyperparameters.linear_init_value'},
                               {'PropertyName': 'hyperparameters.linear_init_sigma'},
                               {'PropertyName': 'hyperparameters.linear_lr'},
                               {'PropertyName': 'hyperparameters.linear_wd'}]
}
```
After getting search suggestions, you can use one of the property names in a search.

**Verify the Datasets Used by Your Training Jobs**

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

**Trace Model Lineage**

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.

**Topics**
- Trace Model Lineage (Console) (p. 1478)
- Trace Model Lineage (API) (p. 1478)

**Trace Model Lineage (Console)**

To trace a model's lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Endpoints**, and choose the relevant endpoint.
3. Scroll to the **Endpoint configuration settings** section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

**Trace Model Lineage (API)**

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```python
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Values": [url]
            }
        ]
    }
}
```

1478
"Value": model['PrimaryContainer']['ModelDataUrl']
})
}
results = smclient.search(**search_params)

After finding the training job, you can review the resources used to train the model.

# Debug and Profile Training Jobs Using Amazon SageMaker Debugger

Debug, profile, and monitor training jobs in real time to detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

## Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model's compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports the Apache MXNet, PyTorch, TensorFlow, and XGBoost frameworks. For more information about available frameworks and versions supported by SageMaker Debugger, see [Supported Frameworks and Algorithms](p. 1480).

The high-level Debugger workflow is as follows:

1. Modify your training script with the `sagemaker-debugger` Python SDK if needed.
2. Configure a SageMaker training job with SageMaker Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker `CreateTrainingJob` request (for Boto3 or CLI).
   - Configure custom training containers (p. 1650) with SageMaker Debugger.
3. Start a training job and monitor training issues in real time.
   - [SageMaker Studio Debugger dashboards in Studio Experiments and trials](p. 1537).
   - [List of Debugger Built-in Rules](p. 1583).
4. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 1514).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 1518).
5. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
   - Studio Debugger Insights dashboard for deep learning frameworks
   - Deep learning framework profiling report
   - SageMaker XGBoost training report
6. Explore deep analysis of the training issues and bottlenecks.
   - For profiling training jobs, see Analyze Data Using the SMDebug Client Library (p. 1575).
   - For debugging model output tensors, see Visualize Debugger Output Tensors in TensorBoard (p. ___).
7. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics
- Supported Frameworks and Algorithms (p. 1480)
- Amazon SageMaker Debugger Architecture (p. 1482)
- Get Started with Debugger Tutorials (p. 1484)
- Debug Training Jobs Using Amazon SageMaker Debugger (p. 1493)
- Profile Training Jobs Using Amazon SageMaker Debugger (p. 1525)
- List of Debugger Built-in Rules (p. 1583)
- Create Debugger Custom Rules for Training Job Analysis (p. 1628)
- Use Debugger with Custom Training Containers (p. 1630)
- Configure Debugger Using Amazon SageMaker API (p. 1633)
- Best Practices for Amazon SageMaker Debugger (p. 1643)
- Amazon SageMaker Debugger Advanced Topics and Reference Documentation (p. 1646)

Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

<table>
<thead>
<tr>
<th>SageMaker-supported frameworks and algorithms</th>
<th>Monitoring system bottlenecks</th>
<th>Profiling deep learning framework operations</th>
<th>Debugging output tensors</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>All AWS Deep learning containers</td>
<td>AWS TensorFlow deep learning containers 2.3.1 or later</td>
<td>AWS TensorFlow deep learning containers 1.15.4 or later</td>
</tr>
<tr>
<td>PyTorch</td>
<td></td>
<td>AWS PyTorch deep learning containers 1.6.0 or later</td>
<td>AWS PyTorch deep learning containers 1.5.0 or later</td>
</tr>
<tr>
<td>MXNet</td>
<td></td>
<td></td>
<td>AWS MXNet deep learning containers 1.6.0 or later</td>
</tr>
</tbody>
</table>
Supported Frameworks and Algorithms

<table>
<thead>
<tr>
<th>Framework</th>
<th>Supported Versions</th>
<th>Availability</th>

<td>Custom training containers (p. 1630) (available for TensorFlow, PyTorch, MXNet, and XGBoost with manual hook registration)</td>
</tr>
</tbody>
</table>

- **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.

- **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.

- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

  **Important**
  For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the `tf.keras` modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. For instructions on how to update your training script, see the section called “TensorFlow” (p. 1496).

  **Important**
  Since PyTorch v1.12.0 and later, SageMaker Debugger deprecates the zero code change support for debugging models. This is due to breaking changes that cause SageMaker Debugger to interfere with the `torch.jit` functionality. For instructions on how to update your training script, see the section called “PyTorch” (p. 1494).

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

**AWS Regions**

Amazon SageMaker Debugger is available in all regions where Amazon SageMaker is in service except the following region.

- Asia Pacific (Jakarta): ap-southeast-3

To find if Amazon SageMaker is in service in your AWS Region, see AWS Regional Services.

**Use Debugger with Custom Training Containers**

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.
For more information about how to build your training container with the `sagemaker-debugger` client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 1630).

**Debugger Open-Source GitHub Repositories**

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker `CreateTrainingJob` and `DescribeTrainingJob` API operations. The `sagemaker-debugger` client library provides tools to register hooks and access the training data through its trial feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and `sagemaker-debugger` API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Python SDK - Debugger APIs
- The `sagemaker-debugger` Python SDK documentation for the Amazon SageMaker Debugger open source client library
- The `sagemaker-debugger` PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations (p. 1647)
- Configure Debugger Using Amazon SageMaker API (p. 1633)

**Amazon SageMaker Debugger Architecture**

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.
- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.
- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

**Note**
By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics.
every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy)
every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and
aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the
output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine
learning models by processing the training data collected in your S3 bucket (see Process Data and
Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules
customized to your model to watch for any issues you want to monitor.

Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring,
profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and
learn how you can debug and improve your machine learning models efficiently by using Debugger.

Topics

• Debugger Tutorial Videos (p. 1484)
• Debugger Example Notebooks (p. 1485)
• Debugger Advanced Demos and Visualization (p. 1487)

Debugger Tutorial Videos

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker
Studio and SageMaker notebook instances.

Topics

• Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker
  Debugger (p. 1484)
• Debug Models with Amazon SageMaker Debugger in Studio (p. 1484)
• Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor (p. 1485)

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize
model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes
the training process transparent by automatically capturing metrics, analyzing training runs, and
detecting problems.

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

You can find the example notebook in this video at Visualizing Debugging Tensors of MXNet training in
the Amazon SageMaker Examples GitHub repository.

Debug Models with Amazon SageMaker Debugger in Studio

Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds

This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect
debugging information from a training model. The example training model used in this video is a simple
convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

**Debug Models with Amazon SageMaker Debugger (part 1)**

You can find the example notebook in the video in [this Studio Demo repository](#) provided by the author. You need to clone the debugger.ipynb notebook file and the mnist_keras_tf.py training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path `keras_script_path` to the `mnist_keras_tf.py` file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as `keras_script_path = "mnist_keras_tf.py"`.

**Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor**

*Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds*

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

**Debug Models with Debugger (part 2)**

You can find the example notebook in the video in [this AWS Dev Days 2020 repository](#) offered by the author.

**Debugger Example Notebooks**

[SageMaker Debugger example notebooks](#) are provided in the [aws/amazon-sagemaker-examples](#) repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at [Amazon SageMaker Studio Tour](#).

To find the examples in a SageMaker Notebook instance, follow the instructions at [SageMaker Notebook Instance Example Notebooks](#).

**Important**

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger Example Notebooks for Profiling Training Jobs**

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 1487).

**Debugger Advanced Demos and Visualization**

The following demos walk you through advanced use cases and visualization scripts using Debugger.

**Topics**

- Train and Tune Your Models with Amazon SageMaker Experiments and Debugger (p. 1487)
- Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training (p. 1490)
- Using SageMaker Debugger to Monitor attentions in BERT Model Training (p. 1490)
- Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs) (p. 1493)

**Train and Tune Your Models with Amazon SageMaker Experiments and Debugger**

*Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds*

**Train and Prune Models with SageMaker Experiments and Debugger**

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as trials through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.
SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

Total params: 50,883,321
Trainable params: 50,883,321
Non-trainable params: 0

Input size (MB): 0.57
Forward/backward pass size (MB): 7.27
Params size (MB): 194.10
Estimated Total Size (MB): 201.95
You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**
To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```python
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

# Add the following code to line 128 of the train.py script to save the pruned models
# under the current SageMaker Studio model directory
torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```
Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple
example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.

The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called attention.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting attention scores and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the attention-head view in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Debug Training Jobs Using Amazon SageMaker Debugger

To prepare your training script and run training jobs with SageMaker Debugger to debug model training progress, you follow the typical two-step process: modify your training script using the sagemaker-debugger Python SDK, and construct a SageMaker estimator using the SageMaker Python SDK. Go through the following topics to learn how to use SageMaker Debugger's debugging functionality.

Topics
- Step 1: Adapt Your Training Script to Register a Hook (p. 1494)
- Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK (p. 1498)
- Action on Amazon SageMaker Debugger Rules (p. 1513)
- Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard (p. 1523)
Step 1: Adapt Your Training Script to Register a Hook

Amazon SageMaker Debugger comes with a client library called the sagemaker-debugger Python SDK. The sagemaker-debugger Python SDK provides tools for adapting your training script before training and analysis tools after training. In this page, you'll learn how to adapt your training script using the client library.

The sagemaker-debugger Python SDK provides wrapper functions that help register a hook to extract model tensors, without altering your training script. To get started with collecting model output tensors and debug them to find training issues, make the following modifications in your training script.

**Tip**
While you're following this page, use the sagemaker-debugger open source SDK documentation for API references.

**Adapt Your PyTorch Training Script**

To start collecting model output tensors and debug training issues, make the following modifications to your PyTorch training script.

For PyTorch 1.12.0

If you bring a PyTorch training script, you can run the training job and extract model output tensors with a few additional code lines in your training script. You need to use the hook APIs in the sagemaker-debugger client library. Walk through the following instructions that break down the steps with code examples.

1. Create a hook.

    **(Recommended) For training jobs within SageMaker**

    ```python
    import smdebug.pytorch as smd
    hook = smd.get_hook(create_if_not_exists=True)
    ```

    When you launch a training job in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498) with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the get_hook function. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns None.

    **(Optional) For training jobs outside SageMaker**

    If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use smd. Hook class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode because the Rules require SageMaker ML training instances and S3 to store outputs from the remote instances in real time. The smd. get_hook API returns None in this case.

    If you want to create a manual hook to save tensors in local mode, use the following code snippet with the logic to check if the smd. get_hook API returns None and create a manual hook using the smd. Hook class. Note that you can specify any output directory in your local machine.
import smdebug.pytorch as smd
hook=smd.get_hook(create_if_not_exists=True)

if hook is None:
    hook=smd.Hook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )

2. Wrap your model with the hook's class methods.

   The hook.register_module() method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498). The collectable tensors through this hook method are weights, biases, activations, gradients, inputs, and outputs.

   ```python
   hook.register_module(model)
   ```

   **Tip**

   If you collect the entire output tensors from a large deep learning model, the total size of those collections can exponentially grow and might cause bottlenecks. If you want to save specific tensors, you can also use the hook.save_tensor() method. This method helps you pick the variable for the specific tensor and save to a custom collection named as you want. For more information, see step 7 (p. 1496) of this instruction.

3. Warp the loss function with the hook's class methods.

   The hook.register_loss method is to wrap the loss function. It extracts loss values every save_interval that you'll set during configuration in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498), and saves them to the "losses" collection.

   ```python
   hook.register_loss(loss_function)
   ```

4. Add hook.set_mode(ModeKeys.TRAIN) in the train block. This indicates the tensor collection is extracted during the training phase.

   ```python
def train():
    ...
    hook.set_mode(ModeKeys.TRAIN)
   ```

5. Add hook.set_mode(ModeKeys.EVAL) in the validation block. This indicates the tensor collection is extracted during the validation phase.

   ```python
def validation():
    ...
    hook.set_mode(ModeKeys.EVAL)
   ```

6. Use hook.save_scalar() to save custom scalars. You can save scalar values that aren't in your model. For example, if you want to record the accuracy values computed during evaluation, add the following line of code below the line where you calculate accuracy.

   ```python
   hook.save_scalar("accuracy", accuracy)
   ```

   Note that you need to provide a string as the first argument to name the custom scalar collection. This is the name that'll be used for visualizing the scalar values in TensorBoard, and can be any string you want.
7. Use `hook.save_tensor()` to save custom tensors. Similarly to `hook.save_scalar()`, you can save additional tensors, defining your own tensor collection. For example, you can extract input image data that are passed into the model and save as a custom tensor by adding the following code line, where "images" is an example name of the custom tensor, `image_inputs` is an example variable for the input image data.

```python
hook.save_tensor("images", image_inputs)
```

Note that you must provide a string to the first argument to name the custom tensor. `hook.save_tensor()` has the third argument `collections_to_write` to specify the tensor collection to save the custom tensor. The default is `collections_to_write="default"`. If you don't explicitly specify the third argument, the custom tensor is saved to the "default" tensor collection.

After you have completed adapting your training script, proceed to the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498).

Adapt Your TensorFlow Training Script

To start collecting model output tensors and debug training issues, make the following modifications to your TensorFlow training script.

Create a hook for training jobs within SageMaker

```python
import smdebug.tensorflow as smd
hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)
```

This creates a hook when you start a SageMaker training job. When you launch a training job in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498) with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the `smd.get_hook` method. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns None.

(Optional) Create a hook for training jobs outside SageMaker

If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger’s built-in Rules don’t work with the local mode. The `smd.get_hook` method also returns None in this case.

If you want to create a manual hook, use the following code snippet with the logic to check if the hook returns None and create a manual hook using the `smd.Hook` class.

```python
import smdebug.tensorflow as smd
hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)
if hook is None:
    hook=smd.KerasHook(
        out_dir="/path/to/your/local/output/",
        export_tensorboard=True
    )
```

After adding the hook creation code, proceed to the following topic for TensorFlow Keras.

**Note**

SageMaker Debugger currently supports TensorFlow Keras only.
Register the hook in your TensorFlow Keras training script

The following procedure walks you through how to use the hook and its methods to collect output scalars and tensors from your model and optimizer.

1. Wrap your Keras model and optimizer with the hook's class methods.

The hook.register_model() method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498). The collectable tensors through this hook method are weights, biases, and activations.

   ```python
   model=tf.keras.Model(...)  
hook.register_model(model)
   ```

2. Wrap the optimizer by the hook.wrap_optimizer() method.

   ```python
   optimizer=tf.keras.optimizers.Adam(...)  
optimizer=hook.wrap_optimizer(optimizer)
   ```

To collect tensors from the model, such as the input and output tensors of each layer, you must run the training in eager mode. Otherwise, SageMaker Debugger will not be able to collect the tensors. However, other tensors, such as model weights, biases, and the loss, can be collected without explicitly running in eager mode.

   ```python
   model.compile(  
       loss="categorical_crossentropy",  
       optimizer=optimizer,  
       metrics=["accuracy"],  
       run_eagerly=True  
   )
   ```

4. Register the hook to the tf.keras.Model.fit() method.

To collect the tensors from the hooks that you registered, add callbacks=[hook] to the Keras model.fit() class method. This will pass the sagemaker-debugger hook as a Keras callback.

   ```python
   model.fit(  
       X_train, Y_train,  
       batch_size=batch_size,  
       epochs=epoch,  
       validation_data=(X_valid, Y_valid),  
       shuffle=True,  
       callbacks=[hook]  
   )
   ```

5. TensorFlow 2.x provides only symbolic gradient variables that do not provide access to their values. To collect gradients, wrap tf.GradientTape by the hook.wrap_tape() method, which requires you to write your own training step as follows.

   ```python
   def training_step(model, dataset):
       with hook.wrap_tape(tf.GradientTape()) as tape:
           pred=model(data)  
           loss_value=loss_fn(labels, pred)  
           grads=tape.gradient(loss_value, model.trainable_variables)  
           optimizer.apply_gradients(zip(grads, model.trainable_variables))
   ```
By wrapping the tape, the `sagemaker-debugger` hook can identify output tensors such as gradients, parameters, and losses. Wrapping the tape ensures that the `hook.wrap_tape()` method around functions of the tape object, such as `push_tape()`, `pop_tape()`, `gradient()`, will set up the writers of SageMaker Debugger and save tensors that are provided as input to `gradient()` (trainable variables and loss) and output of `gradient()` (gradients).

**Note**
To collect with a custom training loop, make sure that you use eager mode. Otherwise, SageMaker Debugger is not able to collect any tensors.

For a full list of actions that the `sagemaker-debugger` hook APIs offer to construct hooks and save tensors, see Hook Methods in the `sagemaker-debugger Python SDK documentation`.

After you have completed adapting your training script, proceed to the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1498).

### Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK

To configure a SageMaker estimator with SageMaker Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters. To fully utilize the debugging functionality, there are three parameters you need to configure: `debugger_hook_config`, `tensorboard_output_config`, and `rules`.

**Important**
Before constructing and running the estimator fit method to launch a training job, make sure that you adapt your training script following the instructions at the section called “Step 1: Adapt Your Training Script to Register a Hook” (p. 1494).

#### Construct a SageMaker Estimator with Debugger-specific parameters

The code examples in this section show how to construct a SageMaker estimator with the Debugger-specific parameters.

**Note**
The following code examples are templates for constructing the SageMaker framework estimators and not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

**PyTorch**

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

session=boto3.session.Session()
region=session.region_name

devicer_hook_config=DebuggerHookConfig(...)  # Define DebuggerHookConfig
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    debugger_hook_config=devicer_hook_config,
    rules=rules,
    hyperparameters={
        "key": "value",
        "other_key": "other_value"
    }
)
```
# Debug Training Jobs

base_job_name="debugger-demo",
instance_count=1,
instance_type="ml.p3.2xlarge",
framework_version="1.12.0",
py_version="py37",

# Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
rules=rules
)
estimator.fit(wait=False)

### TensorFlow

# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

session=boto3.session.Session()
region=session.region_name
debugger_hook_config=DebuggerHookConfig(...) 
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
    rules=rules
)
estimator.fit(wait=False)

### MXNet

# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

debugger_hook_config=DebuggerHookConfig(...) 
 rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]
estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",

    # Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
Configure the following parameters to activate SageMaker Debugger:

- **debugger_hook_config** (an object of `DebuggerHookConfig`) – Required to activate the hook in the adapted training script during the section called “Step 1: Adapt Your Training Script to Register a Hook” (p. 1494), configure the SageMaker training launcher (estimator) to collect output tensors from your training job, and save the tensors into your secured S3 bucket or local machine. To learn how to configure the `debugger_hook_config` parameter, see Configure SageMaker Debugger to Save Tensors (p. 1501).

- **rules** (a list of `Rule` objects) – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in real time. The built-in rules are logics that automatically debug the training progress of your model and find training issues by analyzing the output tensors saved in your secured S3 bucket. To learn how to configure the `rules` parameter, see Configure Debugger Built-in Rules (p. 1507). To find a complete list of built-in rules for debugging output tensors, see the section called “Debugger Rule” (p. 1584). If you want to create your own logic to detect any training issues, see the section called “Create Custom Rules” (p. 1628).

**Note**
The built-in rules are available only through SageMaker training instances. You cannot use them in local mode.

- **tensorboard_output_config** (an object of `TensorBoardOutputConfig`) – Configure SageMaker Debugger to collect output tensors in the TensorBoard-compatible format and save to your S3 output path specified in the `TensorBoardOutputConfig` object. To learn more, see the section called “Visualize Debugger Output Tensors in TensorBoard” (p. 1523).

**Note**
The `tensorboard_output_config` must be configured with the `debugger_hook_config` parameter, which also requires you to adapt your training script by adding the `sagemaker-debugger` hook.

**Note**
SageMaker Debugger securely saves output tensors in subfolders of your S3 bucket. For example, the format of the default S3 bucket URI in your account is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are two subfolders created by SageMaker Debugger: `debug-output`, and `rule-output`. If you add the `tensorboard_output_config` parameter, you'll also find `tensorboard-output` folder.

See the following topics to find more examples of how to configure the Debugger-specific parameters in detail.

**Topics**
- Configure SageMaker Debugger to Save Tensors (p. 1501)
- Configure Debugger Built-in Rules (p. 1507)
- Turn Off Debugger (p. 1512)
- Useful SageMaker Estimator Classmethods for Debugger (p. 1513)

**Configure SageMaker Debugger to Save Tensors**

Tensors are data collections of updated parameters from the backward and forward pass of each training iteration. SageMaker Debugger collects the output tensors to analyze the state of a training...
job. SageMaker Debugger’s CollectionConfig and DebuggerHookConfig API operations provide methods for grouping tensors into collections and saving them to a target S3 bucket.

**Note**
After properly configured and activated, SageMaker Debugger saves the output tensors in a default S3 bucket, unless otherwise specified. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/.

While constructing a SageMaker estimator, activate SageMaker Debugger by specifying the debugger_hook_config parameter. The following steps include examples of how to set up the debugger_hook_config using the CollectionConfig and DebuggerHookConfig API operations to pull tensors out of your training jobs and save them.

**Configure Tensor Collections Using the CollectionConfig API**

Use the CollectionConfig API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```python
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

For a full list of available Debugger built-in collections, see [Debugger Built-in Collections](#).

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following CollectionConfig template to adjust parameters.

```python
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see CollectionConfig in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```python
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(  
        name="losses",
        parameters={  
            "save_interval": 100,  
            "validation_save_interval": 10  
        }  
    )
]
```
Tip
This tensor collection configuration object can be used for both DebuggerHookConfig and Rule API operations.

Configure the DebuggerHookConfig API to Save Tensors

Use the DebuggerHookConfig API to create a debugger_hook_config object using the collection_configs object you created in the previous step.

```python
from sagemaker.debugger import DebuggerHookConfig

d debugger_hook_config=DebuggerHookConfig(
    collection_configs=collection_configs
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig

d debugger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri"
    collection_configs=collection_configs
)
```

For more information, see DebuggerHookConfig in the Amazon SageMaker Python SDK.

Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

Topics
- Tensor Visualization Example Notebooks (p. 1503)
- Save Tensors Using Debugger Built-in Collections (p. 1505)
- Save Tensors Using Debugger Modified Built-in Collections (p. 1506)
- Save Tensors Using Debugger Custom Collections (p. 1506)

Tensor Visualization Example Notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation...
outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.

This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

• **Visualizing and Debugging Tensors from MXNet Model Training**

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the TensorPlot class imported from tensor_plot.py is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The
The tensor_plot.py script provided with the notebook retrieves tensors using Debugger and visualizes the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

### Save Tensors Using Debugger Built-in Collections

You can use built-in collections of tensors using the CollectionConfig API and save them using the DebuggerHookConfig API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the s3_output_path parameter for DebuggerHookConfig is optional. If you do not specify it, Debugger saves the tensors at s3://<output_path>/debug-output/, where the <output_path> is the default output path of SageMaker training jobs. For example:

"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
        LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
```
py_version="py39",
    # debugger-specific hook argument below
deprecated_hook_config=hook_config
)
sagemaker_estimator.fit()

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the CollectionConfig API operation. The following example shows how to tweak the built-in losses collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                 LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    # debugger-specific hook argument below
deprecated_hook_config=hook_config
)
sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```python
```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'
hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                    LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    # debugger-specific hook argument below
debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

Configure Debugger Built-in Rules

Amazon SageMaker Debugger's built-in rules analyze tensors emitted during the training of a model. SageMaker Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 1583).

In the following topics, you'll learn how to use the SageMaker Debugger built-in rules.

Topics
- Use Debugger Built-in Rules with the Default Parameter Settings (p. 1508)
- Use Debugger Built-in Rules with Custom Parameter Values (p. 1508)
- Example Notebooks and Code Samples to Configure Debugger Rules (p. 1509)
Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, rule_configs
rules=
    [Rule.sagemaker(rule_configs.built_in_rule_name_1()),
     Rule.sagemaker(rule_configs.built_in_rule_name_2()),
     ...
     Rule.sagemaker(rule_configs.built_in_rule_name_n()),
     ... # You can also append more profiler rules in the ProfilerRule.sagemaker(rule_configs.*) format.
    ]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 1583).

To find the SageMaker Debugger API reference, see `sagemaker.debugger.rule_configs` and `sagemaker.debugger.Rule`.

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```python
from sagemaker.debugger import Rule, rule_configs
rules=
    [Rule.sagemaker(rule_configs.loss_not_decreasing()),
     Rule.sagemaker(rule_configs.overfit()),
     Rule.sagemaker(rule_configs.overtraining()),
     Rule.sagemaker(rule_configs.stalled_training_rule())
    ]
```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The loss_not_decreasing, overfit, overtraining, and stalled_training_rule monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to IssueFound. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 1513).

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the base_config and rule_parameters parameters for the ProfilerRule.sagemaker and Rule.sagemaker classmethods. In case of the Rule.sagemaker class methods, you can also customize tensor collections through the collections_to_save parameter. The instruction of how to use the CollectionConfig class is provided at Configure Tensor Collections Using the CollectionConfig API (p. 1502).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The base_config argument is where you call the built-in rule methods.
- The rule_parameters argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules (p. 1583).
• The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires name and parameters arguments.
• To find available tensor collections for `name`, see Debugger Built-in Tensor Collections.
• For a full list of adjustable parameters, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig
rules=[
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 1583).

**Example Notebooks and Code Samples to Configure Debugger Rules**

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

**Topics**

• Debugger Built-in Rules Example Notebooks (p. 1509)
• Debugger Built-in Rules Example Code (p. 1510)
• Use Debugger Built-in Rules with Parameter Modifications (p. 1511)

**Debugger Built-in Rules Example Notebooks**

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

• Using a SageMaker Debugger built-in rule with TensorFlow
• Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
• Using a SageMaker Debugger built-in rule with XGBoost
• Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the Studio Experiment List tab. For example, as shown in the following screenshot, you can find and open a Describe Trial Component window of your current training job. On the Debugger tab, you can
check if the Debugger rules, `vanishing_gradient()` and `loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.

There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger Built-in Rules (p. 1583).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules=[
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
```
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    
    # debugger-specific arguments below
    rules=built_in_rules
)
sagemaker_estimator.fit()

**Note**

The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger Built-in Rules with Parameter Modifications (p. 1511) section.

**Use Debugger Built-in Rules with Parameter Modifications**

The following code example shows the structure of built-in rules to adjust parameters. In this example, the stalled_training_rule collects the losses tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))
built_in_rules_modified =[
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters=
        {  
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire' : 'True'
        }
    )
    collections_to_save=[
        CollectionConfig(  
            name="losses",
            parameters=
            {  
                "train.save_interval": "50",
                "eval.save_interval": "10"
            }
        )
    ]
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    )
```
base_job_name=base_job_name_prefix,
instance_count=1,
instance_type="ml.p3.2xlarge",
framework_version="2.9.0",
py_version="py39",

# debugger-specific arguments below
rules=built_in_rules_modified
)
sagemaker_estimator.fit()

For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 1633).

**Turn Off Debugger**

If you want to completely turn off Debugger, do one of the following:

- **Before starting a training job**, do the following:

  To stop both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to True.

  **Warning**
  If you disable it, you won’t be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To stop debugging, set the `debugger_hook_config` parameter to False.

  **Warning**
  If you disable it, you won’t be able to collect output tensors and cannot debug your model parameters.

  ```python
  estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
  )
  ```

  For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```python
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```python
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.
Useful SageMaker Estimator Classmethods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.

- To check the base S3 bucket URI of a SageMaker training job:
  
  ```
  estimator.output_path
  ```

- To check the base job name of a SageMaker training job:

  ```
  estimator.latest_training_job.job_name
  ```

- To see a full CreateTrainingJob API operation configuration of a SageMaker training job:

  ```
  estimator.latest_training_job.describe()
  ```

- To check a full list of the Debugger rules while a SageMaker training job is running:

  ```
  estimator.latest_training_job.rule_job_summary()
  ```

- To check the S3 bucket URI where the model parameter data (output tensors) are saved:

  ```
  estimator.latest_job_debugger_artifacts_path()
  ```

- To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

  ```
  estimator.latest_job_profiler_artifacts_path()
  ```

- To check the Debugger rule configuration for debugging output tensors:

  ```
  estimator.debugger_rule_configs
  ```

- To check the list of the Debugger rules for debugging while a SageMaker training job is running:

  ```
  estimator.debugger_rules
  ```

- To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

  ```
  estimator.profiler_rule_configs
  ```

- To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

  ```
  estimator.profiler_rules
  ```

For more information about the SageMaker estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

**Action on Amazon SageMaker Debugger Rules**

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can
also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

**Topics**
- Debugger Built-in Actions for Rules (p. 1514)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1518)

**Debugger Built-in Actions for Rules**

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 1584). The Debugger rule_configs class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

**Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic**

This section walks you through how to set up an Amazon SNS SMDebugRules topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

**Note**
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

**To create a SMDebugRules topic**

2. In the left navigation pane, choose Topics.
3. On the Topics page, choose Create topic.
4. On the Create topic page, in the Details section, do the following:
   a. For Type, choose Standard for topic type.
   b. In Name, enter SMDebugRules.
5. Skip all other optional settings and choose Create topic. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

**To subscribe to the SMDebugRules topic**

2. In the left navigation pane, choose Subscriptions.
3. On the Subscriptions page, choose Create subscription.
4. On the Create subscription page, in the Details section, do the following:
   b. For Protocol, choose Email or SMS.
   c. For Endpoint, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

**Note**
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.
5. Skip all other optional settings and choose Create subscription. If you want to learn more about the optional settings, see Subscribing to an Amazon SNS topic.

After you subscribe to the SMDebugRules topic, you receive the following confirmation message in email or by phone:

**AWS Notification - Subscription Confirmation**

S

SMDebugRules <no-reply@sns.amazonaws.com>

To:

You have chosen to subscribe to the topic:

To confirm this subscription, click or visit the link below (If this was in error no action is necessary):
Confirm subscription

Please do not reply directly to this email. If you wish to remove yourself from receiving all future SNS subscription confirmation requests please send an email to sns-opt-out

For more information about Amazon SNS, see Mobile text messaging (SMS) and Email notifications in the Amazon SNS Developer Guide.

**Step 2: Set Up Your IAM Role to Attach Required Policies**

In this step, you add the required policies to your IAM role.

**To add the required policies to your IAM role**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Policies, and choose Create policy.
3. On the Create policy page, do the following to create a new sns-access policy:
   a. Choose the JSON tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID.

   ```
   
   "Version": "2012-10-17",
   "Statement": [
     
     "Sid": "VisualEditor0",
     "Effect": "Allow",
     "Action": [
       "sns:Publish",
       "sns:CreateTopic",
       "sns:Subscribe"
     ],
     "Resource": "arn:aws:sns:::SMDebugRules"
   ]
   }
   
   
   c. At the bottom of the page, choose Review policy.
   d. On the Review policy page, for Name, enter sns-access.
   e. At the bottom of the page, choose Create policy.
4. Go back to the IAM console, and choose Roles in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the Permissions tab of the Summary page, choose Attach policies.
7. Search for the sns-access policy, select the check box next to the policy, and then choose Attach policy.

For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The rule_configs is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

**Note**
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

**To add all of the three built-in actions to a single rule**

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),       # Required
        rule_parameters={"paramter_key": value },      # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
)```
To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 1616) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix = 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)

stalled_training_job_rule_email.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)

stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

estimator = Estimator(
    ...,
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)
estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.
The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

![Image of text notification]

**Considerations for Using the Debugger Built-in Actions**

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Debugger ProfilerRule (p. 1584).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

**Create Actions on Rules Using Amazon CloudWatch and AWS Lambda**

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

**CloudWatch Logs for Debugger Rules and Training Jobs**

**To find training job logs and Debugger rule job logs**

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
   - Choose `/aws/sagemaker/TrainingJobs` for training job logs.
   - Choose `/aws/sagemaker/ProcessingJobs` for Debugger rule job logs.
You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

Step 1: Create a Lambda Function

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose Functions and then choose Create function.
3. On the Create function page, choose Author from scratch option.
4. In the Basic information section, enter a Function name (for example, debugger-rule-stop-training-job).
5. For Runtime, choose Python 3.7.
6. For Permissions, expand the drop down option, and choose Change default execution role.
7. For Execution role, choose Use an existing role and choose the IAM role that you use for training jobs on SageMaker.

   Note
   Make sure you use the execution role with AmazonSageMakerFullAccess and AWSLambdaBasicExecutionRole attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose Create function.

The following figure shows an example of the Create function page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) `client` for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

   ```python
   import json
   import boto3
   import logging

   logger = logging.getLogger()
   logger.setLevel(logging.INFO)

   def lambda_handler(event, context):
       training_job_name = event.get("detail").get("TrainingJobName")
       logger.info(f'Evaluating Debugger rules for training job: {training_job_name}"
   ```
eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)
if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

    # should only attempt stopping jobs with InProgress status
    training_job_status = event.get("detail").get("TrainingJobStatus", None)
    if training_job_status != 'InProgress':
        logging.debug(f"Current Training job status({training_job_status}) is not 'InProgress'. Exiting")
        return {
            'statusCode': 200,
            'body': json.dumps('Nothing to do')
        }

    client = boto3.client('sagemaker')

    for status in eval_statuses:
        logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' + str(status))
        if status.get("RuleEvaluationStatus") == "IssuesFound":
            secondary_status = event.get("detail").get("SecondaryStatus", None)
            logging.info(
                f'About to stop training job, since evaluation of rule configuration \
                {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' + 
                f'\n\nAttempting to stop training job "{training_job_name}" status is \
"{training_job_status}", secondary status is "{secondary_status}"' + 
            )
            try:
                client.stop_training_job(
                    TrainingJobName=training_job_name
                )
            except Exception as e:
                logging.error(
                    "Encountered error while trying to " 
                    "stop training job {0}: {}".format( 
                        training_job_name, str(e) 
                    )
                )
            raise e
    return None

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose Save at the top of the configuration page.

**Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger**

**To create a CloudWatch Events rule and link to the Lambda function for Debugger**

2. In the left navigation pane, choose Rules under the Events node.
3. Choose Create rule.
4. In the Event Source section of the Step 1: Create rule page, choose SageMaker for Service Name, and choose SageMaker Training Job State Change for Event Type. The Event Pattern Preview should look like the following example JSON strings:
5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

![Designer panel](image)

---

**Run Example Notebooks to Test Automated Training Job Termination**

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- **Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules**

  This example notebook runs a training job that has a vanishing gradient issue. The Debugger **VanishingGradient** (p. 1604) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.
• **Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule**

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule (p. 1616) built-in rule invokes issues and stops the training job.

**Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination**

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda Designer panel, choose the EventBridge (CloudWatch Events) block linked to the Lambda function. This shows an EventBridge panel below the Designer panel (for example, see the previous screen shot). Select the check box next to EventBridge (CloudWatch Events): debugger-cw-event-rule, and then choose Disable. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

**Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard**

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.

You can enable this by passing DebuggerHookConfig and TensorBoardOutputConfig objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container’s local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

**To save TensorBoard compatible output tensor files using Debugger**

1. Set up a tensorboard_output_config configuration object to save TensorBoard output using the Debugger TensorBoardOutputConfig class. For the s3_output_path parameter, specify the default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the container_local_output_path parameter; instead, it is set to the default local path `/opt/ml/output/tensors`. 
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path='s3://{}'.format(bucket)
)

For additional information, see the Debugger TensorBoardOutputConfig API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default save_interval value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(
    hook_parameters={
        "train.save_interval": "100",
        "eval.save_interval": "10"
    },
    collection_configs=[
        CollectionConfig("weights"),
        CollectionConfig(
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        ),
    ],
)

For more information about the Debugger configuration APIs, see the Debugger CollectionConfig and DebuggerHookConfig APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace estimator and Estimator with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are TensorFlow, PyTorch, and MXNet.

from sagemaker estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
debugger_hook_config=hook_config,
tensorboard_output_config=tensorboard_output_config
)
estimator.fit()

The estimator.fit() method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:
• For the Debugger S3 output path, use `estimator.latest_job_debugger_artifacts_path()`.
• For the TensorBoard S3 output path, use `estimator.latest_job_tensorboard_artifacts_path()`.

4. After the training has completed, check the names of saved output tensors:

   ```python
   from smdebug.trials import create_trial
   trial = create_trial(estimator.latest_job_debugger_artifacts_path())
   trial.tensor_names()
   ```

5. Check the TensorBoard output data in Amazon S3:

   ```
   tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
   print(tensorboard_output_path)
   !aws s3 ls {tensorboard_output_path}/
   ```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

   ```
   !aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
   ```

7. Compress the file directory to a TAR file to download to your local machine.

   ```
   !tar -cf logs.tar logs
   ```

8. Download and extract the TensorBoard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

   ```
   !tar -xf logs.tar
   %load_ext tensorboard
   %tensorboard --logdir logs/fit
   ```

### Profile Training Jobs Using Amazon SageMaker Debugger

To run training jobs with SageMaker Debugger to profile resource utilization status, statistics, and framework operations, add profiler configuration when you construct a SageMaker estimator using the SageMaker Python SDK. Go through the following topics to learn how to use SageMaker Debugger's profiling functionality.

**Topics**

- Configure Debugger Using Amazon SageMaker Python SDK (p. 1526)
- Configure Built-in Profiler Rules Managed by Amazon SageMaker Debugger (p. 1535)
- Amazon SageMaker Debugger in Amazon SageMaker Studio Experiments (p. 1537)
- SageMaker Debugger Interactive Reports (p. 1551)
- Analyze Data Using the SMDebug Client Library (p. 1575)
Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger to profile your training job and resource utilization, use Amazon SageMaker Python SDK and specify Debugger-specific parameters while constructing SageMaker estimators. There are two parameters you need to configure: profiler_config and rules.

**Note**
By default, SageMaker Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. SageMaker Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.

**Important**
To use the new SageMaker Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

**Note**
The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

**PyTorch**

To access the deep profiling feature for PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11 and later.

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)  
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
)```
instance_count=1,
instance_type="ml.p3.2xlarge",
framework_version="1.12.0",
py_version="py37",

# SageMaker Debugger parameters
profiler_config=profiler_config,
rules=rules
)

estimator.fit(wait=False)

**TensorFlow**

To access the deep profiling feature for TensorFlow, currently you need to specify the latest AWS deep learning container images with CUDA 11 and later.

```python
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.8.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

**MXNet**

```python
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
```
instance_count=1,
instance_type="ml.p3.2xlarge",
framework_version="1.7.0",
py_version="py37",

# SageMaker Debugger parameters
profiler_config=profiler_config,
rules=rules
)

estimator.fit(wait=False)

**Note**
For MXNet, when configuring the profiler_config parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

### XGBoost

```python
# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)  # debugger parameters
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)

**Note**
For XGBoost, when configuring the profiler_config parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

### Generic estimator

```python
# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)  # debugger parameters
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_image="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```
where you configure the following parameters:

- `profiler_config` parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the `profiler_config` parameter, see Configure Debugger Monitoring Hardware System Resource Utilization (p. 1529) and Configure Debugger Framework Profiling (p. 1530).

- `rules` parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket. To learn how to configure the `rules` parameter, see Configure Debugger Built-in Rules (p. 1507).

**Note**

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are three subfolders created by Debugger: `debug-output`, `profiler-output`, and `rule-output`. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 1513).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure Debugger Monitoring Hardware System Resource Utilization (p. 1529)
- Configure Debugger Framework Profiling (p. 1530)
- Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1533)
- Turn Off Debugger (p. 1534)

**Configure Debugger Monitoring Hardware System Resource Utilization**

To adjust Debugger system monitoring time intervals, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**

By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators.
Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following example code shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 1537).

**Configure Debugger Framework Profiling**

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms (p. 1480).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

**Start a Training Job with the Default System Monitoring and Framework Profiling**

The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)
```

With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling.
If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see `SageMaker Debugger APIs – FrameworkProfile` in the Amazon SageMaker Python SDK.

### Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      system_monitor_interval_millis=1000,
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

- **For a target time range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

  ```python
  import time
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
      duration=600)
  )
  ```
With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
                                                duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

**Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options**

You can use the following profiling configuration classes to manage the framework profiling options:

- **DetailedProfilingConfig** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.
  
  **Note**
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- **DataloaderProfilingConfig** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
  
  **Note**
  Data loader profiling might lower the training performance while collecting information from data loaders. We don’t recommend enabling data loader profiling for more than a couple of steps.
  Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
  
  **cProfile** – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.
• Pyinstrument – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**

Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig,
                                 PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see DetailedProfilingConfig, DataloaderProfilingConfig, and PythonProfilingConfig in the Amazon SageMaker Python SDK.

### Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

  ```python
  estimator.enable_default_profiling()
  ```
When you use the enable_default_profiling method, Debugger initiates the default system monitoring and the ProfileReport built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

For more information, see estimator.enable_default_profiling in the Amazon SageMaker Python SDK.

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:

```python
estimator.update_profiler(
    rules=[ProfilerRule.sagemaker(rule_configs.BuiltInRule()),
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile()
)
```

For more information, see estimator.update_profiler in the Amazon SageMaker Python SDK.

### Turn Off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To turn off profiling, include the disable_profiler parameter to your estimator and set it to True.

  **Warning**
  
  If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To turn off debugging, set the debugger_hook_config parameter to False.

  **Warning**
  
  If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```python
estimator=Estimator(
    ...,
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```python
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the update_profiler method:

  ```python
  estimator.update_profiler(disable_framework_metrics=true)
  ```
Configure Built-in Profiler Rules Managed by Amazon SageMaker Debugger

Amazon SageMaker Debugger’s built-in profiler rules analyze system metrics and framework operations collected during the training of a model. Debugger offers the `ProfilerRule` API operation that helps configure the rules to monitor training job progress and detect anomalies. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 1583).

Note

The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the `ProfilerReport` rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The ProfilerReport rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

- BatchSize (p. 1587)
- CPUBottleneck (p. 1588)
- GPUMemoryIncrease (p. 1589)
- IOBottleneck (p. 1590)
- LoadBalancing (p. 1592)
- LowGPUUtilization (p. 1592)
- OverallSystemUsage (p. 1594)
- MaxInitializationTime (p. 1594)
- OverallFrameworkMetrics (p. 1595)
- StepOutlier (p. 1595)

Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/`. For more information about how to download the profiling report, see SageMaker Debugger Profiling Report (p. 1552). SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

In the following topics, learn how to use the Debugger built-in rules.

Topics

- Use Debugger Built-in Profiler Rules with the Default Parameter Settings (p. 1535)
- Use Debugger Built-in Profiler Rules with Custom Parameter Values (p. 1536)

Use Debugger Built-in Profiler Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
```
For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 1583).

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```python
from sagemaker.debugger import Rule, rule_configs
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),
    ...
]  # You can also append more debugging rules in the Rule.sagemaker(rule_configs.*) format.
```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The loss_not_decreasing, overfit, overtraining, and stalled_training_rule monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to IssueFound. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 1513).

Use Debugger Built-in Profiler Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the base_config and rule_parameters parameters for the ProfilerRule.sagemaker and Rule.sagemaker class methods. In case of the Rule.sagemaker class methods, you can also customize tensor collections through the collections_to_save parameter. The instruction of how to use the CollectionConfig class is provided at Configure Tensor Collections Using the CollectionConfig API (p. 1502).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The base_config argument is where you call the built-in rule methods.
- The rule_parameters argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules (p. 1583).

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig
rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
]  
```
The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 1583).

For a low-level JSON configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 1633).

Amazon SageMaker Debugger in Amazon SageMaker Studio Experiments

Use the Amazon SageMaker Debugger dashboards in Amazon SageMaker Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

Important

If you’re using existing Studio apps, restart them to use the new Studio features. For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.

- Amazon SageMaker Debugger in Studio Experiments (p. 1550)

Open the Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard in Studio to see profiling progress, results of resource utilization, and system bottlenecks of your training job running on Amazon EC2 instances.
Note
The Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the Debugger insights dashboard, you must shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 1549).

To open the Debugger insights dashboard
1. In the Home page of Studio, choose Experiments in the left navigation pane.
2. Search your training job in the Experiments page. If your training job set up with an experiment run, the job should appear in the Experiments tab; if you didn't set up an experiment run, the job should appear in the Unassigned runs tab.
3. Choose (click) the link of the training job name to open the job details.
4. In the left OVERVIEW panel, choose Debugs. In the Debugs page, you can browse the associated Debugger rules to your training job and their monitoring status.
5. Choose the link of the training job name to open the Debugger insights dashboard. This opens a Debug [your-training-job-name] window. In this window, Debugger provides an overview of the computational performance of your training job on Amazon EC2 instances and identifies system bottleneck problems. While monitoring the system resource utilization, you can also enable profiling to capture framework metrics that consist of data from neural network operations executed during the forward and backward pass and data loading. For more information about how to enable profiling using the Debugger insights dashboard controller, see Enable and Configure Debugger Profiling for Detailed Insights (p. 1539).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see Amazon SageMaker Debugger Insights Dashboard Controller (p. 1538).

Amazon SageMaker Debugger Insights Dashboard Controller

There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

Note
The Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the Debugger insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 1549).
SageMaker Debugger Insights Controller UI

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop a training job, and download a Debugger profiling report.

- If you want to manually refresh the `Debug [your-training-job-name]` page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.

- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 1584).

- To download a comprehensive Debugger profiling report with details and analysis of a training job, choose **Download report**. For more information about the Debugger profiling report, see SageMaker Debugger Profiling Report (p. 1552).

Enable and Configure Debugger Profiling for Detailed Insights

When you enable **Profiling**, Debugger starts collecting framework metrics. Framework metrics are model data collected from the ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the Debugger Built-in Rules for Profiling Framework Metrics (p. 1584).

**Note**

After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling can help you understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using Amazon SageMaker Python SDK, see Configure Debugger Framework Profiling (p. 1530) and Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1533).

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In Studio, turn on **Profiling** to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.
2. The Configure Debugger monitoring and profiling, S3 bucket URI and Collect monitoring data every fields are already set to the default values.

You can choose to change the monitoring interval using the dropdown list. Select from the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.

Specify values for the following fields:

- **S3 bucket URI**: Specify the base S3 bucket URI.
- **Collect monitoring data every**: Select a time interval to collect system metrics.

**Note**

If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.
3. In **Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values are automatically configured to use the current step and for 1-step duration.

- **Detailed profiling**: Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if you’re using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

- **Python profiling**: Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

  - **cProfile** – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

  - **Pyinstrument** – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

  **Note**
  Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For
Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

- **Dataloader profiling**: Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

  **Note**
  The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps.
  Debugger is pre-configured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose **Confirm** to finish your profiling configuration. When the configuration is successfully updated, you should be able to see a **Debugger configuration updated successfully** confirmation message, as shown in following image.

Amazon SageMaker Debugger Insights Dashboard

When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of Amazon EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection profile through the insights dashboard. This guide walks you through the content of the Debugger insights dashboard under the following tabs: **Overview, Nodes**, and **Model insights**.

  **Note**
  The Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**
When you are done using the Debugger insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 1549).

**Important**
In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Debugger Insights – Overview (p. 1542)
- Debugger Insights – Nodes (p. 1545)
- Debugger Insights – Model Insights (p. 1548)

**Debugger Insights – Overview**

On the **Overview** tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.
Training job summary

The Training job summary section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.

This section has the following features:

- The Training progress over time chart shows the timeline of the different training phases over time. If you’re using spot training, you can also find the spot interruptions in the timeline chart.

- The Training job details panel shows the exact time stamps and utilization rate percentage numbers.
  
  - Start time: The exact time when the training job started.
  - End time: The exact time when the training job finished.
  - Job duration: The total training time from the Start time to the End time.
  - Training loop start: The exact time when the first step of the first epoch has started.
  - Training loop end: The exact time when the last step of the last epoch has finished.
  - Training loop duration: The total time between the training loop start time and the training loop end time.
  - Initialization: Time spent on initializing the training job, such as compiling the training script, initiating Amazon EC2 instances, and downloading training data.
  - Finalization: Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the Amazon EC2 instances.

  - Initialization (%): The percentage of time spent on Initialization over the total Job duration.
  - Training loop (%): The percentage of time spent on Training loop over the total Job duration.
  - Finalization (%): The percentage of time spent on Finalization over the total Job duration.
Resource utilization summary

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.

Insights

In the Insights pane, you can find training issues detected by Debugger built-in rules. You can expand each entry in the list to find useful insights, suggestions, a description of the rule, and criteria for initiating the rule.

For more information about the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1583).
On the **Nodes** tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

**CPU and Network utilization**

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to get a closer look at specific time windows.
The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.
Overall system utilization over time

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out which color level corresponds to which utilization rate. For example, in the following heatmap, after the initialization phase has ended, around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance: the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

![System utilization over time heatmap](image)

System resource utilization over time and framework event phase

The System metrics over time graph shows the overall CPU, GPU, and data I/O utilization. The Framework metrics over time graph shows the framework metrics, which are the framework event phases that you can correlate with the System metrics over time graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find which time interval was actually spent for the training loop and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.
Time spent in training

The following graph shows framework metrics from the last 30 steps of the last training loop, with cumulative time spent by different events in each step.

Debugger Insights – Model Insights

On the Model insights tab, you can browse autogenerated training reports for SageMaker XGBoost training jobs. The report provides insights into XGBoost training jobs, such as improvement in accuracy over time, loss value with respect to iteration, class imbalance, and other statistics to evaluate model performance. Depending on the type of supervised learning (binary classification, multi classification,
and regression), the **Model insights** tab is rendered automatically based on the Debugger's XGBoost training HTML report.

**Note**
This feature is available for SageMaker XGBoost training jobs. The training jobs must be initiated using the SageMaker XGBoost training containers version 1.2-1 or later.

**Note**
In the report, plots and recommendations are provided for informational purposes only and are not definitive. You are responsible for making your own independent assessment of the information.

To load model insights content, enable the `CreateXgboostReport` (p. 1596) rule when you start the training job. For more information about enabling the rule through the SageMaker estimator, see `Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule` (p. 1563).

For more information about the content on the model insights tab, see `Debugger XGBoost Training Report Walkthrough`.

To download the HTML report, follow the instructions at `Download the Debugger XGBoost Training Report`.

**Shut Down the Amazon SageMaker Debugger Insights Instance**

When you are not using the Debugger insights dashboard, shut down the instance on which it runs to avoid incurring additional fees.

**To shut down the Debugger insights instance in Studio**

1. In Studio, select the **Running Instances and Kernels** icon ( ).
2. Under the **RUNNING APPS** list, look for the `sagemaker-debugger-1.0` app. Select the shutdown icon ( ) next to the app. The Debugger insights dashboards run on an `ml.m5.xlarge` instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the `sagemaker-debugger-1.0` app.
Amazon SageMaker Debugger in Studio Experiments

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

Visualize Tensors Using Debugger and Studio

Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.

Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.
When rules are initiated for anomalous conditions, Studio presents logs for the failing rule to help you to analyze the causes of the condition.

SageMaker Debugger Interactive Reports

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger Profiling Report (p. 1552).
Note
You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

Important
In the reports, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- SageMaker Debugger Profiling Report (p. 1552)
- SageMaker Debugger XGBoost Training Report (p. 1563)

SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger ProfilerReport (p. 1586) rule invokes all of the monitoring and profiling rules (p. 1584) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

Important
In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Download a Debugger Profiling Report (p. 1553)
- Debugger Profiling Report Walkthrough (p. 1556)
Download a Debugger Profiling Report

Download the Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

**Tip**
You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 1537).

Download using SageMaker Python SDK and AWS CLI

1. Check the current job’s default S3 output base URI.

   \[
   \text{estimator.output_path}
   \]

2. Check the current job name.

   \[
   \text{estimator.latest_training_job.job_name}
   \]

3. The Debugger profiling report is stored under \(<\text{default-s3-output-base-uri}>/ \text{<training-job-name>}/\text{rule-output}\). Configure the rule output path as follows:

   \[
   \text{rule_output_path} = \text{estimator.output_path} + \text{estimator.latest_training_job.job_name} + \\
   \text{“/rule-output”}
   \]

4. To check if the report is generated, list directories and files recursively under the \text{rule_output_path} using \text{aws s3 ls} with the \text{--recursive} option.

   \[
   ! \text{aws s3 ls \{rule_output_path\} --recursive}
   \]

This should return a complete list of files under an autogenerated folder that’s named as \text{ProfilerReport-1234567890}. The folder name is a combination of strings: \text{ProfilerReport} and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

The \text{profiler-report.html} is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using \text{aws s3 cp}. The following command saves all of the rule output files to the \text{ProfilerReport-1234567890} folder under the current working directory.

   \[
   ! \text{aws s3 cp \{rule_output_path\} ./ --recursive}
   \]

   **Tip**
   If using a Jupyter notebook server, run \text{!pwd} to double check the current working directory.

6. Under the \text{/ProfilerReport-1234567890/profiler-output} directory, open \text{profiler-report.html}. If using JupyterLab, choose \text{Trust HTML} to see the autogenerated Debugger profiling report.
7. Open the profiler-report.ipynb file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

Download using Amazon S3 Console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: sagemaker-<region>-111122223333. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the Find objects by prefix input field. Choose the training job name.

4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: debug-output/, profiler-output/, and rule-output/. Choose rule-output/.
5. In the rule-output/ folder, choose ProfilerReport-1234567890, and choose profiler-output/ folder. The profiler-output/ folder contains profiler-report.html (the autogenerated profiling report in html), profiler-report.ipynb (a Jupyter notebook with scripts that are used for generating the report), and a profiler-report/ folder (contains rule analysis JSON files that are used as components of the report).

6. Select the profiler-report.html file, choose Actions, and Download.

7. Open the downloaded profiler-report.html file in a web browser.

Note
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the profiler_config parameter when constructing or updating SageMaker estimators.
To learn how to configure the `profiler_config` parameter before starting a training job, see Configure Debugger Framework Profiling (p. 1530).
To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration (p. 1533).

**Debugger Profiling Report Walkthrough**

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

**Important**

In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

</tbody>
</table>

The summary table contains the following information:
• **start_time** – The exact time when the training job started.
• **end_time** – The exact time when the training job finished.
• **job_duration_in_seconds** – The total training time from the **start_time** to the **end_time**.
• **training_loop_start** – The exact time when the first step of the first epoch has started.
• **training_loop_end** – The exact time when the last step of the last epoch has finished.
• **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
• **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the **start_time** to the **training_loop_start** time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
• **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the **training_loop_end** time to the **end_time**.
• **initialization (%)** – The percentage of time spent on **initialization** over the total **job_duration_in_seconds**.
• **training loop (%)** – The percentage of time spent on **training loop** over the total **job_duration_in_seconds**.
• **finalization (%)** – The percentage of time spent on **finalization** over the total **job_duration_in_seconds**.

**System Usage Statistics**

In this section, you can see an overview of system utilization statistics.

**System usage statistics**

The 95th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also include total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p90 and p50 percentiles.

<table>

</table>

The Debugger profiling report includes the following information:

• **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.
• **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
• **unit** – The unit of the system metrics.
• **max** – The maximum value of each system metric.
• **p99** – The 99th percentile of each system utilization.
• **p95** – The 95th percentile of each system utilization.
• **p50** – The 50th percentile (median) of each system utilization.
• **min** – The minimum value of each system metric.

**Framework metrics summary**

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

**Framework metrics summary**

The following pie charts show how much time your training job spent in "training", "validation" phase or "others". Later one is the accumulated time between steps, so when one step has finished but the next step has not started yet, ideally most time should be spent in training steps. Your training job spent quite a significant amount of time (30.03%) in phase "others". You should check what is happening in between the steps. The pie chart on the right shows a more detailed breakdown. It shows that 93% of the time was spent in "Backward pass". The following pie charts shows that 89% of your training was spent in "Backward pass". There is quite a significant difference between the time spent in forward and backward pass.

The following pie chart shows a breakdown of the CPU/GPU operators. It shows that 16% of the time was spent in executing operators on "gpu_function:dev:11".

Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

**Overview: CPU Operators**

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.
Overview: GPU Operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.

Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
CPU Bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above \( \text{cpu\_threshold} \) (90% by default) and also if the GPU utilization is below \( \text{gpu\_threshold} \) (10% by default).

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
• **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.

• **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

**I/O Bottlenecks**

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

**LoadBalancing in Multi-GPU Training**

In this section, you can identify workload balancing issue across GPUs.

**GPU Memory Analysis**

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger `CreateXgboostReport` (p. 1596) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the `CreateXgboostReport` (p. 1596) rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

**Important**
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 1563)
- Download the Debugger XGBoost Training Report (p. 1564)
- Debugger XGBoost Training Report Walkthrough (p. 1566)

Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

The `CreateXgboostReport` (p. 1596) rule collects the following output tensors from your training job:

- **hyperparameters** – Saves at the first step.
- **metrics** – Saves loss and accuracy every 5 steps.
- **feature_importance** – Saves every 5 steps.
- **predictions** – Saves every 5 steps.
- **labels** – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

**Using the SageMaker generic estimator**

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules = [
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator = Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
)"
# Add the Debugger XGBoost report rule

rules=rules

estimator.fit(wait=False)

## Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

### Download using the SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

   ```python
   estimator.output_path
   ```

2. Check the current job name.

   ```python
   estimator.latest_training_job.job_name
   ```

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/<training-job-name>/rule-output`. Configure the rule output path as follows:

   ```python
   rule_output_path = estimator.output_path + "" + estimator.latest_training_job.job_name + ""/rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

   ```bash
   ! aws s3 ls {rule_output_path} --recursive
   ```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger Profiling Report (p. 1552).

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

   ```bash
   ! aws s3 cp {rule_output_path} ./ --recursive
   ```
Tip
If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose Trust HTML to see the autogenerated Debugger training report.

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: sagemaker-<region>-111122223333. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in Find objects by prefix and then choosing the training job name.
4. In the training job's S3 bucket, choose **rule-output** subfolder. There must be three subfolders for training data collected by Debugger: **debug-output**, **profiler-output**, and **rule-output**.

5. In the **rule-output** folder, choose the **CreateXgboostReport** folder. The folder contains **xbgoost_report.html** (the autogenerated report in html) and **xbgoost_report.ipynb** (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the **xbgoost_report.html** file, choose **Download actions**, and then choose **Download**.

7. Open the downloaded **xbgoost_report.html** file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.
Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Distribution of True Labels of the Dataset (p. 1567)
- Loss versus Step Graph (p. 1567)
- Feature Importance (p. 1568)
- Confusion Matrix (p. 1569)
- Evaluation of the Confusion Matrix (p. 1570)
- Accuracy Rate of Each Diagonal Element Over Iteration (p. 1571)
- Receiver Operating Characteristic Curve (p. 1572)
- Distribution of Residuals at the Last Saved Step (p. 1573)
- Absolute Validation Error per Label Bin Over Iteration (p. 1574)

Distribution of True Labels of the Dataset
This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

Loss versus Step Graph
This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it’s also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that's centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel)

```
! pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

Analyze system and framework metrics

- Access the Monitoring and Profiling Data (p. 1575)
- Plot the System Metrics and Framework Metrics Data (p. 1576)
- Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1577)
- Access the Python Profiling Stats Data (p. 1578)
- Merge Timelines of Different Profiling Trace Files (p. 1580)
- Profiling Data Loader (p. 1582)

Access the Monitoring and Profiling Data

The SMDebug TrainingJob class reads data from the S3 bucket where the system and framework metrics are saved.

To set up a TrainingJob object and retrieve profiling event files of a training job

```
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

Tip

You need to specify the training_job_name and region parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

Note

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.
• If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.

• If you use Studio, turn on profiling using the **Profiling** toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```python
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```python
tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```python
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```python
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

**Plot the System Metrics and Framework Metrics Data**

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=['GPU']`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=['total']`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The `MetricsHistogram` class

```python
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram

metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'], # optional
)
```

- The `StepTimelineChart` class
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart
view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)

- The StepHistogram class

from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram
step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)

- The TimelineCharts class

from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts
view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total']                  # optional
)
view_timeline_charts.plot_detailed_profiler_data([700,710])

- The Heatmap class

from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap
view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'],                 # optional
    plot_height=450
)

Access the Profiling Data Using the Pandas Data Parsing Tool

The following PandasFrame class provides tools to convert the collected profiling data to Pandas data frame.

from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame

The PandasFrame class takes the tj object's S3 bucket output path, and its methods get_all_system_metrics() and get_all_framework_metrics() return system metrics and framework metrics in the Pandas data format.

pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(  
    selected_framework_metrics=[  
        'Step:ModeKeys.TRAIN',  
        'Step:ModeKeys.GLOBAL'

)
Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- **PythonProfileModes.TRAIN** – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- **PythonProfileModes.EVAL** – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- **PythonProfileModes.PREDICT** – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- **PythonProfileModes.GLOBAL** – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- **PythonProfileModes.PRE_STEP_ZERO** – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- **PythonProfileModes.POST_HOOK_CLOSE** – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```python
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- **StepPhase.START** – Use to specify the start point of the initialization phase.
- **StepPhase.STEP_START** – Use to specify the start step of the training phase.
- **StepPhase.FORWARD_PASS_END** – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- **StepPhase.STEP_END** – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- **StepPhase.END** – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools

Debugger supports the Python profiling with two profiling tools:
cProfile – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.

Pyinstrument – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 1532).

The following methods of the PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```python
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a cProfileAnalysis object, and if you want to use PyinstrumentAnalysis, replace the class name.

```python
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the cProfileAnalysis and PyinstrumentAnalysis classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.

- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled steps satisfy \( start_step \leq step < end_step \).

- `start_step` and `end_step` (str) – Specify the start step and end step to fetch the Python profiling stats data.

- `mode` (str) – Specify the mode of training job using the PythonProfileModes enumerator class. The default is PythonProfileModes.TRAIN. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1578) section.

- `start_phase` (str) – Specify the start phase in the target step(s) using the StepPhase enumerator class. This parameter enables profiling between different phases of training. The default is StepPhase.STEP_START. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1578) section.

- `end_phase` (str) – Specify the end phase in the target step(s) using the StepPhase enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the start_phase parameter. The default is StepPhase.STEP_END. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1578) section.

- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.

- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.

- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.
• `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).

• `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

• `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are (PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE). All stats files within each of these combinations are aggregated.

• `fetch_profile_stats_by_job_phase()` – Fetches and aggregates the Python profiling stats by job phase. The job phases are initialization (profiling until step 0), training_loop (training and validation), and finalization (profiling after the hook is closed).

**Merge Timelines of Different Profiling Trace Files**

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

Tip
Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the Monitoring and Profiling Data (p. 1575).

The MergedTimeline class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

• For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.

• For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.

• TensorFlow profiler saves events in a `*trace.json.gz` file.

Tip
If you want to list all of the JSON trace files, use the following AWS CLI command:

```bash
aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.
Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following MergedTimeline API operation and class method from the smdebug.profiler.analysis.utils.merge_timelines module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The MergedTimeline API operation passes the following parameters:

- **path (str)** – Specify a root folder (/profiler-output) that contains system and framework profiling trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the TrainingJob object. For example, estimator.latest_job_profiler_artifacts_path() or tj.profiler_s3_output_path.
- **file_suffix_filter (list)** – Specify a list of file suffix filters to merge timelines. Available suffix filters are ["model_timeline.json", "pythontimeline.json", "trace.json.gz"]. If this parameter is not manually specified, all of the trace files are merged by default.
- **output_directory (str)** – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the path parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- **start (int)** – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- **end (int)** – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
• unit (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the merge_timeline() method and download the merged JSON file.

• Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

• Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at `chrome://tracing` on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

### Profiling Data Loader

In PyTorch, data loader iterators, such as SingleProcessingDataLoaderIter and MultiProcessingDataLoaderIter, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```python
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1577) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The `SMDebug.S3SystemMetricsReader` class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

• `pt_analysis.analyze_dataloaderIter_initialization()`

The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.
The following list shows what analysis is available from this class method:

- Which type of data loader iterators were initialized.
- The number of workers per iterator.
- Inspect whether the iterator was initialized with or without pin_memory.
- Number of times the iterators were initialized during training.

```
pt_analysis.analyze_dataloaderWorkers()
```

The following list shows what analysis is available from this class method:

- The number of worker processes that were spun off during the entire training.
- Median and maximum duration for the worker processes.
- Start and end time for the worker processes that are outliers.

```
pt_analysis.analyze_dataloader_getnext()
```

The following list shows what analysis is available from this class method:

- Number of GetNext calls made during the training.
- Median and maximum duration in microseconds for GetNext calls.
- Start time, End time, duration and worker id for the outlier GetNext call duration.

```
pt_analysis.analyze_batchtime(start_timestamp, end_timestamp,
select_events=['.*'], select_dimensions=['.*'])
```

Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

The following list shows what analysis is available from this class method:

- Profile time spent on each data batch, BatchTime_in_seconds, by finding the difference between start times of current and subsequent GetNext calls.
- Find the outliers in BatchTime_in_seconds and start and end time for those outliers.
- Obtain the system and framework metrics during those BatchTime_in_seconds timestamps. This indicates where the time was spent.

```
pt_analysis.plot_the_window()
```

Plots a timeline charts between a start timestamp and the end timestamp.

**List of Debugger Built-in Rules**

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

**Note**

The maximum numbers of built-in rules for a training job are 20 for ProfilerRule and 20 for Rule. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.
Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger ProfilerRule**

The following rules are the Debugger built-in rules that are callable using the `ProfilerRule.sagemaker` classmethod.

### Debugger Built-in Rules for Generating Profiling Reports

<table>
<thead>

<tr>
<td></td>
<td>• <code>tree_depth</code> (p. 1627)</td>
</tr>
</tbody>
</table>

**To use the built-in rules with default parameter values** – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n()),
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

**To use the built-in rules with customizing the parameter values** – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
]```
To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 1510).
- For a full instruction of using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 1633).

### ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck.cpu_threshold = 90,
            IOBottleneck.threshold = 90
        )
    )
]```
Parameter Descriptions for the OverallSystemUsage Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

**BatchSize**

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

LowGPUtilization

The LowGPUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.
### Parameter Descriptions for the LowGPUUtilization Rule

<table>
<thead>

<td><strong>Optional</strong></td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>n_outliers</strong></td>
<td>How many outliers to ignore before rule returns True</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td><strong>scan_interval_us</strong></td>
<td>Time interval with which timeline files are scanned.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default values: 60000000 (in microseconds)</td>
</tr>
</tbody>
</table>

**CreateXgboostReport**

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- hyperparameters – Saves at the first step
- metrics – Saves loss and accuracy every 5 steps
- feature_importance – Saves every 5 steps
- predictions – Saves every 5 steps
- labels – Saves every 5 steps

**Parameter Descriptions for the CreateXgboostReport Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>base_trial</strong></td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
</tbody>
</table>

```python
rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]```
**DeadRelu**

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns `True`.

**Parameter Descriptions for the DeadRelu Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
</tbody>
</table>

| tensor_regex         | A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. |
|                      | **Optional** |
|                      | Valid values: List of strings or a comma-separated string |
|                      | Default value: ".*relu_output" |

| threshold_inactivity | Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the `threshold_inactivity`, it is considered to be dead. |
|                      | **Optional** |
|                      | Valid values: Float |
|                      | Default values: 1.0 (in percentage) |

| threshold_layer      | Returns `True` if the percentage of inactive ReLUs in a layer is greater than `threshold_layer`. Returns `False` if the percentage of inactive ReLUs in a layer is less than `threshold_layer`. |
|                      | **Optional** |
|                      | Valid values: Float |
|                      | Default values: 50.0 (in percentage) |
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

Note
This rule is not available for the XGBoost algorithm.

ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns True.

Parameter Descriptions for the ExplodingTensor Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>collection_names</td>
<td>The list of collection names whose tensors the rule inspects. Optional</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. Optional</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>only_nan</td>
<td>True to monitor the <code>base_trial</code> tensors only for NaN values and not for infinity. False to treat both NaN and infinity as exploding values and to monitor for both. Optional Default value: False</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*gradient",
            "only_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#).

**Note**
This rule is not available for the XGBoost algorithm.

### PoorWeightInitialization

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

#### Parameter Descriptions for the PoorWeightInitialization Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

                    "save_interval": "500"
                }
            )
        ]
    )
]

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**
This rule is not available for the XGBoost algorithm.

**SaturatedActivation**

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective min_threshold and max_thresholds values. If the activity of a node drops below the threshold_inactivity percentage, it is considered saturated. If more than a threshold_layer percent of the nodes are saturated, the rule returns True.

**Parameter Descriptions for the SaturatedActivation Rule**

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**
This rule is not available for the XGBoost algorithm.

**VanishingGradient**

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified threshold, the rule returns True.

**Parameters Descriptions for the VanishingGradient Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>threshold</td>
<td>The value at which the gradient is determined to be vanishing. Optional</td>
</tr>
</tbody>
</table>

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**
This rule is not available for the XGBoost algorithm.
WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the \texttt{large\_threshold} value or if this ratio is smaller than \texttt{small\_threshold}, the rule returns \texttt{True}.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and \texttt{train.save\_interval} needs to be set equal to \texttt{num\_steps}.

**Parameter Descriptions for the WeightUpdateRatio Rule**

<table>
<thead>
<tr>
<th>Parameter Name,</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{base_trial}</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>

</tr>
<tr>
<td></td>
<td>Default value: 0.000000001</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| epsilon        | A small constant used to ensure that Debugger does not divide by zero when computing the ratio updates to weigh. **Optional**  
Valid values: Float  
Default value: `0.000000001` |

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.weight_update_ratio(),
        rule_parameters={
            "num_steps": "100",
            "large_threshold": "10.0",
            "small_threshold": "0.00000001",
            "epsilon": "0.000000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "train.save_interval": "100"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**  
This rule is not available for the XGBoost algorithm.

### AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

### Parameters Descriptions for the AllZero Rule

<table>
<thead>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
            "tensor_regex": ".*",
            "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(
                name="all",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]```
**ClassImbalance**

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the threshold_imbalance, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above threshold_misprediction, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Parameter Descriptions for the ClassImbalance Rule**

</tbody>
</table>
| threshold_imbalance | that your dataset contains, the larger this sample number should be. **Optional**  
| threshold_misprediction | Valid values: Integer  
| samples | Default value: 500 (assuming a dataset like MNIST with 10 classes)  
| argmax | If True, `np.argmax` is applied to the prediction tensor. Required when you have a vector of probabilities for each class. It is used to determine which class has the highest probability. **Conditional**  
| labels_regex | The name of the tensor that contains the labels. **Optional**  
| predictions_regex | The name of the tensor that contains the predictions. **Optional** |

```python
built_in_rules = [  
    Rule.sagemaker(  
        base_config=rule_configs.class_imbalance(),  
        rule_parameters={  
            "threshold_imbalance": "10",  
            "threshold_misprediction": "0.7",  
            "samples": "500",  
            "argmax": "False",  
            "labels_regex": ".*labels",  
            "predictions_regex": ".*predictions"  
        },  
        collections_to_save=[  
            CollectionConfig(  
                name="custom_output_collection",  
                parameters={  
                    "include_regex": ".*labels\.*predictions",  
                    "save_interval": "500"  
                }  
            )  
        ]  
    )  
]```

1609
LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

        base_config=rule_configs.loss_not_decreasing(),
        rule_parameters={
            "tensor_regex": ".*",
            "use_losses_collection": "True",
            "num_steps": "10",
        }
    ),
]```
Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**
A standard way to prevent overfitting is to regularize your model.

### Parameter Descriptions for the Overfit Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

<td>The step from which to start comparing the validation and training loss.</td>
</tr>
<tr>
<td></td>
<td>Optional</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>patience</td>
<td>The number of steps for which the ratio_threshold is allowed to exceed the value set before the model is considered to be overfit. <strong>Optional</strong></td>
</tr>
<tr>
<td>ratio_threshold</td>
<td>The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a patience number of steps, the model is being overfit and the rule returns True. <strong>Optional</strong></td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
            "tensor_regex": ".*",
            "start_step": "0",
            "patience": "1",
            "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

**Overtraining**

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

**Note**
Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early (p. 1677). For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

### Parameter Descriptions for the Overtraining Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>patience_train</td>
<td>The number of steps to wait before the training loss is considered to not be improving anymore.</td>
</tr>
<tr>
<td>patience_validation</td>
<td>The number of steps to wait before the validation loss is considered to not be improving anymore.</td>
</tr>
<tr>
<td>delta</td>
<td>The minimum threshold by how much the error should improve before it is considered as a new optimum.</td>
</tr>
</tbody>
</table>

**Required**

- Valid values: String
- Default value: 5

**Optional**

- Valid values: Integer
- Default value: 10

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overtraining(),
        rule_parameters={
            "patience_train": "5",
            "patience_validation": "10",
            "delta": "0.01"
        },
        collections_to_save=[
            CollectionConfig(name="losses",
            parameters={
                "save_interval": "500"
            })
        ]
    )
]```

1614
SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

</tr>
</tbody>
</table>
StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its threshold parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tr>
<tr>
<td>training_job_name_prefix</td>
<td>The training job name prefix. It is important that the prefix is set unique per each training job.</td>
</tr>
</tbody>
</table>

**Stalled Training Rule**

This rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a *StopTrainingJob* action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job.

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**TensorVariance**

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the *collection_names* or *tensor_regex* parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

                parameters={
                    "save_interval": "500"
                }]
        )
    )
]```
UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the `numpy.allclose` method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

                }
            )
        ]
    )
]```
CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

</tr>
</tbody>
</table>

---

**NLPSequenceRatio**

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#) (p. 1507).

                }
            )
        ]
    )
]
```

### Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size category_no*category_no and populates it with data coming from (labels, predictions) pairs. For each (labels, predictions) pair, the count in
confusion[labels][predictions] is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: \( \text{confusion}[i][i]/\sum_j(\text{confusion}[j][j]) \geq \text{min\_diag} \)
- For elements off the diagonal: \( \text{confusion}[j][i]/\sum_j(\text{confusion}[j][j]) \leq \text{max\_off\_diag} \)

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(  
                name="labels",
                parameters={
                    "save_interval": "500"
                }  
            ),  
            CollectionConfig(  
                name="predictions",
                parameters={
                    "include_regex": "500"
                }  
            )  
        ]
    )
]
```

**Note**

This rule infers default values for the optional parameters if their values aren't specified.
FeatureImportanceOverweight

This rule accumulates the weights of the n largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

Parameter Descriptions for the FeatureImportanceOverweight Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>threshold</td>
<td>Defines the threshold for the proportion of the cumulative sum of the n largest features. The number n is defined by the nfeatures parameter. Optional</td>
</tr>
<tr>
<td>nfeatures</td>
<td>The number of largest features. Optional</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>Regular expression (regex) of tensor names the rule to analyze. Optional</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.feature_importance_overweight(),
        rule_parameters={
            "threshold": "0.8",
            "nfeatures": "3",
            "tensor_regex": ".*feature_importance/weight"
        }
    )
]
```
TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the depth parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1507).

                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]```
Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics

- Prerequisites for Creating Debugger Custom Rules (p. 1628)
- Use the Debugger Client Library smdebug to Create a Custom Rule Python Script (p. 1628)
- Use the Debugger APIs to Run Your Own Custom Rules (p. 1628)

Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1649)

Use the Debugger Client Library smdebug to Create a Custom Rule Python Script

The smdebug Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, CustomGradientRule. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule
class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at 'path/to/my_custom_rule.py'.
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)

The following list explains the Debugger `Rule.custom` API arguments.

- **name (str):** Specify a custom rule name as you want.
- **image_uri (str):** This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry.
- **instance_type (str):** You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source (str):** This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke (str):** This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save (str):** This specifies which tensor collections you will save for the rule to run.
- **rule_parameters (dictionary):** This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py',
    train_instance_type='ml.p2.xlarge',
    ...
    # debugger-specific arguments below
    rules = [custom_rule]
)

estimator.fit()

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet
- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow
Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 1630).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

Tip
This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 3268) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```bash
### debugger_custom_container_test_notebook.ipynb # a notebook to run python snippet codes
### debugger_custom_container_test_folder # this is a docker folder
### your-training-script.py # your training script with Debugger hook
### Dockerfile # a Dockerfile to build your own container
```

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

Note
This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```python
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...
```
... model.fit(X_train, Y_train,
    batch_size=batch_size,
    epochs=epoch,
    validation_data=(X_valid, Y_valid),
    shuffle=True,
    # smdebug modification: Pass the Debugger hook in the main() as a Keras callback
    callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")
    # hyperparameter settings
    parser.add_argument(...)  
    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)
    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()
    # Start the training.
    train(args.batch_size, args.epoch, model, hook)
if __name__ == '__main__':
    main()

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet training script in script mode. The training script imports the smdebug library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the smdebug hook functionality by adding the callbacks=[hook] argument inside the train function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.
• Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf
# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'
region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}'.format(account_id, region, uri_suffix, 
ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $byoc_image_uri
```
Tip
If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

```bash
docker push $byoc_image_uri
```

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```python
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config = ProfilerConfig(...)  
debugger_hook_config = DebuggerHookConfig(...)  
rules = [Rule.sagemaker(rule_configs.built_in_rule()), ProfilerRule.sagemaker(rule_configs.BuiltInRule())]  
estimator = Estimator(  
    image_uri=$byoc_image_uri,  
    entry_point='./debugger_custom_container_test_folder/your-training-script.py',  
    role=sagemaker.get_execution_role(),  
    base_job_name='debugger-custom-container-test',  
    instance_count=1,  
    instance_type='ml.p3.2xlarge',  
    # Debugger-specific parameters  
    profiler_config=profiler_config,  
    debugger_hook_config=debugger_hook_config,  
    rules=rules  
)  

# start training
estimator.fit()
```

Configure Debugger Using Amazon SageMaker API

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this section covers how to configure the following low-level API operations.

**Topics**
- JSON (AWS CLI) (p. 1634)
- AWS Boto3 (p. 1638)
Amazon SageMaker Debugger built-in rules can be configured for a training job using the `DebugHookConfig`, `DebugRuleConfiguration`, `ProfilerConfig`, and `ProfilerRuleConfiguration` objects through the SageMaker `CreateTrainingJob` API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request `CreateTrainingJob`.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

```
{
    "TrainingJobName": "debugger-aws-cli-test",
    "RoleArn": "arn:aws:iams:::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-YYYYMMDDTT123456",
    "AlgorithmSpecification": {
        "TrainingInputMode": "File",
        "EnableSageMakerMetricsTimeSeries": false
    },
    "HyperParameters": {
        "sagemaker_program": "entry_point/tf-hvd-train.py",
        "sagemaker_submit_directory": "s3://sagemaker-us-west-2-111122223333/debugger-boto3-profiling-test/source.tar.gz"
    },
    "OutputDataConfig": {
        "S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/output"
    },
    "DebugHookConfig": {
        "S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/debug-output",
        "CollectionConfigurations": [
            {
                "CollectionName": "losses",
                "CollectionParameters": {
                    "train.save_interval": "50"
                }
            }
        ],
        "DebugRuleConfigurations": [
            {
                "RuleConfigurationName": "LossNotDecreasing",
                "RuleParameters": {
                    "rule_to_invoke": "LossNotDecreasing"
                }
            }
        ],
        "ProfilerConfig": {
            "S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/ profiler-output",
            "ProfilingIntervalInMilliseconds": 500,
            "ProfilingParameters": {
```

Note
Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647).
Configure Debugger Using SageMaker API

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
"DebugHookConfig": {
    "$S3outputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "gradients",
            "CollectionParameters": {
                "save_interval": "500"
            }
        }
    ]
}
```

This will make the training job save the tensor collection, gradients, every `save_interval` of 500 steps. To find available `CollectionName` values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available `CollectionParameters` parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport",
        "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
    }
],
"ResourceConfig": {
    "InstanceType": "ml.p3.8xlarge",
    "InstanceCount": 1,
    "VolumeSizeInGB": 30
},
"StoppingCondition": {
    "MaxRuntimeInSeconds": 86400
}
```
"DebugRuleConfigurations": [
  {
    "RuleConfigurationName": "VanishingGradient",
    "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
    "RuleParameters": {
      "rule_to_invoke": "VanishingGradient",
      "threshold": "20.0"
    }
  }
]

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1583).

**To configure a Debugger built-in rule for profiling system and framework metrics**

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

**To enable Debugger profiling to collect system and framework metrics**

**Target Step**

```
"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  "ProfilingIntervalInMilliseconds": 500,
  "ProfilingParameters": {
    "DataloaderProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "MetricsRegex": ".*" }",
    "DetailedProfilingConfig": "{ "StartStep": 5, "NumSteps": 3 }",
    // For PythonProfilingConfig,
    // available ProfilerName options: cProfile, Pyinstrument
    // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
    "PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer": "total_time" }",
    // Optional. Local path for profiling outputs
    "LocalPath": "/opt/ml/output/profiler/

  }
}
```

**Target Time Duration**

```
"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  "ProfilingIntervalInMilliseconds": 500,
  "ProfilingParameters": {
    "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "MetricsRegex": ".*" }",
  }
}
```
Configure Debugger Using SageMaker API

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "CPUBottleneck_cpu_threshold": "90",
            "IOBottleneck_threshold": "90"
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1585).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
{
    "ProfilerConfig": {
        "DisableProfiler": boolean,
        "ProfilingIntervalInMilliseconds": number,
        "ProfilingParameters": {
            "string": "string"
        }
    },
    "ProfilerRuleConfigurations": [
        {
            "RuleConfigurationName": "string",
            "RuleEvaluatorImage": "string",
            "RuleParameters": {
                "string": "string"
            }
        }
    ],
    "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```
Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the **DebugHookConfig** and **DebugRuleConfiguration** objects in the **CreateTrainingJob** API operation. The following code sample shows how to configure a custom ImproperActivation rule written with the **smdebug** library using this SageMaker API operation. This example assumes that you've written the custom rule in **custom_rules.py** file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1649). You specify the URL registry address for the pre-built Docker image in the **RuleEvaluatorImage** parameter.

```
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ],
    "DebugRulesConfigurations": [
        {
            "RuleConfigurationName": "improper_activation_job",
            "InstanceType": "ml.c4.xlarge",
            "VolumeSizeInGB": 400,
            "RuleParameters": {
                "source_s3_uri": "s3://bucket/custom_rules.py",
                "rule_to_invoke": "ImproperActivation",
                "collection_names": "relu_activations"
            }
        }
    ]
}
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for **RuleParameters**, see List of Debugger Built-in Rules (p. 1583).

**AWS Boto3**

Amazon SageMaker Debugger built-in rules can be configured for a training job using the **create_training_job()** function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the **RuleEvaluatorImage** parameter, and the following examples walk you through how to set up the request body for the **create_training_job()** function.

The following code shows a complete example of how to configure Debugger for the **create_training_job()** request body and start a training job in us-west-2, assuming that a training script **entry_point/train.py** is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

**Note**

Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of
available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647).

import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'
tar = tarfile.open(source, 'w:gz')  # Specify the directory and name of your training script
tar.add('entry_point/train.py')  # Specify the directory and name of your training script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client('sagemaker')

# Start a training job
sm.create_training_job('debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py'  # training script file location and name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {
                'CollectionName': 'losses',
                'CollectionParameters': {
                    'train.save_interval': '500',
                    'eval.save_interval': '50'
                }
            }
        ]
    },
)
Configure Debugger Using SageMaker API

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

**To enable Debugger to collect output tensors**

Specify the Debugger hook configuration as follows:

```python
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {'CollectionName': 'gradients',
         'CollectionParameters': {
            'train.save_interval': '500',
            'eval.save_interval': '50'
         }
    ]
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

**To enable Debugger rules for debugging the output tensors**

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```python
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'LossNotDecreasing',
        'RuleParameters': {'rule_to_invoke': 'LossNotDecreasing'}
    },
    ProfilerConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
        'ProfilingIntervalInMilliseconds': 500,
        'ProfilingParameters': {
            'DataloaderProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "MetricsRegex": "."}',
            'DetailedProfilingConfig': '{"StartStep": 5, "NumSteps": 3, }',
            'PythonProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "ProfilerName": "cprofile", "cProfileTimer": "total_time"}',
            'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
        },
        ProfilerRuleConfigurations=[
            {
                'RuleConfigurationName': 'ProfilerReport',
                'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}
            }
        ]
    }
]
```
DebugRuleConfigurations=[
   {
      'RuleConfigurationName': 'VanishingGradient',
      'RuleParameters': {
         'rule_to_invoke': 'VanishingGradient',
         'threshold': '20.0'
      }
   }
]

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1583).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

ProfilerConfig={
   'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
   'ProfilingIntervalInMilliseconds': 500,
   'ProfilerParameters': {
      'DataloaderProfilingConfig': '{
         "StartStep": 5,
         "NumSteps": 3,
         "MetricsRegex": ".*"
      },
      'DetailedProfilingConfig': '{
         "StartStep": 5,
         "NumSteps": 3
      },
      'PythonProfilingConfig': '{
         "StartStep": 5,
         "NumSteps": 3,
         "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
         "cProfileTimer": "total_time" # Include only when using cprofile. Available options: cpu, off_cpu, total_time
      },
      'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
   }
}

Target Time Duration

ProfilerConfig={
   'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs

# Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.

- `ProfilingIntervalInMilliseconds`: `500`

- `ProfilingParameters`: {
  - `DataloaderProfilingConfig`: '{
      "StartTimeInSecSinceEpoch": 12345567789,
      "DurationInSeconds": 10,
      "MetricsRegex": ".*"
    }',
  - `DetailedProfilingConfig`: '{
      "StartTimeInSecSinceEpoch": 12345567789,
      "DurationInSeconds": 10
    }',
  - `PythonProfilingConfig`: '{
      "StartTimeInSecSinceEpoch": 12345567789,
      "DurationInSeconds": 10,
      "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
      "cProfileTimer": "total_time" # Include only when using cprofile.
      Available options: cpu, off_cpu, total_time
    }',
  - `LocalPath`: '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```python
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1583).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker client. Configure new `ProfilerConfig` and `ProfilerRuleConfiguration` objects, and specify the training job name to the `TrainingJobName` parameter.

```python
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string': 'string'
    }
},
```
Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1649). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```python
ProfilerRuleConfigurations=[
  {
    'RuleConfigurationName': 'string',
    'RuleEvaluatorImage': 'string',
    'RuleParameters': {
      'string': 'string'
    }
  }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

DebugHookConfig={
  'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
  'CollectionConfigurations': [
    {
      'CollectionName': 'relu_activations',
      'CollectionParameters': {
        'include_regex': 'relu',
        'save_interval': '500',
        'end_step': '5000'
      }
    }
  ],
}

DebugRulesConfigurations=[
  {
    'RuleConfigurationName': 'improper_activation_job',
    'InstanceType': 'ml.c4.xlarge',
    'VolumeSizeInGB': 400,
    'RuleParameters': {
      'source_s3_uri': 's3://bucket/custom_rules.py',
      'rule_to_invoke': 'ImproperActivation',
      'collection_names': 'relu_activations'
    }
  }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1647). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 1583).

Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

Topics
• Choose a Machine Learning Framework (p. 1644)
• Use Studio Debugger Insights Dashboard (p. 1644)
• Download Debugger Reports and Gain More Insights (p. 1644)
• Capture Data from Your Training Job and Save Data to Amazon S3 (p. 1644)
• Analyze the Data with a Fleet of Debugger Built-in Rules (p. 1644)
• Take Actions Based on the Built-in Rule Status (p. 1645)
• Dive Deep into the Data Using the SMDebug Client Library (p. 1645)
• Monitor and Analyze Training Job Metrics (p. 1645)
• Monitoring System Utilization and Detect Bottlenecks (p. 1645)
• Profiling Framework Operations (p. 1646)
• Debugging Model Output Tensors (p. 1646)

Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers.

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see Amazon SageMaker Debugger in Amazon SageMaker Studio Experiments (p. 1537).

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger Interactive Reports (p. 1551).

Capture Data from Your Training Job and Save Data to Amazon S3

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure SageMaker Debugger to Save Tensors (p. 1501).

Analyze the Data with a Fleet of Debugger Built-in Rules

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process
behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 1507) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1583). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 1628).

**Take Actions Based on the Built-in Rule Status**

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1518).

**Dive Deep into the Data Using the SMDebug Client Library**

You can use the SMDebug tools to access and analyze training data collected by Debugger. The TrainingJob and create_trial classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze Data Using the SMDebug Client Library (p. 1575).

**Monitor and Analyze Training Job Metrics**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

**Monitoring System Utilization and Detect Bottlenecks**

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.
To learn how to enable Debugger system monitoring, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1526) and then Configure Debugger Monitoring Hardware System Resource Utilization (p. 1529).

For a full list of available built-in rules for monitoring, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 1584).

### Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1526) and then Configure Debugger Framework Profiling (p. 1530).

For a complete list of available built-in rules for profiling, see Debugger Built-in Rules for Profiling Framework Metrics (p. 1584).

### Debugging Model Output Tensors

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 1480)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.

To learn how to configure Debugger for debugging output tensors, see Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK (p. 1498) and then Configure SageMaker Debugger to Save Tensors (p. 1501).

For a full list of available built-in rules for debugging, see Debugger Built-in Rules for Debugging Model Training Data (Output Tensors) (p. 1585).

### Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

**Topics**

- Amazon SageMaker Debugger API Operations (p. 1647)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 1647)
- Amazon SageMaker Debugger Exceptions (p. 1650)
Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source `sagemaker-debugger` Python SDK that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- `CreateTrainingJob` and `UpdateTrainingJob` use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - `CollectionConfiguration`
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `TensorBoardOutputConfig`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`

- `DescribeTrainingJob` provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `DebugRuleEvaluationStatus`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`
  - `ProfilerRuleEvaluationStatus`

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see `Process Data` (p. 1099).

Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the `ConfigureTrainingJobAPI`.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry
URL of the image using the CreateTrainingJob API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

**Topics**
- Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators (p. 1648)
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1649)

### Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name**: sagemaker-debugger-rules

**Tag**: latest

**Example of a full registry URL:**

904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest

#### Account IDs for Built-in Rules Container Images by AWS Region

**Amazon SageMaker Debugger Exceptions**

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the `smdebug.exceptions` module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:

- **TensorUnavailableForStep** – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.

- **TensorUnavailable** – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.

- **StepUnavailable** – The step was not saved and Debugger has no data from the step.

- **StepNotYetAvailable** – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.

- **NoMoreData** – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.

- **IndexReaderException** – The index reader is not valid.

- **InvalidWorker** – A worker was invoked that was not valid.

- **RuleEvaluationConditionMet** – Evaluation of the rule at the step resulted in the condition being met.

- **InsufficientInformationForRuleInvocation** – Insufficient information was provided to invoke the rule.

**Considerations for Amazon SageMaker Debugger**

Consider the following when using Amazon SageMaker Debugger.
Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

  **Scope of validity of using Debugger for training jobs with Horovod**

<table>
<thead>
<tr>
<th>Deep Learning Framework</th>
<th>Apache MXNet</th>
<th>TensorFlow 1.x</th>
<th>TensorFlow 2.x</th>
<th>TensorFlow 2.x with Keras</th>
<th>PyTorch</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitoring system bottlenecks</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>

<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

  * Debugger does not support framework profiling for TensorFlow 2.x.

  ** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.

- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

  SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 1726) and Saving Checkpoints (p. 1793).
• **Parameter Server** – Debugger does not support parameter server-based distributed training.

  Profiling distributed training framework operations, such as the AllReduced operation of SageMaker distributed data parallel and Horovod operations, is not available.

**Considerations for Monitoring System Bottlenecks and Profiling Framework Operations**

• For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in "/". For example:

  ```python
  FrameworkProfile(local_path="/opt/ml/output/profiler/")
  ```

• For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.

• For AWS TensorFlow, a NoneType error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.

• Python profiling and detailed profiling are only supported for Keras API.

• To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:

  • For TensorFlow

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
    ```

  • For PyTorch

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
    ```

**Considerations for Debugging Model Output Tensors**

• Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.

• Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.

• Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```python
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))
```
Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

Debugger Profiling Report Usage

For all SageMaker training jobs, Amazon SageMaker Debugger runs the ProfilerReport (p. 1586) rule and autogenerates a SageMaker Debugger Profiling Report (p. 1552). The ProfilerReport rule provides a Jupyter notebook file (profiler-report.ipynb) that generates a corresponding HTML file (profiler-report.html).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique ProfilerReport rule's processing job ARN if the user opens the final profiler-report.html file.

Debugger only collects information about whether a user opens the final HTML report. It DOES NOT collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

(Recommended) Option 1: Opt Out before Running a Training Job

To opt out, you need to add the following Debugger ProfilerReport rule configuration to your training job request.

SageMaker Python SDK

```python
estimator=sagemaker.estimator.Estimator(
    ...
    rules=ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport()
        rule_parameters={"opt_out_telemetry": "True"}
    )
)
```

AWS CLI

```
"ProfilerRuleConfigurations": [
    {
      "RuleConfigurationName": "ProfilerReport-1234567890",
      "RuleParameters": {
        "rule_to_invoke": "ProfilerReport",
        "opt_out_telemetry": "True"
      }
    }
]
```

AWS SDK for Python (Boto3)

```python
ProfilerRuleConfigurations=[
```
Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a binary classification problem on a marketing dataset. Your goal is to maximize the area under the curve (auc) metric of the algorithm by training an XGBoost Algorithm (p. 1262) model. You don't know which values of the eta, alpha, min_child_weight, and max_depth hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see Managed Spot Training in Amazon SageMaker (p. 1927).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

```
{
    'RuleConfigurationName': 'ProfilerReport-1234567890',
    'RuleParameters': {
        'rule_to_invoke': 'ProfilerReport',
        'opt_out_telemetry': 'True'
    }
}
```

**Option 2: Opt Out after a Training Job Has Completed**

To opt out after training has completed, you need to modify the profiler-report.ipynb file.

**Note**

HTML reports autogenerated without Option 1 already added to your training job request still report the usage statistics even after you opt out using Option 2.

1. Follow the instructions on downloading the Debugger profiling report files in the Download a Debugger Profiling Report (p. 1553) page.
2. In the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.ipynb.
3. Add `opt_out=True` to the setup_profiler_report() function in the fifth code cell as shown in the following example code:

```python
setup_profiler_report(processing_job_arn, opt_out=True)
```
4. Run the code cell to finish opting out.

1.654
• A dataset
• An understanding of the type of algorithm you need to train
• A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Get Started with Amazon SageMaker (p. 34).

How Hyperparameter Tuning Works

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate your productivity by trying many variations of a model. It looks for the best model automatically by focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore.

Note
Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

Grid Search

When using grid search, hyperparameter tuning chooses combinations of values from the range of categorical values that you specify when you create the job. Only categorical parameters are supported when using the grid search strategy. You do not need to specify the MaxNumberOfTrainingJobs. The number of training jobs created by the tuning job will be automatically calculated to be the total number of distinct categorical combinations possible. If specified, the value of MaxNumberOfTrainingJobs should equal the total number of distinct categorical combinations possible.

Random Search

When using random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn’t depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the tuning.

For an example notebook that uses random search, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.
Bayesian Optimization

Bayesian optimization treats hyperparameter tuning like a *regression* problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing a set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses an Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not yet well understood. The explore/exploit trade-off is common in many machine learning problems.

**Hyperband**

Hyperband is a multi-fidelity based tuning strategy that dynamically reallocates resources. Hyperband uses both intermediate and final results of training jobs to re-allocate epochs to well-utilized hyperparameter configurations and automatically stops those that underperform. It also seamlessly scales to using many parallel training jobs. These features can significantly speed up hyperparameter tuning over random search and Bayesian optimization strategies.

Hyperband should only be used to tune iterative algorithms that publish results at different resource levels. For example, Hyperband can be used to tune a neural network for image classification which publishes accuracy metrics after every epoch.
Hyperband with early stopping

Training jobs can be stopped early when they are unlikely to improve the objective metric of the hyperparameter tuning job. This can help both reduce compute time and avoid overfitting your model. Hyperband uses an advanced internal mechanism to apply early stopping. Thus, the parameter TrainingJobEarlyStoppingType in the HyperParameterTuningJobConfig API must be set to OFF when using Hyperband's internal early stopping feature.

Note
Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process.

Define Metrics

A tuning job optimizes hyperparameters for training jobs that it launches by using a metric to evaluate performance. This guide shows how to define metrics so that you can use a custom algorithm for training, or use a built-in algorithm from Amazon SageMaker.

Amazon SageMaker hyperparameter tuning parses your machine learning algorithm's stdout and stderr streams to find metrics, such as loss or validation-accuracy. The metrics show how well the model is performing on the dataset.

The following sections describe how to use two types of algorithms for training: built-in and custom.

Use a built-in algorithm for training

If you use one of the SageMaker built-in algorithms, metrics are already defined for you. In addition, built-in algorithms automatically send metrics to hyperparameter tuning for optimization. These metrics are also written to Amazon CloudWatch logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch.

For the objective metric for the tuning job, choose one of the metrics that the built-in algorithm emits. For a list of available metrics, see the model tuning section for the appropriate algorithm in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

You can choose up to 40 metrics to monitor in your tuning job. Select one of those metrics to be the objective metric. The hyperparameter tuning job returns the training job that performed the best against the objective metric.

Note
Hyperparameter tuning automatically sends an additional hyperparameter _tuning_objective_metric to pass your objective metric to the tuning job for use during training.

Use a custom algorithm for training

This section shows how to define your own metrics to use your own custom algorithm for training. When doing so, make sure that your algorithm writes at least one metric to stderr or stdout.
Hyperparameter tuning parses these streams to find algorithm metrics that show how well the model is performing on the dataset.

You can define custom metrics by specifying a name and regular expression for each metric that your tuning job monitors. Then, pass these metric definitions to the `CreateHyperParameterTuningJob` API in the `TrainingJobDefinition` parameter in the `MetricDefinitions` field of `AlgorithmSpecification`.

The following shows sample output from a log written to `stderr` or `stdout` by a training algorithm.

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744; Iteration 0 took 0.704s;  Elapsed=0s
```

The following code example shows how to use regular expressions in Python (regex). This is used to search the sample log output and capture the numeric values of four different metrics.

```
[
  {
    "Name": "ganloss",
    "Regex": "GAN_loss=(.*?);",
  },
  {
    "Name": "disc-combined",
    "Regex": "disc-combined=(.*?);",
  },
  {
    "Name": "discloss",
    "Regex": "disc_train_loss=(.*?);",
  },
  {
    "Name": "loss",
    "Regex": "Loss = (.*?);",
  }
]
```

In regular expressions, parenthesis () are used to group parts of the regular expression together.

- For the `loss` metric that is defined in the code example, the expression (.*?) captures any character between the exact text "Loss=" and the first semicolon (;) character.
- The character . instructs the regular expression to match any character.
- The character * means to match zero or more characters.
- The character ? means capture only until the first instance of the ; character.

The loss metric defined in the code sample will capture `Loss = 16.020744` from the sample output.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the SageMaker API, specify the value of the `name` key in the `HyperParameterTuningJobObjective` field of the `HyperParameterTuningJobConfig` parameter that you send to the `CreateHyperParameterTuningJob` operation.

### Define Hyperparameter Ranges

This guide shows how to use SageMaker APIs to define hyperparameter ranges. It also provides a list of hyperparameter scaling types that you can use.

Choosing hyperparameters and ranges significantly affects the performance of your tuning job. Hyperparameter tuning finds the best hyperparameter values for your model by searching over a
range of values that you specify for each tunable hyperparameter. You can also specify up to 100 static hyperparameters that do not change over the course of the tuning job. You can use up to 100 hyperparameters in total (static + tunable). For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning (p. 1684).

Note
SageMaker Automatic Model Tuning (AMT) may add additional hyperparameters(s) that contribute to the limit of 100 total hyperparameters. Currently, to pass your objective metric to the tuning job for use during training, SageMaker adds _tuning_objective_metric automatically.

Use static hyperparameters for the following cases: For example, you can use AMT to tune your model using param1 (a tunable parameter) and param2 (a static parameter). If you do, then use a search space for param1 that lies between two values, and pass param2 as a static hyperparameter, as follows.

```json
param1: ["range_min","range_max"]
param2: "static_value"
```

Static hyperparameters have the following structure:

```json
"StaticHyperParameters": {
    "objective": "reg:squarederror",
    "dropout_rate": "0.3"
}
```

You can use the Amazon SageMaker API to specify key value pairs in the StaticHyperParameters field of the HyperParameterTrainingJobDefinition parameter that you pass to the CreateHyperParameterTuningJob operation.

You can use the SageMaker API to define hyperparameter ranges. Specify the names of hyperparameters and ranges of values in the ParameterRanges field of the HyperParameterTuningJobConfig parameter that you pass to the CreateHyperParameterTuningJob operation.

The ParameterRanges field has three subfields: categorical, integer, and continuous. You can define up to 30 total (categorical + integer + continuous) tunable hyperparameters to search over.

Note
Each value of a categorical hyperparameter range counts as a hyperparameter against the limit.

Hyperparameter ranges have the following structure:

```json
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue": "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
```
If you create a tuning job with a Grid strategy, you can only specify categorical values. You don't need to provide the MaxNumberOfTrainingJobs. This value is inferred from the total number of configurations that can be produced from your categorical parameters. If specified, the value of MaxNumberOfTrainingJobs should be equal to the total number of distinct categorical combinations possible.

### Hyperparameter scaling types

For integer and continuous hyperparameter ranges, you can choose the scale that you want hyperparameter tuning to use. For example, to search the range of values, you can specify a value for the ScalingType field of the hyperparameter range. You can choose from the following hyperparameter scaling types:

**Auto**

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

**Linear**

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude). Uniformly searching values from the range provides a reasonable exploration of the entire range.

**Logarithmic**

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have values greater than 0.

Choose logarithmic scaling when you're searching a range that spans several orders of magnitude.

For example, if you're tuning a Tune a linear learner model (p. 1238) model, and you specify a range of values between .0001 and 1.0 for the learning_rate hyperparameter, consider the following: Searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would. This is because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0. As a result, that leaves only 10 percent of your training budget for the values between .0001 and .1.

**ReverseLogarithmic**

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. Reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

For an example notebook that uses hyperparameter scaling, see these Amazon SageMaker hyperparameter examples on GitHub.
Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- **The job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
- **The training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.
- **The tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

Get Started

You can create a new hyperparameter tuning job, clone a job, add or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose **Hyperparameter tuning jobs** from the **Training** menu, and then choose **Create hyperparameter tuning job**. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the **Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)** (p. 1661) topic.

  **Note**

  When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see **Example: Hyperparameter Tuning Job**. When you call **CreateHyperParameterTuningJob** to tune multiple algorithms, you must provide a list of training definitions using **TrainingJobDefinitions** instead of specifying a single **TrainingJobDefinition**. You must choose just one of these definition types depending on the number of algorithms being tuned.

Topics

- Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 1661)
- Manage Hyperparameter Tuning and Training Jobs (p. 1665)

Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

To create a new hyperparameter optimization (HPO) tuning job for one or more algorithms, you need to define the settings for the tuning job, create training job definitions for each algorithm being tuned, and configure the resources for the tuning job.
Define job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.

Warm Start

If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

**Note**

Warm start is compatible only with tuning jobs created after October 1, 2018. For more information, see Run a warm start job.

Early Stopping

To reduce compute time and avoid overfitting your model, training jobs can be stopped early when they are unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it’s disabled by default. For more information on how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see Stop Training Jobs Early.

Tuning Strategy

Tuning strategy can be either random, Bayesian or Hyperband. These selections specify how automatic tuning algorithms search over specified hyperparameter ranges (selected in a later step). Random search chooses random combinations of values from the specified ranges and can be run sequentially or in parallel. Bayesian optimization chooses values based on what is likely to get the best result given what is known about the history of previous selections. Hyperband uses a multi-fidelity strategy that dynamically allocates resources towards well-utilized jobs and automatically stops those that underperform. The new configuration that starts after stopping other configurations is chosen randomly. Hyperband can only be used with iterative algorithms. For more information search strategies, see How Hyperparameter Tuning Works.

**Note**

Hyperband uses an advanced internal mechanism to apply early stopping. Thus, the parameter TrainingJobEarlyStoppingType in the HyperParameterTuningJobConfig API must be set to OFF when using Hyperband’s internal early stopping feature.

Tags

You enter tags as key-value pairs to assign metadata to tuning jobs to help you manage them. Values are not required. You can use just the key. To see the keys associated with a job, choose the Tags tab on the details page for tuning job. For more information about using tags for tuning jobs, see Manage Hyperparameter Tuning and Training Jobs (p. 1665)

Create Training Job Definitions

To create a training job definition, you need to configure the algorithm and parameters, define the data input and output, and configure resources. You must provide at least one TrainingJobDefinition.
for each HPO tuning job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a job definition. Cloning a job can save time as it copies all of the job settings, including data channels, S3 storage locations for output artifacts. You can then edit the cloned job just for changes needed to configure the algorithm options.

**Topics**
- Configure algorithm and parameters (p. 1663)
- Define Data Input and Output (p. 1664)
- Configure Training Job Resources (p. 1664)
- Add or Clone a Training Job (p. 1664)

**Configure algorithm and parameters**

Each training job definition for a tuning job requires a name, permission to access services, and the specification of algorithm options, an objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job.

**Name**

Provide a unique name for the training definition.

**Permissions**

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let AWS create a role that has the AmazonSageMakerFullAccess IAM policy attached.

**Optional Security Settings**

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a private VPC.

**Note**

Inter-container encryption is only available when creating job definitions from the API.

**Algorithm Options**

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the ECR image information prepopulated.
- If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

**Metrics**

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics. You can define up to 20 metrics for your tuning job to monitor, one of which must be chosen as the objective metric. For more information on how to define a metric for a tuning job, see Define Metrics (p. 1657).

**Objective Metric**

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

**Hyperparameter Configuration**
When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter’s type to static. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define Data Input and Output

Each training job definition for a tuning job must configure the channels for data inputs, data output locations, and optionally any checkpoint storage locations for each training job.

Input Data Configuration

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the algorithm you chose supports multiple input channels, you can specify those too. For example, when using the XGBoost churn prediction notebook, you could add two channels: train and validation.

Checkpoint Configuration

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use Checkpoints in Amazon SageMaker (p. 1928).

Output Data Configuration

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure Training Job Resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource Configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Managed Spot Training in Amazon SageMaker (p. 1927).

Stopping condition

The stopping condition specifies the maximum duration allowed per training job.

Add or Clone a Training Job

Once you have created a training job definition for a tuning job, you are returned to the Training Job Definition(s) panel where you can create additional training job definitions to train additional algorithms. You can select the Add training job definition and work through the steps to define a training job again or choose Clone from the Action menu to replicate an existing training job definition and edit it for the new algorithm. The clone option can save time as it copies all of the job's settings, including the data channels, S3 storage locations. For more information on cloning, see Manage Hyperparameter Tuning and Training Jobs (p. 1665)

Configure Tuning Job Resources

Resource Limits
You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most) and the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

Review and Create HPO Tuning Job

Review the job settings, the training job definition(s), and resource limits. Then select **Create hyperparameter tuning job**.

Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/. Select **Hyperparameter tuning job** from the **Training** menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting **Create hyperparameter tuning job**.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting **Create Model** or you can clone the training job by selecting **Clone**.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in **Add or Clone a Training Job** (p. 1664) step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the **Define job settings** (p. 1662) section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes such as cost allocation or access control. To add tags using the SageMaker SDK, use **AddTags** API. For more information about using tagging for AWS resources, see **Tagging AWS resources**.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm (p. 1262) to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level AWS SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need
An AWS account and an administrator user (p. 35)
An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
A running SageMaker notebook instance (p. 78)

Topics
- Create a Notebook (p. 1666)
- Get the Amazon SageMaker Boto 3 Client (p. 1666)
- Get the SageMaker Execution Role (p. 1667)
- Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 1667)
- Download, Prepare, and Upload Training Data (p. 1668)
- Configure and Launch a Hyperparameter Tuning Job (p. 1669)
- Monitor the Progress of a Hyperparameter Tuning Job (p. 1672)
- Clean up (p. 1676)

Create a Notebook
Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step
Get the Amazon SageMaker Boto 3 Client (p. 1666)

Get the Amazon SageMaker Boto 3 Client
Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np # For performing matrix operations and numerical processing
import pandas as pd # For manipulating tabular data
```
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')

The preceding code cell defines region and smclient objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.

Next Step

Get the SageMaker Execution Role (p. 1667)

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

from sagemaker import get_execution_role
role = get_execution_role()
print(role)

Next Step

Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 1667)

Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. prefix is the path within the bucket where SageMaker stores the data for the current training job.

```
sess = sagemaker.Session()
bucket = sess.default_bucket()  # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

(Optional) To use a specific S3 bucket

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain sagemaker, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```
bucket = "sagemaker-your-preferred-s3-bucket"
```

Note

The name of the bucket doesn't need to contain sagemaker if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the S3FullAccess permission.

Next Step

Download, Prepare, and Upload Training Data (p. 1668)
Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.

For more information about the dataset and the data transformation that the example performs, see the `hpo_xgboost_direct_marketing_sagemaker_APIs` notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```bash
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)     # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)         # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```python
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)  # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0) # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)                                      # Convert categorical variables to sets of indicators
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])

pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job (p. 1669)
Configure and Launch a Hyperparameter Tuning Job

To configure and launch a hyperparameter tuning job, complete the following steps.

Topics

• Specify the Hyperparameter Tuning Job Settings (p. 1669)
• Configure the Training Jobs (p. 1670)
• Name and Launch the Hyperparameter Tuning Job (p. 1672)
• Next Step (p. 1672)

Specify the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the HyperParameterTuningJobConfig parameter to CreateHyperParameterTuningJob when you create the tuning job.

In this JSON object, you specify:

• The ranges of hyperparameters that you want to tune. For more information, see Define Hyperparameter Ranges (p. 1658)
• The limits of the resource that the hyperparameter tuning job can consume.
• The objective metric for the hyperparameter tuning job. An objective metric is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

   Note
   To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see Define Metrics (p. 1657).

The hyperparameter tuning job defines ranges for the eta, alpha, min_child_weight, and max_depth hyperparameters of the XGBoost Algorithm (p. 1262) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the validation:auc metric that the algorithm sends to CloudWatch Logs.

```json
tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ]
    }
}```
Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the `TrainingJobDefinition` parameter of the `CreateHyperParameterTuningJob` call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit. **Note** Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see Define Metrics (p. 1657).
- The container image that specifies the training algorithm.
- The input configuration for your training and test data.
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- The values of algorithm hyperparameters that are not tuned in the tuning job.
- The type of instance to use for the training jobs.
- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the XGBoost Algorithm (p. 1262) built-in algorithm.

SageMaker Python SDK v1

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}//train'.format(bucket, prefix)
s3_input_validation = 's3://{}//validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }
    ],
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {
        "MetricName": "validation:auc",
        "Type": "Maximize"
    },
    "ResourceLimits": {
        "MaxNumberOfTrainingJobs": 20,
        "MaxParallelTrainingJobs": 3
    }
}
```

Amazon SageMaker Developer Guide
Example: Hyperparameter Tuning Job

```json
{
    "S3DataDistributionType": "FullyReplicated",
    "S3DataType": "S3Prefix",
    "S3Uri": s3_input_train
}
}
{
    "ChannelName": "validation",
    "CompressionType": "None",
    "ContentType": "csv",
    "DataSource": {
        "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
        }
    }
}
"OutputDataConfig": {
    "S3OutputPath": "s3://{}/{}//output".format(bucket,prefix)
},
"ResourceConfig": {
    "InstanceCount": 2,
    "InstanceType": "ml.c4.2xlarge",
    "VolumeSizeInGB": 10
},
"RoleArn": role,
"StaticHyperParameters": {
    "eval_metric": "auc",
    "num_round": "100",
    "objective": "binary:logistic",
    "rate_drop": "0.3",
    "tweedie_variance_power": "1.4"
},
"StoppingCondition": {
    "MaxRuntimeInSeconds": 43200
}
}
```

SageMaker Python SDK v2

```python
training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')
s3_input_train = 's3://{}/{}//train'.format(bucket, prefix)
s3_input_validation = 's3://{}/{}//validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        }
    ],
```

1671
Example: Hyperparameter Tuning Job

```json
{
  "ChannelName": "validation",
  "CompressionType": "None",
  "ContentType": "csv",
  "DataSource": {
    "S3DataSource": {
      "S3DataDistributionType": "FullyReplicated",
      "S3DataType": "S3Prefix",
      "S3Uri": s3_input_validation
    }
  }
}
```

```
Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the `CreateHyperParameterTuningJob` API. Pass `tuning_job_config` and `training_job_definition` that you created in previous steps as the values of the parameters.

```python
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name, HyperParameterTuningJobConfig = tuning_job_config, TrainingJobDefinition = training_job_definition)
```

Next Step

Monitor the Progress of a Hyperparameter Tuning Job (p. 1672)

Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics
- View the Status of the Hyperparameter Tuning Job (p. 1673)
- View the Status of the Training Jobs (p. 1675)
- View the Best Training Job (p. 1676)
View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Hyperparameter tuning jobs.
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

View the Status of the Training Jobs

To view the status of the training jobs that the hyperparameter tuning job launched

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

![Training job status counter](image)

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.
**Note**
Hyperparameter tuning jobs can be stopped and the underlying resources deleted, but the jobs themselves cannot be deleted.

**View the Best Training Job**

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

**Next Step**

**Clean up**

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

**Note**
If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

2. Open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/) and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.

4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.

Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto 3), set the TrainingJobEarlyStoppingType field of the HyperParameterTuningJobConfig object that you use to configure the tuning job to AUTO.
- If you are using the Amazon SageMaker Python SDK, set the early_stopping_type parameter of the HyperParameterTuner object to Auto.
- In the Amazon SageMaker console, in the Create hyperparameter tuning job workflow, under Early stopping, choose Auto.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the hpo_image_classification_early_stopping.ipynb notebook in the Hyperparameter Tuning section of the SageMaker Examples in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 373).

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- LightGBM (p. 1229)
- CatBoost (p. 1202)
- AutoGluon-Tabular (p. 1195)
- TabTransformer (p. 1255)
- Linear Learner Algorithm (p. 1238)—Supported only if you use objective_loss as the objective metric.
Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works (p. 1655). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

**Note**

Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons to consider warm start include the following:

- To gradually increase the number of training jobs over several tuning jobs based on results after each iteration.
- To tune a model using new data that you received.
To change hyperparameter ranges that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.

You stopped a previous hyperparameter job early or it stopped unexpectedly.

**Topics**

- Types of Warm Start Tuning Jobs (p. 1679)
- Warm Start Tuning Restrictions (p. 1679)
- Warm Start Tuning Sample Notebook (p. 1680)
- Create a Warm Start Tuning Job (p. 1680)

### Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

**IDENTICAL_DATA_AND_ALGORITHM**

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run a warm start tuning job of type IDENTICAL_DATA_AND_ALGORITHM, there is an additional field in the response to DescribeHyperParameterTuningJob named OverallBestTrainingJob. The value of this field is the TrainingJobSummary for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

**TRANSFER_LEARNING**

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

### Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.

- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
Run a Warm Start Hyperparameter Tuning Job

- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.
- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible values red and blue, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.
- Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.
- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.
- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks (p. 373). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook, click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics
- Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3)) (p. 1680)
- Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 1681)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:
Run a Warm Start Hyperparameter Tuning Job

```python
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
        {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
    ],
    "WarmStartType" : "IdenticalDataAndAlgorithm"
}

Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
smclient.create_hyperparameter_tuning_job(HyperParameterTuningJobName = 'MyWarmStartTuningJob',
    HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning configuration
    TrainingJobDefinition = training_job_definition, # See notebook for job definition
    WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a WarmStartConfig object.
- Pass the WarmStartConfig object as the value of the warm_start_config argument of a HyperparameterTuner object.
- Call the fit method of the HyperparameterTuner object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification - MXNet (p. 1396) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 1658).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                         'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a WarmStartConfig object.

```python
from sagemaker.tuner import WarmStartConfig, WarmStartTypes

parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM, parents=(parent_tuning_job_name))
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, imageclassification is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                         image_shape='3,224,224',
                                         num_classes=257,
                                         num_training_samples=15420,
                                         mini_batch_size=128,
                                         )
```
epochs=30,
optimizer='sgd',
top_k='2',
precision_dtype='float32',
augmentation_type='crop')

Now create the HyperparameterTuner object and pass the WarmStartConfig object that you previously created as the warm_start_config argument.

tuner_warm_start = HyperparameterTuner(imageclassification,
   'validation:accuracy',
   hyperparameter_ranges,
   objective_type='Maximize',
   max_jobs=10,
   max_parallel_jobs=2,
   base_tuning_job_name='warmstart',
   warm_start_config=warm_start_config)

Finally, call the fit method of the HyperparameterTuner object to launch the warm start tuning job.

tuner_warm_start.fit(
   {'train': s3_input_train, 'validation': s3_input_validation},
   include_cls_metadata=False)

Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Regions</th>
<th>Default limits</th>
<th>Can be increased to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of parallel (concurrent) hyperparameter tuning jobs</td>
<td>All</td>
<td>100</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of hyperparameters that can be searched *</td>
<td>All</td>
<td>30</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of metrics defined per hyperparameter tuning job</td>
<td>All</td>
<td>20</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of parallel training jobs per hyperparameter tuning job</td>
<td>All</td>
<td>10</td>
<td>100</td>
</tr>
<tr>
<td>[Bayesian optimization] Number of training jobs per hyperparameter tuning job</td>
<td>All</td>
<td>750</td>
<td>N/A</td>
</tr>
<tr>
<td>[Random search] Number of training jobs</td>
<td>All</td>
<td>750</td>
<td>10000</td>
</tr>
<tr>
<td>Resource</td>
<td>Regions</td>
<td>Default limits</td>
<td>Can be increased to</td>
</tr>
<tr>
<td>----------</td>
<td>---------</td>
<td>----------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>per hyperparameter tuning job</td>
<td>All</td>
<td>750</td>
<td>N/A</td>
</tr>
<tr>
<td>[Hyperband] Number of training jobs per hyperparameter tuning job</td>
<td>All</td>
<td>750</td>
<td>N/A</td>
</tr>
<tr>
<td>[Grid] Number of training jobs per hyperparameter tuning job, either specified explicitly or inferred from the search space</td>
<td>All</td>
<td>750</td>
<td>N/A</td>
</tr>
<tr>
<td>Maximum run time for a hyperparameter tuning job</td>
<td>All</td>
<td>30 days</td>
<td>N/A</td>
</tr>
</tbody>
</table>

* Every possible value in a categorical hyperparameter counts against this limit.

**Resource limit example**

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see SageMaker Limits. Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one ml.m4.xlarge instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 750.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training ml.m4.xlarge instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

**To request a quota increase:**

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
5. In the **Case description** panel, provide a description of your use case.
6. In the **Contact options** panel, select your preferred **Contact methods** (Web, Chat or Phone) and then choose **Submit**.

**Best Practices for Hyperparameter Tuning**

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.

**Topics**
- Choosing a Strategy (p. 1684)
- Choosing the Number of Hyperparameters (p. 1685)
- Choosing Hyperparameter Ranges (p. 1685)
- Using Logarithmic Scales for Hyperparameters (p. 1685)
- Choosing the Best Number of Concurrent Training Jobs (p. 1685)
- Running Training Jobs on Multiple Instances (p. 1685)

**Choosing a Strategy**

For large jobs, using Hyperband can reduce computation time by utilizing its internal early stopping mechanism, reallocation of resources and ability to run parallel jobs. If runtime and resources are limited, use either random search or Bayesian optimization instead. Bayesian optimization uses information.
gathered from prior runs to make increasingly informed decisions about improving hyperparameter configurations in the next run. Because of its sequential nature, Bayesian optimization cannot massively scale. Random search is able to run large numbers of parallel jobs. Consider using grid search if it is important to be able to reproduce results of a tuning job, or if simplicity and transparency of the optimization algorithm are important. Grid search is also a good option when it is important to explore the entire hyperparameter search space evenly.

**Choosing the Number of Hyperparameters**

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

**Choosing Hyperparameter Ranges**

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

**Using Logarithmic Scales for Hyperparameters**

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

**Choosing the Best Number of Concurrent Training Jobs**

When setting the resource limit `MaxParallelTrainingJobs` for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

**Running Training Jobs on Multiple Instances**

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.
Get Started with Distributed Training

If you’re familiar with distributed training, choose one of the following options that matches your preferred strategy or framework to get started. If you want to learn about distributed training in general, see the section called “Basic Distributed Training Concepts” (p. 1688).

The SageMaker distributed training libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput. The libraries offer both data parallel and model parallel training strategies. They combine software and hardware technologies to improve inter-GPU and inter-node communications, and extend SageMaker’s training capabilities with built-in options that require minimal code changes to your training scripts.

• To use SageMaker’s data parallelism library, configure the distribution parameter of the SageMaker framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to set a framework estimator for distributed training with the data parallelism library on two ml.p4d.24xlarge instances.

```python
from sagemaker.framework import Framework
estimator = Framework(
    ...
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution={"smdistributed" : {"dataparallel" : {"enabled" : True}}}
)
```

To learn how to prepare your training script and launch a distributed training job, see SageMaker’s data parallelism library (p. 1695) (see also Distributed Training APIs in the SageMaker Python SDK documentation).

• To use SageMaker’s model parallelism library, configure the distribution parameter of the SageMaker framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to construct a framework estimator for distributed training with the model parallelism library on two ml.p4d.24xlarge instances.

```python
from sagemaker.framework import Framework
distribution={
    "smdistributed": {
        "modelparallel": {
            "enabled": True,
            "parameters": {
                ... # enter parameter key-value pairs here
            }
        },
    },
    "mpi": {
        "enabled": True,
        ... # enter parameter key-value pairs here
    }
}
estimator = Framework(
    ...
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution=distribution
)
```
To learn how to prepare your training script, configure distribution parameters, and launch a distributed training job, see SageMaker's model parallelism library (p. 1728) (see also Distributed Training APIs in the SageMaker Python SDK documentation).

SageMaker also supports the following options to operate mpirun and torchrun in the backend.

- To use PyTorch DistributedDataParallel (DDP) in SageMaker, add distribution={"pytorchddp": {"enabled": True}} to your PyTorch estimator. For more information, see also PyTorch Distributed Training and SageMaker PyTorch Estimator's distribution argument in the SageMaker Python SDK documentation.

  Note
  With the pytorchddpp distribution option, SageMaker operates mpirun in the backend.

  ```python
  from sagemaker.pytorch import PyTorch
  estimator = PyTorch(
      ...
      instance_count=2,
      instance_type="ml.p4d.24xlarge",
      distribution={"pytorchddp": {"enabled": True}}  # runs mpirun in the backend
  )
  ```

- SageMaker supports the PyTorch torchrun launcher for distributed training on Amazon EC2 Trn1 instances powered by the AWS Trainium device, the second generation purpose-built machine learning accelerator from AWS. Each Trn1 instance consists of up to 16 Trainium devices, and each Trainium device consists of two NeuronCores. For specs of the AWS Trainium devices, see Trainium Architecture in the AWS Neuron Documentation.

  Note
  The torchrun launcher option is currently available only for distributed training on Amazon EC2 Trn1 instances.

To train on the Trainium-powered instances, you only need to specify the code name of the Trn1 instances, ml.trn1.*, in string to the instance_type argument of the SageMaker PyTorch estimator class. To find available Trn1 instance types, see AWS Trn1 Architecture in the AWS Neuron Documentation.

  Note
  SageMaker Training on Amazon EC2 Trn1 instances is currently available only for PyTorch.

To operate torchrun for distributed training on Trn1 instances, add distribution={"torch_distributed": {"enabled": True}} to the PyTorch estimator.

The following code shows an example of constructing a SageMaker PyTorch estimator to run distributed training on two ml.trn1.32xlarge instances with the torch_distributed distribution option.

  Note
  To run your PyTorch training job on Trn1 instances with SageMaker, you should modify your training script to initialize process groups with the xla backend and use PyTorch/XLA. To support the XLA adoption process, the AWS Neuron SDK provides PyTorch Neuron that uses XLA to make conversion of PyTorch operations to Trainium instructions. To learn how to modify your training script, see Developer Guide for Training with PyTorch Neuron (torch-neuronx) in the AWS Neuron Documentation.

  ```python
  from sagemaker.pytorch import PyTorch
  estimator = PyTorch(
      ...
  )
  ```
Basic Distributed Training Concepts

SageMaker's distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.

- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: global batch size = (the number of model replicas) * (per-replica batch size). A single batch of global batch size is often referred to as the mini-batch in machine learning literature.

- **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.

- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker's distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library's runtime.

Training
• **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.

• **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.

• **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

### Instances and GPUs

• **Instances**: An AWS machine learning compute instance. These are also referred to as nodes.

• **Cluster size**: When using SageMaker’s distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between AWS ML compute instances, leading to higher device utilization and faster training times.

### Distributed Training Solutions

• **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as AWS ML Instances), and each processing node contains a replica of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

• **Model parallelism**: A strategy in distributed training where the model partitioned across multiple processing nodes (such as AWS ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

• **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

### Advanced Concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: **scaling model size** and **scaling training data**. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD).
In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called mini-batches. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you’re also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker’s distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

Train with Data Parallel and Model Parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:
• Change your model’s hyperparameters.
• Reduce the batch size.
• Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):
• On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
• SageMaker’s distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
  • Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
  • Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
  • Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
  • Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
  • TensorFlow mixed precision APIs in the TensorFlow documentation

Try reducing the input size:
• Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
• Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:
• Your model does not fit on a single device.
• Due to your model size, you’re facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:
• SageMaker’s Data Parallelism Library (p. 1695)
• SageMaker’s Model Parallelism Library (p. 1728)

Optimize Distributed Training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework’s distributed training documentation.
Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

Tip
Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-Batch Size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

- **Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour**, Goya et al.
- **PowerAI DDL**, Cho et al.
- **Scale Out for Large Minibatch SGD: Residual Network Training on ImageNet-1K with Improved Accuracy and Reduced Time to Train**, Codreanu et al.
- **ImageNet Training in Minutes**, You et al.
- **Large Batch Training of Convolutional Networks**, You et al.
- **Large Batch Optimization for Deep Learning: Training BERT in 76 Minutes**, You et al.
- **Accelerated Large Batch Optimization of BERT Pretraining in 54 minutes**, Zheng et al.
- **Deep Gradient Compression**, Lin et al.

Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.

Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer than you are willing to wait. Sometimes, the training doesn’t work at all because the model or the training data is too large. One solution is to increase the number of GPUs you
use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

**Note**
The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.

**Scaling from a Single Instance to Multiple Instances**

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK estimator function by setting your instance_count. For example, you can set instance_type = p3.16xlarge and instance_count = 2. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Availability Zones and Network Backplane

With multiple instances, it’s important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an AllReduce operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

Optimized GPU, Network, and Storage

The p3dn.24xlarge instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as pipe mode. For HPC loads like distributed training, we recommend Amazon FSx for your file storage.

Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker’s container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker's Data Parallelism Library

The SageMaker data parallelism library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

To resolve such overhead problems, SageMaker offers two distributed training options: SageMaker model parallelism and SageMaker data parallelism. This guide focuses on how to train models using the SageMaker data parallelism library.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

To track the latest updates of the library, see the SageMaker Distributed Data Parallel Release Notes in the SageMaker Python SDK documentation.
Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing AWS’s network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

Note
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

</tbody>
</table>
Using instance type p3dn.24xlarge and on 2, 4, and 8 node clusters:

- **BERT**: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- **MaskRCNN**: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using ml.p3dn.24xlarge instances. You can find the training code on the SageMaker examples website. The examples website also has benchmark training code for these models using TensorFlow 2.3.

**Optimal Bandwidth Use with Balanced Fusion Buffer**

SageMaker's distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing balanced fusion buffers. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with \( N \) parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into \( N \) parts, and the \( i \)th part is sent to the \( i \)th parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The \( i \)th server receives the \( i \)th partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass**

SageMaker's distributed data parallel library achieves optimal overlapping of the AllReduce operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs AllReduce in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.

- **Leverages CPUs**: The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
- **Improved GPU usage**: The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

**SageMaker Distributed Data Parallel Architecture**

The library supports larger compute instances that have 8 GPUs per node: ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
• The size of the global batch is \((\text{number of nodes in a cluster}) \times (\text{number of GPUs per node}) \times (\text{per batch shard})\).

• A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.

3. The library launches a training script on each worker.

4. The library manages copies of model weights and gradients from the workers at the end of every iteration.

5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.

To start using the SageMaker distributed data parallel library, see Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 1710) to set up a SageMaker estimator through Amazon SageMaker Python SDK, and Run a SageMaker Distributed Training Job with Data Parallelism (p. 1702) to adapt your training script using the SageMaker distributed data parallel library.

**Supported Frameworks, AWS Regions, and Instances Types**

Before using the SageMaker data parallelism library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

**Supported Frameworks**

The following tables show the deep learning frameworks and their versions that SageMaker and the SageMaker data parallelism library support. The SageMaker data parallelism library is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.
Note
To check the latest updates and release notes of the library, see also the SageMaker Data Parallel Release Notes in the SageMaker Python SDK documentation.

</tbody>
</table>

**Note**
The SageMaker data parallelism library v1.4.0 and later works as a backend of PyTorch distributed. In accordance with the change, the following smdistributed APIs for the PyTorch distributed package are deprecated.

- smdistributed.dataparallel.torch.distributed is deprecated. Use the `torch.distributed` package instead.
- smdistributed.dataparallel.torch.parallel.DistributedDataParallel is deprecated. Use the `torch.nn.parallel.DistributedDataParallel` API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker data parallelism library documentation in the SageMaker Python SDK documentation.

** The URLs of the binary files are for installing the SageMaker data parallelism library in custom containers. For more information, see Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 1713).

PyTorch Lightning

<table>

**Note**

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the PyTorch DLCs. When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide requirements.txt to install pytorch-lightning and lightning-bolts in the SageMaker PyTorch training container.

```python
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the requirements.txt file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

Hugging Face Transformers

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

AWS Regions

The SageMaker data parallelism library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

Supported Instance Types

The SageMaker data parallelism library requires one of the following ML instance types.

<table>
<thead>
<tr>
<th>Instance type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.p3.16xlarge</td>
</tr>
<tr>
<td>ml.p3dn.24xlarge</td>
</tr>
<tr>
<td>ml.p4d.24xlarge</td>
</tr>
<tr>
<td>ml.p4de.24xlarge</td>
</tr>
</tbody>
</table>

For specs of the instance types, see the Accelerated Computing section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```markdown
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.
```

Run a SageMaker Distributed Training Job with Data Parallelism

SageMaker's distributed data parallel library APIs are designed for ease of use and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API** – In most cases, all you have to change in your training script is the data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
Focus on your model training without infrastructure management – When training a deep learning model with the library on SageMaker, you can focus on writing your training script and model training. You can run a training job using estimator classes provided by the SageMaker Python SDK. The estimator classes help prepare ML instances, load datasets from specified data resources, submit the training job using your training script, and shut down the instances after the training job is completed.

To begin, you need to adapt TensorFlow or PyTorch training scripts to use the library. The following topics provide instructions on how to modify your training script.

Topics
• Step 1: Modify Your Own Training Script (p. 1703)
• Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 1710)

Step 1: Modify Your Own Training Script

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed data parallel library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker data parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed data parallel library, see Amazon SageMaker Distributed Training Notebook Examples (p. 1796).

Topics
• Modify a TensorFlow Training Script (p. 1703)
• Modify a PyTorch Training Script (p. 1705)
• Modify a PyTorch Lightning Script (p. 1708)

Modify a TensorFlow Training Script

The following steps show you how to modify a TensorFlow training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the SageMaker distributed data parallel TensorFlow API documentation.

Note
SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of tf core modules except tf.keras modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

Note
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

• Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
• Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
• TensorFlow mixed precision APIs in the TensorFlow documentation

1. Import the library's TensorFlow client and initialize it.
2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as `sdp.local_rank()`.

```python
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the following code block as `sdp.size()`.

```python
learning_rate = learning_rate * sdp.size()
```

4. Use the library's `DistributedGradientTape` to optimize AllReduce operations during training. This wraps `tf.GradientTape`.

```python
with tf.GradientTape() as tape:
    output = model(input)
    loss_value = loss(label, output)

# SageMaker data parallel: Wrap tf.GradientTape with the library's
# DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the following code block as `sdp.broadcast_variables()`.

```python
sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

```python
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

The following is an example TensorFlow training script for distributed training with the library.

```python
import tensorflow as tf
# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker data parallel: Initialize the library
sdp.init()
```
```python
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

    # SageMaker data parallel: Wrap tf.GradientTape with the library's
    DistributedGradientTape
    tape = sdp.DistributedGradientTape(tape)

    grads = tape.gradient(loss_value, mnist_model.trainable_variables)
    opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
        # SageMaker data parallel: Broadcast model and optimizer variables
        sdp.broadcast_variables(mnist_model.variables, root_rank=0)
        sdp.broadcast_variables(opt.variables(), root_rank=0)

    return loss_value

# SageMaker data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

After you have completed adapting your training script, move on to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 1710).

Modify a PyTorch Training Script

In the SageMaker data parallel library v1.4.0 and later, the library is available as a backend option for the PyTorch distributed package. You only need to import the library once at the top of your training script and set it as the PyTorch distributed backend during initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. To find the latest API documentation for the library, see the SageMaker distributed data parallel APIs for PyTorch in the SageMaker Python SDK documentation. To learn more about the PyTorch distributed package and backend options, see Distributed communication package - torch.distributed.

**Important**
Because the SageMaker distributed data parallelism library v1.4.0 and later works as a backend of PyTorch distributed, the following smdistributed APIs for the PyTorch distributed package are deprecated.
SageMaker's Data Parallelism Library

- `smdistributed.dataparallel.torch.distributed` is deprecated. Use the `torch.distributed` package instead.
- `smdistributed.dataparallel.torch.parallel.DistributedDataParallel` is deprecated. Use the `torch.nn.parallel.DistributedDataParallel` API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker distributed data parallel library documentation in the SageMaker Python SDK documentation.

Use the SageMaker Distributed Data Parallel Library as the Backend of `torch.distributed`

To use the SageMaker distributed data parallel library, the only thing you need to do is to import the SageMaker distributed data parallel library's PyTorch client (`smdistributed.dataparallel.torch.torch_smddp`). The client registers smddp as a backend for PyTorch. When you initialize the PyTorch distributed process group using the `torch.distributed.init_process_group` API, make sure you specify `smddp` to the backend argument.

```python
import smdistributed.dataparallel.torch.torch_smddp
import torch.distributed as dist
dist.init_process_group(backend='smddp')
```

**Note**
The smddp backend currently does not support creating subprocess groups with the `torch.distributed.new_group()` API. You cannot use the smddp backend concurrently with other process group backends such as NCCL and Gloo.

If you already have a working PyTorch script and only need to add the backend specification, you can proceed to Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 1711) in the Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 1710) topic.

If you still need to modify your training script to properly use the PyTorch distributed package, follow the rest of the procedures on this page.

**Preparing a PyTorch Training Script for Distributed Training**

The following steps provide additional tips on how to prepare your training script to successfully run a distributed training job using PyTorch.

**Note**
In v1.4.0, the SageMaker distributed data parallel library supports the following collective primitive data types of the `torch.distributed` interface: all_reduce, broadcast, reduce, all_gather, and barrier.

1. Import the PyTorch distributed modules.

```python
import torch
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP
```

2. After parsing arguments and defining a batch size parameter (for example, `batch_size=args.batch_size`), add two lines of code to resize the batch size per worker (GPU). PyTorch's DataLoader operation does not automatically handle the batch resizing for distributed training.

```python
batch_size //= dist.get_world_size()
batch_size = max(batch_size, 1)
```
3. Pin each GPU to a single SageMaker data parallel library process with local_rank—this refers to the relative rank of the process within a given node.

You can retrieve the rank of the process from the LOCAL_RANK environment variable.

```python
import os
local_rank = os.environ["LOCAL_RANK"]
torch.cuda.set_device(local_rank)
```

4. After defining a model, wrap it with the PyTorch DistributedDataParallel API.

```python
model = ...
# Wrap the model with the PyTorch DistributedDataParallel API
model = DDP(model)
```

5. When you call the torch.utils.data.distributed.DistributedSampler API, specify the total number of processes (GPUs) participating in training across all the nodes in the cluster. This is called world_size, and you can retrieve the number from the torch.distributed.get_world_size() API. Also, specify the rank of each process among all processes using the torch.distributed.get_rank() API.

```python
from torch.utils.data.distributed import DistributedSampler
train_sampler = DistributedSampler(
    train_dataset,
    num_replicas = dist.get_world_size(),
    rank = dist.get_rank()
)
```

6. Modify your script to save checkpoints only on the leader process (rank 0). The leader process has a synchronized model. This also avoids other processes overwriting the checkpoints and possibly corrupting the checkpoints.

```python
if dist.get_rank() == 0:
    torch.save(...)
```

The following example code shows the structure of a PyTorch training script with smddp as the backend.

```python
import os
import torch
# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.torch_smddp

# SageMaker data parallel: Import PyTorch's distributed API
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the process group
dist.init_process_group(backend='smddp')

class Net(nn.Module):
    ...
    # Define model

def train(...):
    ...
    # Model training
def test(...):
    ...
    # Model evaluation

def main():
    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size()
    batch_size = max(batch_size, 1)

    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)

    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())

    train_loader = torch.utils.data.DataLoader(..)

    # SageMaker data parallel: Wrap the PyTorch model with the library's DDP
    model = DDP(Net().to(device))

    # SageMaker data parallel: Pin each GPU to a single library process.
    local_rank = os.environ['LOCAL_RANK']
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)

    # Train
    optimizer = optim.Adadelta(...)
    scheduler = StepLR(...)
    for epoch in range(1, args.epochs + 1):
        train(...)
        if rank == 0:
            test(...)
        scheduler.step()

    # SageMaker data parallel: Save model on master node.
    if dist.get_rank() == 0:
        torch.save(...)

if __name__ == '__main__':
    main()
import pytorch_lightning as pl
import smdistributed.dataparallel.torch.torch_smddp

2. Set the world size and the rank for the LightningEnvironment class object. When launching a training job in SageMaker, the SageMaker training toolkit sets up the environment variables "RANK", "LOCAL_RANK", and "WORLD_SIZE". These environment variables represent the processes' global ranks, their local ranks, and the world size, respectively. Use these SageMaker environment variables to configure the LightningEnvironment.

    import os
    from pytorch_lightning.plugins.environments.lightning_environment \ 
        import LightningEnvironment

    env = LightningEnvironment()
    env.world_size = lambda: int(os.environ["WORLD_SIZE"])
    env.global_rank = lambda: int(os.environ["RANK"])

3. Set distributed training strategy using the PyTorch Lightning DDPStrategy module, create a PyTorch Lightning Trainer object, and adapt them to use the SageMaker data parallel library.

(Recommended) For PyTorch Lightning v1.6.0 and later

Create an object (ddp in the following code example) of the DDPStrategy class, and specify "smddp" to the process_group_backend parameter. When configuring a PyTorch Lightning Trainer object, use the SageMaker environment variables to specify the scale of the GPU cluster and the ddp object to set up the distributed training strategy.

    from pytorch_lightning.strategies import DDPStrategy

    ddp = DDPStrategy(
        cluster_environment=env,
        process_group_backend="smddp",
        accelerator="gpu"
    )

    world_size = int(os.environ["WORLD_SIZE"])
    num_gpus = int(os.environ["SM_NUM_GPUS"])
    num_nodes = int(world_size/num_gpus)

    trainer = pl.Trainer(
        devices=num_gpus,
        num_nodes=num_nodes,
        max_epochs=10,
        strategy=ddp
    )

(Optional) For PyTorch Lightning v1.5.10

If you are using DDPPlugin, which is a deprecated functionality, set the distributed strategy as shown in the following code example.

    from pytorch_lightning.plugins.training_type.ddp import DDPPlugin

    os.environ["PL_TORCH_DISTRIBUTED_BACKEND"] = "smddp"
ddp = DDPPlugin(
    parallel_devices=[torch.device("cuda", d) for d in range(num_gpus)],
    cluster_environment=env
)

world_size = int(os.environ["WORLD_SIZE"])
num_gpus = int(os.environ["SM_NUM_GPUS"])
num_nodes = int(world_size/num_gpus)

trainer = pl.Trainer(
    gpus=num_gpus,
    num_nodes=num_nodes,
    max_epochs=10,
    strategy=ddp
)

4. Run `trainer.fit` to start the training job of a PyTorch model. The following code example shows a PyTorch model object wrapped by the PyTorch Lightning Trainer's fit method with the PyTorch Lightning MNIST data module.

```python
from pl_bolts.datamodules import MNISTDataModule
trainer.fit(model, datamodule=MNISTDataModule(batch_size=32))
```

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 1710).

**Note**

When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide `requirements.txt` to install pytorch-lightning and lightning-bolts in the SageMaker PyTorch training container.

```bash
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

**Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK**

To run your adapted script in Step 1: Modify Your Own Training Script (p. 1703), start with creating a SageMaker framework or generic estimator object with the prepared training script and the distributed training configuration parameter. You can use the library in any kind of SageMaker environment and web IDEs, such as SageMaker notebook instance and SageMaker Studio.

Use the high-level SageMaker Python SDK to do one of the following:

- If you want to achieve a quick adoption of your distributed training job in SageMaker, configure a SageMaker PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the framework_version parameter.
- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker, use the SageMaker generic Estimator class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).
Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.

**Tip**
We highly recommend that you use Amazon FSx for Lustre instead of Amazon S3 to increase training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Choose one of the following topics for instructions on how to run your TensorFlow or PyTorch training scripts. After you launch a training job, you can monitor system utilization and model performance using Debug and Profile Training Jobs Using Amazon SageMaker Debugger (p. 1479) or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker Distributed Training Notebook Examples (p. 1796) to get started.

**Topics**
- Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 1711)
- Using the SageMaker Generic Estimator to Extend Prebuilt Containers (p. 1713)
- Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 1713)

**Using the SageMaker Framework Estimators For PyTorch and TensorFlow**

You can activate the SageMaker distributed data parallel library by specifying it as the distribution strategy in the SageMaker framework estimator class.

**SageMaker PyTorch**

```python
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    source_dir="sub-folder-for-your-code",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py38",
    framework_version="1.12.0",

    instance_count=2,
    instance_type="ml.p3.16xlarge",

    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**
PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the SageMaker PyTorch DLCs. Create the following requirements.txt file and save in the source directory where you save the training script.

```
# requirements.txt
```

1711
For example, the tree-structured directory should look like the following.

```py
### pytorch_training_launcher_jupyter_notebook.ipynb
### sub-folder-for-your-code
### adapted-training-script.py
### requirements.txt
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

### SageMaker TensorFlow

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.9.1",
    py_version="py38",

    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,...8
    instance_count=2,

    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",

    # Training using the SageMaker data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

The following two parameters of the SageMaker framework estimator are required to activate the SageMaker data parallelism.

- **distribution** (dict): A dictionary with information on how to run distributed training (default: None).
  - To use `smdistributed.dataparallel` as a distribution strategy, configure a dictionary as shown in the following code:
    ```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

- **custom_mpi_options** (str)(optional): Custom MPI options. The following is an example of how you can use this parameter when defining `distribution`. To learn more, see Custom MPI Options (p. 1722).

```python
distribution = {  
    "smdistributed": {  
        "dataparallel": {  
            "enabled": True,  
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
```

1712
instance_type (str): A type of Amazon EC2 instance to use.

- If using the smdistributed with dataparallel distribution strategy, you must use one of the following instance types: ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge. For best performance, we recommend that you use an EFA-enabled instance, which are ml.p3dn.24xlarge and ml.p4d.24xlarge.

Using the SageMaker Generic Estimator to Extend Prebuilt Containers

You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in Supported Frameworks (p. 1698).

Important

From TensorFlow 2.4.1 and PyTorch 1.8.1, the framework DLCs supports EFA-enabled instance types (ml.p3dn.24xlarge, ml.p4d.24xlarge). We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a FROM statement similar to the following:

```bash
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/pytorch-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"
# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

You can further customize your own Docker container to work with SageMaker using the SageMaker Training toolkit and the binary file of the SageMaker distributed data parallel library. To learn more, see the instructions in the following section.

Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library

To build your own Docker container for training and use the SageMaker data parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker using the data parallel library.

Note

This custom Docker option with the SageMaker data parallel library as a binary is available only for PyTorch.
To create a Dockerfile with the SageMaker training toolkit and the data parallel library

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

```bash
FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
```

**Tip**
The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

```
ARG PYTORCH_VERSION=1.10.2
ARG PYTHON_SHORT_VERSION=3.8
ARG EFA_VERSION=1.14.1
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/${PYTORCH_VERSION}/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-linux_x86_64.whl
ARG PT_S3_WHL_GPU=https://aws-s3-plugin.s3.us-west-2.amazonaws.com/binaries/0.0.1/1c3e69e/awsio-0.0.1-cp38-cp38-manylinux1_x86_64.whl
ARG CONDA_PREFIX="/opt/conda"
ARG BRANCH_OFI=1.1.3-aws
```

3. Set the following environment variables to properly build SageMaker training components and run the data parallel library. You use these variables for the components in the subsequent steps.

```
# Set ENV variables required to build PyTorch
ENV TORCH_CUDA_ARCH_LIST="7.0+PTX 8.0"
ENV TORCH_NVCC_FLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this environment variable for SageMaker to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add environment variable for processes to be able to call fork()
ENV RDMAV_FORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python${PYTHON_SHORT_VERSION}/site-packages/smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib:$LD_LIBRARY_PATH
```
4. Install or update curl, wget, and git to download and build packages in the subsequent steps.

```bash
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt
    apt-get update && apt-get install -y --no-install-recommends
    curl \\
    wget \\
    git \\
    && rm -rf /var/lib/apt/lists/*
```

5. Install Elastic Fabric Adapter (EFA) software for Amazon EC2 network communication.

```bash
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa \\
    && cd /tmp/efa \\
    && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-${EFA_VERSION}.tar.gz \\
    && tar -xf aws-efa-installer-${EFA_VERSION}.tar.gz \\
    && cd aws-efa-installer \\
    && ./efa_installer.sh -y --skip-kmod -g \\
    && rm -rf /tmp/efa
```

6. Install Conda to handle package management.

```bash
RUN curl -fsSL -v -o ~/miniconda.sh -O https://repo.anaconda.com/miniconda/Miniconda3-latest-Linux-x86_64.sh && \\
    chmod +x ~/miniconda.sh && \\
    ~/miniconda.sh -b -p $CONDA_PREFIX && \\
    rm ~/miniconda.sh && \\
    $CONDA_PREFIX/bin/conda install -y python=${PYTHON_SHORT_VERSION} conda-build pyyaml \\
    numpy ipython && \\
    $CONDA_PREFIX/bin/conda clean -ya
```

7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plugin.

a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```bash
RUN DEBIAN_FRONTEND=noninteractive \\
    apt-get install -y --no-install-recommends \\
    build-essential \\
    ca-certificates \\
    ccache \\
    cmake \\
    git \\
    libjpeg-dev \\
    libpng-dev \\
    && rm -rf /var/lib/apt/lists/*

# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch's common and Linux dependencies.

```bash
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja ccade mkl mkl-include setuptools cmake cffi \\
    typing_extensions future six requests dataclasses

# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cudat13
```
c. Clone the PyTorch GitHub repository.

```bash
RUN --mount=type=cache,target=/opt/ccache
cd / \n&& git clone --recursive https://github.com/pytorch/pytorch -b v${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch's default NCCL folder (/pytorch/third_party/nccl) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```bash
RUN cd /pytorch/third_party/nccl \n&& rm -rf nccl \n&& git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \n&& cd nccl \n&& make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \n&& make pkg.txz.build \n&& tar -xvf build/pkg/txz/nccl_*.txz -C $CONDA_PREFIX --strip-components=1
```

e. Build and install PyTorch. This process usually takes slightly more than one hour to complete. It is built using the NCCL version downloaded in a previous step.

```bash
RUN cd /pytorch \n&& CMAKE_PREFIX_PATH="$(dirname $(which conda))/../" python setup.py install \n&& rm -rf /pytorch
```

8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker data parallel library.

```bash
RUN DEBIAN_FRONTEND=noninteractive apt-get update \n&& apt-get install -y --no-install-recommends \n  autoconf \n  automake \n  libtool
RUN mkdir /tmp/efa-ofi-nccl \n&& cd /tmp/efa-ofi-nccl \n&& git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \n&& cd aws-ofi-nccl \n&& ./autogen.sh \n&& ./configure --with-libfabric=/opt/amazon/efa \n  --with-mpi=/opt/amazon/openmpi \n  --with-cuda=/usr/local/cuda \n  --with-nccl=$CONDA_PREFIX \n&& make \n&& make install \n&& rm -rf /tmp/efa-ofi-nccl
```

```bash
RUN pip install --no-cache-dir -U \n  packaging \n  mpi4py==3.0.3
RUN cd /tmp \n&& git clone https://github.com/pytorch/vision.git -b v0.9.1 \n&& cd vision \n&& BUILD_VERSION="0.9.1+cu111" python setup.py install \n&& cd /tmp \n&& rm -rf vision
```
10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

```bash
RUN apt-get update \\
    && apt-get install -y --allow-downgrades --allow-change-held-packages --no-install-recommends \\
    && apt-get install -y --no-install-recommends openssh-client openssh-server \\
    && mkdir -p /var/run/sshd \\
    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/ssh_config.new \\
    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \\
    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \\
    && rm -rf /var/lib/apt/lists/*
```

```
# Configure OpenSSH so that nodes can communicate with each other
RUN mkdir -p /var/run/sshd && \\
    sed 's@session\s*required\s*pam_loginuid.so@session optional pam_loginuid.so@g' -i etc/pam.d/sshd
```

```
RUN rm -rf /root/.ssh/ && \\
    mkdir -p /root/.ssh/ && \\
    ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa && \\
    cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys \\
    && printf "Host *\n    StrictHostKeyChecking no\n" >> /root/.ssh/config
```

11. Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

```bash
RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU}
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/tls/certs/ca-bundle.crt
```

12. Install the `libboost` library. This package is needed for networking the asynchronous IO functionality of the SageMaker data parallel library.

```bash
WORKDIR /
RUN wget https://sourceforge.net/projects/boost/files/boost/1.73.0/boost_1_73_0.tar.gz/download -O boost_1_73_0.tar.gz \\
    && tar -xzf boost_1_73_0.tar.gz \\
    && cd boost_1_73_0 \\
    && ./bootstrap.sh \\
    && ./b2 threading=multi --prefix=${CONDA_PREFIX} -j 64 cxxflags=-fPIC cflags=-fPIC install || true \\
    && cd .. \\
    && rm -rf boost_1_73_0.tar.gz \\
    && rm -rf boost_1_73_0 \\
    && cd ${CONDA_PREFIX}/include/boost
```

13. Install the following SageMaker tools for PyTorch training.

```bash
WORKDIR /root
RUN pip install --no-cache-dir -U \n    smclarify \n    "sagemaker>=2,<3" \n    sagemaker-experiments==0.* \n    sagemaker-pytorch-training
```

14. Finally, install the SageMaker data parallel binary and the remaining dependencies.

```bash
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \\
    apt-get update && apt-get install -y --no-install-recommends \\
    jq \\
    libhwloc-dev \\
    libnuma1
```
After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```bash
# This file creates a docker image with minimum dependencies to run SageMaker data parallel training

**Tip**
For more general information about creating a custom Dockerfile for training in SageMaker, see
Use Your Own Training Algorithms.

**Tip**
If you want to extend the custom Dockerfile to incorporate the SageMaker model parallel library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 1759).

**SageMaker Distributed Data Parallel Configuration Tips and Pitfalls**

Review the following tips and pitfalls before using SageMaker's distributed data parallel library. This list includes tips that are applicable across frameworks.

**Topics**
- Data Preprocessing (p. 1722)
- Single Versus Multiple Nodes (p. 1722)
- Debug Scaling Efficiency with Debugger (p. 1722)
- Batch Size (p. 1722)
- Custom MPI Options (p. 1722)
Data Preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for AllReduce operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single Versus Multiple Nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library's AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as CPUBottleneck, LoadBalancing, and LowGPUUtilization. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a Linear Scaling Rule where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.

Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the mpirun command to start jobs on the cluster nodes.

You can set custom MPI operations using the custom_mpi_options parameter in the Estimator. Any mpirun flags passed in this field are added to the mpirun command and executed by SageMaker for training. For example, you may define the distribution parameter of an Estimator using the following to use the NCCL_DEBUG variable to print the NCCL version at the start of the program:

distribution = {'smdistributed': {'dataparallel': {'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the SCRATCH_2 deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SCRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the Amazon FSx for Lustre documentation:

- How to increase storage capacity
- Aggregate file system performance

Amazon SageMaker Data Parallel Library FAQ

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8-node ml.p3dn.24xlarge clusters, only 8 ml.p3dn.24xlarge instances are used. No additional instances are provisioned.

Q: I have a training job taking 5 days on a single ml.p3.24xlarge instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the library?
The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

Q: Does the library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called “TensorFlow” (p. 1703) and the section called “PyTorch” (p. 1705).

Q: Is the library relevant in a single-host, multi-device setup?

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

Q: Where should the training dataset be stored?

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.

Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

Q: Can the library be used with CPU nodes?

No. The library supports ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances at this time.

Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
- Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
- TensorFlow mixed precision APIs in the TensorFlow documentation

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput...
requirement and more complex network topology. For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the FSx for Lustre User Guide.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity (p. 1723).

Q: (For the library v1.4.0 or later) How do I resolve the Invalid backend error while initializing process group.

If you encounter the error message ValueError: Invalid backend: 'smddp' when calling init_process_group, this is due to the breaking change in the library v1.4.0 and later. You must import the PyTorch client of the library, smdistributed.dataparallel.torch.torch_smddp, which registers smddp as a backend for PyTorch. To learn more, see Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed (p. 1706).

Q: (For the library v1.4.0 or later) I would like to call the collective primitives of the torch.distributed interface. Which primitives does the smddp backend support?

In v1.4.0, the library supports all_reduce, broadcast, reduce, all_gather, and barrier.

Q: (For the library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SageMaker data parallel library is tested with other third-party distributed data parallel libraries and framework implementations that use the torch.distributed modules. Using the SageMaker data parallel library with custom DDP classes works as long as the collectives used by the custom DDP classes are supported by the library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker team through the AWS Support Center or AWS Developer Forums for Amazon SageMaker.

Q: Does the library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SageMaker data parallel library and its minimum dependencies in your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker with the SageMaker data parallel library, see Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 1713).

Data Parallel Troubleshooting

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker team through AWS Support Center or AWS Developer Forums for Amazon Amazon SageMaker.

Topics

- Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 1726)
- An Unexpected Prefix Attached to Model Parameter Keys (p. 1726)
- SageMaker Distributed Training Job Stalling During Initialization (p. 1727)
Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, use Amazon SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following example.

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework `estimator` example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket=s3://{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

estimator = TensorFlow(...
    distribution={"smdistributed": { "dataparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
}
```

- If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see Saving Checkpoints (p. 1793).

An Unexpected Prefix Attached to Model Parameter Keys

For PyTorch distributed training jobs, an unexpected prefix (model for example) might be attached to `state_dict` keys (model parameters). The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```
This takes each state_dict key as a string value, separates the string at the first occurrence of 'model.', and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the PyTorch discussion forum.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the PyTorch documentation.

**SageMaker Distributed Training Job Stalling During Initialization**

If your SageMaker distributed data parallel training job stalls during initialization when using EFA-enabled instances (ml.p3dn.24xlarge and ml.p4d.24xlarge), this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

**To configure inbound and outbound rules for the security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Security Groups in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the Details section, copy the Security group ID.
6. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source, choose Custom, paste the security group ID into the search box, and select the security group that pops up.
7. Choose Save rules to finish configuring the inbound rule for the security group.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.

After you complete the preceding steps for configuring the security group with the inbound and outbound rules, rerun the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

**SageMaker Distributed Training Job Stalling at the End of Training**

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.
Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see Aggregate file system performance and Managing storage and throughput capacity in the Amazon FSx for Lustre User Guide.

SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings

Since v1.4.0, the SageMaker distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the smdistributed APIs for the PyTorch distributed package are deprecated. The warning message should be similar to the following:

```python
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker distributed data parallel library v1.4.0+.
Please use torch.distributed and specify 'smddp' as a backend when initializing process group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at
```

In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See Modify a PyTorch Training Script (p. 1705) to learn about the breaking changes and the new way to use the library with PyTorch.

SageMaker's Model Parallelism Library

Use Amazon SageMaker's model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.

You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the SageMaker Python SDK documentation.

To track the latest updates of the library, see the SageMaker Model Parallel Release Notes in the SageMaker Python SDK documentation.

Introduction to Model Parallelism

Model parallelism is a distributed training method in which the deep learning model is partitioned across multiple devices, within or across instances. This introduction page provides a high-level overview about model parallelism, a description of how it can help overcome issues that arise when training DL models that are typically very large in size, and examples of what the SageMaker model parallel library offers to help manage model parallel strategies as well as memory consumption.

What is Model Parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model you can train, since the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve most optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate Memory Requirements Before Using Model Parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses AMP (FP16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 parameter ~ 2 bytes
- An FP16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the optimizer apply (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory and V100 with 16/32 GB) available on a single GPU. Note that on top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P3 and P4 instances that have NVIDIA A100 or V100 Tensor Core GPUs. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the Accelerated Computing section in the Amazon EC2 Instance Types page.
Even with the accelerated computing instances, it is obvious that models with about 10 billion parameters such as Megatron-LM and T5 and even larger models with hundreds of billions of parameters such as GPT-3 cannot fit model replicas in each GPU device.

How the Library Employs Model Parallelism and Memory Saving Techniques

The library consists of two types of model parallelism features, pipeline parallelism and tensor parallelism, as well as other memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models, such as GPT-2, consisting of hundreds of billions of parameters.

Topics
- Pipeline parallelism (p. 1730)
- Tensor parallelism (available for PyTorch) (p. 1731)
- Optimizer state sharding (available for PyTorch) (p. 1734)
- Activation offloading and checkpointing (available for PyTorch) (p. 1736)
- Choosing the right techniques for your model (p. 1736)

Pipeline parallelism

Pipeline parallelism partitions the set of layers or operations across the set of devices, leaving each operation intact. When you specify a value for the number of model partitions (pipeline_parallel_degree), the total number of GPUs (processes_per_host) must be divisible by the number of the model partitions. To set this up properly, you have to specify the correct values for the pipeline_parallel_degree and processes_per_host parameters. The simple math is as follows:

\[(\text{pipeline_parallel_degree}) \times (\text{data_parallel_degree}) = \text{processes_per_host}\]

The library takes care of calculating the number of model replicas (also called data_parallel_degree) given the two input parameters you provide.

For example, if you set "pipeline_parallel_degree": 2 and "processes_per_host": 8 to use an ML instance with eight GPU workers such as ml.p3.16xlarge, the library automatically sets up the distributed model across the GPUs and four-way data parallelism. The following image illustrates how a model is distributed across the eight GPUs achieving four-way data parallelism and two-way pipeline parallelism. Each model replica, where we define it as a pipeline parallel group and label it as PP_GROUP, is partitioned across two GPUs. Each partition of the model is assigned to four GPUs, where the four partition replicas are in a data parallel group and labeled as DP_GROUP. Without tensor parallelism, the pipeline parallel group is essentially the model parallel group.
To dive deep into pipeline parallelism, see Core Features of the SageMaker Model Parallelism Library (p. 1738).

To get started with running your model using pipeline parallelism, see Run a SageMaker Distributed Training Job with the SageMaker Model Parallel Library.

Tensor parallelism (available for PyTorch)

Tensor parallelism splits individual layers, or nn.Modules, across devices, to be run in parallel. The following figure shows the simplest example of how the library splits a model with four layers to achieve two-way tensor parallelism ("tensor_parallel_degree": 2). The layers of each model replica are bisected and distributed into two GPUs. In this example case, the model parallel configuration also
includes "pipeline_parallel_degree": 1 and "ddp": True (uses PyTorch DistributedDataParallel package in the background), so the degree of data parallelism becomes eight. The library manages communication across the tensor-distributed model replicas.
The usefulness of this feature is in the fact that you can select specific layers or a subset of layers to apply tensor parallelism. To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of pipeline and tensor parallelism, see Extended Features of the SageMaker Model Parallel Library for PyTorch (p. 1761).

Optimizer state sharding (available for PyTorch)

To understand how the library performs optimizer state sharding, consider a simple example model with four layers. The key idea in optimizing state sharding is you don't need to replicate your optimizer state in all of your GPUs. Instead, a single replica of the optimizer state is sharded across data-parallel ranks, with no redundancy across devices. For example, GPU 0 holds the optimizer state for layer one, the next GPU 1 holds the optimizer state for L2, and so on. The following animated figure shows a backward propagation with the optimizer state sharding technique. At the end of the backward propagation, there's compute and network time for the optimizer apply (OA) operation to update optimizer states and the all-gather (AG) operation to update the model parameters for the next iteration. Most importantly, the reduce operation can overlap with the compute on GPU 0, resulting in a more memory-efficient and faster backward propagation. In the current implementation, AG and OA operations do not overlap with compute. It can result in an extended computation during the AG operation, so there might be a tradeoff.
Sample model with

Optimizer State for L1

L1  L2  L3  L4

GPU 0
For more information about how to use this feature, see Optimizer State Sharding.

Activation offloading and checkpointing (available for PyTorch)

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, the activation offloading feature offloads the stored activations to CPU memory and fetches back to GPU during the backward pass to further reduce activation memory footprint. For more information about how to use these features, see Activation Checkpointing and Activation Offloading.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see SageMaker Distributed Model Parallel Best Practices and Configuration Tips and Pitfalls.

Supported Frameworks and AWS Regions

Before using the SageMaker model parallelism library, check the supported frameworks and instance types, and determine if there are enough quotas in your AWS account and AWS Region.

**Note**

To check the latest updates and release notes of the library, see the SageMaker Model Parallel Release Notes in the SageMaker Python SDK documentation.

Supported Frameworks

The SageMaker model parallelism library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

Core Features of the SageMaker Model Parallelism Library

Amazon SageMaker's model parallelism library makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting
algorithms can optimize for speed or memory consumption. The library also supports manual partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or TensorFlow estimators. Use the following sections to learn more about these core features of the library.

**Note**

The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

### Automated Model Splitting

When you use SageMaker's model parallelism library, you can take advantage of automated model splitting, also referred to as automated model partitioning. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

#### How It Works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.

**Automated Model Splitting with PyTorch**

During the first training step, the model parallelism library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameter` size and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.
Automated Model Splitting with TensorFlow

The model parallelism library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallelism parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

Comparison of Automated Model Splitting Between Frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore the model parallelism library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using `smp.partition` context managers.

To use this option, set `auto_partition` to `False`, and define a `default_partition` in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallelism library creates a pipelined execution schedule automatically.

Pipeline Execution Schedule

A core feature of SageMaker's model parallelism library is *pipelined execution*, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A *microbatch* is a smaller
subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by
which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU $i$ might perform
(forward or backward) computation on microbatch $b$ while GPU $i+1$ performs computation on
microbatch $b+1$, thereby keeping both GPUs active at the same time. During a single forward or
backward pass, execution flow for a single microbatch might visit the same device multiple times,
depending on the partitioning decision. For instance, an operation that is at the beginning of the model
might be placed on the same device as an operation at the end of the model, while the operations in
between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using
the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve
better performance by utilizing the GPUs more efficiently.

**Interleaved Pipeline**

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This
allows quicker release of the memory used for activations, using memory more efficiently. It also allows
for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each
device alternates between running forward and backward passes. This means that the backward pass of
one microbatch may run before the forward pass of another microbatch finishes.

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs.
In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass
for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes
backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of
the memory used for activations earlier.

**Simple Pipeline**

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting
the backward pass. This means that it only pipelines the forward pass and backward pass stages within
themselves. The following figure illustrates an example of how this works, over 2 GPUs.

**Pipelining Execution in Specific Frameworks**

Use the following sections to learn about the framework-specific pipeline scheduling decisions
SageMaker’s model parallelism library makes for Tensorflow and PyTorch.

**Pipeline Execution with TensorFlow**

The following image is an example of a TensorFlow graph partitioned by the model parallelism library,
using automated model splitting. When a graph is split, each resulting subgraph is replicated $B$ times
(except for the variables), where $B$ is the number of microbatches. In this figure, each subgraph is
replicated 2 times ($B=2$). An `SMPInput` operation is inserted at each input of a subgraph, and an
`SMPOutput` operation is inserted at each output. These operations communicate with the library
backend to transfer tensors to and from each other.
The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a SMPInput op is a SMPOutput op, and vice versa. This enables the gradients to flow backwards during back-propagation.

This GIF demonstrates an example interleaved pipeline execution schedule with B=2 microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As B grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue SMPInput operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallelism library's PyTorch feature uses a more dynamic pipelining paradigm.
As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

### Run a SageMaker Distributed Training Job with Model Parallelism

Learn how to run a model parallel training job using the SageMaker Python SDK with your own training script and SageMaker's model parallelism library.

There are three use-case scenarios for running a SageMaker training job:

1. You can use one of the prebuilt AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see MNIST with PyTorch 1.6 and Amazon SageMaker's model parallelism library.

2. You can extend the prebuilt containers to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

3. You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library (p. 1758) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker TensorFlow or PyTorch estimator to initialize the library. To learn more, see the following topics.

**Topics**

- Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library (p. 1743)
- Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 1755)

**Step 1: Modify Your Own Training Script Using SageMaker’s Distributed Model Parallel Library**

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker model parallelism library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker model parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that
demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker Distributed Training Notebook Examples (p. 1796).

Topics
- Modify a TensorFlow Training Script (p. 1744)
- Modify a PyTorch Training Script (p. 1749)

Modify a TensorFlow Training Script

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

Note
To find which TensorFlow versions are supported by the library, see the section called “Supported Frameworks and AWS Regions” (p. 1736).

The required modifications you must make to your training script to use the library are listed in TensorFlow (p. 1744).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 1746).

If you want to use manual partitioning, also review Manual partitioning with TensorFlow (p. 1748).

Tip
For end-to-end notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker model parallelism library, see TensorFlow Examples (p. 1797).

The following topics show examples of training scripts that you can use to configure SageMaker's model parallelism library for auto-partitioning and manual partitioning TensorFlow models.

Note
Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics
- TensorFlow (p. 1744)
- TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 1746)
- Manual partitioning with TensorFlow (p. 1748)
- Unsupported Framework Features (p. 1749)

TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's model parallelism library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.
4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.

5. Put the forward and backward logic in a step function and decorate it with `smp.step`.

6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.

7. If there is an evaluation step, similarly place the forward logic inside an `smp.step-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

The following Python script is an example of a training script after the changes are made.

```python
import tensorflow as tf

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data('MNIST-data-%d' % smp.rank())
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank()).batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return the model output

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
```

1745
return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    train_accuracy.merge(predictions)
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()
operation inside `smp.step`. We recommend you to use the model parallelism library with Horovod by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as will be shown in the following example.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```python
import tensorflow as tf
import horovod.tensorflow as hvd

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers
        def call(self, x, training=None):
            # define forward pass and return model outputs
            model = MyModel()

            loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
            optimizer = tf.keras.optimizers.Adam()
            train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

            # smdistributed: Define smp.step. Return any tensors needed outside
            @smp.step
            def get_grads(images, labels):
                predictions = model(images, training=True)
                loss = loss_object(labels, predictions)
                grads = optimizer.get_gradients(loss, model.trainable_variables)
                return grads, loss, predictions

            @tf.function
            def train_step(images, labels, first_batch):
                gradients, loss, predictions = get_grads(images, labels)

                # smdistributed: Accumulate the gradients across microbatches
                # Horovod: Allreduce the accumulated gradients
```
gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
optimizer.apply_gradients(zip(gradients, model.trainable_variables))

# Horovod: Broadcast the variables after first batch
if first_batch:
    hvd.broadcast_variables(model.variables, root_rank=0)
    hvd.broadcast_variables(optimizer.variables(), root_rank=0)

# smdistributed: Merge predictions across microbatches
train_accuracy(labels, predictions.merge())
return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

Manual partitioning with TensorFlow

Use sm.partition context managers to place operations in specific partition. Any operation not placed in any sm.partition contexts is placed in the default_partition. To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

import tensorflow as tf
# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers

    def call(self, x):
        with smp.partition(0):
            x = self.layer0(x)
        with smp.partition(1):
            return self.layer1(x)
model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smpdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)
    # smpdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    # smpdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()

Unsupported Framework Features

The following TensorFlow features are not supported by the library:

- tf.GradientTape() is currently not supported. You can use Optimizer.get_gradients() or Optimizer.compute_gradients() instead to compute gradients.
- The tf.train.Checkpoint.restore() API is currently not supported. For checkpointing, use smp.CheckpointManager instead, which provides the same API and functionality. Note that checkpoint restores with smp.CheckpointManager should take place after the first step.

Modify a PyTorch Training Script

In this section, you learn how to modify PyTorch training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning.

Note
To find which PyTorch versions are supported by the library, see the section called “Supported Frameworks and AWS Regions” (p. 1736).

Tip
For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker model parallelism library, see PyTorch Examples (p. 1797).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.
Topics

- PyTorch (p. 1750)
- Manual Partitioning with PyTorch (p. 1752)
- Important Considerations (p. 1753)
- Unsupported Framework Features (p. 1755)

**PyTorch**

The following training script changes are required to run a PyTorch training script with SageMaker's model parallelism library:

1. Import and initialize the library with `smdistributed.modelparallel.torch.init()`.
2. Wrap the model with `smdistributed.modelparallel.torch.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

   **Note**
   For FP16 training, you need to use the `smdistributed.modelparallel.torch.model_creation()` context manager to wrap the model. For more information, see [FP16 Training with Model Parallelism](p. 1777).

3. Wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`.

   **Note**
   For FP16 training, you need to set up static or dynamic loss scaling. For more information, see [FP16 Training with Model Parallelism](p. 1777).

4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smdistributed.modelparallel.torch.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
9. Perform post-processing on the outputs across microbatches using StepOutput methods such as `reduce_mean`.
10. If there is an evaluation step, similarly place the forward logic inside an `smp.step-decorated function and post-process the outputs using StepOutput API.
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchtext.dataset import SplitDataset
from torchvision import datasets
from smdistributed.modelparallel.torch as smp
```
```python
class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

        # smdistributed: Define smp.step. Return any tensors needed outside.
        @smp.step
        def train_step(model, data, target):
            output = model(data)
            loss = F.nll_loss(output, target, reduction="mean")
            model.backward(loss)
            return output, loss

    def train(model, device, train_loader, optimizer):
        model.train()
        for batch_idx, (data, target) in enumerate(train_loader):
            # smdistributed: Move input tensors to the GPU ID used by the current process,
            # based on the set_device call.
            data, target = data.to(device), target.to(device)
            optimizer.zero_grad()
            # Return value, loss_mb is a StepOutput object
            _, loss_mb = train_step(model, data, target)
            # smdistributed: Average the loss across microbatches.
            loss = loss_mb.reduce_mean()
            optimizer.step()

        # smdistributed: initialize the backend
        smp.init()

        # smdistributed: Set the device to the GPU ID used by the current process.
        # Input tensors should be transferred to this device.
        torch.cuda.set_device(smp.local_rank())
        device = torch.device("cuda")

        # smdistributed: Download only on a single process per instance.
        # When this is not present, the file is corrupted by multiple processes trying
        # to download and extract at the same time
        dataset = datasets.MNIST("../data", train=True, download=False)

        # smdistributed: Shard the dataset based on data-parallel ranks
        if smp.dp_size() > 1:
            partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
            dataset = SplitDataset(dataset, partitions=partitions_dict)
            dataset.select(f"{smp.dp_rank()}")

        # smdistributed: Set drop_last=True to ensure that batch size is always divisible
        # by the number of microbatches
        train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

        model = GroupedNet()
        optimizer = optim.Adadelta(model.parameters(), lr=4.0)

        # smdistributed: Use the DistributedModel container to provide the model
        # to be partitioned across different ranks. For the rest of the script,
        # the returned DistributedModel object should be used in place of
        # the model provided for DistributedModel class instantiation.
        model = smp.DistributedModel(model)
        optimizer = smp.DistributedOptimizer(optimizer)
```

1751
train(model, device, train_loader, optimizer)

**Manual Partitioning with PyTorch**

Use `smp.partition` context managers to place modules in specific devices. Any module not placed in any `smp.partition` contexts is placed in the `default_partition`. The `default_partition` needs to be provided if `auto_partition` is set to `False`. The modules that are created within a specific `smp.partition` context are placed on the corresponding partition.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        with smp.partition(0):
            # define child modules on device 0
        with smp.partition(1):
            # define child modules on device 1

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

        # smdistributed: initialize the backend
        smp.init()

        # smdistributed: Set the device to the GPU ID used by the current process.
        # Input tensors should be transferred to this device.
        torch.cuda.set_device(smp.local_rank())
        device = torch.device("cuda")
```
Important Considerations

When you configure a PyTorch training script using SageMaker's model parallelism library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library's communication basic data types to do this.

- All torch.Tensor arguments to the forward methods of the nn.Modules in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a torch.Tensor argument to a module on which the module output does not depend.

- The argument to the smp.DistributedModel.backward() call must depend on all model outputs. In other words, there cannot be an output from the smp.DistributedModel.forward call that is not used in the computation of the tensor that is fed into the smp.DistributedModel.backward call.

- If there are torch.cuda.synchronize() calls in your code, you might need to call torch.cuda.set_device(smp.local_rank()) immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.

- Since the library places nn.Modules on different devices, the modules in the model must not depend on any global state that is modified inside smp.step. Any state that remains fixed throughout training, or that is modified outside smp.step in a way that is visible to all processes, is allowed.

- You don't need to move the model to GPU (for example, using model.to(device)) when using the library. If you try to move the model to GPU before the model is partitioned (before the first smp.step call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallelism library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.
• If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.

• The weight update (optimizer.step()) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.

• When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not participating in the step.

• If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```python
dataloader = torch.utils.data.DataLoader(
    data,
    batch_size=batch_size,
    num_workers=0,
    pin_memory=True,
    drop_last=True,
    shuffle=shuffle,
)
```

• The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

For example, if you define a `DataLoader` as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...,
        loss_mb = train_step(model, data, target)
        ...

@smp.step
def train_step(model, data, target):
    ...
    return output, loss
```

• The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

For example, you may define the `train` function as follows. This function adds data and target to the current device using `.to()` API before using those input tensors to call `train_step`.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process, # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
```

1754
# smdistributed: Average the loss across microbatches.
loss = loss_mb.reduce_mean()

optimizer.step()

The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does not need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```python
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker's model parallelism library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.

- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in `torch`.

- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.

- `apex`: `FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from `apex` are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn` APIs instead.

Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a SageMaker TensorFlow estimator, a SageMaker PyTorch estimator, or a SageMaker generic Estimator to use the modified training script and model parallelism configuration.

Topics

- Using the SageMaker TensorFlow and PyTorch Estimators (p. 1755)
- Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library (p. 1758)
- Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 1759)

Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the `distribution` parameter, which you can use to specify configuration parameters for using distributed training frameworks. The SageMaker model
parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the distribution parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled": True,  # Required
    "parameters": {
        "partitions": 2,  # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,  # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8,  # Required
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {
            "modelparallel": smp_options,
            "mpi": mpi_options
        },
        base_job_name="SMD-MP-demo",
    }
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/
```

Using the SageMaker PyTorch estimator

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,  # Required
    "parameters": {
        "pipeline_parallel_degree": 2,  # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
    }
}

mpi_options = {
...
```

1756
To enable the library, you need to pass configuration dictionaries to the "smdistributed" and "mpi" keys through the distribution argument of the SageMaker estimator constructors.

**Configuration parameters for SageMaker model parallelism**

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.
  
  **Note**
  
  Using "modelparallel" and "dataparallel" in one training job is not supported.

- "enabled" – Required. To enable model parallelism, set "enabled": True.

- "parameters" – Required. Specify a set of parameters for SageMaker model parallelism.

- For a complete list of common parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

  For TensorFlow, see TensorFlow-specific Parameters.

  For PyTorch, see PyTorch-specific Parameters.

- "pipeline_parallel_degree" (or "partitions" in smdistributed-modelparallel<1.6.0) – Required. Among the parameters for smdistributed, this parameter is required to specify how many model partitions you want to split into.

  **Important**
  
  There is a breaking change in the parameter name. The "pipeline_parallel_degree" parameter replaces the "partitions" since smdistributed-modelparallel v1.6.0. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

- For the "mpi" key, pass a dictionary that contains the following:

  - "enabled" – Required. Set True to launch the distributed training job with MPI.

  - "processes_per_host" – Required. Specify the number of processes MPI should launch on each host. In SageMaker a host is a single Amazon EC2 ML instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through torch.cuda.set_device(smp.local_rank()). To learn more, see PyTorch (p. 1750).
Important

process_per_host must not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

- "custom_mpi_options" (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```bash
--mca btl_vader_single_copy_mechanism none
```

Note

You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:

The following MCA parameter has been listed multiple times on the command line:
MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed once on a command line to ensure there is no ambiguity as to its value.
Please correct the situation and try again.

Tip

If you launch a training job using an EFA-enabled instance type, such as ml.p4d.24xlarge and ml.p3dn.24xlarge, use the following flag for best performance:

```bash
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the estimator.fit() function.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker Distributed Training Notebook Examples (p. 1796).

You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see set up your AWS credentials and Region for development.

### Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library

To extend a prebuilt container and use SageMaker's model parallelism library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker model parallelism library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (cuxyz). For a complete list of DLC images, see Available Deep Learning Containers Images in the AWS Deep Learning Containers GitHub repository.

Tip

We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker model parallelism library.

For example, your Dockerfile should contain a FROM statement similar to the following:
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...
ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the entry_point for your training script. This should be the same path identified with ENV SAGEMAKER_SUBMIT_DIRECTORY in your Dockerfile.

**Tip**
You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (image_uri) to define a SageMaker estimator for training. For more information, see [Extend a Prebuilt Container](#).

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker PyTorch estimator object as follows. This example assumes that you have already defined smp_options and mpi_options.

```python
smd_mp_estimator = Estimator(
    entry_point="your_training_script.py",
    role=sagemaker.get_execution_role(),
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='your_aws_account_id.dkr.ecr.{region}.amazonaws.com/name:tag'
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

**Note**
This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

   FROM <cuda-cudnn-base-image>
Tip

The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (cuxyz) folder, and choose the Dockerfile ending with .gpu or .sagemaker.gpu.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

Important

Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 1713) to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-linux_x86_64.whl

4. Install dependencies that the SageMaker model parallel library requires.

a. Install the METIS library.

**ARG** METIS=metis-5.1.0

**RUN** rm /etc/apt/sources.list.d/*
&& gunzip -f $(METIS).tar.gz 
&& tar -xvf $(METIS).tar 
&& cd $(METIS) 
&& apt-get update 
&& make config shared=1 
&& make install 
&& cd ..
&& rm -rf $(METIS).tar* 
&& rm -rf $(METIS) 
&& rm -rf /var/lib/apt/lists/* 
&& apt-get clean

b. Install the RAPIDS Memory Manager library. This requires CMake 3.14 or later.

**ARG** RMM_VERSION=0.15.0

**RUN** wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz 
&& tar -xvf v${RMM_VERSION}.tar.gz 
&& cd rmm-${RMM_VERSION} 
&& INSTALL_PREFIX=/usr/local ./build.sh librmm 
&& cd ..
5. Install the SageMaker model parallel library.

```bash
RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}
```

6. Install the SageMaker data parallel library.

```bash
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

7. Install the `sagemaker-training toolkit`. The toolkit contains the common functionality that's necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

```bash
RUN pip install sagemaker-training
```

8. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container and host it in Amazon ECR.

**Tip**
For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

### Extended Features of the SageMaker Model Parallel Library for PyTorch

In addition to its core features, the SageMaker model parallelism library offers memory-saving features for training deep learning models with PyTorch: tensor parallelism, optimizer state sharding, activation checkpointing, and activation offloading.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

For each of the following features, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism (p. 1743) section and add few additional parameters and code lines to the SageMaker PyTorch estimator and your training script.

To find an example of how to use the extended features, see Train GPT-2 with PyTorch 1.8.1 and Tensor Parallelism Using the SageMaker Model Parallelism Library.

**Topics**

- Tensor Parallelism (p. 1762)
- Optimizer State Sharding (p. 1772)
- Activation Checkpointing (p. 1773)
- Activation Offloading (p. 1774)
- Ranking Mechanism (p. 1775)
- FP16 Training with Model Parallelism (p. 1777)
- Checkpointing Distributed Models and Optimizer States (p. 1779)
- Sharded Data Parallelism (p. 1780)
Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the set of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

Topics
- How Tensor Parallelism Works (p. 1762)
- Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism (p. 1764)
- Instructions for Checkpointing with Tensor Parallelism (p. 1768)
- Support for Hugging Face Transformer Models (p. 1770)

How Tensor Parallelism Works

Tensor parallelism takes place at the level of nn.Modules; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the set of modules used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules. The modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does not have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a partition of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.

```
A
  ### B
  |   ### E
  |   ### F
  ### C
  ### D
    ### G
    ### H
```

Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

```
dp_rank 0 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 1 (tensor parallel rank 1): A, B:1, C, D, G:1, H
dp_rank 2 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 3 (tensor parallel rank 1): A, B:1, C, D, G:1, H
```
Each line represents the set of modules stored in that dp_rank, and the notation X:y represents the yth fraction of the module X. Note the following:

1. Partitioning takes place across subsets of data parallel ranks, which we call TP_GROUP, not the entire DP_GROUP, so that the exact model partition is replicated across dp_rank 0 and dp_rank 2, and similarly across dp_rank 1 and dp_rank 3.
2. The modules E and F are no longer part of the model, since their parent module B is partitioned, and any execution that is normally a part of E and F takes place within the (partitioned) B module.
3. Even though H is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

How the library adapts tensor parallelism to PyTorch’s nn.Linear module

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices for the modules that are partitioned. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of all data samples across peer devices in the same tensor parallelism group. The device then runs the local fraction of the module on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned nn.Linear module.

The first figure shows a small model with a large nn.Linear module with data parallelism over the two tensor parallelism ranks. The nn.Linear module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the nn.Linear module. Each tp_rank holds half the linear module, and the entirety of the rest of the operations. While the linear module runs, each tp_rank collects the relevant half of all data samples and passes it through their half of the nn.Linear module. The result needs to be reduce-scattered (with summation as the
reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended smdistributed.modelparallel modules for tensor parallelism.

To learn more about the smdistributed.modelparallel modules, see the SageMaker model parallel APIs in the SageMaker Python SDK documentation.

Topics

- Tensor parallelism alone (p. 1764)
- Tensor parallelism combined with pipeline parallelism (p. 1766)

Tensor parallelism alone

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the mpi_options and smp_options dictionaries to specify distributed training options to the SageMaker PyTorch estimator.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "pipeline_parallel_degree": 1,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4,  # tp over 4 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py',  # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.12.0',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```
smp_estimator.fit('s3://my_bucket/my_training_data/')

Tip
To find a complete list of parameters for distribution, see Configuration Parameters for Model Parallelism in the SageMaker Python SDK documentation.

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. In this example, it is assumed that the script is named your_training_script.py.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        smp.distributed.Move input tensors to the GPU ID used by the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        loss.backward()
        optimizer.step()

    smp.init()

    smp.distributed: Initialize the backend

    smp.distributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    torch.set_device(smp.local_rank())
    device = torch.device("cuda")

    smp.distributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
```
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
    smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

# smdistributed: Enable tensor parallelism for all supported modules in the model
# i.e., nn.Linear in this case. Alternatively, we can use
# smp.set_tensor_parallelism(model.fc1, True)
# to enable it only for model.fc1
with smp.tensor_parallelism():
    model = Net()

    # smdistributed: Use the DistributedModel wrapper to distribute the
    # modules for which tensor parallelism is enabled
    model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Tensor parallelism combined with pipeline parallelism

The following is an example of a distributed training option that enables tensor parallelism combined
with pipeline parallelism. Set up the mpi_options and smp_options parameters to specify model
parallel options with tensor parallelism when you configure a SageMaker PyTorch estimator.

Note
Extended memory-saving features are available through Deep Learning Containers for PyTorch,
which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,  # tp over 2 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py',  # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.12.0',
    py_version='py36',
)
Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. Note that the training script now includes the `smp.step` decorator:

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

    # smdistributed: Define smp.step. Return any tensors needed outside.
    @smp.step
    def train_step(model, data, target):
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        model.backward(loss)
        return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
```

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. Note that the training script now includes the `smp.step` decorator:

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

    # smdistributed: Define smp.step. Return any tensors needed outside.
    @smp.step
    def train_step(model, data, target):
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        model.backward(loss)
        return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
```
loss = loss_mb.reduce_mean()

optimizer.step()

# smdistributed: Initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = Net()

# smdistributed: enable tensor parallelism only for model.fc1
smp.set_tensor_parallelism(model.fc1, True)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Instructions for Checkpointing with Tensor Parallelism

The SageMaker model parallelism library supports saving partial or full checkpoints with tensor parallelism. The following guide shows how to modify your script to save and load a checkpoint when you use tensor parallelism.

1. Prepare a model object and wrap it with the library's wrapper function smp.DistributedModel().

   ```python
   model = MyModel(...)
   model = smp.DistributedModel(model)
   ```

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process model.parameters() to assign unique IDs to individual model parameters.

   If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:
unique_params = []
unique_params_set = set()
for p in model.parameters():
    if p not in unique_params_set:
        unique_params.append(p)
        unique_params_set.add(p)
    del unique_params_set
optimizer = MyOpt(unique_params, ...)

3. Wrap the optimizer using the library's wrapper function smp.DistributedOptimizer().

```python
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using smp.save(). Depending on how you want to save checkpoints, choose one of the following two options:

- **Option 1**: Save a partial model on each mp_rank for a single MP_GROUP.

```python
model_dict = model.local_state_dict()  # save a partial model
opt_dict = optimizer.local_state_dict()  # save a partial optimizer state
# Save the dictionaries at rdp_rank 0 as a checkpoint
if smp.rdp_rank() == 0:
    smp.save(
        {"model_state_dict": model_dict, "optimizer_state_dict": opt_dict},
        f"checkpoint.pt",
        partial=True,
    )
```

With tensor parallelism, the library saves checkpointed files named in the following format: checkpoint.pt_{pp_rank}_{tp_rank}.

**Note**

With tensor parallelism, make sure you set the if statement as if smp.rdp_rank() == 0 instead of if smp.dp_rank() == 0. When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong if statement for checkpointing might result in a stalling training job. For more information about using if smp.dp_rank() == 0 without tensor parallelism, see General Instruction for Saving and Loading in the SageMaker Python SDK documentation.

- **Option 2**: Save the full model.

```python
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True)  # save the full model
if smp.rank() == 0:
    smp.save(
        {"model_state_dict": model_dict},
        "checkpoint.pt",
        partial=False,
    )
```

**Note**

Consider the following for full checkpointing:

- If you set gather_to_rank0=True, all ranks other than 0 return empty dictionaries.
- For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
- The full model only needs to be saved at smp.rank() == 0.
5. Load the checkpoints using `smp.load()`. Depending on how you checkpointed in the previous step, choose one of the following two options:

- **Option 1**: Load the partial checkpoints.

```python
checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])
```

You can set `same_partition_load=True` in `model.load_state_dict()` for a faster load, if you know that the partition will not change.

- **Option 2**: Load the full checkpoints.

```python
if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])
```

The `if smp.rdp_rank() == 0` condition is not required, but it can help avoid redundant loading among different MP_GROUPS. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.

### Support for Hugging Face Transformer Models

The SageMaker model parallelism library's tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallelism library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallelism library v1.8.0 and later)
- GPT-Neo (Available in the SageMaker model parallelism library v1.10.0 and later)

**Note**

For any other Transformers models, you need to use the `smdistributed.modelparallel.torch.tp_register_with_module()` API to apply tensor parallelism.

**Note**

To use tensor parallelism for training Hugging Face Transformer models, make sure you use Hugging Face Deep Learning Containers for PyTorch that has the SageMaker model parallelism library v1.7.0 and later. For more information, see the SageMaker model parallelism library release notes.

### Supported Models Out of the Box

For the Hugging Face transformer models supported by the library out of the box, you don't need to manually implement hooks to translate Transformer APIs to `smdistributed` transformer layers. You can activate tensor parallelism by using the context manager `smdistributed.modelparallel.torch.tensor_parallelism()` and wrapping the model by `smdistributed.modelparallel.torch.DistributedModel()`. You don't need to manually register hooks for tensor parallelism using the `smp.tp_register` API.

The `state_dict` translation functions between Hugging Face Transformers and `smdistributed.modelparallel` can be accessed as follows:

- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_state_dict_to_hf_gpt2(state_dict, max_seq_len=None)
- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_hf_state_dict_to_smdistributed_gpt2(state_dict)`
Example usage of the GPT-2 translation function

Start with wrapping the model as shown in the following code.

```python
from transformers import AutoModelForCausalLM
with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)
model = smp.DistributedModel(model)
```

Given a `state_dict` from the `DistributedModel` object, you can load the weights into the original Hugging Face GPT-2 model using the `translate_state_dict_to_hf_gpt2` function as shown in the following code.

```python
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 import translate_state_dict_to_hf_gpt2
max_seq_len = 1024
# [... code block for training ...]
if smp.rdp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)
    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

Example usage of the RoBERTa translation function

Similarly, given a supported HuggingFace model `state_dict`, you can use the `translate_hf_state_dict_to_smdistributed` function to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:

```python
from smdistributed.modelparallel.torch.nn.huggingface.roberta import translate_state_dict_to_hf_roberta
model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)
pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
```
translated_state_dict = translate_state_dict_to_smdistributed(pretrained_model.state_dict())

# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)

# start fine-tuning...

Optimizer State Sharding

Optimizer state sharding is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

How to Use Optimizer State Sharding

You can turn on optimizer state sharding by setting "shard_optimizer_state": True in the modelparallel configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the ith partition get reduced only at the ith data parallel rank. At the end of the first call to an smp.step decorator function, the optimizer wrapped by smp.DistributedOptimizer redefines its parameters to be only limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called virtual parameters and share underlying storage with the original parameters. During the first call to optimizer.step, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, the AllGather operation (as part of the optimizer.step call) runs across the data parallel ranks to achieve consistent parameter states.

Tip

Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.

The degree of data parallelism is calculated by (processes_per_host * instance_count / pipeline_parallel_degree), and the smp.dp_size() function handles the sizing in the background.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8, # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2, # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2, # tp over 2 devices
        "ddp": True,
        "shard_optimizer_state": True
    }
}
```

Adapt your PyTorch training script

See Adapt your PyTorch training script (p. 1767) in the Tensor parallelism combined with pipeline parallelism section. There’s no additional modification required for the script.
Activation Checkpointing

Activation checkpointing (or gradient checkpointing) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

How to Use Activation Checkpointing

With smdistributed.modelparallel, you can use activation checkpointing at the granularity of a module. For all torch.nn modules except torch.nn.Sequential, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the torch.nn.Sequential module, each module tree inside the sequential module must lie completely within one partition for activation checkpointing to work. When you use manual partitioning, be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with Partition assignments: in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

Note
The SageMaker model parallelism library supports both overlapping and non-overlapping allreduce operation in combination with checkpointing.

Note
PyTorch's native checkpointing API is not compatible with smdistributed.modelparallel.

Example 1: The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```python
import torch.nn as nn
import torch.nn.functional as F
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = self.conv2(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        # This call of fc1 will be checkpointed
        x = checkpoint(self.fc1, x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)
```

Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.
import torch.nn as nn
from smdistributed.multiparallel.torch.patches.checkpoint import checkpoint_sequential

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU(),
        )

    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, do the following:

1. Wrap the model by smp.DistributedModel().
2. Define an object for sequential layers.
3. Wrap the sequential layer object by smp.set_activation_checkpointing().

```python
import smdistributed.multiparallel.torch as smp
from transformers import AutoModelForCausalLM

smp.init()
model = AutoModelForCausalLM(*args, **kwargs)
model = smp.DistributedModel(model)

# Call set_activation_checkpointing API
transformer_layers = model.module.module.module.transformer.seq_layers
smp.set_activation_checkpointing(
    transformer_layers, pack_args_as_tuple=True, strategy='each'
)
```

**Activation Offloading**

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, activation offloading is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch’s backward pass, this functionality prefetches the offloaded activations back from the CPU.

**How to Use Activation Offloading**

Use activation offloading to reduce memory usage when the number of microbatches is greater than 1, and activation checkpointing is turned on (see Activation Checkpointing (p. 1773)). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.

To use activation offloading, set "offload_activations": True in the modelparallel configuration.

Activation offloading moves the checkpointed activations in nn.Sequential modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading
happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter "activation_loading_horizon" (default is set to 4, must be int larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

Tip
Activation offloading can be useful for large models with over a hundred billion parameters.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,               # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,       # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,        # tp over 2 devices
        "ddp": True,
        "offload_activations": True,
        "activation_loading_horizon": 4      # optional. default is 4.
    }
}
```

Ranking Mechanism

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the Ranking Basics for Core Features of the SageMaker Model Parallelism Library (p. 1738). With tensor parallelism, the library introduces three types of ranking and process group APIs: smp.tp_rank() for tensor parallel rank, smp.pp_rank() for pipeline parallel rank, and smp.rdp_rank() for reduced-data parallel rank. The corresponding communication process groups are tensor parallel group (TP_GROUP), pipeline parallel group (PP_GROUP), and reduced-data parallel group (RDP_GROUP). These groups are defined as follows:

- A tensor parallel group (TP_GROUP) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, TP_GROUP is the same as model parallel group (MP_GROUP).
- A pipeline parallel group (PP_GROUP) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, PP_GROUP is the same as MP_GROUP.
- A reduced-data parallel group (RDP_GROUP) is a set of processes that hold both the same pipeline parallelism partitions and the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, DP_GROUP. For the model parameters that are distributed within the TP_GROUP, the gradient allreduce operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient allreduce takes place over the entire DP_GROUP.
- A model parallel group (MP_GROUP) refers to a group of processes that collectively store the entire model. It consists of the union of the PP_GROUPS of all the ranks that are in the TP_GROUP of the current process. When the degree of tensor parallelism is 1, MP_GROUP is equivalent to PP_GROUP. It
is also consistent with the existing definition of MP_GROUP from previous smdistributed releases. Note that the current TP_GROUP is a subset of both the current DP_GROUP and the current MP_GROUP.

To learn more about the communication process APIs in the SageMaker model parallelism library, see the Common API and the PyTorch-specific APIs in the SageMaker Python SDK documentation.

This figure shows ranking mechanism, parameter distribution, and associated AllReduce operations of tensor parallelism.

For example, consider process groups for a single node with 8 GPUs, where the degree of tensor parallelism is 2, the degree of pipeline parallelism is 2, and the degree of data parallelism is 4. The upper center part of the preceding figure shows an example of a model with 4 layers. The lower left and lower right parts of figure illustrate the 4-layer model distributed across 4 GPUs using both pipeline parallelism and tensor parallelism, where tensor parallelism is used for the middle two layers. These two lower figures are simple copies to illustrate different group boundary lines. The partitioned model is replicated for data parallelism across GPUs 0-3 and 4-7. The lower left figure shows the definitions of MP_GROUP, PP_GROUP, and TP_GROUP. The lower right figure shows RDP_GROUP, DP_GROUP, and WORLD over the same set of GPUs. The gradients for the layers and layer slices that have the same color are allreduced together for data parallelism. For example, the first layer (light blue) gets the allreduce operations across DP_GROUP, whereas the dark orange slice in the second layer only gets the allreduce operations within the RDP_GROUP of its process. The bold dark red arrows represent tensors with the batch of its entire TP_GROUP.

| GPU0:  | pp_rank 0, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 0 |
| GPU1:  | pp_rank 1, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 1 |
| GPU2:  | pp_rank 0, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 2 |
| GPU3:  | pp_rank 1, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 3 |
| GPU4:  | pp_rank 0, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 0 |
In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, data parallelism (allreduce) takes place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of DP_GROUPS, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).

**FP16 Training with Model Parallelism**

For FP16 training, apply the following modifications to your training script and estimator.

**Note**  
This feature is available in the SageMaker model parallelism library v1.10.0 and later.

**Adapt your PyTorch training script**

1. Wrap your model using the `smdistributed.modelparallel.torch.model_creation()` context manager.

```python
# fp16_training_script.py
import torch
import smdistributed.modelparallel.torch as smp
with smp.model_creation(
    dtype=torch.float16 if args.fp16 else torch.get_default_dtype()
):  
    model = ...
```

**Tip**  
If you are using tensor parallelism, add `tensor_parallelism=smp.tp_size() > 1` to the `smp.model_creation` context manager. Adding this line also helps automatically detect whether tensor parallelism is activated or not.

```python
with smp.model_creation(
    ...,
    tensor_parallelism=smp.tp_size() > 1
):  
    model = ...
```

2. When you wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`, set either the `static_loss_scaling` or `dynamic_loss_scaling` argument. By default, `static_loss_scaling` is set to 1.0, and `dynamic_loss_scaling` is set to False. If you set `dynamic_loss_scale=True`, you can feed dynamic loss scaling options as a dictionary through the `dynamic_loss_args` argument. In most cases, we recommend you use dynamic loss scaling with the default options. For more information, options, and examples of the optimizer wrapper function, see the `smdistributed.modelparallel.torch.DistributedOptimizer` API.

The following code is an example of wrapping an Adadelta optimizer object with dynamic loss scaling for FP16 training.

```python
optimizer = torch.optim.Adadelta(...)  
optimizer = smp.DistributedOptimizer(
    optimizer,
    static_loss_scale=None,
    dynamic_loss_scale=True,
    dynamic_loss_args={
        "scale_window": 1000,
```
Configure a SageMaker PyTorch estimator

Add the FP16 parameter ("fp16") to the distribution configuration for model parallelism when creating a SageMaker PyTorch estimator object. For a complete list of the configuration parameters for model parallelism, see Parameters for `smdistributed`.

```python
from sagemaker.pytorch import PyTorch
smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,
        "tensor_parallel_degree": 2,
        ...
        "fp16": True
    }
}
fp16_estimator = PyTorch(
    entry_point="fp16_training_script.py", # Specify your train script
    ...
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": {...}
    }
)
fp16_estimator.fit(...)  
```

When FP16 training starts, the model and the optimizer are wrapped by `FP16_Module` and `FP16_Optimizer` respectively, which are modified `smdistributed` versions of the Apex utils. `FP16_Module` converts the model to FP16 dtype and deals with the forward pass in FP16.

**Tip**
You can apply gradient clipping by calling `clip_master_grads` before `optimizer.step`.

```python
optimizer.clip_master_grads(max_norm)  # max_norm(float or int): max norm of the gradients
```

**Tip**
When using `torch.optim.lr_scheduler` and FP16 training, you need to pass `optimizer.optimizer` to the LR scheduler rather than the optimizer. See the following example code.

```python
from torch.optim.lr_scheduler import StepLR
scheduler = StepLR(  
    optimizer.optimizer if smp.state.cfg.fp16 else optimizer,  
    step_size=1,  
    gamma=args.gamma
)
```

1778
Checkpointing Distributed Models and Optimizer States

The SageMaker model parallelism library provides checkpoint APIs to save and load distributed models and optimizer states.

**Note**
This feature is available in the SageMaker model parallelism library v1.10.0 and later.

To save a checkpoint of a model trained with model parallelism, use the `smdistributed.modelparallel.torch.save_checkpoint` API with the partial checkpointing (`partial=True`) that saves each model partition individually. In addition to the model and the optimizer state, you can also save any additional custom data through the `user_content` argument.

The checkpointed model, optimizer, and user content are saved as separate files. The `save_checkpoint` API call creates checkpoint folders in the following structure:

- **path**
  - `{tag}_partial` (folder for partial checkpoints)
  - `model_rankinfo.pt`
  - `optimizer_rankinfo.pt`
  - `fp16_states_rankinfo.pt`
  - `user_content.pt`
  - `{tag}` (checkpoint file for full checkpoints)
  - `user_content_{tag}` (user_content file for full checkpoints)
  - `newest` (a file that indicates the newest checkpoint)

To resume training from a checkpoint, use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=True`, using the checkpoint directory and the tag used while saving the checkpoint. Note that the actual loading of model weights happens after model partitioning, during the first run of the `smdistributed.modelparallel.torch.step`-decorated training step function.

When saving a partial checkpoint, the library also saves the model partition decision as files with `.pt` file extension. Conversely, when resuming from the partial checkpoint, the library loads the partition decision files together. Once the partition decision is loaded, you can't change the partition.

To save the final model artifact for inference purposes, use the `smdistributed.modelparallel.torch.save_checkpoint` API with `partial=False`, which combines the model partitions to create a single model artifact. Note that this does not combine the optimizer states.

To initialize training with particular weights, given a full model checkpoint, you can use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=False`. Note that this does not load optimizer states.

**Note**
With tensor parallelism, in general, the `state_dict` must be translated between the original model implementation and the `DistributedModel` implementation. Optionally, you can provide the `state_dict` translation function as an argument to the `smdistributed.modelparallel.torch.resume_from_checkpoint` API. However, for the section called “Supported Models Out of the Box” (p. 1770), the library takes care of this translation automatically.

The following code shows an example of how to use the checkpoint APIs for saving and loading a model trained with model parallelism.

```python
import smdistributed.modelparallel.torch as smp

model = ...
model = smp.DistributedModel(model)
optimizer = ...
```
Sharded Data Parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the training state of a model (model parameters, gradients, and optimizer states) across GPUs in a data parallel group.

**Note**
Sharded data parallelism is available in the SageMaker model parallelism library v1.11.0 and later.

When scaling up your training job to a large GPU cluster, you can reduce the per-GPU memory footprint of the model by sharding the training state over multiple GPUs. This returns two benefits: you can fit larger models, which would otherwise run out of memory with standard data parallelism, or you can increase the batch size using the freed-up GPU memory.

The standard data parallelism technique replicates the training states across the GPUs in the data parallel group, and performs gradient aggregation based on the AllReduce operation. Sharded data parallelism modifies the standard data-parallel distributed training procedure to account for the sharded nature of the optimizer states. A group of ranks over which the model and optimizer states are sharded is called a *sharding group*. The sharded data parallelism technique shards the trainable parameters of a model and corresponding gradients and optimizer states across the GPUs in the *sharding group*.

SageMaker implements sharded data parallelism through the MiCS implementation, which is discussed in the AWS blog post *Near-linear scaling of gigantic-model training on AWS*. In this implementation, you can set the sharding degree as a configurable parameter, which must be less than the data parallelism degree. During each forward and backward pass, MiCS temporarily recombines the model parameters in all GPUs through the AllGather operation. After the forward or backward pass of each layer, MiCS shards the parameters again to save GPU memory. During the backward pass, MiCS reduces gradients and simultaneously shards them across GPUs through the ReduceScatter operation. Finally, MiCS applies the local reduced and sharded gradients to their corresponding local parameter shards, using the local shards of optimizer states. To bring down communication overhead, the SageMaker model parallelism library prefetches the upcoming layers in the forward or backward pass, and overlaps the network communication with the computation.

The training state of the model is replicated across the sharding groups. This means that before gradients are applied to the parameters, the AllReduce operation must take place across the sharding groups, in addition to the ReduceScatter operation that takes place within the sharding group.

In effect, sharded data parallelism introduces a tradeoff between the communication overhead and GPU memory efficiency. Using sharded data parallelism increases the communication cost, but the memory footprint per GPU (excluding the memory usage due to activations) is divided by the sharded data parallelism degree, thus larger models can be fit in the GPU cluster.
The selected sharded data parallelism degree must evenly divide the data parallelism degree. For example, for an 8-way data parallelism job, choose 2, 4, or 8 for the sharded data parallelism degree. While choosing the sharded data parallelism degree, we recommend that you start with a small number, and gradually increase it until the model fits in the memory together with the desired batch size.

**Topics**
- How to Apply Sharded Data Parallelism to Your Training Job (p. 1781)
- Sharded data parallelism with SMDDP Collectives (p. 1782)
- Mixed Precision Training with Sharded Data Parallelism (p. 1785)
- Tips and Considerations for Using Sharded Data Parallelism (p. 1786)

**How to Apply Sharded Data Parallelism to Your Training Job**

To use sharded data parallelism, apply the following modifications to your training script and estimator.

**Adapt your PyTorch training script**

Follow the instructions at Step 1: Modify a PyTorch Training Script (p. 1749) to wrap the model and optimizer objects with the smdistributed.modelparallel.torch wrappers of the torch.nn.parallel and torch.distributed modules.

**Configure a SageMaker PyTorch estimator**

As part of configuring a SageMaker PyTorch estimator in the section called "Step 2: Launch a Training Job" (p. 1755), add the parameters for sharded data parallelism.

To turn on sharded data parallelism, add the sharded_data_parallel_degree parameter to the SageMaker PyTorch Estimator. This parameter specifies the number of GPUs over which the training state is sharded. The value for sharded_data_parallel_degree must be an integer between one and the data parallelism degree and must evenly divide the data parallelism degree. Note that the library automatically detects the number of GPUs so thus the data parallel degree. The following additional parameters are available for configuring sharded data parallelism.

- "sdp_reduce_bucket_size" (int, default: 5e8) – Specifies the size of PyTorch DDP gradient buckets in number of elements of the default dtype.
- "sdp_param_persistence_threshold" (int, default: 1e6) – Specifies the size of a parameter tensor in number of elements that can persist at each GPU. Sharded data parallelism splits each parameter tensor across GPUs of a data parallel group. If the number of elements in the parameter tensor is smaller than this threshold, the parameter tensor is not split; this helps reduce communication overhead because the parameter tensor is replicated across data-parallel GPUs.
- "sdp_max_live_parameters" (int, default: 1e9) – Specifies the maximum number of parameters that can simultaneously be in a recombined training state during the forward and backward pass. Parameter fetching with the AllGather operation pauses when the number of active parameters reaches the given threshold. Note that increasing this parameter increases the memory footprint.
- "sdp_hierarchical_allgather" (bool, default: True) – If set to True, the AllGather operation runs hierarchically: it runs within each node first, and then runs across nodes. For multi-node distributed training jobs, the hierarchical AllGather operation is automatically activated.
- "sdp_gradient_clipping" (float, default: 1.0) – Specifies a threshold for gradient clipping the L2 norm of the gradients before propagating them backward through the model parameters. When sharded data parallelism is activated, gradient clipping is also activated. The default threshold is 1.0. Adjust this parameter if you have the exploding gradients problem.

The following code shows an example of how to configure sharded data parallelism.

```python
import sagemaker
```
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        # "pipeline_parallel_degree": 1,       # Optional, default is 1
        # "tensor_parallel_degree": 1,        # Optional, default is 1
        "ddp": True,
        # parameters for sharded data parallelism
        "sharded_data_parallel_degree": 2,    # Add this to activate sharded data parallelism
        "sdp_reduce_bucket_size": int(5e8),   # Optional
        "sdp_param_persistence_threshold": int(1e6), # Optional
        "sdp_max_live_parameters": int(1e9),  # Optional
        "sdp_hierarchical_allgather": True,   # Optional
        "sdp_gradient_clipping": 1.0          # Optional
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8 # Required
}

smp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.12.0',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-job"
)

smp_estimator.fit('s3://my_bucket/my_training_data/')

### Sharded data parallelism with SMDDP Collectives

The SageMaker data parallelism library offers collective communication primitives (SMDDP collectives) optimized for the AWS infrastructure. It achieves optimization by adopting an all-to-all-type communication pattern by making use of Elastic Fabric Adapter (EFA), resulting in high-throughput and less latency-sensitive collectives, offloading the communication-related processing to the CPU, and freeing up GPU cycles for computation. On large clusters, SMDDP Collectives can offer improvements in distributed training performance compared to NCCL.

**Note**

Sharded data parallelism with SMDDP Collectives is available in the SageMaker model parallelism library v1.13.0 and later, and the SageMaker data parallelism library v1.6.0 and later. See also [Supported configurations](p. 1783) to use sharded data parallelism with SMDDP Collectives.

In sharded data parallelism, which is a commonly used technique in large-scale distributed training, the AllGather collective is used to reconstitute the sharded layer parameters for forward and backward pass computations, in parallel with GPU computation. For large models, performing the AllGather operation efficiently is critical to avoid GPU bottleneck problems and slowing down training speed. When sharded data parallelism is activated, SMDDP Collectives drops into these performance-critical AllGather collectives, improving training throughput.

**Train with SMDDP Collectives**
When your training job has sharded data parallelism activated and meets the Supported configurations (p. 1783), SMDDP Collectives are automatically activated. Internally, SMDDP Collectives optimize the AllGather collective to be performant on the AWS infrastructure and falls back to NCCL for all other collectives. Furthermore, under unsupported configurations, all collectives, including AllGather, automatically use the NCCL backend.

Since the SageMaker model parallelism library version 1.13.0, the "ddp_dist_backend" parameter is added to the modelparallel options. The default value for this configuration parameter is "auto", which uses SMDDP Collectives whenever possible, and falls back to NCCL otherwise. To force the library to always use NCCL, specify "nccl" to the "ddp_dist_backend" configuration parameter.

The following code example shows how to set up a PyTorch estimator using the sharded data parallelism with the "ddp_dist_backend" parameter, which is set to "auto" by default and, therefore, optional to add.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        "partitions": 1,
        "ddp": True,
        "sharded_data_parallel_degree": 64
    }
}

mpi_options = {
    "enabled": True,
    "processes_per_host": 8
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.12.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')

Supported configurations

The AllGather operation with SMDDP Collectives are activated in training jobs when all the following configuration requirements are met.

- The sharded data parallelism degree greater than 1
- Instance_count greater than 1
- Instance_type equal to ml.p4d.24xlarge
- SageMaker training container for PyTorch v1.12.1 or later
- The SageMaker data parallelism library v1.6.0 or later
The SageMaker model parallelism library v1.13.0 or later

Performance and memory tuning

SMDDP Collectives utilize additional GPU memory. There are two environment variables to configure the GPU memory usage depending on different model training use cases.

- **SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES** – During the SMDDP AllGather operation, the AllGather input buffer is copied into a temporary buffer for inter-node communication. The SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES variable controls the size (in bytes) of this temporary buffer. If the size of the temporary buffer is smaller than the AllGather input buffer size, the AllGather collective falls back to use NCCL.
  - Default value: 16 * 1024 * 1024 (16 MB)
  - Acceptable values: any multiple of 8192

- **SMDDP_AG_SORT_BUFFER_SIZE_BYTES** – The SMDDP_AG_SORT_BUFFER_SIZE_BYTES variable is to size the temporary buffer (in bytes) to hold data gathered from inter-node communication. If the size of this temporary buffer is smaller than 1/8 * sharded_data_parallel_degree * AllGather input size, the AllGather collective falls back to use NCCL.
  - Default value: 128 * 1024 * 1024 (128 MB)
  - Acceptable values: any multiple of 8192

Tuning guidance on the buffer size variables

The default values for the environment variables should work well for most use cases. We recommend tuning these variables only if training runs into the out-of-memory (OOM) error.

The following list discusses some tuning tips to reduce the GPU memory footprint of SMDDP Collectives while retaining the performance gain from them.

- **Tuning SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES**
  - The AllGather input buffer size is smaller for smaller models. Hence, the required size for SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES can be smaller for models with fewer parameters.
  - The AllGather input buffer size decreases as sharded_data_parallel_degree increases, because the model gets sharded across more GPUs. Hence, the required size for SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES can be smaller for training jobs with large values for sharded_data_parallel_degree.

- **Tuning SMDDP_AG_SORT_BUFFER_SIZE_BYTES**
  - The amount of data gathered from inter-node communication is less for models with fewer parameters. Hence, the required size for SMDDP_AG_SORT_BUFFER_SIZE_BYTES can be smaller for such models with fewer number of parameters.

Some collectives might fall back to use NCCL; hence, you might not get the performance gain from the optimized SMDDP collectives. If additional GPU memory is available for use, you can consider increasing the values of SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES and SMDDP_AG_SORT_BUFFER_SIZE_BYTES to benefit from the performance gain.

The following code shows how you can configure the environment variables by appending them to mpi_options in the distribution parameter for the PyTorch estimator.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
```
Mixed Precision Training with Sharded Data Parallelism

To further save GPU memory with half-precision floating point numbers and sharded data parallelism, you can activate 16-bit floating point format (FP16) or Brain floating point format (BF16) by adding one additional parameter to the distributed training configuration.

**Note**
Mixed precision training with sharded data parallelism is available in the SageMaker model parallelism library v1.11.0 and later.

**For FP16 Training with Sharded Data Parallelism**

To run FP16 training with sharded data parallelism, add "fp16": True to the smp_options configuration dictionary. In your training script, you can choose between the static and dynamic loss scaling options through the smp.DistributedOptimizer module. For more information, see the section called “FP16 Training with Model Parallelism” (p. 1777).

```python
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "fp16": True
    }
}
```

**For BF16 Training with Sharded Data Parallelism**

The sharded data parallelism feature of SageMaker supports training in BF16 data type. The BF16 data type uses 8 bits to represent the exponent of a floating point number, while the FP16 data type uses 5 bits. Preserving the 8 bits for the exponent allows to keep the same representation of the exponent of a 32-bit single precision floating point (FP32) number. This makes the conversion between FP32 and BF16 simpler and significantly less prone to cause overflow and underflow issues that arise often in
FP16 training, especially when training larger models. While both data types use 16 bits in total, this increased representation range for the exponent in the BF16 format comes at the expense of reduced precision. For training large models, this reduced precision is often considered an acceptable trade-off for the range and training stability.

**Note**
Currently, BF16 training works only when sharded data parallelism is activated.

To run BF16 training with sharded data parallelism, add "bf16": True to the `smp_options` configuration dictionary.

```python
smp_options = {
  "enabled": True,
  "parameters": {
    "ddp": True,
    "sharded_data_parallel_degree": 2,
    "bf16": True
  }
}
```

**Tips and Considerations for Using Sharded Data Parallelism**

Consider the following when using the SageMaker model parallelism library's sharded data parallelism.

- Sharded data parallelism is compatible with FP16 training. To run FP16 training, see the section called “FP16 Training with Model Parallelism” (p. 1777).
- Sharded data parallelism currently is not compatible with tensor parallelism (p. 1762), pipeline parallelism (p. 1730), and optimizer state sharding (p. 1772). To activate sharded data parallelism, set tensor and pipeline parallelism degrees to 1, and turn off optimizer state sharding.

  The activation checkpointing (p. 1773) and activation offloading (p. 1774) features are compatible with sharded data parallelism.

- To use sharded data parallelism with gradient accumulation, set the `backward_passes_per_step` argument to the number of accumulation steps while wrapping your model with the `smdistributed.modelparallel.torch.DistributedModel` module. This ensures that the gradient AllReduce operation across the model replication groups (sharding groups) takes place at the boundary of gradient accumulation.

- You can checkpoint your models trained with sharded data parallelism using the library's checkpointing APIs, `smp.save_checkpoint` and `smp.resume_from_checkpoint`. For more information, see the section called “Checkpointing Distributed Models and Optimizer States” (p. 1779).

- The behavior of the `delayed_parameter_initialization` configuration parameter changes under sharded data parallelism. When these two features are simultaneously turned on, parameters are immediately initialized upon model creation in a sharded manner instead of delaying the parameter initialization, so that each rank initializes and stores its own shard of parameters.

- When sharded data parallelism is activated, the library performs gradient clipping internally when the `optimizer.step()` call runs. You don't need to use utility APIs for gradient clipping, such as `torch.nn.utils.clip_grad_norm_()`. To adjust the threshold value for gradient clipping, you can set it through the `sdp_gradient_clipping` parameter for the distribution parameter configuration when you construct the SageMaker PyTorch estimator, as shown in the section called “How to Apply Sharded Data Parallelism to Your Training Job” (p. 1781) section.

**SageMaker Distributed Model Parallelism Best Practices**

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.
Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

### Tip
If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

### Using large GPU instance types

- In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using `ml.p4d` or `ml.p3dn` instances for training large DL models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.

### Sharding optimizer state

- The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a node with 16 GPUs won't fit on a node with 8 GPUs because there are simply not enough GPUs across which to shard the optimizer state.

For more information, see Optimizer State Sharding (p. 1772).

### Activation checkpointing

- Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the `strategy` argument of the `smp.set_activation_checkpointing` function groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

For more information, see Activation Checkpointing (p. 1773).

### Tensor parallelism

- The degree of tensor parallelism should be a power of two (2, 4, 8, ..., $2^n$), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism (p. 1762).
Pipeline parallelism across nodes

- You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.
- Pipeline parallelism comes with the following three knobs: microbatches, active_microbatches, and prescaled_batch.
  - When you use tensor parallelism with pipeline parallelism, we recommend activating prescaled_batch so that the batch size per model parallel group can be increased for efficient pipelining. With prescaled_batch activated, the batch size set in the training script becomes $\text{tp\_size \times \text{batch\_size}}$ for each rank without prescaled_batch.
  - Increasing the number of microbatches helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.
  - The number of active_microbatches is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing active_microbatches takes up more GPU memory.
- If both GPU and GPU memory are underutilized, increase active_microbatches for better parallelization during pipelining.
- For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism (p. 1766).
- To find descriptions of the aforementioned parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

Offloading activations to CPU

- Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the microbatches parameter.
- When offloading activations, you might be able to increase active_microbatches and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

For more information, see Activation Offloading (p. 1774).

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.

<table>
<thead>
<tr>
<th>The number of model parameters</th>
<th>Instance type</th>
<th>Pipeline parallelism</th>
<th>Tensor parallelism</th>
<th>Optimizer state sharding</th>
<th>Activation checkpointing</th>
<th>Prescaled batch</th>
<th>Batch size</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 billion</td>
<td>16 ml.p4d.24xlarge</td>
<td>1</td>
<td>4</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=40</td>
</tr>
<tr>
<td>30 billion</td>
<td>16 ml.p4d.24xlarge</td>
<td>1</td>
<td>8</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=32</td>
</tr>
</tbody>
</table>
### The number of model parameters

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Pipeline parallelism</th>
<th>Tensor parallelism</th>
<th>Optimizer state sharding</th>
<th>Activation checkpoint</th>
<th>Prescaled batch</th>
<th>Batch size</th>
</tr>
</thead>
<tbody>
<tr>
<td>60 billion</td>
<td>32 ml.p4d.24xlarge</td>
<td>2</td>
<td>8 True</td>
<td>Each transformer layer True microbatches=4, active_microbatches=2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn’t fit, try increasing the degree of tensor parallelism.

### Modifying Your Training Script

- Before you use the SageMaker model parallel library’s features in your training script, review The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls (p. 1790).
- To launch a training job faster, use the SageMaker local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

### Monitoring and Logging a Training Job Using the SageMaker Console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose Training.
2. Choose Training jobs.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the Monitor section to see the automated visualization.
5. To see training job logs, choose View logs in the Monitor section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of algo-n-1234567890. The algo-1 log stream tracks training logs from the main (0th) node.

For more information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 1936).

### Permissions

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add AmazonFSxFullAccess.
- To use Amazon S3 as a data channel, add AmazonS3FullAccess.
- To use Docker, build your own container, and push it to Amazon ECR, add AmazonEC2ContainerRegistryFullAccess.
• To have a full access to use the entire suite of SageMaker features, add AmazonSageMakerFullAccess.

The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker's model parallelism library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow Training Script (p. 1744) and Modify a PyTorch Training Script (p. 1749), respectively.

Batch Size and Number of Microbatches

• The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.

• Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.

• Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set drop_remainder=True in the tf.Dataset.batch() call (in TensorFlow), or set drop_last=True in DataLoader (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

Manual Partitioning

• If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

Data Preparation

• If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with smp.dp_rank(). If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by smp.dp_rank(). This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

Returning Tensors from smp.DistributedModel

• Any tensor that is returned from the smp.DistributedModel.call (for TensorFlow) or smp.DistributedModel.forward (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call
and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The `@smp.step` Decorator

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see `smp.step` in the API documentation.

Delaying Parameter Initialization

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers `smp.delay_param_initialization` context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of an `smp.step`-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```python
with smp.delay_param_initialization(enabled=True):
    model = MyModel()
```

Tensor Parallelism for PyTorch

- If you are using a seed for deterministic results, set the seed based on `smp.dp_rank()` (for example, `torch.manual_seed(42 + smp.dp_rank())`). If you do not do this, different partitions of an `nn.Parameter` are initialized in the same way, impacting convergence.
- SageMaker’s model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, `smp` throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable `SMP_NCCL_THROTTLE_LIMIT`. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set `SMP_NCCL_THROTTLE_LIMIT=-1`.
- The following identity, which holds when the degree of tensor parallelism is 1, does not hold when the degree of tensor parallelism is greater than 1: `smp.mp_size() * smp.dp_size() == smp.size()`. This is because the tensor parallel group is part of both the model parallelism group and the data parallelism group. If your code has existing references to `mp_rank`, `mp_size`, `MP_GROUP`, and so on, and if you want to work with only the pipeline parallel group, you might need to replace the references with `smp.pp_size()`. The following identities are always true:
  - `smp.mp_size() * smp.rdp_size() == smp.size()`
  - `smp.pp_size() * smp.dp_size() == smp.size()`
  - `smp.pp_size() * smp.tp_size() * smp.rdp_size() == smp.size()`
- Since the `smp.DistributedModel` wrapper modifies the model parameters when tensor parallelism is enabled, the optimizer should be created after calling `smp.DistributedModel`, with the distributed parameters. For example, the following does not work:

```python
## WRONG
model = MyModel()
optimizer = SomeOptimizer(model.parameters())
model = smp.DistributedModel(model)  # optimizer now has outdated parameters!
```
Instead, the optimizer should be created with the parameters of the smp.DistributedModel as follows:

```python
## CORRECT
model = smp.DistributedModel(MyModel())
optimizer = SomeOptimizer(model.optimizers())
```

- When a module is replaced with its distributed counterpart through tensor parallelism, the distributed module does not inherit its weights from the original module, and initializes new weights. This means that, for instance, if the weights need to be initialized in a particular call (for example, through a `load_state_dict` call), this needs to happen after the smp.DistributedModel call, once the module distribution takes place.

- When accessing the parameters of distributed modules directly, note that the weight does not have the same shape as the original module. For instance,

```python
with smp.tensor_parallelism():
    linear = nn.Linear(60, 60)

# will pass
assert tuple(linear.weight.shape) == (60, 60)

distributed_linear = smp.DistributedModel(linear)

# will fail. the number of input channels will have been divided by smp.tp_size()
assert tuple(distributed_linear.module.weight.shape) == (60, 60)
```

- Using `torch.utils.data.distributed.DistributedSampler` is strongly recommended for tensor parallelism. This ensures that every data parallel rank receives the same number of data samples, which prevents hangs that might result from different `dp_rank`s taking a different number of steps.

- If you use the `join` API of PyTorch's `DistributedDataParallel` class to handle cases in which different data parallel ranks have different numbers of batches, you still need to make sure that ranks that are in the same `TP_GROUP` have the same number of batches; otherwise the communication collectives used in distributed execution of modules may hang. Ranks that are in different `TP_GROUP`s can have different numbers of batches, as long as `join` API is used.

- If you want to checkpoint your model and use tensor parallelism, consider the following:
  - To avoid stalling and race conditions while saving and loading models when you use tensor parallelism, make sure you call appropriate functions from the following model and optimizer states inside a reduced-data parallelism rank.
  - If you are transitioning an existing pipeline parallel script and enabling tensor parallel for the script, ensure that you modify any `if smp.dp_rank() == 0` block used for saving and loading with `if smp.rdp_rank() == 0` blocks. Otherwise, it might cause your training job to stall.
  - Full checkpointing of optimizer states is currently not supported with tensor parallelism. If you want to resume training from a checkpoint, use partial checkpointing instead.

For more information about checkpointing a model with tensor parallelism, see Instructions for Checkpointing with Tensor Parallelism (p. 1768).

### Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

**Topics**
Considerations for Using SageMaker Debugger with the SageMaker Model Parallelism Library

SageMaker Debugger is not available for the SageMaker model parallelism library. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading'
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework `estimator` as shown in the following example.

```python
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(
    ...
    distribution={"smdistributed": {"modelparallel": { "enabled": True }},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use `checkpoint_s3_uri` with the SageMaker `estimator` call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```python
import os
def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile""
```
import time, subprocess
cmd = ['aws', 's3', 'sync', '--quiet', source, destination]
print(f"Syncing files from {source} to {destination}")
start_time = time.time()
p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
p.wait()
end_time = time.time()
print("Time Taken to Sync: ", (end_time-start_time))
return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
    s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from local path to s3 ""
    import boto3
    # check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")
    # check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")
    s3_bucket = s3_uri.replace('s3://','').split('/')[-1]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(local_path, s3_uri)
    return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
    s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from s3 to local path ""
    import boto3
    # try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}")
    # check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")
    s3_bucket = s3_uri.replace('s3://','').split('/')[-1]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(s3_uri, local_path)
    return

Usage of helper functions:

# base_s3_uri - user input s3 uri or save to model directory (default)
# curr_host - to save checkpoints of current host
# iteration - current step/epoch during which checkpoint is saved
Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and the model parallelism library, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Stalling or Crashing Distributed Training Jobs

If your training job has stalling, crashing, or not responding issues, read the following troubleshooting items to identify what's the cause of the issue. If you need any further support, reach out to the SageMaker distributed training team through AWS Support.

- If you see a distributed training job stalling at the NCCL initialization step, consider the following:
  - If you are using one of the EFA-enabled instances (ml.p4d or ml.p3dn instances) with a custom VPC and its subnet, ensure that the security group used has inbound and outbound connections for all ports to and from the same SG. You also generally need outbound connections to any IP as a separate rule (for internet access). To find instructions on how to add inbound and outbound rules for EFA communication, refer to SageMaker Distributed Training Job Stalling During Initialization (p. 1727).
  - If you see a distributed training job stalling when checkpointing the full model, this might be because the state_dict() call on the model or optimizer was not made on all ranks with rdp_rank()==0 (when using tensor parallelism) or dp_rank()==0 (when using only pipeline parallelism). These ranks need to communicate to construct the checkpoint to be saved. Similar stalling issues can also happen when checkpointing partial optimizer if shard_optimizer_state is enabled.

  For more information about checkpointing a model with model parallelism, see General Instruction for Saving and Loading and Instructions for Checkpointing with Tensor Parallelism (p. 1768).

- If the training job crashes with a CUDA Out of Memory error, this means that the distributed training configuration needs to be adjusted to fit the model on the GPU cluster. For more information and best practices, see Setting Up the Right Configuration for a Given Model (p. 1787).

- If the training job crashes with an uncorrectable ECC error, this means that one of the GPUs in the cluster has gone bad. If you need technical support, share the job ARN with the AWS team and restart your training job from a checkpoint if possible.

  - In rare cases, a job configuration that worked previously but is close to the limits of GPU memory might fail later with a different cluster due to a CUDA Out of Memory error. This could be because some GPU has lower available memory than usual due to ECC errors.

- Network timeout crash might happen when running a multi-node job which doesn't use all GPUs in the node. To get around this, use all GPUs on the node by ensuring that the processes_per_host parameter is set to the number of GPUs in each instance. For example, this is processes_per_host=8 for ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances.

  - If you find that your training job takes a long time during the data downloading stage, make sure the Amazon S3 path you provided to checkpoint_s3_uri for the SageMaker Estimator class is unique for the current training job. If this path is reused across multiple training jobs running
simultaneously, all those checkpoints are uploaded and downloaded to the same Amazon S3 path and might significantly increase checkpoint loading time.

- Use FSx for Lustre when you deal with large data and models.
  - If your dataset is large and fetching it takes a long time, we recommend keeping your dataset in FSx for Lustre.
  - When training models are beyond 10 billion parameters, we recommend using FSx for Lustre for checkpointing.
  - After you create a file system, make sure to wait for the status to become available before starting a training job using it.

**Receiving NCCL Error for a PyTorch Training Job**

If you encountered the following error, it might be due to a process running out of GPU memory.

```
NCCL error in: ../torch/lib/c10d/ProcessGroupNCCL.cpp:825, unhandled system error, NCCL version 2.7.8
ncclSystemError: System call (socket, malloc, munmap, etc) failed.
```

You can resolve this by reducing the batch size or active_microbatches. If auto partitioning is not resulting in a well-balanced partitioning, you might have to consider manual partitioning. For more information, see Pipeline parallelism across nodes (p. 1788).

**Receiving RecursionError for a PyTorch Training Job**

The library does not support calling `super.forward()` inside a module's forward call. If you use `super.forward()`, you might receive the following error message.

```
RecursionError: maximum recursion depth exceeded
```

To fix the error, instead of calling `super.forward()`, you should call `super()._orig_forward()`.

**Amazon SageMaker Distributed Training Notebook Examples**

The following case studies and notebooks provide examples of implementing the SageMaker distributed training libraries for the supported deep learning frameworks (PyTorch, TensorFlow, and HuggingFace) and models, such as CNN and MaskRCNN for vision, and BERT for natural language processing.

These notebooks are provided in the SageMaker examples GitHub repository. You can also browse them on the SageMaker examples website.

The examples are set up to use p3.16xlarge instances for the worker nodes, but you may choose ml.p3dn.24xlarge or ml.p4d.24xlarge instance types for which the SageMaker distributed training libraries are optimized. You can test the notebooks using a cluster of a single node; however, to see a performance improvement as shown in the Training Benchmarks section, use a cluster of multiple nodes (two or more). The examples call out the section in which you modify this configuration.

**Blogs and Case Studies**

The following blogs discuss case studies about using the SageMaker distributed training libraries.

**The SageMaker data parallelism library**

How to Access or Download the SageMaker Distributed Training Notebook Examples

Follow instructions to access or download the SageMaker distributed training example notebooks.

Option 1: Use a SageMaker notebook instance

To use the aforementioned examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance runs Jupyter Notebook and JupyterServer apps on Amazon EC2 instances, which are optimized for machine learning. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 363) in the SageMaker developer guide to create one.

After you have created an instance, in the Notebook instances page of the SageMaker console, do the following:

1. Open JupyterLab.
2. Select the examples icon ( ) in the left tray.
3. Browse the examples for Training and look for notebooks titled Distributed Data Parallel or Distributed Model Parallel.

Option 2: Clone the SageMaker example repository to SageMaker Studio or notebook instance

To download and use the aforementioned example notebooks, do the following to clone the example GitHub repositories:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   
   cd SageMaker

3. Clone the SageMaker examples GitHub repository.
   
   git clone https://github.com/aws/amazon-sagemaker-examples.git

   **Note**
   To download the HuggingFace example notebooks (p. 1797), clone the HuggingFace notebooks GitHub repository:

   git clone https://github.com/huggingface/notebooks

4. In the JupyterLab interface, navigate into the `amazon-sagemaker-examples` folder.
5. In the `training/distributed_training` folder, there are folders for frameworks, and in each of these, there are folders for `data_parallel` and `model_parallel`. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

**Amazon SageMaker Training Compiler**

Use Amazon SageMaker Training Compiler to train deep learning (DL) models faster on scalable GPU instances managed by SageMaker.

**What Is SageMaker Training Compiler?**

State-of-the-art deep learning (DL) models consist of complex multi-layered neural networks with billions of parameters that can take thousands of GPU hours to train. Optimizing such models on training infrastructure requires extensive knowledge of DL and systems engineering; this is challenging even for narrow use cases. Although there are open-source implementations of compilers that optimize the DL training process, they can lack the flexibility to integrate DL frameworks with some hardware such as GPU instances.

SageMaker Training Compiler is a capability of SageMaker that makes these hard-to-implement optimizations to reduce training time on GPU instances. The compiler optimizes DL models to accelerate training by more efficiently using SageMaker machine learning (ML) GPU instances. SageMaker Training Compiler is available at no additional charge within SageMaker and can help reduce total billable time as it accelerates training.

SageMaker Training Compiler is integrated into the AWS Deep Learning Containers (DLCs). Using the SageMaker Training Compiler–enabled AWS DLCs, you can compile and optimize training jobs on GPU instances with minimal changes to your code. Bring your deep learning models to SageMaker and enable SageMaker Training Compiler to accelerate the speed of your training job on SageMaker ML instances for accelerated computing.

**How It Works**

SageMaker Training Compiler converts DL models from their high-level language representation to hardware-optimized instructions. Specifically, SageMaker Training Compiler applies graph-level optimizations, dataflow-level optimizations, and backend optimizations to produce an optimized model that efficiently uses hardware resources. As a result, you can train your models faster than when you train them without compilation.
It is a two-step process to activate SageMaker Training Compiler for your training job:

1. Bring your own DL script and, if needed, adapt to compile and train with SageMaker Training Compiler. To learn more, see Bring Your Own Deep Learning Model (p. 1814).

2. Create a SageMaker estimator object with the compiler configuration parameter using the SageMaker Python SDK.
   a. Turn on SageMaker Training Compiler by adding
      
      ```python
      compiler_config=TrainingCompilerConfig()
      ```
      
   b. Adjust hyperparameters (batch_size and learning_rate) to maximize the benefit that SageMaker Training Compiler provides.

 Compilation through SageMaker Training Compiler changes the memory footprint of the model. Most commonly, this manifests as a reduction in memory utilization and a consequent increase in the largest batch size that can fit on the GPU. In some cases, the compiler intelligently promotes caching which leads to a decrease in the largest batch size that can fit on the GPU. Note that if you want to change the batch size, you must adjust the learning rate appropriately.

 For a reference for batch_size tested for popular models, see Tested Models (p. 1803).

 When you adjust the batch size, you also have to adjust the learning_rate appropriately. For best practices for adjusting the learning rate along with the change in batch size, see the section called “Best Practices and Considerations” (p. 1836).

 c. By running the estimator.fit() class method, SageMaker compiles your model and starts the training job.

 For instructions on how to launch a training job, see Enable SageMaker Training Compiler (p. 1822).

 SageMaker Training Compiler does not alter the final trained model, while allowing you to accelerate the training job by more efficiently using the GPU memory and fitting a larger batch size per iteration. The final trained model from the compiler-accelerated training job is identical to the one from the ordinary training job.

 **Tip**

 SageMaker Training Compiler only compiles DL models for training on supported GPU instances managed by SageMaker. To compile your model for inference and deploy it to run anywhere in the cloud and at the edge, use SageMaker Neo compiler.

 **Supported Frameworks, AWS Regions, Instance Types, and Tested Models**

 Before using SageMaker Training Compiler, check if your framework of choice is supported, the instance types are available in your AWS account, and your AWS account is in one of the supported AWS Regions.
Note
SageMaker Training Compiler is available in the SageMaker Python SDK v2.70.0 or later.

Supported Frameworks
SageMaker Training Compiler supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

Topics
- PyTorch (p. 1801)
- TensorFlow (p. 1801)

For more information, see [Available Images](https://github.com/aws-deep-learning-containers) in the *AWS Deep Learning Containers GitHub repository*.

### AWS Regions

The [SageMaker Training Compiler Containers](https://github.com/aws-deep-learning-containers) are available in the AWS Regions where *AWS Deep Learning Containers* are in service except the China regions.

### Supported Instance Types

SageMaker Training Compiler is tested on and supports the following ML instance types.

- P4 instances
- P3 instances
- G4dn instances
- G5 instances

For specs of the instance types, see the [Accelerated Computing](https://aws.amazon.com/ec2/instance-types/) section in the *Amazon EC2 Instance Types page*. For information about instance pricing, see [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing/).

If you encountered an error message similar to the following, follow the instructions at [Request a service quota increase for SageMaker resources](https://docs.aws.amazon.com/sagemaker/latest/dg/instance-limits.html).

---

ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.
Tested Models

The following table includes a list of the models that have been tested with SageMaker Training Compiler. For reference, the largest batch size that is able to fit into memory is also included alongside other training parameters. SageMaker Training Compiler can change the memory footprint of the model training process; as a result, a larger batch size can often be used during the training process, further decreasing total training time. You must retune your model with the compiler enabled to find this increased batch size. To save time, use the reference table to pick up the largest batch sizes that can be used with the tested models.

Note
The batch sizes are local batch size that fit into each individual GPU in the respective instance type. You should also adjust the learning rate when changing the batch size.

PyTorch 1.12.0

Natural language processing (NLP) models

The following models are tested for training jobs for all combinations of single-node and multi-node with single or multi GPU cores and Automatic Mixed Precision (AMP) as indicated.

Bring Your Own Deep Learning Model

This guide walks you through how to adapt your training script for a compiler-accelerated training job. The preparation of your training script depends on the following:

- Training settings such as single-core or distributed training.
- Frameworks and libraries that you use to create the training script.

Choose one of the following topics depending on the framework you use.

Topics
- PyTorch (p. 1814)
- TensorFlow (p. 1819)

Note
After you finish preparing your training script, you can run a SageMaker training job using the SageMaker framework estimator classes. For more information, see the previous topic at Enable SageMaker Training Compiler (p. 1822).

PyTorch

Bring your own PyTorch model to SageMaker, and run the training job with SageMaker Training Compiler.

Topics
- PyTorch Models with Hugging Face Transformers (p. 1814)

PyTorch Models with Hugging Face Transformers

PyTorch models with Hugging Face Transformers are based on PyTorch's torch.nn.Module API. Hugging Face Transformers also provides Trainer and pretrained model classes for PyTorch to help reduce the effort for configuring natural language processing (NLP) models. After preparing your training script, you can launch a training job using the SageMaker PyTorch or HuggingFace estimator with the SageMaker Training Compiler configuration when you'll proceed to the next topic at Enable SageMaker Training Compiler (p. 1822).

Tip
When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying padding='max_length'. Do not
use padding='longest' because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can trigger recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.

Topics
- Large Language Models Using the Hugging Face Transformers Trainer Class (p. 1815)
- Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API) (p. 1816)

Large Language Models Using the Hugging Face Transformers Trainer Class

If you use the transformers library's Trainer class, you don't need to make any additional changes to your training script. SageMaker Training Compiler automatically compiles your Trainer model if you enable it through the estimator class. The following code shows the basic form of a PyTorch training script with Hugging Face Trainer API.

```python
from transformers import Trainer, TrainingArguments

training_args=TrainingArguments(**kwargs)
trainer=Trainer(args=training_args, **kwargs)
```

Topics
- For single GPU training (p. 1815)
- For distributed training (p. 1815)
- Best Practices to Use SageMaker Training Compiler with Trainer (p. 1816)

For single GPU training

You don't need to change your code when you use the transformers.Trainer class.

For distributed training

PyTorch v1.11.0 and later

To run distributed training with SageMaker Training Compiler, you must add the following _mp_fn() function in your training script and wrap the main() function. It redirects the _mp_fn(index) function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the main() function of your training script.

```python
def _mp_fn(index):
    main()
```

This function accepts the index argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

For Transformers v4.17 and before with PyTorch v1.10.2 and before

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job, and you don't need to make any modification in your training script. Instead, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the entry_point argument and pass your training script to the hyperparameters argument in the SageMaker Hugging Face estimator.
Best Practices to Use SageMaker Training Compiler with Trainer

- Make sure that you use SyncFree optimizers by setting the `optim` argument to `adamw_torch_xla` while setting up `transformers.TrainingArgument`. See also `Optimizer` in the Hugging Face Transformers documentation.

- Ensure that the throughput of the data processing pipeline is higher than the training throughput. You can tweak the `dataloader_num_workers` and `preprocessing_num_workers` arguments of the `transformers.TrainingArgument` class to achieve this. Typically, these need to be greater than or equal to the number of GPUs but less than the number of CPUs.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 1822).

Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API)

If you have a training script that uses PyTorch directly, you need to make additional changes to your PyTorch training script to implement PyTorch/XLA. Follow the instructions to modify your script to properly set up the PyTorch/XLA primatives.

Topics

- For single GPU training (p. 1816)
- For distributed training (p. 1817)
- Best Practices to Use SageMaker Training Compiler with PyTorch/XLA (p. 1818)

For single GPU training

1. Import the optimization libraries.

   ```python
   import torch_xla
   import torch_xla.core.xla_model as xm
   ```

2. Change the target device to be XLA instead of `torch.device("cuda")`

   ```python
   device=xm.xla_device()
   ```

3. If you’re using PyTorch’s Automatic Mixed Precision (AMP), do the following:
   a. Replace `torch.cuda.amp` with the following:

      ```python
      import torch_xla.amp
      ```

   b. Replace `torch.optim.SGD` and `torch.optim.Adam` with the following:

      ```python
      import torch_xla.amp.syncfree.Adam as adam
      import torch_xla.amp.syncfree.SGD as SGD
      ```

   c. Replace `torch.cuda.amp.GradScaler` with the following:

      ```python
      import torch_xla.amp.GradScaler as grad_scaler
      ```

4. If you’re not using AMP, replace `optimizer.step()` with the following:

   ```python
   xm.optimizer_step(optimizer)
   ```
5. If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's ParallelLoader class:

```python
import torch_xla.distributed.parallel_loader as pl
parallel_loader=pl.ParallelLoader(dataloader, [device]).per_device_loader(device)
```

6. Add `mark_step` at the end of the training loop when you're not using `parallel_loader`:

```python
xm.mark_step()
```

7. To checkpoint your training, use the PyTorch/XLA's model checkpoint method:

```python
xm.save(model.state_dict(), path_to_save)
```

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 1822).

**For distributed training**

In addition to the changes listed in the previous For single GPU training (p. 1816) section, add the following changes to properly distribute workload across GPUs.

1. If you're using AMP, add `all_reduce` after `scaler.scale(loss).backward()`:

```python
gradients=xm._fetch_gradients(optimizer)
xm.all_reduce('sum', gradients, scale=1.0/xm.xrt_world_size())
```

2. If you need to set variables for `local_ranks` and `world_size`, use similar code to the following:

```python
local_rank=xm.get_local_ordinal()
world_size=xm.xrt_world_size()
```

3. For any `world_size` (num_gpus_per_node*num_nodes) greater than 1, you must define a train sampler which should look similar to the following:

```python
import torch_xla.core.xla_model as xm
if xm.xrt_world_size() > 1:
    train_sampler=torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=xm.xrt_world_size(),
        rank=xm.get_ordinal(),
        shuffle=True
    )
train_loader=torch.utils.data.DataLoader(
    train_dataset,
    batch_size=args.batch_size,
    sampler=train_sampler,
    drop_last=args.drop_last,
    shuffle=False if train_sampler else True,
    num_workers=args.num_workers
)
```

4. Make the following changes to make sure you use the `parallel_loader` provided by the `torch_xla_distributed` module.

```python
import torch_xla.distributed.parallel_loader as pl
```
train_device_loader=pl.MpDeviceLoader(train_loader, device)

The `train_device_loader` functions like a regular PyTorch loader as follows:

```python
for step, (data, target) in enumerate(train_device_loader):
    optimizer.zero_grad()
    output=model(data)
    loss=torch.nn.NLLLoss(output, target)
    loss.backward()
```

With all of these changes, you should be able to launch distributed training with any PyTorch model without the Transformer Trainer API. Note that these instructions can be used for both single-node multi-GPU and multi-node multi-GPU.

5. For PyTorch v1.11.0 and later

To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the `main()` function of your training script.

```python
def _mp_fn(index):
    main()
```

This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

For Transformers v4.17 and before with PyTorch v1.10.2 and before

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job and requires you to pass a SageMaker distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker Hugging Face estimator.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 1822).

Best Practices to Use SageMaker Training Compiler with PyTorch/XLA

If you want to leverage the SageMaker Training Compiler on your native PyTorch training script, you may want to first get familiar with PyTorch on XLA devices. The following sections list some best practices to enable XLA for PyTorch.

**Note**

This section for best practices assumes that you use the following PyTorch/XLA modules:

```python
import torch_xla.core.xla_model as xm
import torch_xla.distributed.parallel_loader as pl
```

Understand the lazy mode in PyTorch/XLA

One significant difference between PyTorch/XLA and native PyTorch is that the PyTorch/XLA system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch/XLA system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.MpDeviceLoader/`
pl.ParallelLoader, or when you explicitly request the value of a tensor such as by calling loss.item() or print(loss).

**Minimize the number of compilation-and-executions using pl.MpDeviceLoader/pl.ParallelLoader and xm.step_closure**

For best performance, you should keep in mind the possible ways to initiate *compilation-and-executions* as described in Understand the lazy mode in PyTorch/XLA (p. 1818) and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by pl.MpDeviceLoader/pl.ParallelLoader. The MpDeviceLoader is optimized for XLA and should always be used if possible for best performance. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using xm.add_step_closure() to avoid unnecessary compilation-and-executions.

**Use AMP and syncfree optimizers**

Training in Automatic Mixed Precision (AMP) mode significantly accelerates your training speed by leveraging the Tensor cores of NVIDIA GPUs. SageMaker Training Compiler provides syncfree optimizers that are optimized for XLA to improve AMP performance. Currently, the following three syncfree optimizers are available and should be used if possible for best performance.

```
torch_xla.amp.syncfree.SGD
torch_xla.amp.syncfree.Adam
torch_xla.amp.syncfree.AdamW
```

These syncfree optimizers should be paired with torch_xla.amp.GradScaler for gradient scaling/unscaling.

**TensorFlow**

Bring your own TensorFlow model to SageMaker, and run the training job with SageMaker Training Compiler.

**TensorFlow Models**

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API.

**Tip**

For preprocessing your input dataset, ensure that you use a static input shape. Dynamic input shape can initiate recompilation of the model and might increase total training time.

**Using Keras (Recommended)**

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (tf.keras.Model).

**For single GPU training**

There's no additional change you need to make in the training script.

**Without Keras**

SageMaker Training Compiler does not support eager execution in TensorFlow. Accordingly, you should wrap your model and training loops with the TensorFlow function decorator (@tf.function) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.
For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the `@tf.function` decorator in front of every function that you use for constructing a TensorFlow model.

TensorFlow Models with Hugging Face Transformers

TensorFlow models with Hugging Face Transformers are based on TensorFlow's `tf.keras.Model` API. Hugging Face Transformers also provides pretrained model classes for TensorFlow to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Run TensorFlow Training Jobs with SageMaker Training Compiler (p. 1829).

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API, such as the TensorFlow transformer models.

**Tip**

When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.

Topics

- Using Keras (p. 1820)
- Without Keras (p. 1821)

Using Keras

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (`tf.keras.Model`). As noted in the Quick tour page in the Hugging Face Transformers documentation, you can use the models as regular TensorFlow Keras models.

For single GPU training

There's no additional change you need to make in the training script.

For distributed training

SageMaker Training Compiler acceleration works transparently for multi-GPU workloads when the model is constructed and trained using Keras APIs within the scope of `tf.distribute.Strategy.scope()` call.

1. Choose the right distributed training strategy.
   a. For single-node multi-GPU, use `tf.distribute.MirroredStrategy` to set the strategy.

   ```python
   strategy = tf.distribute.MirroredStrategy()
   ```

   b. For multi-node multi-GPU, add the following code to properly set the TensorFlow distributed training configuration before creating the strategy.

   ```python
   def set_sm_dist_config():
       DEFAULT_PORT = '8890'
       DEFAULT_CONFIG_FILE = '/opt/ml/input/config/resourceconfig.json'
       with open(DEFAULT_CONFIG_FILE) as f:
           ...  
   ```
Use `tf.distribute.MultiWorkerMirroredStrategy` to set the strategy.

```python
strategy = tf.distribute.MultiWorkerMirroredStrategy()
```

2. Using the strategy of your choice, wrap the model.

```python
with strategy.scope():
    # create a model and do fit
```

**Without Keras**

If you want to bring custom models with custom training loops using TensorFlow without Keras, you should wrap the model and the training loop with the TensorFlow function decorator (@tf.function) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

**For single GPU training**

TensorFlow 2.0 or later has the eager execution on by default, so you should add the @tf.function decorator in front of every function that you use for constructing a TensorFlow model.

**For distributed training**

In addition to the changes needed for Using Keras for distributed training, you need to ensure that functions to be run on each GPU are annotated with @tf.function, while cross-GPU communication functions are not annotated. An example training code should look like the following:

```python
@tf.function()
def compiled_step(inputs, outputs):  
    with tf.GradientTape() as tape:
        pred=model(inputs, training=True) 
        total_loss=loss_object(outputs, pred)/args.batch_size 
        gradients=tape.gradient(total_loss, model.trainable_variables) 
    return total_loss, pred, gradients

def train_step(inputs, outputs): 
    total_loss, pred, gradients=compiled_step(inputs, outputs) 
    if args.weight_decay > 0.: 
        gradients=[g+v*args.weight_decay for g,v in zip(gradients, model.trainable_variables)] 
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
```
train_loss.update_state(total_loss)
train_accuracy.update_state(outputs, pred)

@tf.function()
def train_step_dist(inputs, outputs):
    strategy.run(train_step, args= (inputs, outputs))

Note that this instruction can be used for both single-node multi-GPU and multi-node multi-GPU.

Enable SageMaker Training Compiler

SageMaker Training Compiler is built into the SageMaker Python SDK and AWS Deep Learning Containers so that you don't need to change your workflows to enable Training Compiler. Choose one of the following topics that matches with your use case.

Topics

- Run PyTorch Training Jobs with SageMaker Training Compiler (p. 1822)
- Run TensorFlow Training Jobs with SageMaker Training Compiler (p. 1829)

Run PyTorch Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics

- Using the SageMaker Python SDK (p. 1822)
- Using the SageMaker CreateTrainingJob API Operation (p. 1829)

Using the SageMaker Python SDK

SageMaker Training Compiler for PyTorch is available through the SageMaker PyTorch and HuggingFace framework estimator classes. To turn on SageMaker Training Compiler, add the compiler_config parameter to the SageMaker estimators. Import the TrainingCompilerConfig class and pass an instance of it to the compiler_config parameter. The following code examples show the structure of SageMaker estimator classes with SageMaker Training Compiler turned on.

Tip
To get started with prebuilt models provided by PyTorch or Transformers, try using the batch sizes provided in the reference table at Tested Models (p. 1803).

Note
The native PyTorch support is available in the SageMaker Python SDK v2.121.0 and later. Make sure that you update the SageMaker Python SDK accordingly.

Note
Starting PyTorch v1.12.0, SageMaker Training Compiler containers for PyTorch are available. Note that the SageMaker Training Compiler containers for PyTorch are not prepackaged with Hugging Face Transformers. If you need to install the library in the container, make sure that you add the requirements.txt file under the source directory when submitting a training job. For PyTorch v1.11.0 and before, use the previous versions of the SageMaker Training Compiler containers for Hugging Face and PyTorch.
For a complete list of framework versions and corresponding container information, see the section called “Supported Frameworks” (p. 1801).

For information that fits your use case, see one of the following options.
For single GPU training

PyTorch v1.12.0

To compile and train a PyTorch model, configure a SageMaker PyTorch estimator with SageMaker Training Compiler as shown in the following code example.

```
from sagemaker.pytorch import PyTorch, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters=
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate

pytorch_estimator=PyTorch(
    entry_point='train.py',
    source_dir='path-to-requirements-file', # Optional. Add this if need to install additional packages.
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='1.12.0',
    py_version='py3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_estimator.fit()
```

Hugging Face Transformers with PyTorch v1.11.0 and before

To compile and train a transformer model with PyTorch, configure a SageMaker Hugging Face estimator with SageMaker Training Compiler as shown in the following code example.

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters=
```
Enable Training Compiler

```

"n_gpus": 1,
"batch_size": batch_size,
"learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.21.1',
    pytorch_version='1.11.0',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disableProfiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

To prepare your training script, see the following pages.

- **For single GPU training (p. 1815)** of a PyTorch model using Hugging Face Transformers' Trainer API
- **For single GPU training (p. 1816)** of a PyTorch model without Hugging Face Transformers' Trainer API

To find end-to-end examples, see the following notebooks:

- Compile and Train a Hugging Face Transformers Trainer Model for Question and Answering with the SQuAD dataset
- Compile and Train a Hugging Face Transformer BERT Model with the SST Dataset using SageMaker Training Compiler
- Compile and Train a Binary Classification Trainer Model with the SST2 Dataset for Single-Node Single-GPU Training

**For distributed training**

**PyTorch v1.12**

For PyTorch v1.12, you can run distributed training with SageMaker Training Compiler by adding the `pytorch_xla` option specified to the `distribution` parameter of the SageMaker PyTorch estimator class.

**Note**

This native PyTorch support is available in the SageMaker Python SDK v2.121.0 and later. Make sure that you update the SageMaker Python SDK.

```

from sagemaker.pytorch import PyTorch, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')
```

1824
### Enable Training Compiler

- An updated max batch size that can fit to GPU memory with compiler
  
  ```python
  batch_size=26
  ```

- Update learning rate

  ```python
  learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count
  ```

  Hyperparameters:
  ```python
  hyperparameters={
      "n_gpus": num_gpus,
      "batch_size": batch_size,
      "learning_rate": learning_rate
  }
  ```

  ```python
  pytorch_estimator=PyTorch(
      entry_point='your_training_script.py',
      source_dir='path-to-requirements-file', # Optional. Add this if need to install additional packages.
      instance_count=instance_count,
      instance_type=instance_type,
      framework_version='1.12.0',
      py_version='py3',
      hyperparameters=hyperparameters,
      compiler_config=TrainingCompilerConfig(),
      distribution ={'pytorchxla': { 'enabled': True }},
      disable_profiler=True,
      debugger_hook_config=False
  )
  ```

  ```python
  pytorch_estimator.fit()
  ```

**Tip**
To prepare your training script, see [PyTorch](p. 1814)

---

Transformers v4.21 with PyTorch v1.11

For PyTorch v1.11 and later, SageMaker Training Compiler is available for distributed training with the `pytorch_xla` option specified to the distribution parameter.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='your_training_script.py',
    instance_count=instance_count,
    instance_type=instance_type,
)```
Tip
To prepare your training script, see the following pages.

- For distributed training (p. 1815) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 1817) of a PyTorch model without Hugging Face Transformers' Trainer API

Transformers v4.17 with PyTorch v1.10.2 and before

For the supported version of PyTorch v1.10.2 and before, SageMaker Training Compiler requires an alternate mechanism for launching a distributed training job. To run distributed training, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the `entry_point` argument, and pass your training script to the `hyperparameters` argument. The following code example shows how to configure a SageMaker Hugging Face estimator applying the required changes.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
um_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

training_script="your_training_script.py"

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate,
    "training_script": training_script  # Specify the file name of your training script.
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='distributed_training_launcher.py',  # Specify the distributed training launcher script.
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.17.0',
    pytorch_version='1.11.0',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    distribution ={'pytorchxla' : { 'enabled': True }},
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```
pytorch_huggingface_estimator.fit()

The launcher script should look like the following. It wraps your training script and configures the distributed training environment depending on the size of the training instance of your choice.

```
# distributed_training_launcher.py
#!/bin/python

import subprocess
import sys

if __name__ == '__main__':
    arguments_command = " ".join([arg for arg in sys.argv[1:]])
    # The following line takes care of setting up an inter-node communication as well as managing intra-node workers for each GPU.
    subprocess.check_call("python -m torch_xla.distributed.sm_dist " + arguments_command, shell=True)
```

**Tip**
To prepare your training script, see the following pages.

- For distributed training (p. 1815) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 1817) of a PyTorch model without Hugging Face Transformers' Trainer API

**Tip**
To find end-to-end examples, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

**Note**
When using the SageMaker Hugging Face estimator, you must specify the transformers_version, pytorch_version, hyperparameters, and compiler_config parameters to enable SageMaker Training Compiler. You cannot use image_uri to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 1801).

- **entry_point** (str) – Required. Specify the file name of your training script.

  **Note**
  To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, specify the file name of a launcher script to this parameter. The launcher script should
Enable Training Compiler

For more information, see the following example notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- Be prepared to wrap your training script and configure the distributed training environment. For more information, see the following example notebooks:
  - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
  - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- source_dir (str) – Optional. Add this if need to install additional packages. To install packages, you need to prepare a requirements.txt file under this directory.
- instance_count (int) – Required. Specify the number of instances.
- instance_type (str) – Required. Specify the instance type.
- transformers_version (str) – Required only when using the SageMaker Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 1801).
- framework_version or pytorch_version (str) – Required. Specify the PyTorch version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 1801).

**Note**
When using the SageMaker Hugging Face estimator, you must specify both transformers_version and pytorch_version.

- hyperparameters (dict) – Optional. Specify hyperparameters for the training job, such as n_gpus, batch_size, and learning_rate. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called “Tested Models” (p. 1803) and SageMaker Training Compiler Example Notebooks and Blogs (p. 1835).

**Note**
To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, you need to add an additional parameter, "training_script", to specify your training script, as shown in the preceding code example.

- compiler_config (TrainingCompilerConfig object) – Required to activate SageMaker Training Compiler. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the TrainingCompilerConfig class.
  - enabled (bool) – Optional. Specify True or False to turn on or turn off SageMaker Training Compiler. The default value is True.
  - debug (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to True. However, the additional logging might add overhead and slow down the compiled training job. The default value is False.
  - distribution (dict) – Optional. To run a distributed training job with SageMaker Training Compiler, add distribution = { 'pytorchxla' : { 'enabled': True } }.

**Warning**
If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called “Considerations” (p. 1837). To turn the Debugger functionalities off, add the following two arguments to the estimator:

```python
disable_profiler=True,
debugger_hook_config=False
```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With TrainingCompilerConfig(debug=False)
Found configuration for Training Compiler
Configuring SM Training Compiler...

• With TrainingCompilerConfig(debug=True)

Found configuration for Training Compiler
Configuring SM Training Compiler...
Training Compiler set to debug mode

Using the SageMaker CreateTrainingJob API Operation

SageMaker Training Compiler configuration options must be specified through the AlgorithmSpecification and HyperParameters field in the request syntax for the CreateTrainingJob API operation.

"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false",
    "sagemaker_pytorch_xla_multi_worker_enabled": "false"  // set to "true" for distributed training
}

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see Supported Frameworks (p. 1801).

Run TensorFlow Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics
• Using the SageMaker Python SDK (p. 1829)
• Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 1833)
• Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation (p. 1835)

Using the SageMaker Python SDK

To turn on SageMaker Training Compiler, add the compiler_config parameter to the SageMaker TensorFlow or Hugging Face estimator. Import the TrainingCompilerConfig class and pass an instance of it to the compiler_config parameter. The following code examples show the structure of the SageMaker estimator classes with SageMaker Training Compiler turned on.

Tip
To get started with prebuilt models provided by the TensorFlow and Transformers libraries, try using the batch sizes provided in the reference table at Tested Models (p. 1803).
Note
SageMaker Training Compiler for TensorFlow is available through the SageMaker TensorFlow and Hugging Face framework estimators.

For information that fits your use case, see one of the following options.

**For single GPU training**

**TensorFlow**

```python
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
  "n_gpus": 1,
  "batch_size": batch_size,
  "learning_rate": learning_rate
}

tensorflow_estimator=TensorFlow(
  entry_point='train.py',
  instance_count=1,
  instance_type='ml.p3.2xlarge',
  framework_version='2.9.1',
  hyperparameters=hyperparameters,
  compiler_config=TrainingCompilerConfig(),
  disable_profiler=True,
  debugger_hook_config=False
)

tensorflow_estimator.fit()
```

To prepare your training script, see the following pages.
- **For single GPU training (p. 1819)** of a model constructed using TensorFlow Keras (tf.keras.*).
- **For single GPU training (p. 1820)** of a model constructed using TensorFlow modules (tf.* excluding the TensorFlow Keras modules).

**Hugging Face Estimator with TensorFlow**

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size
```

1830
To prepare your training script, see the following pages.

- For single GPU training (p. 1820) of a TensorFlow Keras model with Hugging Face Transformers
- For single GPU training (p. 1821) of a TensorFlow model with Hugging Face Transformers

For distributed training

Hugging Face Estimator with TensorFlow

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters=
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.21.1',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_huggingface_estimator.fit()
```
Enable Training Compiler

tensorflow_huggingface_estimator.fit()

Tip
To prepare your training script, see the following pages.

- For distributed training (p. 1820) of a TensorFlow Keras model with Hugging Face Transformers
- For distributed training (p. 1821) of a TensorFlow model with Hugging Face Transformers

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

Note
When using the SageMaker Hugging Face estimator, you must specify the transformers_version, tensorflow_version, hyperparameters, and compiler_config parameters to enable SageMaker Training Compiler. You cannot use image_uri to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 1801).

- entry_point (str) – Required. Specify the file name of your training script.
- instance_count (int) – Required. Specify the number of instances.
- instance_type (str) – Required. Specify the instance type.
- transformers_version (str) – Required only when using the SageMaker Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 1801).
- framework_version or tensorflow_version (str) – Required. Specify the TensorFlow version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 1801).

Note
When using the SageMaker TensorFlow estimator, you must specify framework_version.
When using the SageMaker Hugging Face estimator, you must specify both transformers_version and tensorflow_version.

- hyperparameters (dict) – Optional. Specify hyperparameters for the training job, such as n_gpus, batch_size, and learning_rate. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called “Tested Models” (p. 1803) and SageMaker Training Compiler Example Notebooks and Blogs (p. 1835).
- compiler_config (TrainingCompilerConfig object) – Required. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the TrainingCompilerConfig class.
  - enabled (bool) – Optional. Specify True or False to turn on or turn off SageMaker Training Compiler. The default value is True.
  - debug (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to True. However, the additional logging might add overhead and slow down the compiled training job. The default value is False.

Warning
If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called “Considerations” (p. 1837). To turn the Debugger functionalities off, add the following two arguments to the estimator:
disable_profiler=True,
debugger_hook_config=False

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With `TrainingCompilerConfig(debug=False)`
  
  | Found configuration for Training Compiler | Configuring SM Training Compiler... |

- With `TrainingCompilerConfig(debug=True)`
  
  | Found configuration for Training Compiler | Configuring SM Training Compiler... | Training Compiler set to debug mode |

Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers

AWS Deep Learning Containers (DLC) for TensorFlow use adapted versions of TensorFlow that include changes on top of the open-source TensorFlow framework. The SageMaker Framework Deep Learning Containers are optimized for the underlying AWS infrastructure and Amazon SageMaker. With the advantage of using the DLCs, SageMaker Training Compiler integration adds more performance improvements over the native TensorFlow. Furthermore, you can create a custom training container by extending the DLC image.

**Note**
This Docker customization feature is currently available only for TensorFlow.

To extend and customize the SageMaker TensorFlow DLCs for your use-case, use the following instructions.

**Create a Dockerfile**

Use the following Dockerfile template to extend the SageMaker TensorFlow DLC. You must use the SageMaker TensorFlow DLC image as the base image of your Docker container. To find the SageMaker TensorFlow DLC image URIs, see Supported Frameworks.

```bash
# SageMaker TensorFlow Deep Learning Container image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/tensorflow-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"
# This environment variable is used by the SageMaker container
# to determine user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# Add more code lines to customize for your use-case
...
```

For more information, see [Step 2: Create and upload the Dockerfile and Python training scripts](#).

Consider the following pitfalls when extending SageMaker Framework DLCs:

- Do not explicitly uninstall or change the version of TensorFlow packages in SageMaker containers. Doing so causes the AWS optimized TensorFlow packages to be overwritten by open-source TensorFlow packages, which might result in performance degradation.
• Watch out for packages that have a particular TensorFlow version or flavor as a dependency. These packages might implicitly uninstall the AWS optimized TensorFlow and install open-source TensorFlow packages.

For example, there's a known issue that the tensorflow/models and tensorflow/text libraries always attempt to reinstall open source TensorFlow. If you need to install these libraries to choose a specific version for your use case, we recommend that you look into the SageMaker TensorFlow DLC Dockerfiles for v2.9 or later. The paths to the Dockerfiles are typically in the following format: tensorflow/training/docker/<tensorflow-version>/py3/<cuda-version>/Dockerfile.gpu. In the Dockerfiles, you should find the code lines to reinstall AWS managed TensorFlow binary (specified to the TF_URL environment variable) and other dependencies in order. The reinstallation section should look like the following example:

```bash
# tf-models does not respect existing installations of TensorFlow
# and always installs open source TensorFlow
RUN pip3 install --no-cache-dir -U \
    tf-models-official==x.y.z

RUN pip3 uninstall -y tensorflow tensorflow-gpu \
    ; pip3 install --no-cache-dir -U \
    $(TF_URL) \
    tensorflow-io==x.y.z \n    tensorflow-datasets==x.y.z
```

### Build and push to ECR

To build and push your Docker container to Amazon ECR, follow the instructions in the following links:

- **Step 3: Build the container**
- **Step 4: Test the container**
- **Step 5: Push the container to Amazon ECR**

### Run using the SageMaker Python SDK Estimator

Use the SageMaker TensorFlow framework estimator as usual. You must specify `image_uri` to use the new container you hosted in Amazon ECR.

```python
import sagemaker, boto3
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'
region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'

byoc_image_uri = 'https://{}.{}/{}:{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/tf-custom-container-test:latest
```
estimator = TensorFlow(
    image_uri=image_uri,
    role=get_execution_role(),
    base_job_name='tf-custom-container-test-job',
    instance_count=1,
    instance_type='ml.p3.8xlarge'
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

# Start training
estimator.fit()

Enable SageMaker Training Compiler Using the SageMaker
CreateTrainingJob API Operation

SageMaker Training Compiler configuration options must be specified through the
AlgorithmSpecification and HyperParameters field in the request syntax for the
CreateTrainingJob API operation.

"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false"
}

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler
implemented, see Supported Frameworks (p. 1801).

SageMaker Training Compiler Example Notebooks
and Blogs

The following blogs, case studies, and notebooks provide examples of how to implement SageMaker
Training Compiler.

Example notebooks are provided in the SageMaker examples GitHub repository, and you can also browse
them on the SageMaker examples website.

Blogs and Case Studies

The following blogs discuss case studies about using SageMaker Training Compiler.

- New – Introducing SageMaker Training Compiler
- Hugging Face Transformers BERT fine-tuning using Amazon SageMaker Training Compiler
- Speed up Hugging Face Training Jobs on AWS by Up to 50% with SageMaker Training Compiler

Examples Notebooks

To find examples of using SageMaker Training Compiler, see the Training Compiler page in the Amazon
SageMaker Example Read the Docs website.
SageMaker Training Compiler Best Practices and Considerations

Review the following best practices and considerations when using SageMaker Training Compiler.

Best Practices

Use the following guidelines to achieve the best results when you run training jobs with SageMaker Training Compiler.

General Best Practices

- Make sure that you use one of the Supported Instance Types (p. 1802) and Tested Models (p. 1803).
- When you create a tokenizer for an NLP model using the Hugging Face Transformers library in your training script, make sure that you use a static input tensor shape by specifying padding='max_length'. Do not use padding='longest' because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.
- Measure GPU memory utilization to make sure that you use the maximum batch size that can fit into the GPU memory. Amazon SageMaker Training Compiler reduces the memory footprint of your model during training, which typically allows you to fit a larger batch_size in the GPU memory. Using a larger batch_size results in a better GPU utilization and reduces the total training time.

When you adjust the batch size, you also have to adjust the learning_rate appropriately. For example, if you increased the batch size by a factor of \( k \), you need to adjust learning_rate linearly (simple multiplication by \( k \)) or multiply by the square root of \( k \). This is to achieve the same or similar convergence behavior in the reduced training time. For reference of batch_size tested for popular models, see Tested Models (p. 1803).
- To debug the compiler-accelerated training job, enable the debug flag in the compiler_config parameter. This enables SageMaker to put the debugging logs into SageMaker training job logs.

```python
huggingface_estimator=HuggingFace(
    ...
    compiler_config=TrainingCompilerConfig(debug=True)
)
```

Note that if you enable full debugging of the training job with the compiler, this might add some overhead.

Best Practices for PyTorch

- If you bring a PyTorch model and want to checkpoint it, make sure you use PyTorch/XLA’s model save function to properly checkpoint your model. For more information about the function, see torch_xla.core.xla_model.save in the PyTorch on XLA Devices documentation.

To learn how to add the modifications to your PyTorch script, see Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API) (p. 1816).

For more information about the actual application of using the model save function, see Checkpoint Writing and Loading in the Hugging Face on PyTorch/XLA TPUs: Faster and cheaper training blog.
- To achieve the most optimal training time for distributed training, consider the following.
• Use instances with multiple GPUs instead of using single-gpu instances. For example, a single ml.p3dn.24xlarge instance has faster training time compared to 8 x ml.p3.2xlarge instances.
• Use instances with EFA support such as ml.p3dn.24xlarge and ml.p4d.24xlarge. These instance types have accelerated networking speed and reduce training time.
• Tune the preprocessing_num_workers parameter for datasets, so that model training is not delayed by slow preprocessing.

Considerations
Consider the following when using SageMaker Training Compiler.

Performance degradation due to logging, checkpointing, and profiling

• Avoid logging, checkpointing, and profiling model tensors that lead to explicit evaluations. To understand what an explicit evaluation is, consider the following code compiling example.

```python
a = b+c
e = a+d
```

A compiler interprets the code as follows and reduces the memory footprint for the variable $a$:

```python
e = b+c+d
```

Now consider the following case in which the code is changed to add a print function for the variable $a$.

```python
a = b+c
e = a+d
print(a)
```

The compiler makes an explicit evaluation of the variable $a$ as follows.

```python
e = b+c+d
a = b+c    # Explicit evaluation
print(a)
```

In PyTorch, for example, avoid using `torch.tensor.items()`, which might introduce explicit evaluations. In deep learning, such explicit evaluations can cause overhead because they break fused operations in a compilation graph of a model and lead to recomputation of the tensors.

If you still want to periodically evaluate the model during training while using SageMaker Training Compiler, we recommend logging and checkpointing at a lower frequency to reduce overhead due to explicit evaluations. For example, log every 10 epochs instead of every epoch.

• Graph compilation runs during the first few steps of training. As a result, the first few steps are expected to be exceptionally slow. However, this is a one-time compilation cost and can be amortized by training for a longer duration because compilation makes future steps much faster. The initial compilation overhead depends on the size of the model, the size of the input tensors, and the distribution of input tensor shapes.

Incorrect use of the PyTorch/XLA APIs when using PyTorch directly

PyTorch/XLA defines a set of APIs to replace some of the existing PyTorch training APIs. Failing to use them properly leads PyTorch training to fail.
• One of the most typical errors when compiling a PyTorch model is due to a wrong device type for operators and tensors. To properly compile a PyTorch model, make sure you use XLA devices \( \text{xm.xla_device()} \) instead of using CUDA or mixing CUDA devices and XLA devices.

• `mark_step()` is a barrier just for XLA. Failing to set it correctly causes a training job to stall.

• PyTorch/XLA provides additional distributed training APIs. Failing to program the APIs properly causes gradients to be collected incorrectly, which causes a training convergence failure.

To properly set up your PyTorch script and avoid the aforementioned incorrect API uses, see *Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API)* (p. 1816).

**SageMaker Training Compiler FAQ**

Use the following FAQ items to find answers to commonly asked questions about SageMaker Training Compiler.

**Q. How do I know SageMaker Training Compiler is working?**

If you successfully launched your training job with SageMaker Training Compiler, you receive the following log messages:

- With `TrainingCompilerConfig(debug=False)`
  
  Found configuration for Training Compiler
  Configuring SM Training Compiler...

- With `TrainingCompilerConfig(debug=True)`
  
  Found configuration for Training Compiler
  Configuring SM Training Compiler...
  Training Compiler set to debug mode

**Q. Which models does SageMaker Training Compiler accelerate?**

SageMaker Training Compiler supports the most popular deep learning models from the Hugging Face transformers library. With most of the operators that the compiler supports, these models can be trained faster with SageMaker Training Compiler. Compilable models include but are not limited to the following: `bert-base-cased`, `bert-base-chinese`, `bert-base-uncased`, `distilbert-base-uncased`, `distilbert-base-uncased-finetuned-sst-2-english`, `gpt2`, `roberta-base`, `roberta-large`, `t5-base`, and `xlm-roberta-base`. The compiler works with most DL operators and data structures and can accelerate many other DL models beyond those that have been tested.

**Q. What happens if I enable SageMaker Training Compiler with a model that isn't tested?**

For an untested model, you might need to first modify the training script to be compatible with SageMaker Training Compiler. For more information, see *Bring Your Own Deep Learning Model* (p. 1814) and follow the instructions on how to prepare your training script.

Once you have updated your training script, you can start the training job. The compiler proceeds to compile the model. However, training speed may not increase and might even decrease relative to the baseline with an untested model. You might need to retune training parameters such as `batch_size` and `learning_rate` to achieve any speedup benefits.

If compilation of the untested model fails, the compiler returns an error. See *SageMaker Training Compiler Troubleshooting* (p. 1839) for detailed information about the failure types and error messages.

**Q. Will I always get a faster training job with SageMaker Training Compiler?**
No, not necessarily. First, SageMaker Training Compiler adds some compilation overhead before the ongoing training process can be accelerated. The optimized training job must run sufficiently long to amortize and make up for this incremental compilation overhead at the beginning of the training job.

Additionally, as with any model training process, training with suboptimal parameters can increase training time. SageMaker Training Compiler can change the characteristics of the training job by, for example, changing the memory footprint of the job. Because of these differences, you might need to retune your training job parameters to speed up training. A reference table specifying the best performing parameters for training jobs with different instance types and models can be found at Tested Models (p. 1803).

Finally, some code in a training script might add additional overhead or disrupt the compiled computation graph and slow training. If working with a customized or untested model, see the instructions at Best Practices to Use SageMaker Training Compiler with PyTorch/XLA (p. 1818).

Q. Can I always use a larger batch size with SageMaker Training Compiler?

Batch size increases in most, but not all, cases. The optimizations made by SageMaker Training Compiler can change the characteristics of your training job, such as the memory footprint. Typically, a Training Compiler job occupies less memory than an uncompiled training job with the native framework, which allows for a larger batch size during training. A larger batch size, and a corresponding adjustment to the learning rate, increases training throughput and can decrease total training time.

However, there could be cases where SageMaker Training Compiler might actually increase memory footprint based on its optimization scheme. The compiler uses an analytical cost model to predict the execution schedule with the lowest cost of execution for any compute-intensive operator. This model could find an optimal schedule that increases memory use. In this case, you won't be able to increase batch sizes, but your sample throughput is still higher.

Q. Does SageMaker Training Compiler work with other SageMaker training features, such as the SageMaker distributed training libraries and SageMaker Debugger?

SageMaker Training Compiler is currently not compatible with SageMaker’s distributed training libraries.

SageMaker Training Compiler is compatible with SageMaker Debugger, but Debugger might degrade computational performance by adding overhead.

Q. Does SageMaker Training Compiler support custom containers (bring your own container)?

SageMaker Training Compiler is provided through AWS Deep Learning Containers, and you can extend a subset of the containers to customize for your use-case. Containers that are extended from AWS DLCs are supported by SageMaker Training Compiler. For more information, see Supported Frameworks and Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 1833). If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

**SageMaker Training Compiler Troubleshooting**

If you run into an error, you can use the following list to try to troubleshoot your training job. If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

Training job is not converging as expected when compared to the native framework training job

Convergence issues range from “the model is not learning when SageMaker Training Compiler is turned on” to “the model is learning but slower than the native framework”. In this troubleshooting guide, we
assume your convergence is fine without SageMaker Training Compiler (in the native framework) and consider this the baseline.

When faced with such convergence issues, the first step is to identify if the issue is limited to distributed training or stems from single-GPU training. Distributed training with SageMaker Training Compiler is an extension of single-GPU training with additional steps.

1. Set up a cluster with multiple instances or GPUs.
2. Distribute input data to all workers.
3. Synchronize the model updates from all workers.

Therefore, any convergence issue in single-GPU training propagates to distributed training with multiple workers.
A flow chart to troubleshoot convergence issues in training jobs when using SageMaker Training Compiler. Descriptions are in the following sections.

Convergence issues occurring in single-GPU training

If your convergence issue stems from single-GPU training, this is likely due to improper settings for hyperparameters or the `torch_xla` APIs.

**Check the hyperparameters**

Training with SageMaker Training Compiler leads to change in the memory footprint of a model. The compiler intelligently arbitrates between re-use and re-compute leading to a corresponding increase or decrease in memory consumption. To leverage this, it is essential to re-tune the batch size and associated hyperparameters when migrating a training job to SageMaker Training Compiler. However, incorrect hyperparameter settings often cause oscillation in training loss and possibly a slower convergence as a result. In rare cases, aggressive hyperparameters might result in the model not learning (the training loss metric doesn't decrease or returns NaN). To identify if the convergence issue is due to the hyperparameters, do a side-by-side test of two training jobs with and without SageMaker Training Compiler while keeping all the hyperparameters the same.

**Check if the torch_xla APIs are properly set up for single-GPU training**

If the convergence issue persists with the baseline hyperparameters, you need to check if there’s any improper usage of the `torch_xla` APIs, specifically the ones for updating the model. Fundamentally, `torch_xla` continues to accumulate instructions (deferring execution) in the form of graph until it is explicitly instructed to run the accumulated graph. The `torch_xla.core.xla_model.mark_step()` function facilitates the execution of the accumulated graph. The graph execution should be synchronized using this function **after each model update** and **before printing and logging any variables**. If it lacks the synchronization step, the model might use stale values from memory during prints, logs, and the subsequent forward passes, instead of using the most recent values that have to be synchronized after every iteration and model update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from the use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient un-scaling, gradient clipping, and then scaling
3. Model update
4. Synchronizing the graph execution with `mark_step()`

To find the right APIs for the operations mentioned in the list, see the guide for [migrating your training script to SageMaker Training Compiler](https://aws.amazon.com/sagemaker/)

**Consider using Automatic Model Tuning**

If the convergence issue arises when re-tuning the batch size and associated hyperparameters such as the learning rate while using SageMaker Training Compiler, consider using **Automatic Model Tuning** to tune your hyperparameters. You can refer to the [example notebook on tuning hyperparameters with SageMaker Training Compiler](https://aws.amazon.com/sagemaker/).

Convergence issues occurring in distributed training

If your convergence issue persists in distributed training, this is likely due to improper settings for weight initialization or the `torch_xla` APIs.

**Check weight initialization across the workers**
If the convergence issue arises when running a distributed training job with multiple workers, ensure there is a uniform deterministic behavior across all workers by setting a constant seed where applicable. Beware of techniques such as weight initialization, which involves randomization. Each worker might end up training a different model in the absence of a constant seed.

**Check if the torch_xla APIs are properly set up for distributed training**

If the issue still persists, this is likely due to improper use of the torch_xla APIs for distributed training. Make sure that you add the following in your estimator to set up a cluster for distributed training with SageMaker Training Compiler.

```python
distribution={'torchxla': {'enabled': True}}
```

This should be accompanied by a function `mp_fn(index)` in your training script, which is invoked once per worker. Without the `mp_fn(index)` function, you might end up letting each of the workers train the model independently without sharing model updates.

Next, make sure that you use the `torch_xla.distributed.parallel_loader.MpDeviceLoader` API along with the distributed data sampler, as guided in the documentation about migrating your training script to SageMaker Training Compiler, as in the following example.

```python
torch.utils.data.distributed.DistributedSampler()
```

This ensures that the input data is properly distributed across all workers.

Finally, to synchronize model updates from all workers, use `torch_xla.core.xla_model._fetch_gradients` to gather gradients from all workers and `torch_xla.core.xla_model.all_reduce` to combine all the gathered gradients into a single update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient synchronization across all workers
3. Gradient un-scaling, gradient clipping, and then gradient scaling
4. Model update
5. Synchronizing the graph execution with `mark_step()`

Note that this checklist has an additional item for synchronizing all workers, compared to the checklist for single-GPU training.

**Training job fails due to missing PyTorch/XLA configuration**

If a training job fails with the `Missing XLA configuration` error message, it might be due to a misconfiguration in the number of GPUs per instance that you use.

XLA requires additional environment variables to compile the training job. The most common missing environment variable is `GPU_NUM_DEVICES`. For the compiler to work properly, you must set this environment variable equal to the number of GPUs per instance.

There are three approaches to set the `GPU_NUM_DEVICES` environment variable:
• **Approach 1** – Use the environment argument of the SageMaker estimator class. For example, if you use an ml.p3.8xlarge instance that has four GPUs, do the following:

```python
# Using the SageMaker Python SDK's HuggingFace estimator
hf_estimator=HuggingFace(
    ...
    instance_type="ml.p3.8xlarge",
    hyperparameters={...},
    environment={
        ...
        "GPU_NUM_DEVICES": "4" # corresponds to number of GPUs on the specified instance
    },
)
```

• **Approach 2** – Use the hyperparameters argument of the SageMaker estimator class and parse it in your training script.

1. To specify the number of GPUs, add a key-value pair to the hyperparameters argument.

   For example, if you use an ml.p3.8xlarge instance that has four GPUs, do the following:

   ```python
   # Using the SageMaker Python SDK's HuggingFace estimator
   hf_estimator=HuggingFace(
       ...
       entry_point = "train.py",
       instance_type= "ml.p3.8xlarge",
       hyperparameters = {
           ...
           "n_gpus": 4 # corresponds to number of GPUs on specified instance
       }
   )
   hf_estimator.fit()
   ```

2. In your training script, parse the n_gpus hyperparameter and specify it as an input for the GPU_NUM_DEVICES environment variable.

   ```python
   # train.py
   import os, argparse
   if __name__ == "__main__":
       parser = argparse.ArgumentParser()
       ...
       # Data, model, and output directories
       parser.add_argument("--output_data_dir", type=str,
           default=os.environ["SM_OUTPUT_DATA_DIR"])
       parser.add_argument("--model_dir", type=str,
           default=os.environ["SM_MODEL_DIR"])
       parser.add_argument("--training_dir", type=str,
           default=os.environ["SM_CHANNEL_TRAIN"])
       parser.add_argument("--test_dir", type=str,
           default=os.environ["SM_CHANNEL_TEST"])
       parser.add_argument("--n_gpus", type=str,
           default=os.environ["SM_NUM_GPUS"])
       args, _ = parser.parse_known_args()
       os.environ["GPU_NUM_DEVICES"] = args.n_gpus
   ```

• **Approach 3** – Hard-code the GPU_NUM_DEVICES environment variable in your training script. For example, add the following to your script if you use an instance that has four GPUs.

   ```python
   # train.py
   import os
   ```
os.environ["GPU_NUM_DEVICES"] = 4

**Tip**
To find the number of GPU devices on machine learning instances that you want to use, see Accelerated Computing in the Amazon EC2 Instance Types page.

**SageMaker Training Compiler doesn't reduce the total training time**

If the total training time does not decrease with SageMaker Training Compiler, we highly recommend you to go over the SageMaker Training Compiler Best Practices and Considerations (p. 1836) page to check your training configuration, padding strategy for the input tensor shape, and hyperparameters.

**Amazon SageMaker Training Compiler Release Notes**

See the following release notes to track the latest updates for Amazon SageMaker Training Compiler.

**SageMaker Training Compiler Release Notes: December 8, 2022**

**Bug Fixes**
- Fixed the seed for PyTorch training jobs starting PyTorch v1.12 to ensure that there is no discrepancy in model initialization across different processes. See also PyTorch Reproducibility.
- Fixed the issue causing PyTorch distributed training jobs on G4dn and G5 instances to not default to communication through PCIe.

**Known Issues**
- Improper use of PyTorch/XLA APIs in Hugging Face’s vision transformers might lead to convergence issues.

**Other Changes**
- When using the Hugging Face Transformers Trainer class, make sure that you use SyncFree optimizers by setting the optim argument to adamw_torch_xla. For more information, see Large Language Models Using the Hugging Face Transformers Trainer Class (p. 1815). See also Optimizer in the Hugging Face Transformers documentation.

**Migration to AWS Deep Learning Containers**

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- PyTorch v1.12.0

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 1800).
SageMaker Training Compiler Release Notes: October 4, 2022

Currency Updates

- Added support for TensorFlow v2.10.0.

Other Changes

- Added Hugging Face NLP models using the Transformers library to TensorFlow framework tests. To find the tested Transformer models, see the section called “Tested Models” (p. 1803).

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow v2.10.0

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 1800).

SageMaker Training Compiler Release Notes: September 1, 2022

Currency Updates

- Added support for Hugging Face Transformers v4.21.1 with PyTorch v1.11.0.

Improvements

- Implemented a new distributed training launcher mechanism to activate SageMaker Training Compiler for Hugging Face Transformer models with PyTorch. To learn more, see Run PyTorch Training Jobs with SageMaker Training Compiler for Distributed Training (p. 1824).
- Integrated with EFA to improve the collective communication in distributed training.
- Added support for G5 instances for PyTorch training jobs. For more information, see the section called “Supported Frameworks, AWS Regions, Instance Types, and Tested Models” (p. 1800).

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- HuggingFace v4.21.1 with PyTorch v1.11.0

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 1800).
SageMaker Training Compiler Release Notes: June 14, 2022

New Features

- Added support for TensorFlow v2.9.1. SageMaker Training Compiler fully supports compiling TensorFlow modules (tf.*) and TensorFlow Keras modules (tf.keras.*).
- Added support for custom containers created by extending AWS Deep Learning Containers for TensorFlow. For more information, see Enable SageMaker Training Compiler Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 1833).
- Added support for G5 instances for TensorFlow training jobs.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow 2.9.1

To find a complete list of the pre-built containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 1800).

SageMaker Training Compiler Release Notes: April 26, 2022

Improvements

- Added support for all of the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

SageMaker Training Compiler Release Notes: April 12, 2022

Currency Updates

- Added support for Hugging Face Transformers v4.17.0 with TensorFlow v2.6.3 and PyTorch v1.10.2.

SageMaker Training Compiler Release Notes: February 21, 2022

Improvements

- Completed benchmark test and confirmed training speed-ups on the ml.g4dn instance types. To find a complete list of tested ml instances, see Supported Instance Types (p. 1802).

SageMaker Training Compiler Release Notes: December 01, 2021

New Features

Migration to AWS Deep Learning Containers

- Amazon SageMaker Training Compiler passed benchmark testing and is migrated to AWS Deep Learning Containers. To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 1800).

Amazon SageMaker Clarify Bias Detection and Model Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided. For additional information about bias metrics and explainability and how to interpret them, see Learn How Amazon SageMaker Clarify Helps Detect Bias, Fairness Measures for Machine Learning in Finance, and the Amazon AI Fairness and Explainability Whitepaper.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection and model explainability:

- Amazon SageMaker Clarify Processing – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Topics

- Prerequisites (p. 1848)
- How SageMaker Clarify Processing Jobs Work (p. 1849)
- Get Started with a SageMaker Clarify Container (p. 1850)
- Configure a SageMaker Clarify Processing Job Container's Input and Output Parameters (p. 1851)
- Configure the Analysis (p. 1852)
- Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 1859)
- Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 1863)
- Amazon SageMaker Clarify Model Explainability (p. 1884)
- Troubleshoot SageMaker Clarify Processing Jobs (p. 1892)

Prerequisites

Before you begin, you need to meet the following prerequisites:
• You need to provide an input dataset as tabular files in CSV or JSON Lines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.

• You need to provide a model artifact that supports either the CSV or JSON Lines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.

• When creating processing jobs with the SageMaker container image, you need the following:
  • Network isolation must be disabled for the processing job.
  • If the model is in a VPC, the processing job must be in the same VPC as the model.
  • The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the "arn:aws:iam::aws:policy/AmazonSageMakerFullAccess" managed policy.

How SageMaker Clarify Processing Jobs Work

A SageMaker processing job uses the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

• pretraining bias metrics
• posttraining bias metrics
• SHAP values for explainability
• Partial dependence plots (PDP)

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the ProcessingOutput parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a shadow endpoint. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.
Get Started with a SageMaker Clarify Container

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process Data (p. 1099) in your account.

The image URIs for the containers are in the following form:

```<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0```

For example:

```205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0```

The following table lists the addresses by AWS Region.

**Docker Images for Clarify Processing Jobs**

<table>
<thead>
<tr>

**Configure a SageMaker Clarify Processing Job Container's Input and Output Parameters**

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as Amazon S3 object or prefix, and an analysis configuration file with input name "analysis_config" as an Amazon S3 object. The job also requires an output parameter: the output location as an Amazon S3 prefix.

You can create and run a processing job with SageMaker `CreateProcessingJob` API using the AWS SDK or CLI or SageMaker Python SDK.

Using SageMaker Python SDK, create a `Processor` using the SageMaker Clarify container image URI:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
instance_count=1,
instance_type='ml.c5.xlarge',
max_runtime_in_seconds=1200,
volume_size_in_gb=100)
```

After you finish creating the Clarify processor, you need to set up the input and output object for the processor.
Note
If you provide the "dataset_uri" through the "analysis_config.json" (see the following topic at Configure the Analysis (p. 1852)), you don't need to create the dataset_input object.

```python
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
    input_name="analysis_config",
    source=analysis_config_path,
    destination="/opt/ml/processing/input/config",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")

dataset_input = ProcessingInput(
    input_name="dataset",
    source=dataset_path,
    destination="/opt/ml/processing/input/data",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")

analysis_result_output = ProcessingOutput(
    source="/opt/ml/processing/output",
    destination=analysis_result_path,
    output_name="analysis_result",
    s3_upload_mode="EndOfJob")
```

Configure the Analysis

The inputs for the analysis are configured by the parameters of the ProcessingInput API. The "analysis_config" value of the input_name specifies the JSON file named analysis_config.json that contains the configuration values. The path to the JSON file is provided in the source parameter of ProcessingInput. Examples of analysis configuration JSON files are provided for JSON files for CSV, JSON Lines, image, and text datasets following the parameter descriptions.

Topics
- Parameters for JSON configuration files (p. 1852)
- Example JSON configuration files (p. 1856)

Parameters for JSON configuration files

In the JSON configuration file, you can specify the following parameters.

- "dataset_type" – (Required) Format of the dataset. Valid values are "text/csv" for CSV, application/jsonlines for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable computer vision explainability. For more information see Common Data Formats for Inference.

- "dataset_uri" – (Optional) Dataset S3 prefix/object URI (if not given as ProcessingInput). If it is a prefix, the processing job recursively collects all S3 files under the prefix. For computer vision, the URI is required and it can either be a path to the image manifest file, or to the bucket of images to be explained.

- "excluded_columns" – A list of names or indices of the columns which are to be excluded from making model inference API calls.

- "features" – (Optional) JMESPath for locating the feature columns for bias metrics, if the dataset format is JSON Lines.
• "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  • "name_or_index" – Facet column name or index.
  • "value_or_threshold" – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.
• "group_variable" – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.
• "headers" – (Optional) A list of column names in the dataset. If the dataset_type is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
• "joinsource_name_or_index" – (Optional) The name or index of the column in the dataset that acts as an identifier column, for example, while performing a join. This column is only used as an identifier, and not used for any other computations. This is an optional field in all cases except when the dataset contains more than one file, and "save_local_shap_values" is set to true.
• "label" – (Optional) Target attribute for the model to be used for bias metrics. Specified as a column name, or as index if the dataset format is CSV, or as JMESPath if the dataset format is JSON Lines.
• "label_values_or_threshold" – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.
• "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.
  • "pdp" – (Optional) Section for configuring partial dependence plots (PDP). Shows the dependence of the target response on a set of input features of interest. Marginalizes over the values of all other input features.
    • "features": ["pdp_feature_1", "pdp_feature_2"...] – (Optional) The list of feature names or indices for which partial dependence plots are to be computed and plotted. If SHAP is not requested, the features must be provided.
    • "grid_resolution" – (Required) Used for numerical features. Represents that number of buckets into which the range of numerical values is divided. This specifies the granularity of the grid for the PDP plot.
    • "top_k_features" – (Optional) If the features parameter is not provided, and shap is provided, Clarify chooses the top k features based on SHAP attributions. You can set this value to specify how many of the top features must be used for PDP plots. The default is 10.
• "post_training_bias" – (Optional) Section on posttraining bias metrics.
  • "methods" – A list of posttraining metrics to be computed.
• "pre_training_bias" – (Optional) Section on pretraining bias metrics.
  • "methods" – A list of pretraining metrics to be computed.
• "shap" – (Optional) Section on SHAP value computation.
  • "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
    • "mean_abs" – Mean of absolute SHAP values for all instances.
    • "mean_sq" – Mean of squared SHAP values for all instances.
    • "median" – Median of SHAP values for all instances.
  • "baseline" – (Optional) A list of rows (at least one), or an S3 object URI. To be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values) and omit any column that must be excluded before being sent to the model. This includes label column, joinsource column, and columns included in the "excluded_columns" field.
    • For Computer Vision, a path to the baseline image that is used to mask out features from the input image. Default: RGB Noise mask.
• For natural language processing (NLP) of text columns, the baseline value should be the value used to replace the unit of text specified by the granularity in the "text_config". Valid values for the unit of text are token, sentence, and paragraph.

• "num_clusters" – (Optional) If "baseline" is not provided, Clarify attempts to compute a baseline by clustering the dataset. The "num_clusters" determines the number of clusters that the dataset is clustered into. Each cluster contributes to a baseline, so the number of clusters directly affects the runtime of SHAP explanations.

• "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.

• "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Use true to save them; false to not save them. The default is false.

• "seed" – (Optional) Seed value for the random number generator to obtain a deterministic SHAP result.

• "text_config" – (Required) The configuration that specifies the natural language processing (NLP) features. If this config is provided, text features are treated as text and explanations are provided for individual units of text. The unit of text is specified by the "granularity".

• "granularity" – (Required) For NLP, determines the unit of granularity for the analysis of text features. Valid values are "token", "sentence", or "paragraph". Each of these units is considered a feature, and SHAP values are computed for the feature specified.

• "image_config" – (Optional) Section for configuring SHAP configuration parameters for computer vision explainability.

• "context" – (Optional) Masks the area around the bounding box of the detected object when running SHAP. Valid values are 0 to mask everything, or 1 to mask nothing. The default value is 1.

• "iou_threshold" – (Optional) Minimum intersection over union (IOU) metric for evaluating predictions against the original detections. Used because detection boxes will shift during masking. The default value is 0.5.

• "max_objects" – (Optional) Used to filter objects detected by the computer vision model by top confidence score. The default is 3.

• "model_type" – Either an object detection model or an image classification model.

• "num_segments" – (Optional) Determines the approximate number of segments to be labeled in the input image. The default is 20.

• "segment_compactness" – (Optional) Determines the shape and size of the image segments generated by SKLearn's slic method. For more details, see scikit-image slic documentation. The default is 5.

• "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The default value is false.
• **predictor** – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
  
  • **accept_type** – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as content_type.

  • **accelerator_type** – (Optional) The type of Elastic Inference (EI) accelerator to attach to the instance. Example: ml.eia1.medium. For more information, see Use Amazon SageMaker Elastic Inference (EI) (p. 2371).

  • **content_template** – (Optional) A template string used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have only one placeholder, $features, which is replaced by the features list at runtime. For example, given "content_template":"{"myfeatures":$features}", if an instance (no label) is 1,2,3, then model input becomes JSON Line '{"myfeatures":[1,2,3]}'.

  • **content_type** – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as the dataset_type format.

  • **custom_attributes** – (Optional) Provides additional information about a request for an inference that is submitted to a model hosted on an Amazon SageMaker endpoint. The information is an opaque value that is forwarded verbatim. You can use this value, for example, to provide an ID that tracks a request. You can also use this value to provide metadata that a service endpoint was programmed to process. The value must consist of no more than 1024 visible US-ASCII characters, as specified in Section 3.3.6. Field Value Components of the Hypertext Transfer Protocol (HTTP/1.1).

  • **endpoint_name** – (Optional) Specifies an existing endpoint to use for getting predictions. Using an existing endpoint reduces the bootstrap time, but can cause a significant load increase for existing endpoints. Be cautious when specifying an existing production endpoint.

  • **endpoint_name-prefix** – (Optional) Provides a custom prefix to the name of the temporary endpoint.

  • **initial_instance_count** – Instance count for the shadow endpoint.

  • **instance_type** – Instance type for the shadow endpoint.

  • **label** – (Optional) Index or JMESPath location in the model output for the target attribute that is used by the bias metrics. If the label is not provided in the CSV accept_type case, then Clarify assumes that the model output is a single numeric value corresponding to the score or probability.

  • **label_headers** – (Optional) A list of values that the "label" takes in the dataset. Associates the scores returned by the model endpoint with their corresponding label values. Used to extract the label value with the highest score as the predicted label.

  • **model_name** – Model name created by CreateModel API, with container mode as SingleModel.

  • **probability** – (Optional) Index or JMESPath location in the model output for probabilities or scores to be used for explainability. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.

  • **target_model** – (Optional) Sets the target model name when using a multi-model endpoint. For more information about multi-model endpoints, see Request Syntax.

  • **probability_threshold** – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. This parameter is used in object detection to filter out objects detected with confidence scores lower than the probability_threshold value. The default value is 0.5.

  • **report** – (Optional) Section on report parameters. A report is generated if this section is present.

  • **name** – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".
Configure the Analysis

- "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".
- "version" – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.

Example JSON configuration files

Here are examples of analysis configuration JSON files for CSV, JSON Lines, image, and text datasets.

Topics

- Analysis configuration JSON file for a CSV dataset (p. 1856)
- Analysis configuration JSON file for a JSON Lines dataset (p. 1857)
- Analysis configuration JSON file for an image dataset (p. 1858)
- NLP analysis configuration JSON file for a text dataset (p. 1859)

Analysis configuration JSON file for a CSV dataset

The following code sample shows how to configure an analysis for a CSV dataset.

```json
{
  "dataset_type": "text/csv",
  "headers": [
    "feature_0",
    "feature_1",
    "feature_2",
    "feature_3",
    "target"
  ],
  "label": "target",
  "label_values_or_threshold": [1],
  "probability_threshold": 0.7,
  "facet": [
    {
      "name_or_index": "feature_1",
      "value_or_threshold": [1]
    },
    {
      "name_or_index": "feature_2",
      "value_or_threshold": [0.7]
    }
  ],
  "group_variable": "feature_3",
  "joinsource_name_or_index": 'column_name',
  "methods": {
    "shap": {
      "baseline": [
        "yes",
        3,
        0.9,
        1
      ],
      "num_samples": 1000,
      "agg_method": "mean",
      "use_logit": true,
      "save_local_shap_values": true,
      "num_clusters": 5
    }
  }
}
```
Configure the Analysis

```json
{
    "seed": 1234,
    "pre_training_bias": {
        "methods": "all"
    },
    "post_training_bias": {
        "methods": "all"
    },
    "report": {
        "name": "report",
        "title": "Analysis Report"
    },
    "predictor": {
        "model_name": "my_model",
        "instance_type": "ml.m5.xlarge",
        "initial_instance_count": 1,
        "content_type": "text/csv",
        "accept_type": "text/csv",
        "accelerator_type": "ml.eia1.medium",
        "custom_attributes": "c00b4f9-df62-4c85-a0bf-7c525f9104a4",
        "label": 0,
        "probability": 1,
        "endpoint_name_prefix": "myendpointprefix",
        "target_model": ""
    }
}
```

Model output as CSV is as follows:

```
Current,[0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02905467338860035]
```

Corresponding predictor configuration is as follows:

```json
"predictor": {
    "accept_type": "text/csv",
    "label": 0,
    "probability": 1,
    ...
}
```

Analysis configuration JSON file for a JSON Lines dataset

The following code sample shows how to configure an analysis for a JSON Lines dataset.

```json
{
    "dataset_type": "application/jsonlines",
    "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
    "headers": ["Label", "Feature1", "Feature2"],
    "label": "data.label",
    "features": "data.features.values",
    "facet": [
        {
            "name_or_index": "Feature1",
            "value_or_threshold": [1, 5]
        },
        {
            "name_or_index": "Feature2",
            "value_or_threshold": [2, 6]
        }
    ]
}
```
Dataset as S3 prefix is as follows:

```json
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```json
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```json
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSON Lines is as follows:

```json
{"predicted_label": "Current", "score": [0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860055]}
```

Corresponding predictor configuration is as follows:

```json
"predictor": {
  ....
  "accept_type": "application/jsonlines",
  "label": "predicted_label",
  "probability": "score",
  ...
}
```

Analysis configuration JSON file for an image dataset

The following code sample shows how to configure an analysis for object detection with Computer Vision.

```json
"dataset_type": "application/x-image",
"dataset_uri": "s3://<BUCKET/KEY>
"probability_threshold": 0.7,
"methods": {
  "shap": {
    "num_samples": 500,
```
NLP analysis configuration JSON file for a text dataset

The following code sample shows how to configure an analysis for natural processing.

```json
{
  "dataset_type": ...

  "methods": {
    "shap": {
      "baseline": "...
      "num_samples": 100
      "text_config": {
        "granularity": "(token|sentence|paragraph)"
      }
    }
  }
}
```

Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 879). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias (for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

Topics
- Compute Resources Required for SageMaker Clarify Processing Jobs (p. 1860)
- Run the Clarify Processing Job (p. 1860)
- Run the Clarify Processing Job with Spark (p. 1861)
- Get the Analysis Results (p. 1861)
Compute Resources Required for SageMaker Clarify Processing Jobs

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:

- Processing jobs can take several minutes or more to complete.
- Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
- Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see Amazon SageMaker Pricing.

Run the Clarify Processing Job

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a DataConfig object, specify information about your trained model with ModelConfig, and provide information about the formats of your predictions with ModelPredictedLabelConfig.

```python
bias_report_output_path = 's3://{}/{}/clarify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=bias_report_output_path,
    label='Target',
    headers=training_data.columns.to_list(),
    dataset_type='text/csv')
model_config = clarify.ModelConfig(
    model_name=model_name,
    instance_type='ml.c5.xlarge',
    instance_count=1,
    accept_type='text/csv')
predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)
```

Use BiasConfig to provide information on which columns contain the facets (sensitive groups, Sex), what the sensitive features (facet_values_or_threshold) might be, and what the desirable outcomes are (label_values_or_threshold).

```python
bias_config = clarify.BiasConfig(
```

1860
Run SageMaker Clarify Processing Jobs

You can run both the pretraining and posttraining analysis in the processing job at the same time with `run_bias()`.

```
clarify_processor.run_bias(
    data_config=bias_data_config,
    bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predictions_config,
    pre_training_methods='all',
    post_training_methods='all')
```

View the results in Studio or download them from the `bias_report_output_path` S3 bucket.

**Run the Clarify Processing Job with Spark**

Apache Spark is a unified analytics engine for large-scale data processing. When working with large datasets, you can use the Spark processing capabilities of SageMaker Clarify to enable your Clarify processing jobs to run faster. To use Spark processing for Clarify jobs, set the instance count to a number greater than one. Clarify uses Spark distributed computing when there is more than one instance per Clarify processor.

The following example shows how to use SageMakerClarifyProcessor to create a Clarify processor with 5 instances.

Clarify runs any jobs associated with this processor using Spark distributed processing.

```
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=5,
    instance_type='ml.c5.xlarge',
    max_runtime_in_seconds=1200,
    volume_size_in_gb=100)
```

If you configure a Clarify job to save local SHAP values in the SHAPConfig class, Spark saves the local SHAP value as multiple part files in parallel.

If you add more instances, we recommend that you also increase the number of instances in the model configuration ModelConfig for the shadow endpoint. This is to prevent the processing instances from being bottlenecked by the shadow endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint to processing instances.

**Get the Analysis Results**

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:

- `analysis.json` – Bias metrics and SHAP values in JSON format.
- `report.ipynb` – Static notebook to visualize the bias metrics and SHAP values.
- `explanations_shap/out.csv` – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.
In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```
{
  "explanations": { . . . },
  "pre_training_bias_metrics": { . . . },
  "post_training_bias_metrics": { . . . }
}
```

SHAP values are in the "explanations" section. Values correspond to the global SHAP value for each feature column.

```
"explanations": {
  "kernel_shap": {
    "label0": {
      "global_shap_values": {
        "feature_0": 0.022486410860333206,
        "feature_1": 0.007381025261958729,
        "feature_2": 0.006843906804137847
      },
      "expected_value": 0.508233428001
    }
  }
}
```

The bias metrics are in the pretraining and posttraining bias metrics sections.

```
{
  "post_training_bias_metrics": {
    "label": "target",
    "label_value_or_threshold": "1",
    "facets": {
      "feature_2": {
        "value_or_threshold": "1",
        "metrics": [
          { "name": "DI", "description": "Disparate Impact (DI)", "value": 0.711340206185567 },
          { "name": "DCR", "description": "Difference in Conditional Rejections (DCR)", "value": -0.34782608695652184 }
          ... 
        ]
      }
    }
  }
}
```

For more information on bias metrics and SHAP values and how to interpret them, see the Amazon AI Fairness and Explainability Whitepaper.

A bar chart of top SHAP values and tables with the bias metrics are provided in the report notebook.
Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet \(d\), experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 868).

For additional information about posttraining bias metrics, see Learn How Amazon SageMaker Clarify Helps Detect Bias and Fairness Measures for Machine Learning in Finance.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

  This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 137). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet \(a\) and for a disfavored facet \(d\). These labels \(y\) are referred to as observed labels to distinguish them from the predicted labels \(y^*\) that are assigned by a machine learning model during the training or inferences stages of the ML life cycle. These labels are used to define probability distributions \(P_a(y)\) and \(P_d(y)\) for their respective facet outcomes.
labels:
- $y$ represents the $n$ observed labels for event outcomes in a training dataset.
- $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.

outcomes:
- A positive outcome (with value 1) for a sample, such as an application acceptance.
  - $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
  - $n'^{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
- A negative outcome (with value 0) for a sample, such as an application rejection.
  - $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
  - $n'^{(0)}$ is the number of predicted labels for negative outcomes (rejections).

facet values:
- facet $a$ – The feature value that defines a demographic that bias favors.
  - $n_a$ is the number of observed labels for the favored facet value: $n_a = n_a^{(1)} + n_a^{(0)}$ the sum of the positive and negative observed labels for the value facet $a$.
  - $n'_a$ is the number of predicted labels for the favored facet value: $n'_a = n'_a^{(1)} + n'_a^{(0)}$ the sum of the positive and negative predicted outcome labels for the facet value $a$. Note that $n'_a = n_a$.
- facet $d$ – The feature value that defines a demographic that bias disfavors.
  - $n_d$ is the number of observed labels for the disfavored facet value: $n_d = n_d^{(1)} + n_d^{(0)}$ the sum of the positive and negative observed labels for the facet value $d$.
  - $n'_d$ is the number of predicted labels for the disfavored facet value: $n'_d = n'_d^{(1)} + n'_d^{(0)}$ the sum of the positive and negative predicted labels for the facet value $d$. Note that $n'_d = n_d$.

probability distributions for outcomes of the labeled facet data outcomes:
- $P_a(y)$ is the probability distribution of the observed labels for facet $a$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $a$ labeled with positive outcomes to the total number, $P_a(y^1) = n_a^{(1)}/n_a$ and the ratio of the number of samples with negative outcomes to the total number, $P_a(y^0) = n_a^{(0)}/n_a$.
- $P_d(y)$ is the probability distribution of the observed labels for facet $d$. For binary labeled data, this distribution is given by the number of samples in facet $d$ labeled with positive outcomes to the total number, $P_d(y^1) = n_d^{(1)}/n_d$ and the ratio of the number of samples with negative outcomes to the total number, $P_d(y^0) = n_d^{(0)}/n_d$.

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

### Posttraining bias metrics

<table>
<thead>
<tr>
<th>Posttraining bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
</table>
| Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1872) | Measures the difference in the proportion of positive predictions between the favored facet $a$ and the disfavored facet $d$. | Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias? | Range for normalized binary & multicategory facet labels: [-1, +1] 
Range for continuous labels: (-∞, +∞) 
Interpretation: 
- Positive values indicate that the favored facet $a$ has a higher proportion of predicted positive outcomes. |

**Difference in Positive Proportions in Predicted Labels (DPPL)**

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions (y’ = 1) for facet a and the proportion of positive predictions (y’ = 1) for facet d. For example, if the model predictions grant loans to 60% of a middle-aged group (facet a) and 50% other age groups (facet d), it might be biased against facet d. In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

$$DPPL = q_a' - q_d'$$
Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a positive predicted outcome of value 1 and \( n_a \) the is number of members of facet \( a \).
- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

If DPPL is close enough to 0, it means that posttraining demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((-\infty, +\infty)\).

- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \). This is referred to as positive bias.
- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.
- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.

**Disparate Impact (DI)**

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1872). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions \((y' = 1)\) for facet \( d \) over the proportion of positive predictions \((y' = 1)\) for facet \( a \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), then DI = \( .5/ .6 \approx 0.8 \), which indicates a positive bias and an adverse impact on the other aged group represented by facet \( d \).

The formula for the ratio of proportions of the predicted labels:

\[
\text{DI} = \frac{q'_d}{q'_a}
\]

Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a positive predicted outcome and \( n_a \) the is number of members of facet \( a \).
- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) a who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

For binary, multicategory facet, and continuous labels, the DI values range over the interval \([0, \infty)\).
• Values less than 1 indicate that facet \textit{a} has a higher proportion of predicted positive outcomes than facet \textit{d}. This is referred to as \textit{positive bias}.

• A value of 1 indicates demographic parity.

• Values greater than 1 indicate that facet \textit{d} has a higher proportion of predicted positive outcomes than facet \textit{a}. This is referred to as \textit{negative bias}.

\textbf{Difference in Conditional Acceptance (DCAcc)}

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels \(y')\) for a certain facet as compared to what was observed in the training dataset (labels \(y\)). For example, if there were more acceptances (a positive outcome) observed in the training dataset for loan applications for a middle-aged group (facet \textit{a}) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet \textit{d}), this might indicate potential bias in the way loans were approved favoring the middle-aged group.

The formula for the difference in conditional acceptance:

\[ \text{DCAcc} = c_a - c_d \]

Where:

• \(c_a = n_a^{(1)} / n_a^{(1)}\) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet \textit{a} to the predicted number of positive outcome (acceptances) for facet \textit{a}.

• \(c_d = n_d^{(1)} / n_d^{(1)}\) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet \textit{d} to the predicted number of predicted positive outcomes (acceptances) for facet \textit{d}.

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

\textbf{Example 1: Positive bias}

Suppose we have dataset of 100 middle-aged people (facet \textit{a}) and 50 people from other age groups (facet \textit{d}) who applied for loans, where the model recommended that 60 from facet \textit{a} and 30 from facet \textit{d} be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet \textit{a} and 20 from facet \textit{d} were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17) and granted loans to 33% more from other age groups than the observed labels suggested (20/30 = 0.67). The calculation of the DCAcc value gives the following:

\[ \text{DCAcc} = 70/60 - 20/30 = 1/2 \]

The positive value indicates that there is a potential bias against the middle-aged facet \textit{a} with a lower acceptance rate as compared with the other facet \textit{d} than the observed data (taken as unbiased) indicate is the case.

\textbf{Example 2: Negative bias}

Suppose we have dataset of 100 middle-aged people (facet \textit{a}) and 50 people from other age groups (facet \textit{d}) who applied for loans, where the model recommended that 60 from facet \textit{a} and 30 from facet \textit{d} be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet \textit{a} and 40 from facet \textit{d} were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and granted loans to 33% more from other age groups than the observed labels suggested (40/30 = 1.33). The calculation of the DCAcc value gives the following:
DCAcc = 50/60 - 40/30 = -1/2

The negative value indicates that there is a potential bias against facet $d$ with a lower acceptance rate as compared with the middle-aged facet $a$ than the observed data (taken as unbiased) indicate is the case.

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions $y'$ by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of $y'$. The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is $(-\infty, +\infty)$.

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is higher than the same ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $a$. The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is the similar to the ratio for facet $d$. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is less than that ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.

### Difference in Conditional Rejection (DCR)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels $y'$) to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels $y$). For example, if there were more observed rejections (a negative outcome) for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were rejected that favored the middle-aged group over other groups.

The formula for the difference in conditional acceptance:

$$DCR = r_d - r_a$$

Where:

- $r_d = \frac{n_d(0)}{n_d'}$ is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet $d$ to the predicted number of negative outcome (rejections) for facet $d$.
- $r_a = \frac{n_a(0)}{n_a'}$ is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet $a$ to the predicted number of negative outcome of value 0 (rejections) for facet $a$.

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet
d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet a and 40 from facet d were rejected. In other words, the model rejected 17% more loans from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and rejected 33% fewer loans from other age groups than the observed labels suggested (40/30 = 1.33). The DCR value quantifies this difference in the ratio of observed to predicted rejection rates between the facets. The positive value indicates that there is a potential bias favoring the middle aged group with lower rejection rates as compared with other groups than the observed data (taken as unbiased) indicate is the case.

$$DCR = \frac{40}{30} - \frac{50}{60} = \frac{1}{2}$$

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet a and 20 from facet d were rejected. In other words, the model rejected 17% fewer loans from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17), and rejected 33% more loans from other age groups than the observed labels suggested (20/30 = 0.67). The negative value indicates that there is a potential bias favoring facet a with lower rejection rates as compared with the middle-aged facet than the observed data (taken as unbiased) indicate is the case.

$$DCR = \frac{20}{30} - \frac{70}{60} = -\frac{1}{2}$$

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is (-∞, +∞).

- Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet d is greater than that ratio for facet a. These values indicate a possible bias against the qualified applicants from facet a. The larger the value of DCR metric, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet a is the similar to the ratio for facet d. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
- Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet d is less than that ratio facet a. These values indicate a possible bias against the qualified applicants from facet d. The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

### Specificity difference (SD)

The specificity difference (SD) is the difference in specificity between the favored facet a and disfavored facet d. Specificity measures how often the model correctly predicts a negative outcome (y'=0). Any difference in these specificities is a potential form of bias.

Specificity is perfect for a facet if all of the y=0 cases are correctly predicted for that facet. Specificity is greater when the model minimizes false positives, known as a Type I error. For example, the difference between a low specificity for lending to facet a, and high specificity for lending to facet d, is a measure of bias against facet d.

The following formula is for the difference in the specificity for facets a and d.

$$SD = \frac{TN_a}{(TN_a + FP_d)} - \frac{TN_d}{(TN_d + FP_a)} = TNR_d - TNR_a$$

The following variables used to calculated SD are defined as follows:

1876
TN_d are the true negatives predicted for facet d.
FP_d are the false positives predicted for facet d.
TN_a are the true negatives predicted for facet a.
FP_a are the false positives predicted for facet a.

\[ \text{TNR}_a = \frac{\text{TN}_a}{\text{TN}_a + \text{FP}_a}, \]
\[ \text{TNR}_d = \frac{\text{TN}_d}{\text{TN}_d + \text{FP}_d} \]
is the true negative rate, also known as the specificity, for facet a.

For example, consider the following confusion matrices for facets a and d.

### Confusion matrix for the favored facet a

<table>
<thead>
<tr>
<th>Class a predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

### Confusion matrix for the disfavored facet d

<table>
<thead>
<tr>
<th>Class d predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the specificity difference is
\[ SD = \frac{18}{18+5} - \frac{20}{20+10} = 0.7826 - 0.6667 = 0.1159, \]
which indicates a bias against facet d.

The range of values for the specificity difference between facets a and d for binary and multiclass classification is \([-1, +1]\). This metric is not available for the case of continuous labels. Here is what different values of SD imply:

- Positive values are obtained when there is higher specificity for facet d than for facet a. This suggests that the model finds less false positives for facet d than for facet a. A positive value indicates bias against facet d.
- Values near zero indicate that the specificity for facets that are being compared is similar. This suggests that the model finds a similar number of false positives in both of these facets and is not biased.
- Negative values are obtained when there is higher specificity for facet a than for facet d. This suggests that the model finds more false positives for facet a than for facet d. A negative value indicates bias against facet a.

### Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet a and disfavored facet d. Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the y=1 cases are correctly predicted as y’=1 for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets a and d) that should qualify for loans...
are detected correctly by the model? If the recall rate is high for lending to facet $a$, but low for lending to facet $d$, the difference provides a measure of this bias against the group belonging to facet $d$.

The formula for difference in the recall rates for facets $a$ and $d$:

$$RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TPR_a = \frac{TP_a}{TP_a + FN_a}$ is the recall for facet $a$ or its true positive rate.
- $TPR_d = \frac{TP_d}{TP_d + FN_d}$ is the recall for facet $d$ or its true positive rate.

For example, consider the following confusion matrices for facets $a$ and $d$.

**Confusion Matrix for the Favored Facet $a$**

<table>
<thead>
<tr>
<th>Class $a$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

**Confusion Matrix for the Disfavored Facet $d$**

<table>
<thead>
<tr>
<th>Class $d$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is $RD = 65/70 - 20/27 = 0.93 - 0.74 = 0.19$ which indicates a bias against facet $d$.

The range of values for the recall difference between facets $a$ and $d$ for binary and multcategory classification is $[-1, +1]$. This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

**Difference in Acceptance Rates (DAR)**

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference
in the precision of the model for predicting acceptances from these two facets. Precision measures the
fraction of qualified candidates from the pool of qualified candidates that are identified as such by the
model. If the model precision for predicting qualified applicants diverges between the facets, this is a
bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$\text{DAR} = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FP_a$ are the false positives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FP_d$ are the false positives predicted for facet $d$.

For example, suppose the model accepts 70 middle-aged applicants (facet $a$) for a loan (predicted
positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model
accepts 100 applicants from other age demographics (facet $d$) for a loan (predicted positive labels) of
whom only 40 are actually accepted (observed positive labels). Then $\text{DAR} = \frac{35}{70} - \frac{40}{100} = 0.10$, which
indicates a potential bias against qualified people from the second age group (facet $d$).

The range of values for DAR for binary, multategory facet, and continuous labels is $[-1, +1]$.

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive
outcomes (qualified applicants) for facet $a$ is larger than the same ratio for facet $d$. These values
indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false
positives in facet $d$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive
outcomes (qualified applicants) for facets $a$ and $d$ have similar values indicating the observed labels for
positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive
outcomes (qualified applicants) for facet $d$ is larger than the ratio facet $a$. These values indicate a
possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in
facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN)
predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference
in the precision of the model for predicting rejections from these two facets. Precision measures the
fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by
the model. If the model precision for predicting unqualified applicants diverges between the facets, this
is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$\text{DRR} = \frac{TN_d}{TN_d + FN_d} - \frac{TN_a}{TN_a + FN_a}$$

Where:

- $TN_d$ are the true negatives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TP_a$ are the true negatives predicted for facet $a$. 
• FN_a are the false negatives predicted for facet a.

For example, suppose the model rejects 100 middle-aged applicants (facet a) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model rejects 50 applicants from other age demographics (facet d) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then DRR = 40/50 - 80/100 = 0, so no bias is indicated.

The range of values for DRR for binary, multicategory facet, and continuous labels is [-1, +1].

• Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet d is larger than the same ratio for facet a. These values indicate a possible bias against the favored facet a caused by the occurrence of relatively more false negatives in facet a. The larger the difference in the ratios, the more extreme the apparent bias.

• Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets a and d have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.

• Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet a is larger than the ratio facet d. These values indicate a possible bias against the disfavored facet d caused by the occurrence of relatively more false positives in facet d. The more negative the difference in the ratios, the more extreme the apparent bias.

Accuracy Difference (AD)

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet a) than for another age-based demographic (facet d), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet a, ACC_a, minus that for facet d, ACC_d:

\[ AD = ACC_a - ACC_d \]

Where:

• \( ACC_a = \frac{TP_a + TN_a}{(TP_a + TN_a + FP_a + FN_a)} \)
  • \( TP_a \) are the true positives predicted for facet a
  • \( TN_a \) are the true negatives predicted for facet a
  • \( FP_a \) are the false positives predicted for facet a
  • \( FN_a \) are the false negatives predicted for facet a

• \( ACC_d = \frac{TP_d + TN_d}{(TP_d + TN_d + FP_d + FN_d)} \)
  • \( TP_d \) are the true positives predicted for facet d
  • \( TN_d \) are the true negatives predicted for facet d
  • \( FP_d \) are the false positives predicted for facet d
 Detect Posttraining Data and Model Bias

- FN_d are the false negatives predicted for facet d

For example, suppose a model approves loans to 70 applicants from facet a of 100 and rejected the other 30. 10 should not have been offered the loan (FP_a) and 60 were approved that should have been (TP_a). 20 of the rejections should have been approved (FN_a) and 10 were correctly rejected (TN_a). The accuracy for facet a is as follows:

\[ \text{ACC}_a = \frac{(60 + 10)}{(60 + 10 + 20 + 10)} = 0.7 \]

Next, suppose a model approves loans to 50 applicants from facet d of 100 and rejected the other 50. 10 should not have been offered the loan (FP_d) and 40 were approved that should have been (TP_d). 40 of the rejections should have been approved (FN_d) and 10 were correctly rejected (TN_d). The accuracy for facet a is determined as follows:

\[ \text{ACC}_d = \frac{(40 + 10)}{(40 + 10 + 40 + 10)} = 0.5 \]

The accuracy difference is thus \[ \text{AD} = \text{ACC}_a - \text{ACC}_d = 0.7 - 0.5 = 0.2 \]. This indicates there is a bias against facet d as the metric is positive.

The range of values for AD for binary and multicategory facet labels is \([-1, +1]\).

- Positive values occur when the prediction accuracy for facet a is greater than that for facet d. It means that facet d suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet d.
- Values near zero occur when the prediction accuracy for facet a is similar to that for facet d.
- Negative values occur when the prediction accuracy for facet d is greater than that for facet a. It means that facet a suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet a.

**Treatment Equality (TE)**

The treatment equality (TE) is the difference in the ratio of false negatives to false positives between facets a and d. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

\[ \text{TE} = \frac{\text{FN}_d}{\text{FP}_d} - \frac{\text{FN}_a}{\text{FP}_a} \]

Where:

- FN_d are the false negatives predicted for facet d.
- FP_d are the false positives predicted for facet d.
- FN_a are the false negatives predicted for facet a.
- FP_a are the false positives predicted for facet a.

Note the metric becomes unbounded if FP_a or FP_d is zero.

For example, suppose that there are 100 loan applicants from facet a and 50 from facet d. For facet a, 8 were wrongly denied a loan (FN_a) and another 6 were wrongly approved (FP_a). The remaining predictions were true, so TP_a + TN_a = 86. For facet d, 5 were wrongly denied (FN_d) and 2 were wrongly approved (FP_d). The remaining predictions were true, so TP_d + TN_d = 43. The ratio of false negatives to false
positives equals $8/6 = 1.33$ for facet $a$ and $5/2 = 2.5$ for facet $d$. Hence $TE = 2.5 - 1.33 = 1.167$, even though both facets have the same accuracy:

$$\text{ACC}_a = \frac{(86)}{(86+ 8 + 6)} = 0.86$$

$$\text{ACC}_d = \frac{(43)}{(43 + 5 + 2)} = 0.86$$

The range of values for differences in conditional rejection for binary and multicategory facet labels is $(-\infty, +\infty)$. The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false negatives to false positives for facet $d$ is greater than that for facet $a$.
- Values near zero occur when the ratio of false negatives to false positives for facet $a$ is similar to that for facet $d$.
- Negative values occur when the ratio of false negatives to false positives for facet $d$ is less than that for facet $a$.

**Note**

A previous version stated that the Treatment Equality metric is computed as $FP_a / FN_a - FP_d / FN_d$ instead of $FN_d / FP_d - FN_a / FP_a$. While either of the versions can be used. For more information, see Fairness measures for Machine Learning in Finance.

### Conditional Demographic Disparity in Predicted Labels (CDDPL)

The demographic disparity metric (DDPL) determines whether facet $d$ has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range $(-1,+1)$.

The formula for the demographic disparity predictions for labels of facet $d$ is as follows:

$$\text{DDPL}_d = \frac{n_d^{(0)}}{n_d^{(0)} + n_d^{(1)}} - \frac{n_d^{(1)}}{n_d^{(0)} + n_d^{(1)}} = P_d^{R}(y_d^{0}) - P_d^{A}(y_d^{1})$$

Where:

- $n_d^{(0)} = n_a^{(0)} + n_d^{(0)}$ is the number of predicted rejected labels for facets $a$ and $d$.
- $n_d^{(1)} = n_a^{(1)} + n_d^{(1)}$ is the number of predicted accepted labels for facets $a$ and $d$.
- $P_d^{R}(y_d^{0})$ is the proportion of predicted rejected labels (value 0) in facet $d$.
- $P_d^{A}(y_d^{1})$ is the proportion of predicted accepted labels (value 1) in facet $d$.
